Medicine Chief Appointed.—Colonel D. Frank Powell, of Minnesota, has appointed a full blooded Indian to the position of Medicine Chief of the Winnebago nation. At a grand council of the chiefs and warriors soon to be convened the appointment will be confirmed. They will thoroughly test the new chief's fitness for the place and will make him write his name in blood on the register of the tribe.

CORRESPONDENCE

CORRECTION.

To the Editor of AMERICAN MEDICINE:—In the issue of May 4 the omission of the decimal makes me say that Dr. Kelly has 44% of secondary hemorrhages. That is an evident error; it should be .44%.
WILLIAM R. PRYOR, M.D.

UNAUTHORIZED USE OF SCIENTIFIC CONTRIBUTIONS.

To the Editor of AMERICAN MEDICINE:—In June, 1900, I published in the *New York Medical Journal* an article written without any idea as to its possible use as an advertisement to the firm manufacturing the product mentioned. It has lately been used in abstract in advertising pages in a manner that places me in a very embarrassing and unpleasant light before the profession. Is there no way to prevent such use of matter intended to have a scientific bearing only?

Sincerely yours,

CARLE LEE FELT, M.D.

Philadelphia, May 1, 1901.

[Authors have in the copyrights of the journals in which they publish, the means to prevent such use of their names and scientific work. Journals usually copyright for the purpose of protecting those contributing to their columns.]

SALINE INJECTIONS IN PNEUMONIA.

BY

CHAS. F. A. FRANCIS, M.D.,

of Brooklyn, N. Y.

Observing in Dr. William Crawford Johnson's article that saline injections were used first by Dr. Clarence A. Penrose in 1899, I would say that I advised the use of the chlorids of the serum and the sugar found there in their normal proportions in an article published in the *Medical Bulletin* of February, 1897. I am informed that Dr. F. P. Henry, of Philadelphia, made an extensive use of saline injections in 1892. The formula I recommended was as follows:

- ℞ C. P. sodium chlorid 46 grains
 - C. P. potassic chlorid 2½ grains
 - C. P. honey or grape sugar 3½ grains
 - Sterilized water ℥xvi.
- Place chemicals and honey in water and boil. Cool to 101° or 103°F.

TRAUMATIC RUPTURE OF EYEBALL.

BY

GEO. S. HULL, M.D.,

of Pasadena, Cal.

Carroll Scott, aged 2 years, and his brother, aged 4 (both very heavy children) collided forcibly while Carroll was descending a hill and his brother ascending. The brother held in his hand a pine stick 25 inches long, ¾ in. x 1 in. at the one end, cut off square, and ¼ in. x 1 in. at the other end. The larger end struck Carroll on the upper left eyelid at outer aspect. The lid was not cut by the blow, no blood being upon the stick. On examining the eye under ether about 18 hours after the accident the following conditions presented: The eyeball was shrunken about one-third on account of loss of vitreous. An irregular tear extended across the cornea and into the sclera, the rent beginning at inner margin of cornea about 2 mm. above base and running almost straight across the cornea to the outer margin where it curved upward extending to middle of outer margin. A branch of the rent ran into the sclera beginning below the middle of outer margin of cornea and running about 6 mm. into the sclera. The iris was badly entangled in the wound. On enucleating the ball it was found that the lens had been forced out with a portion of the vitreous.

It is certain that the blunt end of the stick did not strike the ball directly. The location of the rent so low down, when the blow was delivered upon the upper lid, may be partly accounted for when we remember that when the eyelids close suddenly for protection the ball is at once turned upwards.

PRACTICAL THERAPEUTICS

Under the charge of
A. A. STEVENS,
Assisted by
L. F. APPLEMAN.

Ichthyol in Smallpox.—Kamneff (*Therap. Monatsh.*, December, 1900, p. 682) reports having used a 12 to 20% ointment of ichthyol in the treatment of a number of cases of smallpox with most excellent results. Marked amelioration of all the symptoms occurs from the first day of its use. The duration of the disease is shortened and no marks are left on the face or elsewhere.

Dionin as a Sedative.—Krijevsky (*Paris University Thesis*, 1900) considers dionin superior to codein as a sedative, analgesic and hypnotic. Used hypodermically, in doses of $\frac{1}{4}$ to $\frac{1}{2}$ of a grain, the sedative effect becomes noticeable in about 15 minutes. Cough is favorably influenced both in acute and chronic conditions. No untoward effects have been noticed, even after long-continued use of the drug. The author considers that $\frac{1}{4}$ to $\frac{1}{2}$ of a grain in 24 hours is generally sufficient, and higher doses than $1\frac{1}{2}$ grains a day are seldom required.

Persistent Hiccough.—A method of treating persistent hiccough, which is not so widely known as it deserves to be, is the one first suggested by Laborde. It consists in drawing the tongue outward and upward, and subjecting it to rhythmic traction for from 12 to 14 times a minutes. Noir has recently reported 2 cases in which this treatment proved very successful. The first case was in a girl of 6 years, extremely nervous, who had paroxysms of hiccoughs of such severity that death from exhaustion was feared. Traction on the tongue, however, for a minute and half, immediately stopped the spasm and it did not recur. The second case was in a tuberculous patient with diabetes, who had been troubled with hiccough for several days. After all forms of medicinal treatment had been used without avail, traction on the tongue was tried and it proved completely successful. In 2 cases occurring within our own experience Laborde's treatment gave speedy relief.

Immediate Withdrawal of the Drug in a Cocain Habitue.—Norris (*Philadelphia Medical Journal*, February 9, 1901), reports the case of a dentist 30 years of age, who contracted the cocain habit subsequent to the local use of the drug in the treatment of hemorrhoids 10 years previously. When first seen at the hospital he was taking an average of 16 grains daily. Upon admission the cocain was abruptly withdrawn, strychnin sulfate, 1-30 of a grain, was given every 4 hours, and suphonal, 2 grains, repeated every 2 hours. The patient slept fairly well the first night; on the second he required no hypnotic. He complained of no craving for cocain, and stated that he felt quite as well as he did before beginning the use of the drug, and was allowed to leave the hospital 1 week after admission. The features of special interest are the sudden, complete withdrawal of the cocain without producing any of the distress so common after the discontinuance of a long-established drug habit, and that after 12 hours the patient experienced no craving for the drug.

Salt Solution for Intravenous Injection.—Carwardine (*Operative and Practical Surgery*), states that while the ordinary normal salt solution made extemporaneously with table salt may answer for emergencies, the surgeon should keep a bottle of sterilized salt solution more nearly resembling the composition of the blood plasma and of the same density:

℞ Sodium chlorid	200 grains
Potassium chlorid	12 grains
Sodium sulfato	100 grains
Sodium carbonate	100 grains
Sodium phosphate	3 grains
Distilled water	$\frac{1}{2}$ pint.

This is sterilized, and at the time of use its bulk is increased to 2 pints by the addition of boiled water.

Chloreton as a Local Anesthetic.—E. R. Rasely (*International Journal of Surgery*, April, 1901,) writes that in hundreds of minor operations he has used chloreton as a substitute for cocain. He claims that the drug produces complete anesthesia without depression or exhilaration. He employs a saturated aqueous solution along the line of incision. He believes that chloreton could be substituted with advantage for cocain in subarachnoid anesthesia.

Hemorrhoids.—J. P. Tuttle (*International Journal of Surgery*, April, 1901,) believes that in many acute cases of internal hemorrhoids we should have recourse to local and general measures rather than to operative procedures. Cold water enemas once or twice a day in order to produce smooth and easy movements of the bowels, and at the same time cause contraction of the bloodvessels, are very beneficial. At the same time injections of mild but nonirritating astringents, such as fluid extract of krameria, fluid extract of hamamelis, or fluid extract of pinus canadensis, will have a very soothing and curative influence. Suppositories of ichthyol, tannic acid and belladonna are often of great benefit, except where there is a mild degree of hemorrhage. Iodoform is also sometimes of much benefit, especially if there is an eroded condition of the parts. Resinous cathartics, such as podophyllin, aloin, gamboge, etc., irritate the parts and should not be used. Small quantities of saline laxatives, especially sodium phosphates before breakfast, followed after breakfast by the cold enema, will have a much better effect on the liver and the hemorrhoids as well, than any more drastic measures.

Adrenalin.—Mayer (*Philadelphia Medical Journal*, April 27, 1901) states that Takamine has isolated from the suprarenal gland the blood-pressure-raising principle in a stable crystalline form. He has named this adrenalin. It is a light, white crystalline substance, having a bitterish taste, only slightly soluble in cold water, but readily so in the presence of acids and alkalies. Various salts—sulfate, benzoate, hydrochlorid and tartrate—have also been made. A fraction of a drop of aqueous solution of adrenalin or its salt, in the strength of 1 to 10,000, blanches the normal conjunctiva within 30 to 60 seconds. It is a powerful astringent. Intravenous injections cause an enormous rise of blood-pressure. Adrenalin is 625 times stronger than the fresh extract, and about 1,000 times stronger than the fresh gland. The solutions slowly change color, becoming pink, brown, and finally muddy, but these changes do not appear to affect the action of the drug. The addition of a small amount of chloreton to the solution keeps it clear and retards the color changes. The author's solution was in daily use for a month and was still clear and active. The following conclusions are drawn: Adrenalin solutions supply every indication in rhinologic practice for which the aqueous solutions of the extract have been hitherto applied; they can be used in sterile form; they remain unchanged for a long time; a solution of 1 to 1,000 is very strong and is all sufficient for operative cases, and 1 to 5,000 or 1 to 10,000 for every purpose of local medication; they may be safely applied to persons of every age and of either sex.

Home Treatment of Tuberculosis.—Flick (*Proceedings of the Philadelphia County Medical Society*, March, 1901) states that no harm ever comes from telling a patient that he has tuberculosis. With a knowledge of his disease he becomes a good patient, whereas otherwise he would have been an indifferent one. He should be made to understand thoroughly that successful treatment means continuous struggle for a long time, possibly for a period of from 3 to 5 years. A tuberculous patient is not always cured when he appears to be cured, and treatment should be kept up for a long time after the patient appears to be well. Everything which the patient does must be passed in review by the physician. With many patients certain articles of diet will have to be stopped; as a general proposition, stimulants had better be stopped and also pastry of every kind. When the patient has poor digestion only one meal of solid food a day should be advised. In all cases large quantities of easily digested food should be commended. From 3 to 6 quarts of milk, and from 6 to 12 raw eggs

a day should be insisted upon to be taken. Vegetables, fruits and nuts should form part of the daily routine diet. Instructions should be given about the intervals at which food should be taken, the manner in which it should be kept and prepared. Eggs should be absolutely fresh. Milk should be sterilized. When forced feeding is not well borne, despite every care, pepsin, pancreatin, hydrochloric acid or diastase may be given. Abundance of fresh air, night and day, should be insisted upon. During the day the patient should rest in the open air, and at night he should sleep with the windows open. The body must of course be kept warm by clothing. There is nothing so poisonous to a tuberculous subject as rebreathed air. The old bugaboo of draughts need not be taken into consideration in planning for fresh air, so long as the patient is properly protected by clothing. When the disease is active absolute rest is necessary. In the incipient stage and in quiescent tuberculosis moderate exercise may be commended. A regular time should be prescribed for everything that the patient does. He should have 8 hours sleep and he should have it during the night. A single overexertion, one act of dissipation, or a few hours in a crowded hall may turn the tide of the case from recovery to fatality.

Treatment of Dysentery.—Symons advocates (*British Medical Journal*, April 13, 1901) douches of tannic acid, 30 grains to a pint of warm water, every 4 hours, hot hip baths, perhaps a little opium by the mouth, rest in bed, and a strictly milk diet.

Tropaeocain in Medullary Analgesia.—Schwarz (*Centralbl. f. Chirurgie*, March 2, 1901) reports 16 cases of medullary analgesia in which he employed successfully tropaeocain instead of cocain. The untoward effects—pallor, nausea, fever, headache and vertigo—were not observed. The amount of the drug injected did not exceed $\frac{1}{4}$ of a grain.

Exophthalmic Goiter.—G. R. Murray (*Practitioner*, April, 1901) states that thyroid extract not only fails to do good in Grave's diseases, but that it frequently does positive harm. Thymus gland may be given with safety. Opinions differ as to its utility. In one of his cases the patient took 3 dried thymus tablets each day for 9 months, and as a result the pulse rate, which varied from 132 to 143, gradually fell to 84, the goiter disappeared entirely, the tremor became much less, and the exophthalmos was diminished. In other cases improvement has also been observed, but not to such a marked extent. The inunction of red iodid of mercury ointment into the skin over the goiter, repeated sufficiently often to keep up slight redness, is useful. Of internal remedies belladonna is in general use. Tincture of convallaria in doses of 10 minims may be given with advantage 3 times a day when the pulse rate is high. Bromids are of service when there is excessive tremor or nervousness. Liquor arsenicalis, which may be combined with any of the above, and given in small doses of 3 or 4 minims twice or thrice daily for 6 or 8 weeks at a time, is in many cases of great value.

Thiocol in the Treatment of Pulmonary Tuberculosis in Children.—Kaplansky (*Merk's Archives*, March, 1901) reports several cases of tuberculosis in which thiocol was administered, and gives the following conclusions as to its use: (1) Creasote in some form must occupy the first place in the medicinal treatment of infantile tuberculosis; (2) among the derivatives of creasote or guaiacol, thiocol deserves the preference, and it will eventually become the remedy of choice; (3) the results of experiments on animals permit us to assume that thiocol exercises a direct antitubercular effect in the animal organism, and does not merely produce a favorable influence on the general nutrition and on certain symptoms of tuberculosis; (4) the experimental data, as well as clinical experience, justify us in giving thiocol a trial not only in pulmonary tuberculosis, but in other forms as well; as, for instance, in tuberculous pleurisy and peritonitis; (5) the administration of thiocol in all forms of tuberculosis is the more indicated because, on account of its solubility in water, and its absence of odor and taste, it is readily taken by children, and because it is perfectly innocuous.

THE WORLD'S LATEST LITERATURE

British Medical Journal,

April 20, 1901. [No. 2103.]

1. Medical Notes from the Imperial Yeomanry Hospital at Pretoria. J. W. WASHBOURN.
2. Reminiscences of the Welsh Hospital in South Africa (Springfontein and Pretoria). J. LYNN THOMAS.
3. No. 6 General Hospital, Johannesburg. ARCHIBALD WATSON.
4. Clinical Notes on the Wounded in South Africa. J. W. SMITH.
5. The Princess Christian Hospital in South Africa. GEORGE V. WORTHINGTON.
6. Veld Sores. ALEXANDER OGSTON.
7. Some Observations on Veld Sore. W. H. HARLAND.
8. Report on 295 Cases of Enteric Fever, General Hospital, Tin Town, Ladysmith. DAVID MELVILLE.
9. Enteric Fever in South Africa: Effective Sterilization of Excreta. Major H. A. CUMMINS.
10. Venesection in the Treatment of Gunshot Wounds of the Chest. Captain F. J. W. PORTER.

1.—Washbourn, in some medical notes from the Imperial Yeomanry Hospital at Pretoria, details some interesting observations on epidemic jaundice, enteric fever, dysentery, phlebitis, and certain undetermined fevers. [A.O.J.K.]

2.—Welsh, in reminiscences of the Welsh Hospital in South Africa, illustrates the methods of pitching marquees and claims for Keogh's peculiar advantages. The merits of a forceps-tourniquet and the telephone probe for locating bullets are detailed. [J.W.M.]

3.—Watson describes the disposition and management of the General Hospital at Johannesburg, and comments upon the cases treated therein. [A.O.J.K.]

4.—Smith, in Notes on the Wounded in South Africa, reports several cases of perforating wounds of the thoracic and abdominal cavities in which prompt recovery occurred. Wounds caused by expanding bullets or shells often suppurated, and in 1 case amputation was necessary. Erysipelas, septiemia, and hospital gangrene were practically unknown. Six cases of wounds of large joints recovered without infection. The almost uniform aseptic healing of wounds is attributed to the absence of serious oozing, and the sealing of small wounds by the sun and air before they became contaminated. When a bullet is lodged deeply and causes no trouble he advises that it should be left alone. [J.W.M.]

5.—Worthington describes the disposition and management of the Princess Christian Hospital in South Africa and comments upon the cases treated therein. [A.O.J.K.]

6.—Ogston discusses veld sores which are considered peculiar to South Africa and consist of a semitranslucent swelling of the epidermis with the formation of a blister, often multiple, of the size of a shilling in the center, which on rupture leaves an ulcer surrounded by a fiery red area. These occur on the arms, hands, legs and feet. He attributes this condition to the inoculation of a virus by the horse fly into an existing abrasion. The fluid from the primary swelling contains quantities of micrococci.

7.—Harland in some observations on veld sores describes their first appearance as a papule the size of a pin head, which increases in size and contains a clear yellowish serous fluid which in a few days becomes turbid. It usually ruptures spontaneously, leaving a painful scab-covered sore, from which seropus exudes. They are usually multiple, and appear on the back of the hand and fingers. Occasionally one large pustule covers the hand, and accompanying the dirty variety is a lymphangitis with glandular enlargement. Elevation of temperature, headache and constipation are often present. The treatment consists of rest, administration of a mild aperient, applications of borie or carbolic fomentations during the sloughing stage and a mild ointment later. The condition which is most common among the cavalry is attributed to the sting of the horse-fly. [J.W.M.]

8.—Melville makes a report on 295 cases of enteric fever treated in the General Hospital in Tin Town, Ladys-

smith. In 40% of the cases there was no rose rash; in 20% the rose spots were thickly scattered over the trunk and extremities. Diarrhea was present in only 5 cases; constipation was constant and difficult to deal with. In 2 cases there was violent maniacal delirium. Of the patients 30 had been inoculated with protective serum; in these cases the complications were more numerous, the duration of the fever longer, and the death-rate higher than in the uninoculated. Hemorrhage occurred in 17 of the total number of cases; perforation with peritonitis in 3 cases, all of which terminated fatally. Pneumonia occurred in 11 cases, thrombosis in 5 cases and relapse in 23 cases. Five cases were of the malarial type. There occurred 2 cases of typhoid toes. The low death-rate (2.38%) is attributed to the use of carbolic acid internally, 2 drops every 4 hours, to sponging with cold water, and to the excellent nursing. [A.O.J.K.]

9.—Cummins makes a second report upon effective sterilization of excreta in the hospitals in South Africa.—The method, which consists in boiling the excreta in a cauldron, was described in the *British Medical Journal*, November 10, 1900. [A.O.J.K.]

10.—Porter reports a case of gunshot wound of the chest in which he attributes recovery to venesection. There was a hemorrhage into the pleural cavity and the heart became too feeble to maintain the circulation through the undamaged lung. By venesection 10 ounces of blood were removed and the heart-strain relieved. The advisability of such treatment in cases of pneumonia in sthenic patients is suggested. [J.W.M.]

The Lancet.

7. Case of Recovery after Operation for Diffuse Peritonitis from Perforation of the Appendix. CHARLES A. MORTON.
8. The Open-air Treatment of Phthisis at Home: a Short History of a Case. F. WHINFIELD BARTLETT.

1.—Rolleston reports a case of **duodenal stricture due to carcinoma** in a patient of 50 who for 2 years suffered from abdominal pain, and vomiting on taking food, and was on admission to the hospital weak and anemic. The vomit contained bile, but no free acid. The urine contained a large quantity of creatinin, probably as a result of the patient's rapid wasting. Pyemia developed, the source of infection being a transfusion wound. Death from exhaustion followed. Necropsy showed a tight stricture of the third portion of the duodenum, due to malignant disease. Only 10 cases of primary malignant disease of the duodenum were found in 18,000 autopsies at Guy's Hospital. The disease may be limited to the first, second or third portion, that of the second being the most frequent. [J.W.M.]

2.—Hughes, describing a condition that he designates **autopsychorhythmia or repetition psychoneurosis**, discusses certain morbid rhythmic forms of automaticity and rhythmic forms of mental alienation, and illustrates his remarks by reference to the histories of a number of patients that have come under his observation. [A.O.J.K.]

3.—Lamb, as a result of an examination of the local water supplies, found a marked correspondence between cholera and the prevalence of comma bacteria in well waters at Gujerat during the famine of 1900. The comma-shaped bacteria were not the true cholera vibrio, although they belong to the same tribe of microorganisms. It is suggested that all curved bacteria thrive under similar conditions, and that the

discovery of comma-shaped bacteria, though not the true cholera vibrio, should serve as a warning as to the danger of cholera in the neighborhood. Of 25 wells treated with potassium permanganate 17 contained no comma-shaped bacteria; the remaining 7 contained them in small numbers. In one well not treated comma-shaped bacteria were found in numbers. No inferences are drawn from this observation. [A.O.J.K.]

4.—Roper, in discussing the question of when to operate in perforative peritonitis, states that the salient and early signs of perforation of a gastric ulcer are pain, tenderness, rigidity, presence of fluid and gas in the peritoneum, and collapse. These are followed later by a period of calm, with abdominal distention, increase of fluid and probably evidence of intestinal paresis. In appendicitis the following points are given as a means of determining the existence of an abscess: (1) The condition of the patient—the pulse, the temperature, and the aspect; (2) the condition of the abdomen; and (3) the presence or absence of a swelling. Each condition is considered in detail. If evidence of abscess formation appears, it should be evacuated as early as safety permits. In such a case a sudden fall in temperature without a corresponding improvement in pulse indicates a probable sloughing of the appendix. Operation is not advised during the early shock which follows perforation. The patient should be stimulated and the period of calm which follows waited for. [J.W.M.]

5.—Stone reports a case of recurring attacks of catalepsy alternating with violent mental excitement, occurring in a woman of 27. The patient suffered with marked menstrual irregularities and was much improved by dilation and curetting of the uterus. [A.O.J.K.]

6.—Coates, writing of the causation and treatment of profuse epistaxis in people beyond middle age, reports 5 cases of epistaxis occurring in persons beyond 50 years of age. The attacks were sudden in their onset, profuse, generally lasting from $\frac{1}{2}$ an hour to an hour or more, and tending to recur for several days. The sequence of events that led up to the epistaxis is said to have been essentially in each case and as follows: (a) long continued high arterial tension; (b) some sudden cardiac failure; (c) overfilling of the whole venous system, the weakened heart not being able sufficiently to empty the engorged veins against the high pressure in the arterial system due to contracted arterioles; (d) leakage from an overfilled vein. Treatment must be directed toward emptying the overfilled veins. This is best accomplished by acting on the capillaries and arterioles—with nitroglycerin, amyl nitrite, and later the more slowly acting nitrites, such as erythrol tetranitrite, or possibly even thyroid tablets. When the capillaries and arterioles are dilated and pervious, then comes the time for strychnin and strophanthus. In some cases plugging of the nares may have to be resorted to. [A.O.J.K.]

7.—Morton reports a case of diffuse peritonitis from perforation of the appendix, in which recovery followed operation. He refers to the distinction between diffuse and general peritonitis, and also to the fact that all recurrent cases of appendicitis cannot be postponed until the quiescent period as is illustrated in the case reported, in which 48 hours after the onset the symptoms were pain and tenderness, with general distention. Temperature below 100° and pulse 80. Because of the increasing distention and tenderness, operation was performed. A large quantity of pus was found, with a diffuse peritoneal involvement. Drainage was established and recovery followed. The case shows that a severe peritoneal infection may exist with a pulse and temperature almost normal and an absence of those signs which usually accompany septic peritonitis. [J.W.M.]

8.—Bartlett reports the result of the open-air treatment of tuberculosis at home—the patient being a woman of 38, with well marked consolidation and excavation of the left apex, commencing involvement of the right apex, and tubercle bacilli in the sputum. The treatment, begun in February, consisted of residence out of doors between breakfast-time and sunset, nutritious diet, creasote, and various symptomatic medications. At the end of a year, the patient was much improved—she was plump and had a healthy complexion: her cough and expectoration had almost disappeared; fever and night sweats had

ceased; and physical signs of commencing disease of the right lung had disappeared. [A.O.J.K.]

1.—The **gyromele** is a flexible steel cable, with spiral end, provided with a metallic pellet covered with wool, cotton or sponge, and fastened in a revolving apparatus like a drill, which is put in motion after introduction, causing vibrations which are perceived by auscultation and palpation, when the end is in close contact with the organ's wall. It is the only instrument which manifests itself as soon as it enters the stomach. The cardia can be located by gently withdrawing until resistance is met. Accidents are reduced to a minimum by its elasticity, flexibility, cushioned extremity and rotary motion. Cases are cited showing the exactness of diagnosis obtainable by it as to location and nature of lesions. The method of obtaining adherent mucus and bacteria from the stomach walls, after cleansing the lumen by a douche, is described. This is of the greatest diagnostic importance. **Exploration of the pylorus and duodenum** with aspiration of the contents is also described. The technic is minutely given, and the method of obtaining x-ray outlines by means of bismuth, emulsion, etc., is explained. [H.M.]

2.—The perineal and pelvic tissues are made tense by placing the patient abdomen downward and thighs straddling a Trendelenburg table which is then inclined sharply upward. A cotton tampon is pushed well up the cleansed rectum. Incisions are made on each side, extending from a little above the upper border of the coccyx just inside the body of the ischium, downward and slightly inward just within the border of that bone, passing the tuber ischii and ending about $\frac{1}{4}$ of an inch anteriorly to the anus. A transverse cut connects the converging ends, care being taken to avoid the sphincter. The left forefinger, ball downward, is inserted in the rectum, the thumb presses against this, while the hand exercises upward traction. The knife in the right hand dissects through the levator ani and visceral layer of pelvic fascia, keeping close to the rectal wall, using the inserted forefinger as a guide and thus avoiding damage to the urethra. Both forefingers are then inserted through the cut into the lymph space between the prostate and rectum and the path of the wound divulged. The loose rectal connections are stripped from bladder and seminal vesicles in the same way; the operation for which the incision was made is completed; and the walls united by deep sutures to avoid tendency to rectal prolapse, a space being left for drainages in the middle of the transverse cut. The indications for the operation with new methods of **treating disease of the vesicles** are touched upon. [H.M.]

3.—But 62 cases of **asthenic bulbar paralysis** have been reported, the first in 1877. Nothing is known as to etiology or

pathology. Some consider it toxic, and Buzzard's experiments tend to prove the disease is nervous and not a myopathy, galvanism causing prompt and vigorous contraction after exhaustion by faradism. There is no reaction of degeneration, no atrophy, no fibrillary twitchings, no sensory or trophic disturbances, no ataxia, bladder, or renal troubles. The special senses and intelligence are unaffected. Characteristic symptoms are **weak and rapidly exhausted muscles**, the tendency to affect not only the bulbar muscles, but those of the eye, and extremities, the occurrence of exacerbations and remissions. The disease is prone to attack the respiratory muscles, the majority of deaths being due to asphyxia. It is most likely to be mistaken for hysteria, neurasthenia, true bulbar paralysis or multiple neuritis. No specific treatment is known. Complete rest and general tonics are advised. A case is reported. [H.M.]

4.—In the few rare instances in which **general treatment** results in immediate local change in nose and throat as in rheumatic and syphilitic conditions, the laryngologist may appropriately conduct the general treatment, but under other circumstances he should refer the case to the general practitioner. A resume of complications is given to show the absurdity of any other course, also of the general treatment of general pharyngitis from the textbooks of numerous specialists. [H.M.]

5.—After allusion to the shortening of this measurement due to the erosions of tubercular disease, Halsted's explanation of the lengthening in the first stage is given. The **increase in hysterie hip disease** was noted in 1 case by Charcot, but is nowhere described as characteristic. The value of this sign in differential diagnosis lies in the fact that it rarely occurs except in the early stages of tuberculous disease, but lasts as long as the morbid condition in hysteria. It is more marked in women on account of the greater width of the pelvis. [H.M.]

6.—Associated with the **aphasia** was **left-sided paresis** of the muscles of the tongue and lower part of the face. The sudden onset pointed to embolus or hemorrhage. The patient could call the name of an object into consciousness and distinguish between correct and incorrect pronunciation. The most probable explanation of the inability to name objects is that there is a **naming center**, probably somewhere in the temporal lobe, possibly part of the superior temporal gyrus, and that a tract leading from this center to the center for the preservation of the motor memories of speech was damaged. This would likely run through the insula and thus be easily reached by a lesion that had, judging from the word blindness and motor paralysis present, involved the angular gyrus and extended subcortically in a direction to impair the function of fibers running from the centers for the lower part of the face and tongue to the internal capsule. [H.M.]

7.—The **nitrosugars** are really nitrate-esters, closely allied to nitroglycerin, etc., and having the same paralyzing influence on the unstriated muscle of vessel-walls, lowering tension, their action being slighter and more prolonged, however. They are much less stable than erythrol tetranitrate, and it is therefore doubtful if they will find a place in therapeutics. Their taste is very bitter. [H.M.]

8.—The classic **Cesarean** section is the operation of choice and the life of the infant alone under certain conditions indicates it, as, when not performed as a last resort, the mortality as shown by statistics is very low. It is indicated in many cases of pelvic deformity, eclampsia, placenta previa and prolapse of the cord. The **Porro** is mutilating and has a higher mortality. One case is reported in which 3 successful Cesarean operations were performed. The danger of subsequent operations is not an indication for the Porro. The latter has about the same mortality as hysterectomy for fibroids and should be performed only when the patient demands it, or on account of infection or neoplasm. [H.M.]

9.—**Sea air** is warmer, more aseptic, freer from dust and contains more ozone than land air except in the highest altitudes. The rising and lowering of the temperature is slower. The traveler is induced by these conditions to spend most of his time in the open air in enforced rest. Sea air is sedative to the nervous system, increases metabolism, weight, appetite and inclination to sleep and is **indicated** in many cases of disease

of the respiratory tract, scrofulous affections, anemias, neurasthenia, chorea and even rheumatism. [H.M.]

10.—Murphy describes a sterile adhesive rubber dam which will stand considerable traction without separation from the skin and is not affected by antiseptics or wound secretions. It may be applied to any part of the body, the incision and sutures are made through it and it is removed after the operation is completed. It is applicable also in suppurating and draining wounds to prevent erosion or eczema from irritating discharges. [H.M.]

11.—Statistics tabulated from 227 cases of traumatic injury to the spine show operative mortality to be only 31.89%. These figures leave no doubt of the advantage of the operative over the conservative treatment. The figures of a table of statistics inserted are decidedly against immediate operation. The latter should be delayed until it is evident the patient will not succumb to the direct effects of the injury. Some incomplete recoveries have been due to incomplete relief of compression from not removing enough laminae, leaving projecting bone or blood clots and failing to look out for compression from inflammatory processes. Care should be taken to note that the cord dilates to its full size and pulsation returns. The dura should be opened if discolored and any blood clot removed. Patients have survived the loss of large quantities of cerebrospinal fluid. When a portion of a displaced body or an articular process has to be removed supporting apparatus should be employed. Wiring may be considered. Operations in the region of the cauda equina come under a different ruling from those in which the medulla may be affected and do not differ from those done upon nerve tissue in any other part of the body. The article concludes with 4 previously unpublished cases in detail, and a synopsis of 120 other cases. [H.M.]

Boston Medical and Surgical Journal.

May 2, 1901. [Vol. CXIV, No. 18.]

1. Contusions of the Abdomen. CHARLES L. SCUDDER.
2. Observations on the Use of Antistreptococcus Serum in the Treatment of Puerperal Sepsis with a Report of 5 Cases. FRANK A. HIGGINS.
3. A Case of Cesarean Section in a Face Presentation, Complicated by Uterine Fibroid. EMMA S. CALL.
4. Notes from the Neurological Department of the Massachusetts General Hospital: Exophthalmic Goiter and Fright. E. W. TAYLOR.

1.—Scudder, in discussing contusions of the abdomen, details the signs of injury of each organ and outlines the treatment. Shock, hemorrhage and peritonitis are general conditions. Shock may be of nervous origin, or it may be due to hemorrhage or extravasation of visceral contents. The symptoms are: pallor, low temperature, nausea, cold extremities, irregular, compressible and rapid pulse, shallow respiration, anuria. Secondary shock suggests intraabdominal hemorrhage or visceral rupture. Intraabdominal hemorrhage is dangerous because of loss of volume of blood. The symptoms are shock, restlessness, thirst, sighing respiration, with evidence of fluid in the abdominal cavity, rapid, feeble pulse, and subnormal temperature. The symptoms of peritonitis are pain, tenderness, vomiting, abdominal distention and muscular rigidity. He concludes that cases in which there is but little shock, and those in which shock is profound, should not be operated on. Immediate operation is indicated in persistent, moderate shock, progressive hemorrhage and in peritoneal infection. [J.W.M.]

2.—Higgins reports 5 cases of puerperal sepsis treated with antistreptococcus serum. They were all in an extremely critical condition when the serum was used and only 2 recovered. From his observations in these cases he thinks we cannot fail to be disappointed in the results of the serum treatment, and also cannot but conclude that as a curative agent its power is limited to a very narrow line of cases. It has also impressed him that the serum has a marked depressing effect upon the patient, and is not to be administered to a very sick patient off-hand in large and frequent amounts, as the directions are given which come with the serum. When used, it is best endured by the patient and less depression follows, in doses of 10 cc.

repeated not oftener than every 12 hours until some result is observed. This is usually shown by a marked decline in pulse and temperature. Larger doses administered repeatedly may result in dangerous symptoms. He believes that the serum treatment has no place in the routine treatment of puerperal sepsis, that it should be used only in desperate cases after failure to obtain improvement by other and usually more efficient methods, and that if no improvement is shown after use for 2, or at most 3 days, and the injection of 40 to 60 cc., it should be discontinued. It is only in occasional cases of pure streptococcus infection that antistreptococcus serum is apparently of great value as a life-saving measure, while in the majority of cases of streptococcus infection, and in all cases of mixed infection, it is useless to expect the serum to cure the disease. [W.K.]

3.—Call reports a case of face presentation complicated by a fibroid in which the child was delivered by Cesarean section and the mother recovered. It was thought that an earlier operation might have saved both lives. [W.K.]

4.—Three cases of exophthalmic goiter following fright are reported. Careful investigation would doubtless show emotional disturbance as a precursor in many cases. The manner of development is not comprehended. The legal bearings of the relationship in accident cases is considered. [H.M.]

Medical Record.

May 4, 1901. [Vol. 59, No. 18.]

1. The Operation for Radical Cure of Inguinal Hernia, at the End of the Century, as I saw it Performed by Bassini, Lucas-Championnière, De Garmo, Coley and Broca. CAMPBELL FORD.
2. Varicella in Adults. ALVAH H. DOTY.
3. A Plea for the Conservation of Breast Milk in Whole or in Part. THOMAS S. SOUTHWORTH.
4. On Bandages for Nephroptosis. GEORGE M. EDEBOILS.
5. Version: Indication, Technique, Limitation. S. MARX.
6. Axis-Traction Forceps. EGBERT H. GRANDIN.
7. Cesarean Section. EDWIN B. CRAGIN.

1.—Ford describes in detail the clinic of Bassini and the technic of his radical cure for hernia. The variations of the operation as used by Lucas-Championnière, De Garmo, Coley, and Broca are then given. The uses of the several sutures suggested by Ford are explained. [A.G.E.]

2.—Chickenpox sometimes occurs in a typical form in adults. Three signs are of value in diagnosing it from smallpox. In the latter the true skin is involved, giving the shotty sensation and resulting in pitting. The vesicle is hard and resisting. In varicella the vesicles are superficial, and can be torn by sweeping the edge of the fingernail quickly and firmly over them. Occasionally a scar is caused by irritation, involving the deeper tissue. Smallpox eruptions come in one crop, chickenpox in successive crops, and the vesicles are not preceded by papules. The hands and feet are almost always involved in smallpox, rarely in chickenpox. What will pass for umbilication is sometimes found in varicella and syphilis. Constitutional symptoms are less reliable in diagnosis than the eruption. [H.M.]

3.—The normal breast milk is the best and safest nourishment for an infant. According to Southworth 97% of infant mortality from gastrointestinal disease occurs among infants not nourished exclusively from the breast. The official statistics of the German Government show that of artificially fed infants 51% die during the first year, while only 8% of those exclusively nursed perish during the same period. In view of such facts, and also of the increasing proportion of artificially fed infants due largely to the ignorance of mothers, Southworth considers it incumbent upon the family physician and the obstetrician to enlighten this ignorance. It becomes his duty to instruct the mother as to the proper diet, exercise, etc., necessary to promote the secretion of nutritious milk for her child; also the necessity for its regular nursing at proper intervals. He emphasizes the fact that there is very often a great lack of fluids taken into the system by the mother and that it is essential to drink water freely during lactation; or better still, milk, the gruels, and cocoa, which have definite food and milk

making possibilities. An extended experience has convinced Southworth that it is important to conserve the maternal milk even if it is not sufficient for the child, stimulating its increase by proper diet and supplementing by artificial feeding; as such a course is more conducive to the child's healthy growth than to be completely bottle-fed. Modifications of cow's milk are usually vastly superior to infant foods. [w.k.]

4.—Edebehls gives 3 special reasons why pads which make pressure upon the kidney should not be employed: (1) The kidney can not be held in place; (2) pressure would be harmful even if it were efficient; (3) because of the relation between movable right kidney and chronic appendicitis. Edebehls proposes surgical intervention for the cure of chronic nephritis. When the kidney is not movable he would simply denude it of its capsula proper and allow new vascular connections between the kidney and its fatty capsule. In cases of movable kidney, nephropexy is indicated when relief cannot be obtained from a simple bandage or corset. [A.G.E.]

5.—In the opinion of Marx the indications for true internal version are: Malpositions and malpresentations; contracted pelvis, either relatively or absolutely so; prolapsus funis or allied conditions; for all other unclassified conditions, such as placenta previa; except under very rare conditions, in all cases in which the head remains above the brim, the exception being in those cases in which there is present a uterine rupture or a very much thinned-out lower uterine zone showing plainly the contraction ring of Bandl. In technic he considers these rules of inestimable value: (1) Always be sure of the position and the presentation; (2) certify to the fact that the fetus is alive or at best is not in immediate grave danger. Unless an easy and rapid delivery will produce a living child, it would be far better to do an elective perforation than to subject the mother to any other operation which carries with it increased danger; (3) do your version as early as you can in the presence of an intact fruit sac; or, at least, as soon after the membranes have ruptured as possible; (4) always introduce the hand corresponding to the position of the fetal feet; (5) always turn the child in such a fashion as will keep nature's classic ovoid intact; that is, carry the foot along the abdominal plane of the fetus and not away from it. It is difficult to state the limitations of the operation of version, but with the average pelvis and average child, version should be performed when the head remains above the brim, and no operative measures short of perforation should be instituted in the presence of a dead or dying fetus. Version stands midway between forceps and Cesarean section and the field of symphysiotomy is becoming smaller and smaller. [w.k.]

6.—Grandin claims that the axitraction forceps can best be used to advantage in the following indications: Traction in the correct axis; traction with expenditure of the least effort on the part of the operator; traction with the least compression of the fetal head; traction with the least interference with normal mechanism (e.g., rotation); traction with the least consequent damage to the maternal parts. The cardinal principle in using axitraction forceps is that, while making traction, the traction rod must ever remain parallel to and almost in contact with the handles. Neglect or ignorance of this rule renders the axitraction forceps a very dangerous instrument. [w.k.]

7.—Cragin gives a brief abstract of 9 cases of Cesarean section with favorable results for both mother and child in all save 1, in which there was carcinoma of uterus and vagina. It is only when a woman cannot be delivered of a living child by forceps or version that a cutting operation comes into consideration. If then the mother and child are both in good condition, the question arises whether the operation shall be symphysiotomy or Cesarean section. Cragin would never use the former for a patient having a true conjugate of less than 7 cm., neither is it indicated in cases in which the parturient canal is obstructed by tumors either uterine or ovarian, nor in case of obliquely contracted pelvis with an ankylosis of one or both sacroilliac synchondroses. In all such, Cesarean section is the proper operation. Even in those cases in which symphysiotomy comes in direct competition with it, that is in which the true conjugate varies from 7 cm. to 9 cm., viewed from the standpoint of mortality, ease and rapidity of convalescence, and convenience of the

surgeon, Cesarean section deserves the preference. Cragin in the first 4 operations lifted the uterus through the abdominal wall before making the uterine incision; but on account of the length of the abdominal incision required, in the subsequent cases he incised the uterus *in situ* and delivered the child before raising the uterus out of the abdominal wound. If the uterus or appendages are infected or diseased, or the pelvic deformity is extreme, he prefers to follow the Cesarean section by hysterectomy. [w.k.]

Medical News.

May 4, 1901. [Vol. LXXVIII, No. 18.]

1. Medical Department of the University of Pennsylvania. CHARLES W. DULLES.
2. A Report of 24 Operations Performed During Spinal Anesthesia. WILLIAM SEAMAN BAINBRIDGE.
3. Some Sources of Error in Laboratory Clinical Diagnosis. THEODORE C. JANEWAY.

2.—Bainbridge reports the performance of 24 operations under spinal anesthesia from which he summarizes the following points, viz.: That cocaine is more satisfactory than eucain, as the effect is more potent, less evanescent and more complete. Anesthesia following the introduction of cocaine by lumbar puncture may extend to the upper extremities, eyes, mouth and throat. The preparation of the patient is as for general anesthesia, and the administration of moderate doses of bromide diminishes and often prevents the unpleasant effects. Anesthesia lasts from 30 minutes to 4 hours. In a few cases temporary motor paraplegia or vertigo occurs. Normal or diseased kidneys are not affected. Usually the tactile power, muscular sense and ability to detect heat and cold are unimpaired. A slight rise of temperature usually occurs after the operation, but circulation and respiration are but slightly disturbed. [J.W.M.]

3.—Janeway holds that clinical diagnosis cannot be made in the laboratory. Only the clinician with a judicial mind is capable of balancing all the facts. In laboratory diagnosis there are 2 sources of error, faulty technic and inaccurate reasoning. The errors may be inherent in the methods themselves or due to carelessness or ignorance in their application. Common mistakes in testing urine, sputum, blood and stomach contents with diagnostic inferences are considered in minute detail. [H.M.]

Philadelphia Medical Journal.

May 4, 1901. [Vol. 7, No. 18.]

1. Puerperal Polyneuritis and Poliomyelitis. JAMES STEWART.
2. Localization of Sound and Its Bearing on Hearing—Especially in Unilateral Deafness. B. ALEX. RANDALL.
3. The German Clinics of Today. JOHN C. HEMMETER.
4. Volvulus and Intussusception of Meckel's Diverticulum. JOSEPH MCFARLAND.
5. Deaths from Anesthetics. D. H. GALLOWAY.
6. Esophoria, or Latent Squint. FRANCIS VALK.
7. Strangulated Hernia. WALTER LATHROP.
8. Ammonium Persulfate Solution. A New Decolorizing Fluid for Staining Spores and Sputum. ROBT. L. PITFIELD.

1.—The history of a case of puerperal polyneuritis and poliomyelitis resulting in death is narrated by Stewart with a description of the autopsy and microscopic examination of tissues. The patient was 33 years of age and mother of 5 children. She experienced a gradually ascending paralysis which began with a sensation of numbness in the limbs about 2 months before delivery, and afterward slowly increased, causing loss of power and motion. About 6 months from the beginning of the trouble, the diaphragm showed signs of failure, symptoms of pneumonia set in and she died in 2 days. All the usual causes of neuritis were absent, such as lead, alcohol, acute or chronic disease, etc.; but she had suffered from very severe vomiting, and a number of cases of puerperal neuritis have been reported in which the severe vomiting was the only marked feature present. The postmortem examination in this case showed a normal cord, but the peripheral nerves were swollen and of

reddened yellow color and studded with black granular spots and degenerated fibers. Most cases of multiple neuritis of puerperal origin are instances of postpartum neuritis usually attributed to sepsis and show a degeneracy of parenchymatous tissue. [W.K.]

2.—Randall urges the importance of securing and retaining **binaural hearing**. When unilateral deafness is present, there is an inability to localize sound accurately, owing to the fact that one side of the brain has placed upon it a greater psychical effort in the reception and analysis of the impressions. [H.H.C.]

3.—The main features of the **German clinics** noted by Hemmeter, of Baltimore, are the treatment of each patient from an individual standpoint, the employment of a great variety of methods for the cure of disease and relief of suffering, of which diet and nutritional therapeutics are especially emphasized. He urges the need of a journal in America which shall be recognized as one of high scientific standard, dealing with the treatment of disease by physical methods and diet. The great increase in malignant diseases in this country is referred to, the expediency of a congress being suggested, to outline methods and means for their study and relief. [H.H.C.]

4.—McFarland gives in detail the postmortem findings in a man who died with symptoms partly attributable to intestinal obstruction and partly to uremia. A **Meckel's diverticulum** about 4 cm. in length was found rotated upon its long axis about ¼ of a circle, and then **invaginated for about 2 cm. into the ileum**, reducing the lumen of the intestine to ½ its normal size. [A.G.E.]

5.—Galloway states that **3 deaths from anesthetics** occurred recently in Chicago within 10 days. He cites several instances of carelessness on the part of anesthetizers, and says that few surgeons make any effort to remedy this state of affairs. The profession adheres too strongly to the belief that if a patient is taken off the table alive the anesthesia has been entirely successful. The responsibility for unnecessary deaths often extends to medical colleges, in many of which anesthetics are barely mentioned. [A.G.E.]

6.—The **conservative course in treating esophoria** is recommended by Valk. In detecting the condition he lays great stress upon testing the power of the eyes to move under the stimulation of the fusion force or duetion. Treatment is by glasses, prisms with glasses, tenotomy of the internal recti, or, best of all, shortening the external rectus. [A.G.E.]

7.—Lathrop gives the symptoms and **treatment of strangulated hernia**. He is opposed to the use of taxis except when operation is refused or a long wait is necessary. [A.G.E.]

8.—The following **formulas for a spore-staining solution** is given by Pitfield, a new decolorizing reagent, ammonium persulfate, being the chief ingredient.

R	Ammonium persulfate	5 grams.
	Alcohol, 95%	50 cc.
	Water	10 cc.

"To demonstrate spores, prepare a coverslip as usual, spreading it very lightly; fix in flame and then stain with boiling carbolfuchsin or Ehrlich's anilin water, gentian violet or fuchsin. The coverslip should remain in the boiling stain for at least a minute. Wash and drop on the solution of ammonium persulfate. At the end of a half minute wash in water and counterstain. The preparation will show red or violet spores, and bacilli stained with the contrast stain. In case the spores are not stained, repeat the staining process and decolorize for a shorter period and then counterstain." [H.H.C.]

The American Gynecological and Obstetrical Journal.

1. The Treatment of Displacements of the Uterus, with Adhesions. F. H. DAVENPORT.
2. Causes of Dysmenorrhea. ALBERT M. JUDD.
3. The Causes and the Significance of the Obstetric Hemorrhages. J. J. CLIFTON EDGAR.
4. Osteofibroma of the Uterus. GEO. BEN. JOHNSTON.
5. A Case of Natural Ureterointestinal Anastomosis. C. A. KIRKLEY.
6. The Treatment of Cancer of the Uterus. J. WESLEY BOVÉE.

1.—In his article on the **treatment of displacement of the uterus with adhesions**, Davenport classifies the symptoms as follows: (1) those due to the original trouble, namely, the peritonitis, and (2) those due to the resulting displacement. He condemns the practice of "breaking up" adhesions by the bimanual manipulation, either with or without anesthesia; preferring abdominal section. In adherent uterus, with a mass on either or both sides of the uterus, he advocates placing the patient in Sims' position, and packing the vagina quite firmly with pledgets of cotton soaked in glycerin. This procedure should be repeated every 2 or 3 days, each time packing more firmly. After several treatments, pelvic massage should be added, and attempts made to dislodge the uterus. If the adhesions are very dense, and little can be accomplished by this method of treatment, a radical abdominal operation should be done; in this class of cases he prefers supravaginal hysterectomy to suspending the uterus. [Since suspension of the uterus has proved so successful in a large majority of these cases, hysterectomy in every case would certainly be too radical a procedure. F.C.H.]

2.—Judd has made a study of the **causes of dysmenorrhea** in 700 patients, and concludes his article as follows: Most cases of dysmenorrhea are due to congestive inflammatory conditions of the uterus and its adnexa. In a certain proportion of cases the neurotic condition is a larger element in the causation of the pain than the inflammatory condition. [F.C.H.]

3.—Edgar discusses the **causes and the significance of the obstetrical hemorrhages**, under the following divisions: (1) the metrorrhagia of pregnancy; antepartum hemorrhages. May be due to abortion or miscarriage; placenta previa; premature separation of a normally-situated placenta; ectopic gestation; traumatic or spontaneous rupture of the uterus; menstruation during gestation; the exanthemas; to conditions of the heart, liver and abdominal viscera producing obstructed venous return; hematosalpinx; fibroma, sarcoma and polypus of the uterine body, and polypus and epithelioma of the cervix. (2) the metrorrhagia of labor; partum and intrapartum hemorrhage. These are due principally to premature separation of a normally or abnormally situated placenta; to ruptures of the uterus or cervix; fibroid tumors, malignant disease of the genital tract or rupture of varicose veins; uterine inertia (especially occurring with a partial or complete separation of the placenta); lacerations of the genital tract; insufficient contraction of the lower uterine segment, in cases of low implantation of the placenta; partial or complete inversion. (3) Puerperal metrorrhagia proper, or secondary postpartum hemorrhages. Puerperal hemorrhages are those occurring from 6 hours after the third stage of labor until the completion of the normal period of involution, namely 6 weeks. The causes are general and local. Among the **general causes** are: mental emotions; disturbances of the general circulation; certain blood conditions, as extreme malarial poisoning, albuminuria and puerperal sepsis, and the acute infectious diseases. Among the **local causes** are: anything which interferes with the proper contraction of the uterus (as retained blood-clots, a secondary placenta); a distended bladder or rectum; retroflexion; inversion; fibroid and polypoid tumors; cervical lacerations; malignant diseases of the uterus and simple subinvolution. Other causes are: assuming the upright position too soon after delivery and too early sexual intercourse. [F.C.H.]

4.—Johnson reports a very interesting case of **osteofibroma of the uterus**, for which he did a panhysterectomy. The specimen was forwarded to Dr. William Welch for examination, who rendered a report about as follows: The tumor must be referred to embryonic remnants, and there is no objection to considering it as a teratoid formation, although not a very complex one. Besides the bone and smooth muscle, there is a great deal of peculiar embryonic connective tissue in the growth, partly mucoid in character, and partly more cellular, and this tissue is quite unlike any found in ordinary myomatous tumors. [F.C.H.]

5.—Kirkley reports a case of **natural ureterointestinal anastomosis**, following an abdominal section for bilateral pyosalpinx. The patient was evidently of the hemorrhagic diathesis. A drainage tube was employed, and was removed at

the end of 24 hours. On the fourth day, pus was present in the track of the drainage tube; the cavity was thoroughly irrigated and gauze drainage instituted. Although free drainage was maintained, the entire pelvic cavity appeared to be a pyogenic surface. On the fifteenth day fecal matter appeared in the discharge through the abdominal opening, and on the twenty-second day, urine. A secondary operation for closure of the fistula was deemed inadvisable, and after persisting for 2 weeks, urine ceased to escape, closely followed by the disappearance of the fecal matter. After the urine ceased to escape through the abdominal opening, it passed per rectum. Three years after the operation, he again saw the patient, and the urine was still escaping into the bowel. This time the uterus was everted. Had hysterectomy been practicable at first, it would have been far better for the patient, and it may yet have to be done, but so long as the patient can be comfortable, and with only the inconvenience of passing urine per rectum, the attendant complications and the unknown intraabdominal conditions make that operation somewhat uninviting. [F.C.H.]

6.—In this article on the **treatment of cancer of the uterus**, Bovée merely desires to contrast the various plans of treating the disease after it is discovered, and to call special attention to the advance surgery of it. He describes the various radical operations devised by Ries, Rumpf, Clark, Werder, Pryor, Chalot and Wertheim. He condemns the operation done by Chalot, and considers the operations of Pryor and Wertheim by far the most radical. Bovée prefers his modification, which is a combination of those of Werder, Ries and Pryor. [F.C.H.]

Münchener medicinische Wochenschrift.

March 19, 1901. [48 Jahrg., No. 12.]

1. Experimental Investigation of Hand Disinfection. PAUL and SARWEY.
2. Clinical Experiences with Intravenous Injections of Cinnamic Acid in the Treatment of Tuberculosis of the Lungs. KUHN.
3. The Therapeutic Value of Heroin and Aspirin. NUSCH.
4. The Treatment of Gonorrhoea with Protargol. NIESSEN.
5. The Technique of Lorenz's Reposition of Congenital Hipjoint Luxation. SCHLESINGER.
6. Treatment of Ileus with Atropin. SIMON.
7. A Case of Ileus Treated with Atropin. HÖCHTLEN.
8. The Treatment of Ulcer of the Leg. SCHULZE.
9. Max v. Peltenkofer. LEHMANN.

1.—In their sixth paper on their investigations of various methods of **disinfecting the hands**, Paul and Sarwey take up the use of sublimate, or, more properly, the mercuric salts. Their experiments concern chiefly the use of ammonium sulfid as an agent to counteract the injurious effects of corrosive sublimate on the hands after disinfection by means of solutions of that salt. As a general result of their investigations, they come to the conclusion that the methods in present use are too uncertain and too faulty, and that new methods must be devised in order to keep a noninfected operative wound germ-free and thus capable of healing with no more reaction than a subcutaneous lesion. [H.H.C.]

2.—Kühn has employed **hetol** (sodium cinnamate) after the method of Landerer in the treatment of **tuberculosis**. In all cases the results were slight, and could just as well be attributed to an improvement in the patient's mode of life as to the action of the drug. The treatment, which is carried out by intravenous injection, is, however, harmless, and further investigations are warranted. [D.R.]

3.—Nusch believes that **heroin** is preferable to morphin as a remedy for the cough of tuberculosis. He never observed disagreeable aftereffects, and does not think that it is more toxic than morphin. **Aspirin** is the acetic acid ester of salicylic acid. It is useful as an antirheumatic, antineuralgic, analgesic and antipyretic, and does not possess the disturbing effects of salicylic acid. The dose is .25 to .5 grams ($3\frac{1}{2}$ to $7\frac{1}{2}$ grains). [D.R.]

4.—In summing up the results obtained by the use of **protargol** in 244 cases of **gonorrhoea** in the Münich lazarette, Niessen finds that: (1) By this treatment the gonococci disappear from the secretion in acute anterior urethritis in about

the same length of time (3 weeks) as when treated with silver nitrate; (2) in $\frac{1}{2}$ to $\frac{2}{3}$ % solution the salt causes very little discomfort; (3) complications are less liable to occur than by use of silver nitrate; (4) in the mucous and serous stages in which gonococci are no longer present, astringents are better than protargol; (5) the protargol treatment does not shorten the course of the disease more than the best of the earlier methods. [H.H.C.]

5.—Schlesinger reports 6 successful cases of **reposition of congenital hipjoint luxation** by means of Lorenz's method. He advocates the use of a plaster cast to fix the limb in the position desired, after which at the most only 3 trials are necessary to reduce the dislocation. [H.H.C.]

6 and 7.—(See editorial).

8.—In the treatment of **leg ulcers** Schulze recommends an ointment composed of camphor, 2 grams (30 grains); zinc oxid, 15 to 20 grams ($3\frac{1}{2}$ to 5 drams); lard, enough to make 100 grams ($3\frac{1}{2}$ oz.). If this ointment is not well-borne, a solution of camphor in olive oil may be employed, made as follows: Camphor, 2 grams (30 grains); olive oil, 50 grams ($1\frac{1}{2}$ oz.), to which 40 to 50 grams ($1\frac{1}{2}$ to $1\frac{3}{4}$ oz.) of zinc oxid are added. Cloths are soaked in this and laid upon the ulcer. The dressings are changed 2 or 3 times a day. [D.R.]

1.—(Editorial.)

2.—A peculiar case of **cirrhosis of the liver** in a man of 53 who had been a life-long alcoholic. The symptoms were those of what has been called **mixed cirrhosis**; that is, cirrhosis in which, in addition to enlargement of the liver and spleen, and marked jaundice, there were signs of stasis in the portal circulation—acites, distention of the abdominal veins, gastrointestinal catarrh and edema of the lower extremities. Autopsy showed an enlarged, coarsely granular liver, of a greenish-yellow color; parenchymatous myocarditis and parenchymatous nephritis. Counting from the commencement of the symptoms until death, the disease had lasted only 6 weeks; although it might be inferred from the histologic picture, which showed the presence of an abundant old fibrous tissue, that the disease had begun earlier. The author believes that some other factor must have been added to the alcohol; perhaps an infectious or a toxic one. [D.R.]

3.—Experiments on dogs show that a mixture of **plasmou and tropon** is well utilized, and may bring about a retention of nitrogen in the system and an increase in body weight. The amount of unused nitrogen, as evidenced by an analysis of the feces, was determined in various conditions experimentally induced in dogs. After extirpation of the pancreas, the mean loss was greater than after extirpation with transplantation of that organ. [D.R.]

4.—It is generally accepted that miners and other workers in coal have a **greater resistance to tuberculosis** than persons engaged in other dust occupations, such as masons, sculptors, etc. In an endeavor to explain this phenomenon, Papanotiriu made some experiments to determine whether coal of different kinds has a direct inhibitory action on the tubercle bacilli. He found that this was not the case. [D.R.]

5.—Although the Japanese dancing mouse is apparently devoid of a sense of **equilibrium**, and performs unceasing gyrations, there is no noteworthy difference between its **organs of hearing and equilibrium** (semicircular canals and utriculi) and those of the ordinary house mouse. [D.R.]

6.—An unsuccessful attempt to remove a **button** from the **left lung** of a youth of 17 is reported by Spiess. The button was

inhaled over 6 years previous to the final attempts at removal, which consisted in the use of Killian's instrument modified to suit the case by Spiess. After tracheotomy the forceps was introduced a number of times and the foreign body felt in an abscess-cavity, but could not be removed because of contraction of the neck of the cavity. The patient finally died of hemorrhage and tuberculous infection. [H.H.C.]

7.—Diehl reports the case of a woman of 22 who, as a result of an attempt at suicide, was compelled to use a permanent silver tracheal canula. In changing the old for a new canula, the former, the shield of which had broken off, was aspirated, after which, in her anxiety, the patient thrust the new canula into the tracheal opening, thus pushing the old one still farther down. On the following day, during the preparation for tracheotomy, and while the patient was under anesthesia, a violent fit of coughing resulted in the expulsion of the old canula intact. [H.H.C.]

1.—Brill reports 3 cases of primary splenomegaly occurring in a single family—a woman aged 34 years, a man aged 30 years, and a boy who died at the age of 9 years. The distinctive features of the disease in the living brother and sister are; The enormous enlargement of the spleen, that of the sister being the greater; the enlargement of the liver, that of the brother being the greater; the profuse perspiration and sudamina; the absence of anemia for more than 10 years after the disease had been established; the tendency to hemorrhage, manifested in the occasional oozing of blood from the gums in the sister, in an occasional epistaxis in the brother, and in the attack of hemorrhagic furunculosis in each; the peculiar brownish-yellow (nonicteric) color of the skin; the long duration of the disease; the feeling of comfort and ease, notwithstanding the enormous size of the spleen and the pressure upon the thoracic viscera; the yellow, wedge-shaped conjunctival thickening of each side of the cornea of each eye, that in neither case look like pinguiculas. At the time of reporting both patients showed a moderate reduction in the number of erythrocytes and a somewhat greater reduction in the hemoglobin—blood of the chlorotic type. It is believed that the symptom-complex is sufficient to separate the cases from cases of splenic anemia and to place them in a special group. A search of the literature, revealing the darkness in which the pathology of the spleen is concealed, discloses but 6 cases that B. believes are similar, if not identical, to the 3 he reports. He suggests that the disease, perhaps, has a relation to some perversion of visceral development occurring in families. Finally he discusses the enlargement of the liver occurring in the cases, and the relation of the affection to diseases variously described, splenomegalic hepatic cirrhosis, Banti's disease, and the like. [A.O.J.K.]

2.—Arneill, in a discussion of enteroptosis, insists upon the frequency of the association of ptoses of the different abdominal organs, stating that it is unscientific and unsatisfactory to select for discussion one dislocation, such as gastropotosis or nephrotosis, and thrust upon it, as is sometimes done, the dignity of a special disease. Basing his observations upon 80 cases from Dock's clinic, he speaks of the history, the methods of examination, the etiology, and the treatment of the affection. With regard to methods of examination, inspection often reveals a fulness below the umbilicus and a depression in the epigastrium. The various abdominal organs should be palpated in both the upright and recumbent position. In examining the stomach, the method of distention by generating carbonic acid

by means of tartaric acid and sodium bicarbonate is preferred. Of the 80 cases examined, 69 were women and 11 men. In 24 cases both kidneys were dislocated, in 33 cases the right kidney alone, and in 4 cases the left kidney alone. Stiller's phenomenon—the costal stigma or floating tenth rib (thought to be significant of neurasthenia and enteroptosis)—was present in 8 of 15 cases; in the remaining 7 cases, the rib had membranous attachments. In 69 of the 80 cases there was downward dislocation of the stomach. In a few cases there were both dislocation and dilation. Thirty-five of the 56 women had borne children; 20 had never borne children. The symptoms varied considerably. A number of the patients were simply debilitated; in a much larger class nervous symptoms predominated; and in others there were striking symptoms on the part of the stomach and kidneys. It is believed that there is no connection between enteroptosis and tuberculosis nor between enteroptosis and chlorosis. In some cases there seems to be a congenital predisposition to the disease; in other cases there is a lack of tone in the tissues that makes it possible for trifling causes to produce the enteroptosis. Of special etiologic factors the following may be mentioned: All conditions tending to diminish intraabdominal pressure, frequent child-bearing, ascites requiring tapping, operations for intraabdominal tumors, severe infective diseases and chronic wasting diseases that weaken the abdominal muscles and cause a disappearance of the fat, and straining at stool, a cause usually overlooked. As regards treatment, in the majority of cases operation is contraindicated. Abdominal bandages may relieve some cases; exercise and massage are useful. He has seen marked benefit from the use of tincture of nux vomica, increased gradually to 70 or 80 drops 3 times daily, combined with overfeeding. [A.O.J.K.]

3.—Edsall, writing of the estimation of the urinary sulfates in the diagnosis of pancreatic disease, as a result of personal observation and of study of the literature, concludes that if there be found no reduction in the ethereal sulfates, the result deserves little consideration; if, on the other hand, the ethereal sulfates are found much reduced, the other factors in the case must be considered. If there is diarrhea or gastric hyperchlorhydria, or if the patient is on milk diet alone, or any other diet which very largely reduces bacterial activity, a low ratio of the ethereal sulfates cannot be considered of great importance, nor can much stress be laid on a low, absolute value of the ethereal sulfates if the value for the preformed sulfates be coincidentally low. If, however, these factors are not present, and particularly if, with suspicion of pancreatic disease, factors that usually cause an increase of the ethereal sulfates be present, and yet the values be found low, the test would appear to be of distinct practical importance in diagnosis. As to the importance of fatty stools in the diagnosis of pancreatic disease, it is pointed out that poor fat absorption is of itself of no importance in the diagnosis of pancreatic disease if icterus be present. The importance of this statement is especially evident in view of the fact that in carcinoma—the most common disease of the pancreas—icterus is very common. With regard to the splitting of fats said to be much reduced in pancreatic disease, it is stated that it seems probable that a negative result of the test is not of much value, for such a result is subject to about the same considerations as obtain with regard to the ethereal sulfates. A positive result, however, as far as our knowledge goes, would seem to indicate pancreatic disease if diarrhea is absent. [A.O.J.K.]

4.—Adriance, basing his remarks upon an examination of 40 premature infants, discusses their anatomic and physiologic characteristics, considering their general features and the different organ-features seriatim. Of the 40 infants, 24 died; 11 of them, however, succumbed to infantile diseases of later life. A predisposition to unbalanced nutrition on the part of the infants, artificial feeding, and the unhygienic conditions of institution-life are large factors in the death-rate. As regards prognosis, the more premature the infant the more hazardous the outlook, few infants born before the twenty-ninth week being saved. The temperature has no prognostic value; attacks of cyanosis are not necessarily fatal; continued loss of flesh is discouraging and the sooner a steady gain is noted the better. As regards to treatment, the necessity of attention to details is

The following-named contract dental surgeons will proceed from Washington, D. C., to San Francisco, Cal., and report for transportation to Manila, P. I., where they will report for assignment to duty: HUGO C. RIETZ, WILLIAM H. WARE.

CHALMERS, Major THOMAS C., surgeon, Presidio, is granted leave for one month.

MCCALLUM, Captain FRANCIS M., assistant surgeon, is assigned to temporary duty with troops on the army transport Grant, to sail for the Philippine Islands.

PEED, Captain GEORGE P., assistant surgeon, Presidio, is granted leave for 1 month, to take effect on the day of muster out of the 25th infantry, U. S. volunteers.

STROMBERGER, HENRY H., acting assistant surgeon, will proceed to his home, Washington, D. C., for annulment of contract.

METZGER, Major JOHN A., surgeon, recently appointed, is relieved from further duty with the 35th infantry, U. S. volunteers, and will report for transportation to Manila, P. I., where he will report for assignment to duty.

WILLIAMS, Captain ROBERT E., assistant surgeon, recently appointed, is relieved from further duty at Fort McDowell, and will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

The following-named officers are detailed to represent the medical department of the army in the annual meeting of the American Medical Association to be held at St. Paul, Minn., June 4 to 7: Major TIMOTHY E. WILCOX, surgeon; Major CHARLES RICHARD, surgeon. The officers named will proceed to St. Paul, Minn., in time to reach that place on or before June 4, and upon the adjournment of the association will return to their proper stations.

The following-named officers are detailed to represent the medical department of the army at the tenth annual meeting of the Associations of Military Surgeons of the United States to be held in St. Paul, Minn., May 30 to June 1: Major JOHN VAN R. HOFF, surgeon; Captain ALFRED E. BRADLEY, assistant surgeon. Major Hoff will proceed to St. Paul, Minn., in time to reach that place on or before May 30, and upon the adjournment of the association will return to his station.

CURRY, Captain JOSEPH J., assistant surgeon, leave granted is extended 7 days.

CARLING, Captain JOHN, assistant surgeon, recently appointed, is relieved from further duty with the 35th infantry, U. S. volunteers, and will report for transportation to Manila, P. I., where he will report for assignment to duty.

STROMBERGER, H. H., contract surgeon, is granted leave for 1 month.

Changes in the Medical Corps of the U. S. Navy, for the week ended May 4, 1901:

LAW, H. L., surgeon, retired, detached from the recruiting rendezvous, Buffalo, N. Y., and ordered home.

WRIGHT, B. L., assistant surgeon, ordered to the Massachusetts, May 1.

RODMAN, S. S., assistant surgeon, detached from the Adams, May 11, and ordered to the Alert, May 11.

Changes in the U. S. Marine-Hospital Service for 7 days ended May 2, 1901:

CARMICHAEL, D. A., surgeon, to assume temporary command of San Francisco quarantine station—April 27, 1901.

WERTENBAKER, C. P., passed assistant surgeon, to proceed to Prescott, Arkansas, for special temporary duty—April 27, 1901.

GREENE, J. B., passed assistant surgeon, detailed for temporary duty in the Bureau—April 29, 1901.

HEISER, V. G., assistant surgeon, to proceed to Norfolk, Va., for special temporary duty, April 27, 1901. To proceed to Quebec, Canada, and report to the United States Commissioner of Immigration, for duty—May 1, 1901.

SCHLAAR, W. F., hospital steward, granted leave of absence for 26 days—March 29, 1901.

Changes in the Medical Corps of the U. S. Army for the week ended May 4, 1901:

KULP, Major JOHN S., surgeon, is relieved from duty in the division of the Philippines, and will proceed to San Francisco, Cal., thence to Fort Hancock. A delay of one month en route is authorized.

GILBERT, Major WILLIAM W., is granted leave for 2 months, on surgeon's certificate, to take effect upon arrival in the United States.

BLOCK, W. H., acting assistant surgeon, is granted leave for 1 month.

HORR, Captain E. F., assistant surgeon, is relieved from duty at Manzanillo, Cuba, and will proceed to Columbia Barracks, Quemados, Cuba, for duty.

GRAVES, Captain LEONARD K., assistant surgeon, now in Brooklyn, N. Y., will upon the expiration of leave granted him April 22, proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

SPARRENBURGER, Captain FREDERICK H., assistant surgeon, recently appointed, now in San Francisco, Cal., will report for transportation to Manila, P. I., where he will report for assignment to duty.

RAYNOR, Captain WILLIS J., assistant surgeon, is relieved from duty at Fort Washakie, to take effect upon the expiration of the leave granted him April 19, when he will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

MASON, Captain CHARLES F., assistant surgeon, will report to Lieutenant Colonel Calvin De Witt, president of the examining board at the Army Medical Museum Building, Washington, D. C., for examination for promotion.

WILCOX, STARLING S., contract surgeon, now at Columbus, Ohio, will report at Columbus Barracks for duty, to relieve contract surgeon Najib Taky-nd-Dcen, who will proceed to San Francisco, Cal., and report for assignment to duty with troops en route to the Philippine Islands, and upon arrival at Manila will report for assignment to duty.

OHLINGER, LORIN B., contract surgeon, now at the U. S. general hospital, Fort Bayard, will report to the commanding officer of that hospital for duty.

SMITH, A. B., contract surgeon, is granted leave for 10 days.

SCHERRER, ELMER A., contract surgeon, is relieved from duty at Fort Grant, and will proceed to Fort Washakie, for duty.

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free: foreign postage, \$2.50. Subscriptions may begin at any time. Volumes end with the last issues of June and of December.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

Pneumonia More Fatal than Tuberculosis, is the teaching of statistics. In New York, from 1890 to 1900, there were 56,092 deaths from pneumonia, and 50,490 from pulmonary tuberculosis, and in Chicago the relative figures are 25,228, and 22,957. The increased mortality from pneumonia is ascribed to influenza, which although also increasing the fatality of tuberculosis, does so to a much greater degree in the more acute disease, pneumonia. The fact that the first death from influenza in New York was reported in December, 1889, shows how suddenly the causes of death may change, and how quickly we must be prepared to deal with new and dangerous diseases. The report of the New York State Board of Health for the month of March shows that influenza has caused about 1,500 deaths, and that 76% of the deaths from acute respiratory diseases were from pneumonia. The fundamental condition underlying the rise and continuance of an acute infectious disease, such as influenza, is probably the tremendously increased amount of travel. Reinfection from new foci constantly occurs in places in which the disease is dying out, and every city or part of the country is bound up with all others by the railroads. The problem of disease in a high state of civilization becomes more than ever one of prevention, and yet how slow is civilization to recognize and act upon the fact. Millions for tribute but not one cent for defense, is the motto of the modern "statesman."

Physicians' Strikes.—We have long wondered when physicians, irritated by a hundred forms of popular ingratitude, would go on strike. While laboring heroically to prevent disease and thus committing professional suicide, we are constantly maligned, the lowest kind of protection is generally denied to us by the lawmakers and Government-protected quackery flourishes. But according to the proverb, even the worm will turn; and it has turned in Germany. The Sickness Bureaus (*Krankenkassen*) are the intermediaries whereby about 30,000,000 people obtain practically free medical service—of course at the expense of the profession. When the bureaus made the physicians into slaves by all sorts of demands, at about 15 cents a call, or \$75 a year, most naturally there was "a strike," or what the newspapers call a recurrence of the old question of "recognizing the Union." Fifteen cent fees for cases of obstetrics, or operations, was more than human nature, even of the long-suffering bureaucratic German type could endure.

The strange thing in all these cases is that the public does not recognize that the service obtained by such methods and prices can hardly be called medical. How can therapeutics be possible under such conditions? Physicians would be more than human who could keep such ludicrous relations from vitiating into extremes of abuse and degradation. It is as poor financial policy for the patient as for the doctor. We wish that the charges of "medical monopoly" by the hate-filled antis were truer or more possible of realization among us.

The Most Illogical Thing in the World is to sacrifice life itself in the fight for the luxuries of life. The Health Department of Chicago finds that during the week of high stock speculation in Chicago there was an increase of about 25% in the normal number of deaths of people 60 years of age and over. Money, of course, represents only the means of carrying on the business of life, and when the craze for it reaches such an intensity that it hastens death, it becomes a positive disease. In all the severe symptoms of the disease exhibited in the trust-formings, stock-waterings, and stock-speculations, our quiet professional world goes on with its beneficent work of healing, untouched, directly, we hope, by the furious greed of wealth that uses up life in the illogical chase for the means of living. It is fortunate if the gathering and analysis of vital statistics has become so accurate that the figures are able to point us to the origins of disease and the lessened deathrate. And yet there were always in our ears the warning axiomatic words, "What shall it profit a man if he shall gain the whole world and lose his own soul?" Disease and death are old teachers of morality. How slowly is the lesson learned!

The Relation of Gallstones to Acute and Chronic Cholecystitis.—The most interesting and perhaps the most important papers read before the American Surgical Association in Baltimore were those by Mr. A. W. Mayo Robson, of Leeds, England, and Dr. Eugene L. Opie, of Baltimore, Mr. Robson's especially from the clinical and operative side, and Dr. Opie's from the experimental. Opie has demonstrated that bile, when injected through the pancreatic duct into the pancreas, produces at once a very extensive acute hemorrhagic pancreatitis. Some of the animals died within 20 hours after the onset. In a few instances recovery took place. This demonstration seems to explain the cause of the

hemorrhagic pancreatitis when associated with a small stone in the diverticulum of Vater.

Anatomically we know that into this diverticulum both the common bile and the pancreatic ducts open. A small gallstone, smaller than the diameters of the diverticulum, may plug completely or partially the opening into the duodenum at the papillas, but on account of its smaller size it does not obstruct the orifices of the two ducts; so that the bile completely or partially dammed from the intestinal canal may pass from the common duct into the diverticulum and then through the pancreatic duct into the pancreas and produce acute hemorrhagic pancreatitis. Opie has proven conclusively that bile can produce such lesions, and without the aid of infectious agents. Clinically he has observed the same possibility in the patient operated on by Professor Halsted. This patient, admitted in a moribund condition, died a few hours after the exploratory laparotomy. Clinically the symptoms were intense epigastric pain, profound collapse, slight jaundice, and bile in the urine. At the autopsy there were found widespread, disseminated fat necrosis and a huge swollen pancreas with areas of hemorrhage within and without. In the diverticulum of Vater a small gallstone was found which plugged the orifice of the papillas, but did not prevent the bile from entering the diverticulum from the common bile-duct. The large pancreatic duct and some of its branches were bile-stained. This case seems to confirm Opie's experimental work. In the second case in the same clinic a similar pathologic condition was found, except that the patient had survived the hemorrhagic stage, and when death took place there was a large peripancreatic abscess. In the literature many cases of acute hemorrhagic pancreatitis have been associated clinically with a previous history of gallstone colic and at some of the autopsies gallstones had been found. It may be possible for the small stone to lodge in the diverticulum long enough to dam back the bile in the pancreatic duct, produce the hemorrhagic pancreatitis and then slip into the duodenum and be lost, so that at the autopsy the relation between the gallstone and the pancreatic lesion is lost sight of. Opie's experimental work and his one most positive autopsy-finding seem to prove without a question that a gallstone lodged in this position is one of the causes of hemorrhagic pancreatitis. Other causes there may be, but these are yet to be demonstrated. Surgically this relation should be borne in mind, so that at the operation for hemorrhagic or suppurative pancreatitis the gallstone in this position should be sought for and removed, whenever the condition of the patient will allow this procedure. Flexner, in his work on "Experimental Pancreatitis," published in the Festschrift to Professor Welch, in 1900, has demonstrated that many substances injected into the pancreas produce pancreatitis, and states (p. 745) "the element of infection plays an insignificant if not an entirely unessential part." The possibility that bile could be dammed back into the pancreas and produce hemorrhagic pancreatitis was not demonstrated or considered. Nor had Opie considered this possibility in his article of "Fat Necrosis" in the same publication.

The relation of gallstones to chronic pancreatitis is of

more practical surgical interest, because the condition is cured by proper operative interference. Both Robson and Opie have demonstrated both clinically and experimentally that a stone lodged in the common duct just above the diverticulum of Vater, or completely plugging the diverticulum, produces obstruction, not only to the biliary, but to the pancreatic secretions, which in the pancreas leads to chronic interstitial pancreatitis. This lesion in the pancreas gives it a hard nodular form, often mistaken for carcinoma. Clinically, it is associated with great loss of strength and weight. The disease is rapidly cured by the removal of the stone. Every surgeon is familiar with the rapidity with which the emaciated jaundiced subjects improve after the removal of the stone. In some cases the stone is not found at the operation. The stone or stones probably have passed into the intestine. Robson has demonstrated that such patients are relieved by cholecystotomy and drainage. This relieves tension, allows the absorption of the exudate and the pancreatic duct becomes patent again. The chronic interstitial pancreatitis disappears; the general health and condition of the patient improves. This explains instances in the experience of every abdominal surgeon. Such patients give a history of recurrent gallbladder attacks with more or less jaundice and more or less loss of flesh and strength. At the operation no stone is found to explain the symptoms. If the pancreas is palpated it is found to be hard and nodular, almost like in carcinoma, the bile dark and inspissated. If cholecystotomy and drainage for a few weeks is performed, the condition is entirely relieved. Robson reports cases which he thought at the operation might be carcinoma, relieved by this procedure. These observations would seem to indicate that we would better perform temporary cholecystotomy in all cases coincident with the removal of stones from the common duct.

The Proper Study of Mankind is the Child, might be taken as the motto of the modern educator. In advocating the establishment of a Physiologic Laboratory under our Government Mr. Arthur MacDonald says:

"Much money has been given and great interest manifested for the discovery of new chemical elements or the search for unknown planets. We erect statues and found art galleries at great expense. These things may not all be immediately useful. Indeed, the highest art spurns even the idea of utility; and yet when it is proposed to study a child thoroughly to gain an insight into its nature, to find the causes of its defects, so that we may protect it and help it to become a good citizen, the utilitarian cry is heard. The time has come when it is important to study a child with as much exactness as we investigate the chemical elements of a stone or measure the mountains on the moon.

"Our Government pays out millions to catch, try, and care for criminals, but gives very little to study the causes that lead to crime. The study of man, to be of most utility, must be directed first to the causes of crime, pauperism, alcoholism and other forms of abnormality. To do this the individuals themselves must be studied. As the seeds of evil are usually sown in childhood and youth, it is here that all investigation should commence, for there is little hope of making the world better if we do not seek the causes of social evils at their beginnings. The most rigid and best method of study of both children and adults is that of the laboratory, with instruments of precision in connection with sociologic data. Such inquiry consists in

gathering sociologic, pathologic, and abnormal data as found in children, in criminal, pauper, and defective classes, and in hospitals. Such experiments or measurements should be made as are of interest not only to sociologists, psychophysicists, and anthropologists, but also to physiologists and pathologists.”

The Increase of Smallpox in the United States.—

According to the Public Health Reports there have been the following numbers of cases of smallpox from December 28, 1900, to May 3, 1901, compared with those of the same period in 1900 :

State.	Cases.	Deaths.	Same period, 1900.	
			Cases.	Deaths.
Alabama.....	45	3	172	1
California.....	64	3
Colorado.....	1,763	96	2

These figures show plainly that somebody is at fault. That it is not the medical profession is demonstrable. Vaccination is protective, and the lessened mortality with almost three times the number of cases proves that we are treating the disease itself four times more successfully than a year ago. We fear that the Boards of Health, the law-makers, public lethargy, and the anti-vaccination cranks are to blame.

Blood-examination as an Aid to Surgical Diagnosis.—

The papers on this subject read before the American Surgical Association at Baltimore last week demonstrate the important place that the microscopic examination of blood has taken in the differential diagnosis of surgical lesions. Such examinations most certainly cannot be considered a fad. Although the number of observations are as yet somewhat meager, and as yet cannot be considered scientifically classified ; nevertheless they are sufficient in many conditions to be of most practical value, and if properly interpreted by

a surgeon who will take the trouble to become familiar with the results, they will undoubtedly guide rather than misguide him to an earlier diagnosis in many acute lesions, especially abdominal, which would prove fatal without this early recognition. J. C. DaCosta, Jr.'s paper was of great importance in that it presented clearly the anemia in appendicitis. This anemia, present in many cases of appendicitis, associated as it always is with a slight rise in the number of leukocytes, explains some of the cases of a slight leukocytosis out of proportion to the inflammatory lesion found at the operation. These observations demonstrate that at the first examination of the blood in appendicitis a red count and a hemoglobin test as well as a white count should be made, in order that the element of leukocytosis due to the anemia should be estimated before interpreting the full significance of the white blood-count. The paper written by Drs. Blake, Hubbard, and Cabot, of Boston, is of especial importance, and establishes pretty conclusively that there is no leukocytosis after simple fractures or uncomplicated fractures. These observations will, therefore, aid us in the early recognition of simple or compound fractures. The most important perhaps is their demonstration that the leukocytosis, after ether, with or without operation, or after the ordinary operative interference, with or without ether, is slight when present at all—from 12,000 to 15,000 and fleeting, 12 to 36 hours. The paper of DaCosta and Kalteyer dealt with a number of very careful and elaborate observations on the effect of a general anesthetic on the condition of the blood. Their experiments seem to prove that an anesthetic diminishes the hemoglobin, especially the hemoglobin carrying power of the individual red cell. This experimental work explains therefore, the danger of a general anesthetic in marked anemia, especially that form in which the hemoglobin percentage is very low. Bloodgood's paper dealt chiefly with the leukocytosis of appendicitis, peritonitis, and intestinal obstruction. The number of observations was not sufficient to allow him to make positive statements, but was sufficient for certain conclusions which so far have been of great practical value in his own experience. In the first 48 hours of acute appendicitis a high leukocytosis, above 18,000, especially a rapidly rising leukocytosis is, with very few exceptions, associated with grave inflammatory lesions of the appendix, such as gangrene, an appendix distended with pus, or beginning local or general peritonitis. In a few instances the rising and the high leukocytosis have been the chief or only positive indication for operative interference, and in each instance proved of great value, perhaps the saving of the patient's life. A leukocytosis, even up to from 20,000 to 25,000 is always associated with intestinal obstruction. This rise is rapid and early, and in many cases an indication of the lesion before the clinical signs are clearly established. In peritonitis, if the patient has any resistance, the leukocytes rise rapidly and high, even to 40,000, soon falling to normal or below.

Should Ambidexterity be Encouraged? — Is answered in the negative by a writer in the *American Journal of Insanity*, and upon the ground that, while

coarse movements may be performed nearly as well by one half of the body as by the other, accurate and expert movements require a higher organization of one-half of the brain than the other. Hence the more expert hand should be consciously still more and more specialized; making the ordinarily quiescent half of the brain assume control tends, it is said, to impairment of mental processes as well as inferiority of physiologic speed and dexterity. All of which we deny, both fact and theory being untrue. The writer has doubtless been misled by observation of the function of speech, which is single and in execution requires the control of a single center. We have but one voice, but we have two hands which in many cases at different instants may be put in action with the same dexterity. Many surgeons can operate equally well with either hand; many artists paint with either hand, and we have seen men who could write as well with the one hand as with the other. The critic of ambidexterity may reply that this is impossible with synchronous movements, forgetting that in the musician, and especially in the pianist and organist, there is the most marvelous expertness of both hands executing most complicated and entirely different functions, and at the same instant. The arguments against ambidexterity appear not only inconclusive but are squarely contradicted by facts. Surely also they are against a desirable freedom of the mind. Without the musician's ambidexterity life would be deprived of much charm. We should encourage "divided attention," and that large power of the mind over the body shown in the synchronous control of multiform activities.

A Hydrotherapeutic Institute for Philadelphia.

—Dr. Simon Baruch, of New York, read before the Philadelphia County Medical Society last week an extremely interesting paper entitled "The Lessons of a Decade in Hydrotherapy." In the discussion following this paper, it was urged by a member of the Society that there should be established in every important medical center and, if possible, in every town containing a sufficient number of physicians, a central therapeutic institute for the practical application of those remedial measures other than drugs that may be grouped under the term of "Physiologic Therapeutics." It was suggested that such an institution could be under the supervision of the local medical association, so that it should be managed on strictly professional and scientific lines. No patients should be received, except with written order from their attending physicians. It should afford facilities for hydrotherapy, for pneumatotherapy, for electrotherapy, for the application of massage and various kinds of exercises, for the use of heat and light—in a word, for the employment of all the physical agencies which are so important in treatment, and yet so much neglected. This neglect arises largely from the fact that while it is comparatively easy to write prescriptions for drugs, no one physician can thoroughly equip himself with the necessary apparatus for all the physical methods of treatment, or attain the highest skill in the manipulation of all such instruments; or, indeed, take the time to apply any one group of them in the treatment of every case in which they might do good. We

seek to reach the result in some other way; sometimes succeeding; often failing. At such an institute as has been suggested, skilled nurses and attendants, trained in the necessary manipulation, could carry out much of the treatment, and those applications requiring special medical education and technical dexterity could be entrusted to resident physicians or externes appointed for the purpose. Physicians could refer their patients to the institute with prescriptions for definite applications of water, light, heat, electricity, air, etc., as they are now referred to the drug store with definite prescription for drugs.

As a result of the suggestion made at the County Medical Society, we understand that a movement has been set on foot to make a beginning in this city by the establishment of facilities for hydrotherapeutic treatment open to any member of the profession, and that Dr. Baruch has been asked to become consulting physician and to make visits on stated occasions (weekly or as may be necessary) in order that the benefit of his knowledge and experience may be had for the installation of the necessary apparatus, for the training of the attendants and for the supervision of the numerous details necessary to insure the success of the enterprise at its beginning. The proposed plan, we understand, would be for the physicians to send their patients either with definite prescriptions for the applications to be made, or for preliminary testing and report of the patient's susceptibility and reaction to hydrotherapeutic measures in general. Upon the receipt of this report, with such suggestions as might seem desirable, or as the physician might ask for, the latter would then write a definite prescription, which would be followed out according to his order. If he preferred, he could personally supervise the applications.

The proposition seems feasible, and its execution would mark a decided step in advance, both in professional cooperation and in the direction of scientific therapeutics. We trust that the movement may be successful, and that it may stimulate a more general study of the nonmedicinal measures applicable for the relief of chronic disorders, and a better utilization of them by the rank and file of the profession.

In reply to our note concerning the melancholia following or ascribed to influenza, an astute correspondent wrote that treatment according to the uric acid theory would bring immediate relief. And in fact it did so. But inquiry of wise therapeutists elicits the qualification that the efficacy of sodium salicylate is by no means limited to rheumatic affections, or explainable on the uric acid hypothesis. In passing, it may be added that an excellent method of ordering the drug is as follows:

R
Sodium salicylate 4 drams
Compound tincture of cardamom 1 ounce
Elixir of orange to make 3 ounces
Take one teaspoonful in water after meals.

We read in the daily newspapers that a Frenchman has left 10,000,000 francs to the city of Rouen for the purpose of giving a prize annually as a marriage gift to two giants, the design being to improve the physical

stature of the race. This seems the silliest of all "rewards of vice," which much modern philanthropy is. Giants are usually diseased, the more certainly so the larger they are, and they are of less service to the world than people of ordinary size. Indeed, giantism is itself a disease. Then, too, the law of inheritance doesn't always work as planned by the foolish Count. His marriage prize would probably have the very opposite result from what he wished.

The Semeiologic Value of Dreams is the serioeomic theme of a discourse by two Frenchmen in the *Revue Scientifique*, in which the writings of others are also summarized. It seems that at least 131 authors have played with this Gallic subject. Fancy exhausts itself in a division of dreams due to established maladies, the dreams of malaria, those of circulatory origin, etc. One writer first proves an influence upon the waking state due to dreams, and then gravely advises the production of such dreams, by suggestion, as shall later prove beneficial!

Miss Dora Donald, superintendent of the South Dakota School for the Blind, at Gary, tells (*Bulletin of Iowa State Institutions*) of her success in teaching Linnie Haguewood, a deaf, dumb and blind girl, and in transforming her from a "selfish and irrational being" into an educated, self-controlled and self-supporting woman. Money was furnished by the State and by a private citizen for her education. The girl "lacks the imaginative genius displayed by Helen Keller." Miss Donald may well be proud of her work.

The *London Post-Magazine Almanach* has compiled a table with estimated losses of all the great fires of the last ½ century. No fire loss of less than \$500,000 is included. The two greatest fires, characteristically, were in the United States—that of Chicago, \$165,000,000, and that of Boston, \$70,000,000. The table foots up \$440,000,000, and if the small fires could have been included the entire loss would have been at least \$1,000,000,000. Has there been made any estimate of the number of lives lost by these fires?

Antichild-labor is becoming an important factor in the politics and industries of the South. The negro children are not allowed to work in the mills on account of their color, and they attend school while the children of the poor whites are slaving long hours in the mills. This strange reversal of the usual order of things is arousing great opposition and may lead to laws against all child-labor, which should have been enacted long ago. The women, fortunately, are carrying on the campaign.

The after-dinner speaking mania at medical banquets is at its height. What a pity it is that men who have nothing to say, and who do not wish to say it, are compelled to say it to men who do not wish to hear it. The worst sort of postprandial nonsense is that prepared in

advance. "Born of the occasion and mellowed by the charm of the hour," should be the ideal, and any man who speaks over five minutes or who indulges in obscenity should be hissed down instanter.

Under the guise of medicine-selling and bitters-traffic there is a deal of the worst sort of whisky-shop business done by apothecaries and by country stores. Many if not all of these pernicious "bitters" are sorry mixtures of cheap alcohols, wines, etc., with various disguising drugs, which quickly and surely destroy both body and soul of the unfortunate habitue. We are glad to see that the law of Maine prevents shipment into the State of these "medicines."

The United States Senate Committee have reported the results of their investigation as to the relative merits of the slow sand filtration of water and the rapid or mechanical filtration for the supply of Washington. The committee find that either system removes the bacteria, and that the slow method is the better for clear water, while the rapid method with a coagulant is preferable for turbid water.

An examination of the brains of two great mathematicians by Professor Retzius and Professor Möbius, leads to no definite location of the mathematical centrum. There was in both cases a shortening of the sylvian fissure. Whether this will finally be placed in the lateral parts of the frontal lobes, or in the parietal region, remains for future researches to determine.

There is a very general feeling that the repeal of the army canteen law was a bitter mistake. The repeal seems to be increasing drunkenness among the soldiers, and insubordination and disease. A total abstainer writes: "All the good the women wanted to do they undid, and all the good that was being done without them they have utterly ruined."

Chicago thinks of flushing the streets to keep them clean, while Milwaukee is about to abandon the method for a dry sweeping patent process which draws the dust and dirt by an air-blast into a chamber so that it is not blown or scattered about. If it works, the patentee of the machine should have his million dollar reward.

Dr. A. P. Grinnell, of Burlington, Vt., says that there are more than 3,300,000 doses of opium annually sold in Vermont by the general stores. This does not include that dispensed by physicians or sold in patent nostrums. This equals a half-dose daily for every inhabitant. Is this an indirect result of prohibition?

Some bacteriologist should investigate the trailing skirt of city ladies and tell us how many cases of tuberculosis and how many deaths are probably due to this disgusting fashion.

AMERICAN NEWS AND NOTES

GENERAL.

Utilizing Murderers.—The *American Journal of Sociology* proposes to advance medical science by using those criminals condemned to capital punishments as subjects for experiments instead of confining them exclusively to animals.

Rinderpest has destroyed all the cattle on the entire island of Masbate, the United States Philippine Commission report. The raising of beef cattle was the chief industry of the people and Manila formerly derived its supply of meat from there.

Antivivisection.—The opponents of vivisection in England are pleading for the abolition and prohibition of vivisection while the same class here are pleading for restriction. The Great Britain antivivisection act permits the practice unobserved, while the Massachusetts laws guards this point by the admission of any authorized agent of an incorporated society, to any place registered under the law for the practice of vivisection.

Army Dentists.—Provision has been made in the recently enacted bill by Congress for the appointment of 30 dentists in the army. They must serve for 3 years, and will receive a remuneration of \$1,800 a year. A candidate must be between the ages of 24 and 40, and must successfully pass an examination before a board of 3 examining surgeons appointed by the Secretary of War. The uniform of an assistant surgeon and the rank of first lieutenant will be given to those appointed.

Disease Disseminated by Flies.—Dr. L. O. Howard, of the United States Department of Agriculture, in a paper for the *Journal of the Washington Academy of Sciences* has shown the role played by flies in the spread of typhoid fever during the Spanish-American war. He has made a study of house flies in different States of the Union, and after the examination of 23,087 of them he concludes that the least carelessness in the disposal of garbage or foul matter renders the house fly an imminent source of danger.

Obituary.—CHARLES R. SOUDER of Atlantic City, May 7, aged 73.—HORACE L. HOWSE of Moss Point, Miss., May 3, aged 77.—E. STANLEY PERKINS of Philadelphia, May 6, aged 56.—GEORGE CYPRIAN JARVIS of Hartford, Conn., May 7, aged 67.—ABRAHAM DEYO of Gardiner, N. Y., May 5, aged 71.—W. W. BARNES of Farmersville, La., May 6.—MARTIN E. DOWNES of Magnolia, Del., May 9, aged 34.—GEORGE CHRISTIE McDERMOTT of Cincinnati, May 8, aged 53.—WILLIAM WALLACE WALKER of Schulenburg, Texas, May 6, aged 56.—DAVID SHEPARD HOLMAN, scientist and inventor, at Bangor, Me., May 12, aged 75.—ROBERT BOLLING of Philadelphia, aged 68.—GEORGE W. PEMBROKE of Friendship, Md., May 12, aged 58.—CHARLES RICE of New York, May 13, aged 60.—JAMES HAYES of Plainfield, N. J., May 12.—NORMAN ARMETT SMITH of Greenwich, Conn., May 12, aged 78.

Smallpox.—Many new cases are reported in New York City in widely scattered localities and an order to vaccinate all the police was executed. Two new cases have been found in Philadelphia the past week, and in Gloucester City 2 more deaths are reported. At Lamb's Creek, Pa., 7 cases are reported and many people exposed. At Rootstown, O., there are 50 cases; it was thought by the local physicians to be chickenpox until investigated by an expert. Smallpox has broken out in 15 places in Indiana. In West Superior, Wis., the local authorities will ask to have the lumber camps burned, as they are considered breeders of smallpox. In Berkeley, Cal., an outbreak is reported among the children of the State Institution for the Deaf, Dumb and Blind. It is reported widely prevalent among the Indians on the Western Reservations and raging at the Yorktown Agency, S. D., among the white population. About 100 malignant cases are reported among the Indians at Colgate, I. T., and the Indian bureau has shipped 1,000 vaccine points to that place. The existence and spread of the disease is confirmed at Sitka.

EASTERN STATES.

Plague Among Rats.—In Waldoboro, Maine, a soldier returned from the Philippines had brought with him some pet rats confined in a cage, all of which recently died of some strange disease. Several members of the State Board of Health diagnosed this disease as bubonic plague and had the rats and cage burned.

Gifts to Hospitals.—Miss Margaret P. Wright and Miss Henrietta Wright of Northampton, Mass., purpose building an annex to Dickinson Hospital, in that city, at a cost of \$10,000, as a memorial to their brother. Announcement is also made of a gift of \$5,000 to the hospital by Thomas M. Shepard for another annex to the hospital in memory of his father, the late Henry M. Shepard of Northampton.

Use of Narcotics in Vermont.—Dr. A. P. Grinnell, of Burlington, reports his investigations in regard to the consump-

tion of narcotics in the State of Vermont. In the regular drug stores and in 160 of the general stores there is sold 3,300,000 doses of opium every month, besides what is administered by doctors and in patent medicines. By dose, 1 grain of opium, $\frac{1}{2}$ grain of morphin, $\frac{1}{4}$ ounce paregoric and 20 drops of laudanum is meant. Some stores were not willing to state the amount sold and in these cases the physician put down zero, so the amount given would seem to be even less than the actual amount. In one town, barely represented on the map, $3\frac{1}{2}$ pounds of gum opium, 6 ounces of morphin, 5 pints of paregoric, 5 pints of laudanum and 3 ounces of powdered quinin were consumed each month.

NEW YORK.

Census Returns.—A census is reported to have been taken recently by an inquisitive reporter of a mile of Fifth avenue, New York, where rich men dwell, with the result of finding 15 children under the age of 12, an average of 1 child in 3 houses. A later investigation of the East Side tenement district showed 63 children in 1 house, more than 4 times the number in the whole Fifth avenue mile.

An Echo of Days Before "the Anatomy Act."—In Maple Grove cemetery, Hoosic Falls, south of the postoffice, there is a headstone upon which is the following:

Her body was stolen by fiendish men,

Her Bones anatomized;

Her Soul, we trust, has risen to God,

Where few Physicians Rise.—*Troy Times.*

The New York Academy of Medicine has received \$10,000 from Mrs. Sarah Barker Gibbs and Miss George Barker Gibbs for the establishment of the Edward N. Gibbs Memorial Prize Fund, the income to be awarded triennially to the physician of regular standing in the medical profession of the United States of America who shall present the best original essay upon the etiology, pathology and treatment of the diseases of the kidney.

Insurance and Christian Science.—At a late session of the New Jersey Grand Council of the Royal Arcanum the 200 representatives of the 117 councils in the State were opposed to the payment of the benefits due members, if they refused or neglected to procure medical aid when ill. Future candidates for membership in the order in New Jersey are not eligible unless they agree to obtain medical aid when ill, under penalty of forfeiture of insurance.

The Humane Society in Albany and vicinity is pushing forward successfully its work of preparing a new home and offices in connection with the house of detention for the temporary care of unfortunate and criminal children while awaiting trial for minor offenses, or those taken from brutal guardians, for the starving, the runaway or the lost, the suffering and homeless, pending the investigation in each case. About \$25,000 will be required, of which more than half has already been paid in.

Bequests to Hospitals.—The German Hospital of New York is the recipient of a bequest of \$1,000 from the late Colonel Henry Roehr. Joel Goldenberg has bequeathed the following: \$4,000 to the Montefiore Home; \$2,000 to the Presbyterian Hospital; \$5,000 to the Mount Sinai Training School for Nurses; \$3,000 to the Mount Sinai Hospital. He has also bequeathed the entire residuary estate to the Mount Sinai Hospital for the establishment and maintenance of a special ward to be in charge of his nephew, Dr. Herman Goldenberg. This ward is to be known as the "Joel Goldenberg Ward."

PHILADELPHIA, PENNSYLVANIA, ETC.

Dr. S. Louis Zeigler has been appointed a surgeon at the Wills Eye Hospital, in place of Dr. George C. Harlan, resigned.

Whooping Cough has been added to the list of contagious diseases by the Hygiene Committee of the Board of Public Education of Philadelphia. The disease will thus be a cause for exclusion from the public schools.

Rabies.—Dr. R. M. Waldron, deputized by the Pennsylvania State Board of Health to investigate a reputed outbreak of rabies in Rostraver township, reports its existence in the most virulent form all along the river and not only horses and cattle are affected, but sheep, hogs and even cats. A large number of cattle, horses and sheep have been killed. The trouble originated in a rabid dog.

Contagion in Books.—It is stated that since the incorporation of one of the public libraries of Philadelphia in 1891, about 10,500,000 books have been received, handed, and rehandled by employes of the institution and that not one has contracted a contagious disease. Since March 15 there have been reported to the library 492 cases of infectious disease; of these, 13 were in visitors to the library.

Sources of Tuberculosis.—The Women's Sanitary League has begun active measures against the practice of spitting in public places and overcrowding in street cars as pregnant

sources of tuberculosis. The members of the league will appeal to the legislature urging the passage of the bill now before it to prevent crowding in street cars, and the legislative committee of the league will ask City Councils to frame an ordinance against the spitting practice.

The Committee on the Nathan Lewis Hatfield Prize for Original Research in Medicine, of the College of Physicians of Philadelphia, has awarded to Professor H. F. Harris, M.D., Atlanta, Ga., the sum of \$500 for an original research, conducted at the instance of the committee, entitled "A Study of the Alterations Produced in the Large Intestine of Dogs by the Amoeba Coli, by Heat, and by Various Chemic Substances, with Notes on the Anatomy and Histology of the Viscus."

PENNSYLVANIA HOSPITAL.

One Hundred and Fiftieth Anniversary.—The exercises commemorating the one hundred and fiftieth anniversary of the founding of the "Mother of American Hospitals" were held in the new entrance hall of the hospital, May 11. Among the guests were many American physicians and not a few representatives of foreign societies and medical associations.

The address of welcome was delivered by the President of the Board of Managers, Benjamin H. Shoemaker. He spoke briefly of the first action taken to found the hospital and introduced as the speaker of the occasion Mr. John B. Garrett, a member of the Board of Managers, who delivered the **commemorative address**. This was historical in character, the progress of the hospital being traced from its inception to the present time. At the time of its foundation the Province of Pennsylvania had a population of about 200,000 and the city of Philadelphia 25,000. It was remarkable that, less than 70 years after Penn's treaty with the Indians and 25 years before the Declaration of Independence was signed, an institution for the care of the sick should be established, and, what was more remarkable for those times, that it should include provision for the insane. Benjamin Franklin was largely responsible for the inception of the institution but his name is not prominently identified with its early history. He states in his autobiography that in 1751 "Dr. Bond, a particular friend of mine, conceived the idea of establishing a hospital in Philadelphia (a very beneficent design which has been attributed to me, but was originally his) for the reception and care of sick persons, whether the inhabitants of the province or strangers." Dr. Bond, after vainly endeavoring to secure subscriptions for the new enterprise, appealed to Franklin who was more successful. A petition bearing 33 signatures was finally presented to the officials of the province. This petition contained neither Bond's nor Franklin's name but it was in the handwriting of the latter and he has always been considered the author. In it is a plea for the insane which is far beyond the general ideas of the time regarding those unfortunate individuals. From that time lunacy was regarded as a disease, although it was 40 years before either England or France recognized insanity as such and made provision for its treatment in hospitals. The wisdom of the founders is shown by the fact that the charter of the institution has never been changed except to widen the limits of the property.

May 11, 1751, the act incorporating the "Contributors to the Pennsylvania Hospital" was signed by Governor Hamilton and from that day the institution dates its history. In August of the same year subscriptions to the amount of £2,751 were reported, this making available £2,000 voted by the Assembly. The house of Judge John Kinsey on Market street below Sixth was rented for a temporary hospital. In 1754 the lot of ground on Pine street from Eighth to Ninth, on which the hospital now stands, was purchased. In 1755 the corner-stone of the new hospital was laid. The inscription on the stone (written by Franklin, who was the first clerk and second president of the Board of Managers of the institution) is as follows:

In the Year of Christ
 MDCCCLV
 George the Second Then Happily Reigning
 (For He Sought the Happiness of His People)
 Philadelphia Flourishing
 (For Its Inhabitants were Publick Spirited)
 This Building
 By the Bounty of the Government, and of Many Private
 Persons,
 Was Plousty Founded
 For the Relief of the Sick and Miserable:
 May the God of Mercies
 Bless the Undertaking.

In 1756 all patients were removed from the temporary hospital to the new building. In November, 1766, Dr. Thomas

Bond gave the first clinical lecture, this being the beginning of systematic medical teaching on this continent. In 1767 the remainder of the square from Eighth to Ninth streets was acquired, this giving an entire area of 4.3 acres.

The founding of the insane department marked a distinct epoch in the history of the hospital. A partial separation of the insane and of the sexes was begun in 1825 but the accommodations were inadequate. In 1835 a tract of 101 acres was purchased in West Philadelphia, buildings erected, and in 1841 the insane patients were removed thereto. Drs. Rush and Physick took charge of cases and thus took a distinct step in the specializing of medicine. This period also marks the beginning of a distinct advance in the treatment of the insane and in the results attained. The history of the insane department has been one of constant advance. A building for men was erected in 1859. Game rooms, gymnasium, reading room, natatorium, etc., have been added from time to time. The department now has accommodations for 270 men and 250 women. Mr. Garrett paid a warm tribute to the memory of Dr. Thomas S. Kirkbride, who was for a long time medical superintendent and from whom the department took the name of Kirkbride's Asylum.

The Pennsylvania Hospital has received no State or municipal aid for over a century. During its 60 years of existence the insane department has expended nearly \$8,000,000, and this without reducing the endowment fund in the least. The hospital proper has been remodeled and reequipped to meet the demands of modern medicine and surgery. The medical and surgical patients are in separate structures, there are 2 nurses' homes, the dispensary is a separate building, a mechanical and chemical filter with a capacity of 250,000 gallons daily has been installed, a garbage incinerator burns all the refuse, a laboratory of clinical medicine has been endowed, and numerous other improvements have been made. Four resident physicians and from 15 to 25 trained nurses are graduated yearly. Truly the "Mother of American Hospitals" is an institution of which the city, commonwealth and nation may alike be justly proud.

After the commemorative exercises were over the visitors made an inspection of the hospital buildings. A like inspection of the insane department will be made May 18.

SOUTHERN STATES.

Luther H. Reichelderfer has been appointed superintendent of Garfield Hospital, Washington, D.C.

Medical Inspection by the health authorities in the public schools of New Orleans has been prohibited by the City Council. The School Board had protested that the investigations were too severe.

Mosquitos.—South Carolina is waging war upon the mosquito by the use of petroleum in the stagnant pools. The authorities of Winchester, Va., are engaged also in the extermination of the mosquito.

The Mississippi Valley Medical Association announces a change in the dates of the next meeting from September 10, 11 and 12 to September 12, 13 and 14, owing to the fact that the first named dates conflicted with another Association meeting.

Effects of the Galveston Storm.—H. D. West, in a review of the medical aspects of this storm, states that 52 days after the storm, which occurred on September 8, 1900, there was a remarkable outbreak of typhoid fever, and by the following December the number of cases was 300. Strangely enough, by February but 29 cases of the epidemic remained. The cause of this unusual outbreak of typhoid Dr. West attributes to a contaminated water-supply and food infected through the media of flies. A remarkable feature of the occurrence was that it was virtually a house epidemic; in one family there were as many as 6 people ill at one time. Gastrointestinal catarrh was universally present after the storm, and this, no doubt, placed the people in a receptive condition. Scarlet fever, diphtheria, influenza and dengue were also present to a limited extent. An epidemic of smallpox was also threatened. Dr. West says that an immense improvement has since been made in the sanitary condition of the city, but he deplors the fact that the Legislature has refused to create a State Board of Health.

WESTERN STATES.

Blackleg and Anthrax are reported prevalent among the herds in San Joaquin and adjoining counties, Cal., and an epidemic is feared.

Free Instruction for the Blind.—The Social and Mutual Advancement Association, of Chicago, will give free lessons to the blind of the city, who have not yet learned to read embossed print.

The State Board of Medical Registration and Examination of Ohio, under the provisions of the Love law, has admitted 103 physicians to practise without requiring them to pass examination.

Diphtheria has broken out among the students and employees of St. Thomas' College, a Catholic Theological Seminary in St. Paul, Minn. Eight of the students have been sent to the City Hospital.

The Chicago Homeopathic Medical College has opened its doors to women. They will be admitted on an equality with male students. There is now no homeopathic college in the West that debar women.

Sweat-shops in Wisconsin.—The Soltwedel Antisweatshop Bill has passed both Houses. It greatly extends the list of articles which are forbidden to be made in rooms which are also used as living rooms.

Osteopathy Law.—The State Medical Society of Nebraska, in a recent meeting and contrary to the suggestion of the retiring President, Dr. McClanahan, by a nearly unanimous vote, put itself on record as bitterly opposed to legalizing the practice of osteopathy, and appropriated \$200 to fight the constitutionality of the law passed by the last Legislature giving that school a standing.

Gastric Ulceration.—A disease due to hasty eating and consequent abuse of the digestive organs by crowding too much work upon them in a limited time, was discussed at a recent meeting of the Chicago Medical Society, when Dr. Andrews stated that this disease, discovered and labeled as a distinct disease, about 5 years ago, is much more on the increase than appendicitis, and much more dangerous. It has increased 200% within its brief medical history.

Home for Epileptics.—Among the bills pending in the State Legislature of Illinois is one to found a State Home for Epileptics, of which there are estimated to be from 5,000 to 10,000. A large majority of these are confined in county almshouses and hospitals and in State hospitals for the insane where they are deprived of the opportunity to work for their own maintenance as many of them might do. The site is under consideration, but the decision has not been reached.

Investigation of the Plague.—Dr. Lewellys F. Barker, of Rush Medical College, who 2 years ago was sent by the Johns Hopkins University to study the plague conditions in India and China, and was appointed by the Government to investigate the plague cases in San Francisco, asserts that though experts are of the opinion that another great plague may soon develop, the world will never again be visited by such an epidemic as the "black death." Improved sanitary conditions remove this dread. An epidemic among rats, he states, has invariably preceded all the great plague epidemics in history. So far back as 800 years ago, Hindu writings verify this statement. Dr. Barker has himself noted this manifestation in India, and the same phenomenon has been noted in Japan.

Meeting of the American Medical Editors' Association.—The annual meeting of the American Medical Editors' Association will be held at St. Paul, Minn.; President's Address, Dr. Alex. J. Stone, of St. Paul; "Relative Value of Medical Advertising," by Dr. John Punton, of Kansas City, Missouri; paper, subject unannounced, by Dr. John V. Shoemaker, of Philadelphia; "Improvements in Medical Education," by Dudley S. Reynolds, of Louisville; "Some Thoughts on the Ethics of Medical Journalism," by Burnside Foster, of St. Paul; "Editorial Corps and Medical Journalism," by George F. Butler, of Alma, Michigan; "Relation of the Medical Editor to Original Articles," by Harold Moyer, of Chicago; and paper, subject unannounced by Dr. George H. Simmons, of Chicago.

Registering Births and Deaths.—A bill requiring reports of births and deaths and their registration and regulating the disposal of the dead has passed both Houses in Illinois and becomes operative January 1, 1902. This bill provides that the physician or midwife, and in case of their absence, the parent or householder, shall report every birth within 30 days after its occurrence to the county clerk, who quarterly shall certify the list received to the county treasurer, and each informer shall then receive 25 cents. It also provides that no one shall dispose of a dead body unless he has received a permit to do so, which permit shall bear date of issue, the name of the deceased, date and cause of death, the manner in which the body will be disposed of and the place of such disposal, the name of the person to whom the permit is issued, the name of the attending physician, midwife or coroner, and shall be signed by the official by whom it is issued. Fines or imprisonment will attend the violation of the law.

CANADA.

Woman's Appointment.—The Ontario Government has been asked by the National Council of Women to appoint a woman to the post of assistant medical superintendent on the staff of the new Coburg Asylum for females.

McGill University.—Sir William MacDonald, who has already contributed \$2,500,000 to the funds of the institution, has again announced that he will further subscribe to the extent of \$150,000. Of this amount \$75,000 will go to endow the chair of chemistry, \$62,500 for the chair of botany, and \$12,500 will be added to the chair of physics. Lady Strathcona and the Hon. Mrs. Howard will bear the expense of a new wing to the medical building which will be erected during the course of the coming summer. It will be 4 stories in height, and will be supplied with lecture theatres, museums, and chemical laboratories.

FOREIGN NEWS AND NOTES

GENERAL.

Death from Wild Animals.—English colonial reports for 1899 show that in that year tigers caused the death of 899 persons; wolves, 338; leopards, 327; elephants, bears, hyenas and crocodiles, 1,400, while venomous serpents destroyed 24,621 persons.

Sensibility of Plants to Poison.—Henri Coupin has presented to the Academie des Sciences a note of his recent work dealing with the sensibility of higher plants to minute quantities of toxic substances in a state of extreme dilution and the serious disturbance to the health of the plant. Copper sulfate was the most deadly substance discovered by him, 1/10000 of its weight in water being sufficient to react disastrously. Mercuric chlorid, 20 times less toxic than the copper sulfate, came next in toxic effect. One part of the cadmium chlorate in 10,000,000 parts of water, and 1 part silver nitrate in 1,000,000 parts of water were found deadly to plants. The question raised by their investigation is whether the character of the vegetation of a country is affected by minute quantities of such substances contained in the soil.

Obituary.—ARTHUR SAMUELS of Liverpool, April 21, aged 70. ARTHUR EDMONDSTONE WATSON of Torquay, April 26, aged 31. KARL LAUSENAUER, Professor of Nervous Diseases and Psychiatry at the University of Budapest, April 27, aged 53. He was influential in bringing about many reforms in the care of the insane in Hungary and in causing special departments for their care to be erected in connection with the large hospitals. JOHN E. W. CRUISE of New South Wales, aged 36. ROBERT HUNTER of Sydney, New South Wales. SAMUEL REYNOLDS of Victoria, New South Wales, aged 77. J. A. LORIMER of Farnham, England, April 27, aged 54. WILLIAM GALLETLY of Elgin, England, April 26, aged 46. JOHN CAVAFY of Hove, England, April 28. FRANCIS H. WARRURTON COTNAM of Southampton, April 19, aged 38. ARTHUR J. CUMMINGS of Exmouth, Devon, April 23, aged 83. VERTUE EDWARDS of Shottisham, April 23, aged 82. WILLIAM GRISTOCK of Abbotsbury, Croydon, England, April 23, aged 47. JAMES D. C. WHITING of West Dulwich, Surrey, April 23.

GREAT BRITAIN.

Contagion on Pencils.—To prevent the spread of contagion the medical directors of the London School Board insist that each child should have its own pencil.

A New Sign of Mumps.—In the *British Medical Journal* of April 13, 1901, Trosilian refers to the fact that it is difficult in children to discover the opening of Stenson's duct, whereas in several cases of mumps under his observation it was plainly visible as a bright red papilla.

Improved X-ray Tubes.—Smith, a Welsh electrician, is reported as the inventor of 2 x-ray tubes for which he claims superior advantages over the ordinary tubes, as they are not injurious, one of them tending to heal burns and wounds. One makes bones and not flesh visible on a photograph plate, while the other makes neither visible, the plate only showing foreign substances.

The study of the rats that infect the wharves, riverside premises and sewers, has been promulgated by the London County Council. The aim of the Council is to prevent the spread of disease, and therefore the conditions of the rodents are being closely investigated. If an unusual mortality is noticed among them a bacteriologic examination will be made. Up to the present time nothing alarming has been discovered, but the most stringent measures are being employed for their extermination.

A Crusade Against Poor Ventilation is being waged in London. The factory superintendents have been notified that they must see to it that the air of their workrooms is kept pure and fresh. The strongest opposition to the movement is expressed by the persons who would be directly benefited by the change. The habitual breathers of the impure air of the overcrowded, overheated workrooms assume, when told of proper ventilation, that the temperature must be kept at the freezing point. Therefore before the crusaders can hope to attain success in the movement they must explain fully to the superintendents and workers what is meant by proper ventilation.

CONTINENTAL EUROPE.

Professor Franz Nissl, of Heidelberg, has recently been awarded the Sömmerring prize of the Senckenburg Society for Natural History at Frankfurt-a-M., in recognition of his investigations of the structure of nerve cells.

Statistics of the French Universities issued by the French bureau of instruction state that there are 29,901 students of all nationalities, of whom 12,289 or nearly one-half are studying at Paris. Of this number 8,393 are students of medicine and 2,868 students of pharmacology.

Alcoholism in Moscow.—Statistics show that in the course of 10 years about 20,000 men and 5,000 women have been treated in the municipal hospitals of Moscow for the effects of inebriety.

Improved Sanitation Among Barbers has been demanded recently by Berlin officials. The Berlin Barbers' Union, at its quarterly meeting, agreed that their prices should be raised 50% in the future because of increased expense required in fitting their shops and extra labor required in executing the new demands.

The Greek Medical Congress will be held at Athens May 19 to 23, 1901. Members from all parts of the Orient and many of the chief European cities will be present. Among the topics that will be discussed are: Pulmonary Tuberculosis in Greece, Alcoholism, and School Hygiene.

In Memory of Bunsen, Kirchhoff and Helmholtz.—Academies and societies throughout Germany, personal friends, but not the general public, will be asked to contribute toward a fund to erect a monument at Heidelberg in memory of these scientists. A committee, composed mainly of physicians, of which Dr. A. Kussmanl of the University of Strasburg is the chairman, has been organized for this purpose.

The Association of Medical Men of the Seine have decided to open a central office to which their clients will send their bills and which will undertake to collect the money for a commission of 5% with a minimum of 50 centimes for expenses. A list will be kept showing the names of people who are known to be poor pay. Each doctor using the association will be charged an annual sum of 10 francs. It is not proposed to open the office until at least 300 subscribers are secured.

Pasteur Institute in Berlin reports during the year 1900 384 patients treated with a mortality of 0.27%. The percentage of mortality since its foundation in 1898 is 0.3%. A large majority of the cases come from near the Austrian and Russian boundaries from infected animals wandering over into the Prussian territory to find victims. Germany has rid herself of smallpox by compulsory vaccination and would be able to exterminate rabies except for the carelessness of her neighbors.

A Cure for Blindness has been announced by Dr. Heller, director of the Hohe Warte Asylum for the Blind, at Vienna. The cure is said to be successful only in a very limited number of cases, in which the organs of sight are perfectly formed, but in which the visual centers of the brain are said to be at fault, and can be educated and developed. The cure has attracted widespread attention in Europe, and has been denounced as nonsense and swindle by Professors Hirschberg and Schweigger in letters to the *Berliner Lokalt-Anzeiger*.

The Eighth Antialcohol Congress was held at Vienna, April 9 to 13, 1901. Many prominent physicians were present and took part in the proceedings. The efforts of the Congress seem to have been directed more to the promotion of temperance than of total abstinence. That the alcohol question is quite a different question in Europe than in the United States may be seen from the statement made by Dr. Hartel, minister of instruction at Vienna, that 50% of the school children in Vienna are accustomed to take alcoholic beverages. He also stated that the average consumption per person in Austria is: 9 liters of liquors, 18.9 liters of wine, and 65 liters of beer; figures which seem almost incredible to an American.

Giulio Bizzozero, Professor of Pathology at Turin University, died April 12, 1901, aged 55. He was well known among scientific investigators from his studies of the blood, bone-marrow, and from the introduction of many valuable methods in microscopic anatomy. He first described blood-plagues and showed their relation to blood coagulation. His handbook of clinical microscopy attracted much attention when it appeared and is still one of the standard texts on this subject; it has been translated into several foreign languages. Bizzozero was born at Varese in Lombardy. He studied medicine at Pavia, where he graduated in 1866, and afterwards did special work with Virchow at Berlin and Frey at Zürich. He was a privatdocent at Pavia until 1872 when he was called to Turin as Professor of Pathology.

Child Exchange.—A plan devised by some charitable women for furthering the proper development of children has been adopted in Berlin, and a society has been formed among the families of certain German and Austrian states, England and Norway. The object of the society is to give the children of large cities an opportunity to spend part of their vacation at some small town in the country or at the seaside among new surroundings in the fresh air, while the country children see the sights of the large cities. The physical gainer by this exchange will be for the most the city children, but the intellectual profit for the country children will be as great, and their bodies are usually sound enough. By this system of exchange the vacation is not a source of expense to parents, except for traveling expenses, and it is believed that many children will be assured a pleasant and profitable vacation who would otherwise be unable to get away from home. The president of the society is the proprietor of a well known bookstore in Berlin.

SOCIETY REPORTS

XXX CONGRESS OF THE GERMAN SURGICAL ASSOCIATION.*

HELD AT BERLIN, APRIL 10, 11 AND 12, 1901.

[Continued from page 193.]

Extirpation of the Larynx: WERCKMEISTER (Zittau) presented a patient upon whom he had operated 2 years previously, removing the entire larynx because of carcinoma. The patient made a good recovery from the operation and had remained perfectly well since.

Operation for Traumatic Separation of the Lower Epiphysis of the Femur: SCHUCHARDT (Stettin) presented a boy upon whom he had operated for this injury. The result in this case was excellent.

Excision of Tissue by aid of the Esophagoscope for Diagnostic Purposes: GOTTSSTEIN (Breslau) advocates excision of small bits of tissue for microscopic examination in cases of tumors of the esophagus. By this means early diagnosis is possible, and when the procedure is carried out with the aid of the esophagoscope the danger is slight and the advantages great. Gottstein has never seen bad results follow.

The Operative Treatment of Suppuration in the Posterior Mediastinum: V. HACKER (Innsbruck) had the impression that up to the present time suppurations about the esophagus in the posterior mediastinum had almost invariably resulted fatally. He reported a case in which suppuration followed ulceration and perforation of the esophagus. The pus had burrowed very deeply, but it was evacuated through an incision in the neck, and a good recovery followed.

Pneumonia and Celiotomy: HEULE (Breslau), from his observations in the Breslau Clinic, was led to believe that pneumonias more frequently followed abdominal operations than operations on other parts of the body. To determine this point he experimented with animals, and found that those exposed to cold recovered much more slowly than those carefully protected; lung affections invariably followed and using cold solutions to flush the peritoneal cavity a pneumonia followed the next day. To obviate this danger so far as possible it has been the regular practice at the Breslau clinic to protect the extremities of the patients, to warm the operating table and to use hot solutions in flushing the abdominal cavity. Since this regime was adopted in 1899 there has been an increase in the number of celiotomies, but a decrease in the number of pneumonias. While the irritating effect of the anesthetic, the inspiration of foreign material and the frequent presence of infection is often the cause of pneumonia, Heule believes that the loss of bodily heat is more often at fault.

Discussion.—KRÖNLEIN (Zurich) believes that the use of a poor quality of ether may be responsible for many pneumonias. He does not use special measures to prevent the loss of bodily heat, yet he has had but 1 death from pneumonia, occurring in a man of 77 who had undergone a severe operation.

KÜMMELL (Hamburg) has had 40 pneumonias and 11 deaths out of 1,070 celiotomies; 4 of these were other pneumonias. The patients affected were for the most part in very poor general condition and had some inflammatory trouble in the air-passages before operation. The position in bed should be frequently changed with patients in whom a tendency to lung trouble is suspected, and they should be allowed to sit at the earliest possible moment.

STEMPEL (Breslau) believes that fat embolism is a frequent cause of lung trouble following operation, particularly with very fat patients. He reported a case in which he found a large fat embolus in a branch of the pulmonary artery after an abdominal operation.

New Uses for the Mikulicz Tampon: SAMTER (Königsberg). While the tamponade was originally designed for use in packing off large spaces, Samter believes that it may be of advantage in many abdominal operations, particularly those about the stomach and gall-passages, to support sutures, arrest hemorrhage, etc. He reports a case of fecal fistula which was healed by the use of the tampon.

The Mechanism of Acute Dilatation of the Stomach: KELLING (Dresden) has made a series of postmortem examinations to determine the cause of postoperative dilatation of the stomach. In many cases he found a passive valve-like closure arising from folds in the duodenum. The stomach may, by gross errors in diet, be filled beyond its capacity for emptying itself. Absence of motility may be caused to some degree by the anesthesia. Gastroptosis is a predisposing cause. In the treatment of these cases of acute dilatation Kelling is decidedly opposed to the performance of gastroenterostomy indiscriminately. We should first try to make a diagnosis as to the cause of the difficulty, and then strive to remove the cause. Very

*Reported specially for AMERICAN MEDICINE by Martin B. Tinker, M.D., University of Berlin, member of the German Surgical Association, with grateful acknowledgment of the aid of Dr. Wohlgenuth, authorized reporter for the German Medical Press, and the members of the Association who kindly furnished abstracts.

often jejunostomy is preferable to gastroenterostomy for the vicious circle of regurgitation of bile and pancreatic juice follows the latter operation in a certain number of cases.

Hyperemesis Lactantium: Report of a Case Arising from Pyloric Spasm, Cured by Stretching the Pylorus: MEINHARD SCHMIDT (Cuxhaven) discussed the causes of hyperemesis in young children, and expressed the opinion that the trouble arises, not as frequently from stenosis caused by congenital hypertrophy as is generally believed, as from spasmodic contraction of the pylorus. He reported a case of hyperemesis in which he overcame the tendency to spasmodic closure by stretching the pylorus with forceps.

Discussion.—LONKER (Bochum). The case just reported should not be confused with cases like that which he reported at the meeting a year ago. In that case there was really closure of the pylorus from a large congenital overgrowth of muscle fibers which perfectly justified gastroenterostomy. Hyperemesis was not the only symptom in this case; there being so much obstruction that this prevented food from entering the intestine and thus interfered with defecation.

BORCHARD (Posen) mentioned 2 cases of acute dilation of the stomach following operation out of the 11 operations on the stomach which he had performed. The cause of trouble in both of these cases was interference with the ability of the stomach to empty itself because of adhesions and a weakened musculature.

Uranoplastic Operations: v. EISELSBERG (Wien) discussed various operations which have been proposed for closing defects of the palate. His results after the operations which are in general use have not been encouraging, a defect frequently remaining. To overcome the difficulties in some unusually bad cases v. Eiselsberg has resorted to some very ingenious procedures, which he illustrated by means of drawings and photographs. In one case he dissected up a flap of skin and muscle from the forearm, skingrafted the raw surface of it and after the graft had taken well he freshened the edges of the graft and the defect and sutured the tongue of tissue into place so as to close the palate. In another case he made use of part of the vomer and inferior turbinate bones to partly close a bad defect. In a case of saddle nose with defect of the palate he freshened the left little finger and sutured it into place so as to close the defect and support the nose. The results in these cases were brilliantly successful.

Discussion.—WOLFF (Berlin) believes that while such extensive operations may occasionally be helpful they are unnecessary. He advocates operation in 2 stages: first dissecting up the flaps and chiseling off the pterygoid bone, as suggested by Billroth. Then after better circulation in the flaps has been established the flaps are sutured.

v. EISELSBERG believes that in spite of operation in 2 stages many defects will be left.

CZERNY (Heidelberg) completes the operation at 1 sitting; he operates with the head of the patient hanging over the end of the table, uses silver or silkwormgut sutures, often chisels the pterygoid bone free and has fistulas remaining in about a fourth of his cases.

Resection of the Elbow for Ankylosis: WOLFF (Berlin) showed a patient who had a very useful strong elbow after resection. Skiagraphs showed the partial formation of new joint surfaces through the callus thrown out, but as the head of the radius lacked support it projected almost through the skin.

Discussion.—v. EISELSBERG mentioned a case in which he operated for double ankylosis of the elbow following scarlet fever. On one side he obtained a movable joint; on the other side the callus caused ankylosis but at a right angle so that a useful arm resulted.

SCHIEDE (Bonn) reported successful resection of the elbow for ankylosis following typhoid fever.

KOCHER (Bern) after resection, sometimes leaves the bones in a dislocated position until connective tissue has formed over the fresh ends of the bone, then places the bones in corrected position and begins passive motion early. This prevents bony ankylosis and gives a freely movable joint.

Treatment of Ankylosis of the Patella: CRAMER (Wiesbaden) reported a case in which he freed an ankylosed patella and interposed a flap of muscle as suggested by Helferich to prevent recurrence of bony ankylosis.

The Treatment of Fractured Patella: WOLFF (Berlin) presented a patient upon whom he had operated for fractured patella, using a modified form of Malgaigne's hook with poor result. He then resorted to Helferich's osteoplastic method. The patient walked with a decided limp and did not ascend stairs readily. In spite of this Wolff considered the result unusually good.

A member of the association whose patella had been broken 15 years previously and who had been treated without complicated apparatus or osteoplastic operation, demonstrated to the society by running rapidly up the stairs that even by simpler means good functional results may be obtained.

Amputation Stumps: BUNGE (Königsberg) discussed the causes of painful stumps. While unwilling to state definitely that bone-marrow is sensitive he believes that it is certain that medullary callus is very sensitive and may become very painful. To prevent the formation of this painful medullary callus

he advises scooping out the bone-marrow for a distance of about 3 cm. from the end of the bone. Another sensitive tissue is the periosteum and this should also be removed from the lower end of the bone. If the skin becomes adherent to the bone it may give rise to pain, hence large skin flaps should be made which should not be allowed to come in contact with the bone. Bunge showed a boy whose leg he had amputated some months previously, removing the marrow and periosteum carefully from near the end of the tibia but not from the fibula. The tibia was not in the least painful on pressure but the boy winced when pressure was made over the end of the fibula.

Discussion.—BIER (Greifswald) while recognizing the value of Bunge's experiments, believes that in most cases his method of using the osteoplastic flap to cover the end of the bone gives a natural bony limit, and should be preferred. The osteoplastic flap method is not suitable for use in case infection is present, however, and considerably more time is required to amputate in this way than by the usual method.

The Parasite of Carcinoma: NILS SJORRING (Lund, Sweden; a guest) has found in carcinomatous tumors small protozoan-like bodies with amoeboid movements. In stained preparations, concentric layers can be seen. By injecting these bodies into white mice he was able to produce epithelial-celled tumors exactly resembling carcinoma in structure. Microscopic preparations were demonstrated.

Discussion.—ISRAEL (Berlin) considered the bodies seen only bits of tissue, such as may be seen in improperly prepared sterile media, with nothing that could be certainly called protozoa.

GUSSENBAUER (Vienna) stated that he had seen these bodies years previously, but had never considered them of any importance.

JÜRGENS (Berlin) said that Sjørborg had demonstrated these bodies at Aix-la-Chapelle as the cause of sarcoma. He did not consider them of any importance.

A New Method of Reducing Luxations: HOFMEISTER (Tübingen) mentioned Stimson's method of reducing luxations by means of continuous traction with weights, and showed a somewhat complicated system of pulleys and weights which he uses to accomplish the same results as are obtainable by Stimson's simple sand bags and bandage.

Operations for Habitual Dislocations and Old Dislocations: HILDEBRAND (Basel) reported reducing an old dislocation of the jaw by prying and pushing the condyle of the jaw into place, after dividing the zygoma, and without the necessity for opening the joint. In a case of habitual dislocation of the shoulder he found the edge of the glenoid cavity broken off; after forming a new cavity, there was no further trouble.

Bloody Reposition of Old Dislocations of the Hip in Adults: PAYR (Graz) uses Kocher's incision; he avoids chiseling off the insertion of muscles as far as possible, adopting Mikulicz suggestion to chisel off the trochanters only in cases with slight shortening. The operation is a severe one and the greatest care in asepsis is demanded, particularly after the tissues have been injured by violent attempts to reduce the dislocation without operation. A heavy curved bladed knife was shown which is used in scooping connective tissue out of the acetabulum; a very large elevatorium which is used in breaking up adhesions and a powerful lever for prying the head of the femur into place. After the dislocation is reduced and the wound closed, extension or a plaster-of-paris fixation bandage is applied. At the end of the third week passive motion is begun. In cases of traumatic origin recurrence is not to be feared. Payr has operated in 5 cases; 3 traumatic and 2 pathologic; 1 patient died; 1 recovered with a perfectly stiff joint; there was a limited amount of motion in 1 case and almost normal motion in 2 other cases.

Discussion.—SCHEDE (Bonn) operated in one case of double traumatic dislocation of the hip. He found it necessary to separate all muscle attachments in order to get rid of their contraction which was preventing reduction.

DREHMANN (Breslau) considers chiseling of the trochanters a measure of the greatest importance and has never had difficulty in uniting them with the shaft afterward.

Resection of the Entire Humerus: ROTER (Berlin) presented a patient whose entire humerus he had removed by disarticulation at the elbow and shoulder, thus saving a useful forearm. He dissected out the main nerves and vessels except the musculospiral nerve, 20 cm. of which he was obliged to resect because of its close connection with the bone. These were saved together with the skin and subcutaneous tissue. The forearm was attached to the shoulder by suturing what remained of the capsules of the elbow and shoulder joints. The musculo-spiral nerve had completely regained its function 9 months after the operation. Before the operation the growth was thought to be a sarcoma but it proved to be an osteofibroma; the specimen was shown. It included the entire arm except the skin, main nerves and vessels. The patient showed her perfect ability to use her forearm and hand.

KATZENSTEIN (Berlin) showed 2 patients suffering from spina bifida occulta. In both cases the lumbar region was affected. A young man had paralysis, atrophy and outward rotation of the right leg. A boy of 17 had severe sensory and trophic disturbances of both lower extremities. The symptoms appeared late in both cases (at 11 years old and 15 years old, respectively), probably because in some way, as the

patients developed the dura, water made traction on the spinal cord.

Contractures Resulting from Kneejoint Inflammation: HEUSNER (Barmen) presented 2 patients. In the case of one of these he divided all tendons and transplanted the biceps tendon, suturing it to the patella. The contracture in flexion was relieved, but later bowlegs developed, Heusner believed, because of the tendency of the biceps to produce outward rotation as well as extension. In the second case he transplanted the biceps tendon to the outer side of the patella and the semitendinosus to the inner side of the patella, with a perfectly satisfactory result.

Multiple Cirroid Angioma of the Sole of the Foot: STEINER (Berlin) presented a young woman from whose foot he had removed this newgrowth. The tumor appeared when she was a child, and for 3 years it was treated with compression, and no increase in size was noted. Rupture of one of the vessels then occurred, necessitating excision of the tumor. A flap of skin and subcutaneous fat was turned down into the sole from the back of the foot, and the defect was covered by skin-grafting.

Coxa Valga: REICHARD (Magdeburg) presented a patient in whose case he considered this diagnosis certain, because of the low position of the trochanter, which was 12 cm. below Nélaton's line.

LEVY-DORN (Berlin) demonstrated apparatus for protecting the hands of the operator while using the x-ray apparatus.

Discussion.—HOFFA (Würzburg) considered Reichard's case not one of coxa valga, but of infantile paralysis.

Congenital Dislocation of the Hip: JOACHIMSTHAL (Berlin) demonstrated 5 specimens of congenitally dislocated hips, 2 of them double sided. In all the specimens the acetabulum was present, but it was smaller and flatter than normal, and triangular in form. On 3 of the peloes a new cavity for the head of the bone had been formed externally and above the acetabulum. The head and entire upper end of the femur was atrophied in all cases, and the head flattened. The angle of the neck to the shaft was that of coxa vara. Joachimsthal then presented several patients whose congenital luxations he had reduced some time previously without operation, and showed the corresponding skiagraphs of the joints. The results were excellent.

Extirpation of the Pancreas for Carcinoma: FRANKE (Braunschweig.) Resection of the pylorus was performed in the case of a woman of 65 for a benign growth causing stenosis. A year later a tumor was felt and on opening the abdomen the pancreas was found to be affected. The disease was limited to the head but the entire gland was removed, the operation being accompanied with much difficulty because of the injury of the great vessels. Sugar first appeared in the urine 18 days later, the amount reaching 3%, but the stools were not fatty, there was no diarrhea or other symptoms. The patient died 6 months later and at the necropsy extensive metastases in the mesenteric glands were found. A second case was reported in which only partial removal was possible, the tumor being adherent to the vena cava. The patient recovered from the operation but died of volvulus later. In a third case exploratory laparotomy was performed but the operation was not carried further because metastases were present in the liver. The first symptoms of carcinoma of the pancreas is severe abdominal pain; cachexia develops rapidly; gastrointestinal disturbances are not important, nor is icterus which was formerly supposed to be one of the earliest symptoms. Early diagnosis is extremely important. If general practitioners would send their cases early, radical operation would be possible. In no case has death resulted from the operation itself. In doubtful cases exploratory celiotomy is justifiable.

Discussion.—KORTE (Berlin) mentioned a case which was accompanied by stasis of the bile and cholecystitis. The tumor was encapsulated, but the hemorrhage at removal was severe and the patient succumbed a short time after operation. A case was also reported in which the patient died of diabetic coma. At the necropsy most of the creas was found healthy only the tail being diseased.

HILDEBRAND (Basel) inquired whether it was certain that the entire organ had been removed in Franke's case. Franke replied that the entire organ was removed and no trace of a supplementary pancreas was found after careful search.

A Fetal Inclusion in the Mesocolon: AHRENS (Bonn) reported the case of a girl who from childhood had a distended abdomen. When she was 8 years old this disappeared and the cause was thought to have been rickets. When she was 16 years old, however, the tumor appeared again in the left side and reached the size of a man's head. Hydronephrosis was suspected and a lumbar incision was made, and a tumor discovered in the folds of the mesocolon. On puncture, brownish fluid escaped; the entire amount was found to be 4 liters. The kidney was perfectly normal. After removal, a Mikulicz tampon was inserted, and in 3 weeks the patient was well. Examination of the specimen proved it to be a secondary stomach of hour-glass form, 26 cm. long and with a well-developed cardia and pylorus. Histologic study of sections of the wall showed that it had the structure of the stomach; pepsin could be demonstrated. In the mucous membrane were several ulcers, and hemorrhage from these was evidently the source of the fluid contents of the tumor.

The Pathogenesis and Treatment of Keloids: GOLDMANN (Freiburg i. B.) has found in studying these newgrowths that there is an absence in them of the elastic tissue-fibers of the skin. He compares keloids with aneurysms which arise from loss of the elastic coat of the arteries. Contrary to general belief he has also found medullated nerve-fibers in these tumors. In the treatment he advises excision and closure of the defect by transplantation.

A Method of Closing the Intestine: RINDFLEISCH (Stendal) in his title refers to his method of closure of the intestine without suture. What he really did in a case of gangrenous hernia was to invaginate the gangrenous intestine and suture the serosa.

The Surgical Treatment of Acute Appendicitis: REHN (Frankfurt a/M.) Quite contrary to the views of most members of the Congress, as expressed at previous meetings, Rehn has found himself driven by experience to resort more and more frequently to early operation in appendicitis, and by so doing he has decidedly reduced his mortality. There is an almost universal fear of opening the abdomen, but had his cases been treated in this way the mortality would have been enormous. In most difficult cases Rehn has performed transperitoneal operation 180 times; 134 patients recovered, 46 died. In 35 cases there was a bad peritonitis. The worst cases are accompanied by subphrenic abscess, and from this cause alone 27 patients died. There were no deaths in 24 operations undertaken before suppuration had occurred. Out of 33 cases with acute gangrene there were 22 recoveries. Rehn does not believe in waiting for operation in the interval, but operates immediately and considers it less dangerous than to wait. We should have less fear of peritonitis arising from infection at the operation in these cases. The presence of bacteria alone by no means makes it certain that there will be peritonitis. Much depends on the variety of organism, its virulence in the particular case and the number of organisms present. In operating, Rehn advises a free incision, opening directly into the peritoneal cavity, walling off with gauze, resection of the appendix and intestinal suture, free flushing with salt solution and suture of the abdominal incision with drainage. Opium should be used with great caution, as it obscures the clinical picture. The factor of greatest importance is that the favorable movement for operation be not allowed to pass.

The Treatment of Appendicitis: ROTTER (Berlin) lays great stress on the importance of opening Douglass pouch, not by the transperitoneal route but through the rectum or vagina. He does not share Rehn's beliefs as to the tolerance of the peritonium. He divides his cases into 2 groups: of 530 cases recently under his observation only 196 were operated upon and of this number 109 had diffuse peritonitis; his mortality rate was 19%. In an earlier series of 213 cases, 55 were operated upon; 26 had diffuse peritonitis; in this series the mortality rate was 31%. Of the patients upon whom he operated by the transperitoneal method 3 died. In 61 cases in which the abscess was opened from below the mortality rate was only 10%.

Early Operation in Acute Appendicitis: SPRENGEL (Braunschweig) entirely agreed with Rehn in his views as to the necessity for early operation in appendicitis. He mentioned the case of a patient whom he was treating expectantly and who died very suddenly from perforation. Study of this case seemed to indicate that early operation would have saved the patient. This led Sprengel to consider whether it would not be better to operate early in all cases, for the severest symptoms may appear suddenly in any case in a few hours. At present if allowed to choose, Sprengel always operates within the first 24 hours.

The Treatment of Acute Appendicitis: RIESE (Britz) recommended Doyen's method of treating the stump by ligating the base, resecting, inverting into the cecum and burying the sutures. (This method was advocated and used by Dabarn, of New York, at least 5 years before it was described by Doyen.)

Discussion.—BAUMGÄRTNER (Baden-Baden) advises vaginal examination of women suspected with having appendicitis and believes that oöphoritis will often be found instead of appendicitis.

HIRSCHBERG (Frankfurt a/M.) believes that Rehn's method of transperitoneal operation is adapted only for the treatment of cases in large city hospitals.

KÜMMEL (Hamburg) does not agree with Rehn and Sprengel, but prefers conservative treatment in appendicitis. In 1,042 cases treated in the Hamburg-Eppendorf Hospital there has been a mortality of but 1.6%.

RIEDEL (Jena) had collected from general practitioners, statistics of 1,000 cases and the finds that in 50% of the cases the patients come to the surgeons sooner or later. Riedel now advocates operation within the first 24 hours and considers the dangers of such early operation very slight.

KORTE (Berlin) believed that it is extremely difficult to determine in just what cases early operation is necessary and was inclined to favor conservative measures.

SPRENGEL prefers to operate in some cases in which operation is not of urgent importance, rather than to take the risk of waiting.

REHN thought that Rotter in his statistics had confused encapsulated abscesses with diffuse peritonitis.

AMERICAN THERAPEUTIC SOCIETY.

ANNUAL MEETING HELD AT WASHINGTON, D. C., MAY 7, 8
AND 9, 1901.

[Specially reported for AMERICAN MEDICINE.]

The Progress of Therapeutics.—Dr. REYNOLD W. WILCOX, New York, delivered the presidential address (the president, Dr. HORATIO C. WOOD, Philadelphia, being absent through illness). The paper will appear in a future number of AMERICAN MEDICINE.

The first paper on the program was read by Dr. FRANCIS P. MORGAN, Washington, and consisted of **Suggestions Concerning the Use of the Metric System in Prescription Writing.**

The Chairman reported that the new pharmacopeia would give the average doses for adults expressed in the metric system with the approximate equivalent expressed in the old system enclosed in brackets. He added that the work of the Revision Committee was rapidly approaching completion, a practical agreement having been come to as to the substances that were to be removed from the list and also as to the claims of the large number proposed for admission—the restrictions imposed by the convention being always borne in mind.

Proposed Bureau of Materia Medica and Therapeutics.—Dr. F. E. STEWART, New York, read a paper on the **Relation of the Pharmacist to the Physician and the Relation of Pharmacy to Materia Medica and Drug Therapeutics**, which will appear in a future issue of AMERICAN MEDICINE. A resolution submitted by Dr. Stewart was referred to the Judicial Committee, on whose recommendation a special committee was afterwards appointed to consider and report upon the proposal to establish such a bureau as was advocated in the paper.

A paper on the **Inertness of Petroleum Compounds when Given Medicinally** was read by Dr. ROBERT REYBURN (Washington). The paper, with the accompanying discussion, will appear in a future issue of AMERICAN MEDICINE.

Heart Disease Therapeutics: Dr. THOMAS E. SATTERTHWAITE (New York) introduced the consideration of this subject by reading a paper on the **Therapeutics of Chronic Heart Diseases and Their Complications.** He remarked that, notwithstanding all the recent advances in cardiac therapeutics (and the changes of the last 10 years had been revolutionary), physicians who gave particular attention to these diseases were less and less disposed to cry up special remedies for special affections. This was particularly true in regard to valvular diseases, where they now attached less importance to abnormal sounds and more to the attendant phenomena, and especially to the character of the lesions behind the sounds. The gravity of a lesion was not always measured by the intensity of the murmur. A loud and harsh murmur was not incompatible with an average length of life, whereas a valve might be almost occluded, as in mitral stenosis, without giving any recognizable auscultatory sign. With the best opportunities and the largest experience, one might not always be able to distinguish between a functional and an organic murmur. Single valve lesions were the exception rather than the rule, and there were frequently complications which made it additionally difficult to make a diagnosis from auscultatory signs alone. Summing up the changes that had recently taken place in treatment, he said that the idea of complete rest had been superseded by rest alternating with bodily activity; venesection had given place to determination of the blood to the surface by means of resistant exercises and carbonated baths; hydrogog cathartics had been replaced by stomachics and mild laxatives and diuretics, and heart stimulants by general nerve stimulants, or sedatives, alteratives and nutrients, while drugs of the digitalis group were utilized chiefly for their diuretic action in renal complications, mainly parenchymatous, nephritis or abdominal dropsy. Drugs of the digitalis group, including strophanthus, convallaria and adonis, were always uncertain and therefore always dangerous, and should only be employed either when other remedies were inadmissible, or in liver or kidney complications for brief periods, or where nothing more was possible than a short prolongation of life.

Discussion.—Dr. SOLOMON said he thought digitalis should be still recognized as occupying a position in the front rank in the treatment of chronic heart disease, and as to the complaints about the uncertainty of its action, he said that there were certain preparations on the market which had been so tested as to be thoroughly reliable. The question of the standardization of drugs was important in this connection.

Dr. E. M. HOUGHTON, Detroit, said the effect of some physiologic tests he had been making was to upset the commonly accepted idea that drugs of the digitalis group tended to produce gastrointestinal irritation. His experiments were still in progress; when they were completed he would be prepared to report on them in detail.

Dr. J. N. HALL, Denver, reported 2 cases of **Aneurysm Successfully Treated by Wiring and Electrolysis**, and a paper by Dr. ELI H. LONG, Buffalo, on **Principles of Cardiac Therapeutics in Recent Valvular Disease**, was read by the secretary, the author being unable to be present.

A practical demonstration of the **Therapeutic Value of Hypnotism** was given by Dr. FRANCIS H. MINER, Washing-

ton, the subject upon whom he operated being a boy of 17, who had been a typical cigaret fiend, but who had been cured by means of suggestion under hypnotic influence. Replying to Dr. Solomon, Dr. Miner said that until the public was educated on the subject, hypnotism could not be used without endangering the doctor's reputation. Dr. Solomon reported some interesting experiences of his own in hypnotism, and Dr. T. L. COLEY, of Philadelphia, and the chairman (Dr. WILCOX) discussed the modifications of view which had taken place on the part of the eminent French neurologist, Charcot. Dr. Wilcox added that he would never hypnotize patients, first because of the peculiar reputation it gave a doctor, and secondly several patients who had come under his observation after being hypnotized had shown vitiated will power. Dr. MINER asked whether the chairman thought this was the result of the hypnotism or that the will power had never existed. Dr. Wilcox admitted that the will power probably never existed to any extent.

Trade and Scientific Names of Drugs: Dr. A. C. BARNES called attention to the fact that the next 2 papers on the program referred to drugs which were spoken of under their trade names, namely chloreton and heroin. While not desiring to interfere with the reading of these papers, which stood in the names of 2 able and competent men, he said it would be more consistent with the aims and objects of the society if the drugs were given their scientific nomenclature. The meeting concurring in this view of the matter, Dr. E. M. HOUGHTON, Detroit, who read the paper on chloreton, spoke of it as **aceton-chloroform** or **trichlor-tertiary-butyl alcohol**. After describing the chemical process by which the product was made, he quoted a variety of reports showing its usefulness as a hypnotic, local anesthesia, antiseptic and analgesic. Dr. Barnes said that as it was evident that chloreton was a drug that had come to stay and was destined to cover a wide field of usefulness, it could not be too generally made known to the profession. There were reasons why it should have the distinctive name of chloreton, and therefore he thought the society should take action on a suggestion previously made by Dr. Stewart and request the manufacturers of the drug to donate the name to science. The chairman said this was a matter that might properly be referred to the Judicial Committee, which was accordingly done. The author of the paper on **Heroin**, Dr. SMITH ELY JELLIFFE, New York, not being present, the paper was not read.

A paper demonstrating the **Therapeutic Value of Alcohol** was read by Dr. SOLOMON, Louisville.

New Office-Bearers.—The election of office-bearers resulted as follows: President, Dr. Reynold W. Wilcox, New York; first vice-president, Dr. Howard H. Barker, Washington; second vice-president, Dr. Thomas E. Satterthwaite, New York; third vice-president, Dr. Leon L. Solomon, Louisville; secretary, Dr. Noble P. Barnes, Washington; recorder, Dr. William M. Sprigg, Washington; treasurer, Dr. John S. McLain, Washington; curator, Dr. George C. Ober, Washington. It was agreed to hold the next annual meeting in New York on the second Tuesday in May and 2 following days.

XIX GERMAN MEDICAL CONGRESS.*

HELD AT BERLIN, APRIL 16, 17, 18 AND 19, 1901.

[Continued from page 213.]

THIRD SESSION.

The Recuperative Power of the Heart as Measure of Its Ability: MENDELSON (Berlin) observed the effect of various amounts of work on the frequency of the pulse. He found in health that (1) in the case of moderate exertion, the slightly increased rate returns at once to normal when the work ceases; (2) after greater exertion (reckoned as 200 to 500 kilogrammeters) the pulse-frequency falls, returning to normal during the next 2 to 3 minutes; (3) still greater exertion is followed by increased pulse-rate which, either directly, or after a period of diminished frequency, returns to normal. Mendelson explains the slowing of the pulse as an expression of the inability of the heart during the normal diastole to cover the increased metabolism during systole. All hearts show these 3 stages, depending on the relation between anabolism during diastole and catabolism during systole, and the wider the limits of the stages the greater the functional ability of the heart. In hearts, lesions which clinically seem well compensated the amount of work which the heart can do, and during diastole cover the expenditure of systole may be very little.

Discussion.—KRAUS (Graz) emphasized the complexity of the question, and denied that return to the previous pulse-rate need necessarily mean a return to a similar condition of metabolism.

BAELTZ (Tokio) maintained that the proof of complete recuperation after a certain effort was ability to repeat the work without further injury to the heart. He cited the case of the Japanese runners, who will cover 60 to 70 miles in a day, end-

*Specially reported for AMERICAN MEDICINE by Dr. Chas. P. Emerson with grateful acknowledgment of indebtedness to Prof. Ewald, editor of the *Berliner Klinische Wochenschrift*, for his assistance in the preparation of this report.

ing with normal pulse, and able to repeat the exertion on the following day.

Artificially Produced Hyperemia as a Therapeutic Measure: RIER (Greifswald) (read by special invitation) employs hyperemia in the treatment of many inflammatory conditions. In the case of a diseased joint he loosely applies a tourniquet above the joint to hinder venous circulation, and tightly bandages the limb below the joint. In the case of the arm the bandage begins at the tip of the fingers (each having a separate bandage). The inflamed area is left uncovered between the tourniquet and bandage. There must be a "hot congestion" produced. The joint must feel hot and be of a red or bluish-red color. Never should the compression be enough to produce a "cold congestion" of bluish color. The white (lymph) congestion is dangerous. If pain is not at once diminished there has been some error in the application of the method. He advised this procedure in tuberculosis of the joints (in which case he does not claim it will render an operation unnecessary). He has obtained good results in gonorrheal joints and in acute articular rheumatism; also in pyemic joints and in erysipelas, but no results in lues or carcinoma of joints. The results were particularly good in subacute gonorrheal rheumatism.

BIER ascribes the beneficial action of this treatment to several factors. (1) It raises the bactericidal power of the tissues. Animal experiments showed that of 69 animals so treated and then inoculated with otherwise fatal doses of anthrax cultures, 51 recovered. (2) Venous stasis is conducive to connective tissue, perforation and formation of scar tissue, which may be important by encapsulating infected areas. (3) It aids in resolving exudates, best seen in chronic articular rheumatism. Since the absorption is hindered (proven by the delay of a tuberculin reaction tested on the treated limb) BIER recommends combining the treatment with massage, the bandage being removed once or twice a day and the joint massaged. In the case of chronic rheumatism thus treated pain and stiffness rapidly disappear.

Active Hyperemia was also recommended, produced by heat, especially hot air. The limb should be heated by as hot air as can be endured for 2 hours daily. In this case BIER gave reasons to show that it is not the heat but the hyperemia resulting which does the good. Like the passive hyperemia, the active aids in resolution in all chronic joint troubles, and quiets pain, but unlike the former it promotes absorption as experiments showed, hence it is to be recommended in many cases as superior to massage where there is blood or other exudate present, and is especially good to remove edema. The bactericidal action of the active hyperemia is very doubtful. Hot air is excellent in neuralgia, and in still other conditions. Neither active nor passive hyperemia improved the nutrition of atrophic limbs.

Discussion.—MÜLLER (Würzburg) reported his examinations of the blood of limbs thus treated. Hyperemia (artificial) increases the count of the red cells, even to 6,000,000 per cmm., and the Hb in proportion, while the serum diminishes, since it is pressed into the lymph spaces. Among the chemical changes are diminution of O, increase of CO₂ and an interchange of sodium and potassium salts between serum and corpuscles, probably one also of organic constituents which may explain the beneficial results. In answer to a question Bier replied that in a case of chronic articular rheumatism he had employed the treatment steadily for 4 years.

Paroxysmal Arrhythmia: Hoffmann (Düsseldorf) considers these attacks of paroxysmal cardiac arrhythmia (tachycardia) which have sudden onset and abrupt termination and which last a few hours or days, as very different from the continuous arrhythmia seen in myocarditis. The analysis of the pulse curve and auscultation show the cause is the insertion of extra systoles in the rhythm and the speaker gave evidence from experiments on frogs' hearts to show that these extra beats originated at the venous ostia. By short electrical stimulation of the large veins of the frog's heart resulted similar attacks during which the frequency of contraction was just doubled.

Discussion.—GERHARDT (Strassburg) by registering venous pulse on men confirmed Hering's results; as in the pulsus bigeminus the auricle may beat before, with or after the ventricle.

The Effect of External Stimulation on the Deeper Vessels: HINTZ (Erlanger) found that heat or cold applied to the skin of the chest can change the temperature of the pleura several degrees. Chemical stimuli, iodine, alcohol, mustard, produce pleural hyperemia which can raise the temperature there through a few tenths of 1 degree. Hintz measured the temperature by thermoelectrical apparatus.

The Value of Iodine as a Vasomotor Drug: GUMPRECHT (Weimar). Experiments on rabbits showed that iodine had no effect on the heart nor vessels, unless in large doses when it acted as a poison. Observations on men by means of the Riva-Rocci apparatus were also negative, especially in arterial sclerosis. The speaker, therefore, was inclined to doubt its much praised clinical value.

Discussion.—ASHER (Bern) cited Barbera's experiments showing that iodine had some action on the heart through its accelerator and depressor nerves. HINTZ (Erlanger) called attention to the increased permeability of the vessels following its use.

B. LEWY (Berlin) claimed its value (after long use) in arrhythmia of the heart was well established.

Intestinal Fermentation.—Dyspepsia: STRASSRUOER (Bonn) reported further work done by SCHMIDT and himself using the former's (Schmidt's) fermentation test for proving the functional ability of the intestine. They believe that on a standard light test diet there will normally be no carbohydrates in the feces. The detection of these by the fermentation test is evidence of disturbed intestinal digestion.

They describe a new symptom complex to which they give the name Fermentation Dyspepsia (Gährungs dyspepsie), whose only objective symptom is the character of the stools which always give the fermentation test. The feces are yellow, frothy, very acid, and smell of butyric acid; mucus is usually absent, bile often. Subjectively there are "dyspeptic" disturbances and pain in the region of the umbilicus. In such cases the metabolism experiments showed diminished digestion and absorption of the food, especially of the carbohydrates, as their charts already showed.

Discussion.—EWALD (Berlin) considered the fermentation test untrustworthy. He thought the microscopic examination of the feces gave more information concerning both starch and albumin digestion. ROSENHEIM (Berlin) doubted that the figures on the charts exhibited were striking enough to be of diagnostic importance. He thought milk should be omitted from the Schmidt standard diet since it is so poorly digested by many persons.

The Fat-splitting Ferment of the Stomach: VOLHARD (Giessen) was able to demonstrate the presence of a fat-splitting ferment in the stomach. This may be extracted by glycerin from the finely chopped gastric mucosa of the pig's stomach. It is found only in the fundus mucosa, none in that of the pyloric region. Its independence of bacteria may be demonstrated. Its action depends more on the condition of the fat, *i. e.*, whether emulsified or not, than on its nature. Since the acid gastric juice prevents emulsification the sphere of action of this ferment is limited to the previously emulsified fat of the food. The action of the ferment does not vary proportionally to the time allowed, nor to the amount of fat present; its action is always incomplete, the maximum in the case of yolk of egg being 60-70% of the entire amount.

Discussion.—ELLINGER (Königsberg) confirmed Volhard's statements.

ALBU (Berlin) mentioned the fact that in motor disturbances of the stomach more fat acid is present after a given period of digestion of milk than in a normal stomach, and suggested that in such cases the conditions for fat-splitting were more favorable.

BIAL (Kissingen) and NAUNYN (Strassburg) also took part.

The Reason for the Failure of Free Hydrochloric Acid in Carcinoma of the Stomach: REISSNER (Nauheim) found that the amount of HCl of the gastric juice during health and disease after a test breakfast ran parallel to the total Cl. The one exception to this rule is cancer of the stomach in which case there is an increase in the fixed chlorides which is indicative, when present, of ulceration. The ulceration causes neutralization of the secreted HCl as well as diminution of the secretion.

Leukocytosis in Clinical and Experimental Hydrophobia: COURMONT (Lyon) reported the first observation on the leukocytosis in hydrophobia of man, dogs, rabbits and guinea-pigs. There is an increase of the polymorphous nuclear neutrophils from the very first. Their percentage may reach even 95. This continues till the death. He considers the diagnosis should never be made if the leukocytosis fails.

The Serum Diagnosis of Tuberculosis: COURMONT (Lyon) explained that the reason why the agglutination test for the diagnosis of tuberculosis had in Germany fallen into disrepute as untrustworthy, was because it is necessary to test repeatedly the pathogenicity of the cultures of tubercle bacilli to be sure they are still suitable for use, since the success of the test depends on the virulence of the culture. Observing this precaution the results obtained at Lyons justified the claims previously made for the method by Arloing. In a long series of observations made of animals at the Lyons slaughter houses the diagnosis was confirmed in all but one case. BENDIX (Berlin) agreed with the speaker as to the accuracy of the results if a virulent culture be used.

The Extent of Starch Digestion in the Mouth and Stomach of Man: MÜLLER (Würzburg) ascribes to the ptyalin of the saliva a much more extensive action than has hitherto been considered the case. He reported the experiments made in conjunction with 2 other observers (Hensay and Daicher) from which they concluded that the action of the saliva is not inferior in extent to that of the pancreatic juice. After a meal of bread from 60-80%, even 100% of the starch is rendered soluble in the very brief space of 5-10 minutes. Although the maximum of amylolytic action occurs in subacidity, yet the rapidity with which it takes place renders it to a great extent unaffected by the HCl even in cases of hyperacidity. The end product is chiefly dextrose, hence fermentation does not as a rule occur in the stomach. Müller spoke also of the importance this rapid action of saliva upon the starch has for the motility of the stomach, the digestion of vegetable proteids.

Discussion.—MOUTZ (Munich) agreed with Müller concerning the gastric starch digestion with hyperacidity. The HCl

Inhibits starch digestion only when there is insufficient albumin present to bind it (the HCl).

VOLHARD (Giessen) confirmed Müller's results by a series of quantitative determinations on the extent of gastric starch digestion, and agreed concerning the importance for starch digestion of the formation of bound HCl.

FOURTH SESSION.

Demonstration of a Preparation of "Idiopathic" Dilation of the Esophagus: STRAUSS (Berlin) demonstrated a preparation from a 29-year-old patient. In the lower part of the esophagus was a sac-like dilation, 30 cm. long and 15 cm. in breadth. There was no anatomic stenosis; the patient suffered also from gastrica aepsia and motor insufficiency. Strauss discussed at length the theories advanced to explain such cases, and suggested the importance of postfetal faulty development. He also emphasized the importance of lesions of the mucosa of the esophagus in producing spasm of the cardiac orifice. Strauss also demonstrated instruments of value in the diagnosis and treatment of malformations of the esophagus.

Demonstration of Multiple Periostitis: v. JAKSEH (Prag). This was a very interesting case of multiple periostitis associated with a condition of the blood strongly suggesting leukemia. The patient was a young girl. Skiagraphs were shown to prove that the process on the bones had in part healed during the course of the disease. During the development of the disease the bone-changes were accompanied by a steady increase of mononuclear neutrophilic leukocytes (v. Jakseh did not use the term "myelocyte" in describing or referring to these cells) and a decrease in the polymorphonuclear leukocytes. Toward the end there were many nucleated reds, 400 per e. m. m., and many red cells showing polychromatophilic degeneration present, while the eosinophiles increased from 600 to 1,000 per e. m. m. The patient died from the anemia. At the necropsy were found splenic tumor and leukemic degeneration of the bone-marrow. The case is interesting from the point of view of diagnosis, since the development of the nodes ran parallel with the blood changes. It is desirable that in cases of leukemia the bones be examined for nodes by the x-rays method, and that the blood be examined in all cases of periostitis. The case presented may represent a new type of leukemia.

Demonstration of a Case of Diaphragmatic Hernia: STRUPPLER (Munich). The first symptoms followed 3 months after a trauma which the patient, a young man, received 6½ years ago, and consisted of discomfort in the chest after eating. The diagnosis should be made from the physical signs and the skiagraphs. The stomach, surrounded by omentum and intestine, is evidently located in the center of the left half of the thorax, reaching to the middle of the scapula.

Demonstration of a case of Diaphragmatic Hernia: HIRSCH (Leipzig). This case was very similar to that reported above. In these cases the skiagraphs, showing the position in the chest of a stomach tube filled with mercury, were of particular interest. In this case it reached the third rib.

Demonstration of an Apparatus for Measuring Blood Pressure. FRANCKE (Munich). This apparatus consisted of an arm rest which held the wrist quite fixed, and a pad which could be pressed down against the radial artery until a pulse indicator just beyond it showed the pulsations to be obliterated. The pressure exerted by the pad could then be read off in mms. of mercury.

Syphilis of the Lung. HAUSEMANN (Berlin) presented preparations from 3 cases which he considered showed the lesions of lues of the lung. He spoke of the difficulties in the way of making such a diagnosis which he believes can be safely made if the following conditions are satisfied; unmistakable luetic lesions of other organs, and fresh gumma-like masses in the lung in which tubercle bacilli cannot be demonstrated, either microscopically or by inoculation of animals. In 1 case the nodules (gummata) were present on the pleura. He showed specimens demonstrating the later history of the gumma in which stages it presents nothing characteristic. He considered that certain specimens showed the coexisting lesions of lues and tuberculous. (The specimens from the 3 first mentioned cases contained many tubercular nodules, many of which were caseous, some 1 cm. in diameter, round and isolated. The gross lung showed on brief inspection no marked newgrowth of connective tissue.) [This communication was received with considerable applause.]

A Method of Determining the Exact Size and Position of a Foreign Body by Means of the X-rays: LEVY-DORN (Berlin). This method is claimed to allow the correct representation to be made on the skin of a foreign body, or of the position of the internal organs by vertical projection of the shadows. The apparatus was exhibited.

A Case of Giant Cell Degeneration of the Hematopoietic Organs with Unusual Blood Conditions: MICHAELIS (Berlin). The case was that of a woman 50 years of age who was admitted to the hospital 10 weeks after an attack of influenza. The patient was cachectic although well nourished. The spleen was much enlarged, lymph glands not palpable. Blood examination: Leukocytes 1:220 of the reds; 75% lympho-

cytes, 7% neutrophile myelocytes; a few nucleated reds found early, none later. There was no hemorrhagic diathesis. At the necropsy the spleen was enormous and soft, lymph-glands not enlarged. Bone-marrow red, not soft, no other bone changes. Microscopically the bone-marrow contained an increased number of giant cells, which were also abundant in the lymph-glands, blood, spleen and liver. The latter 2 organs showed also some small round cell infiltration. Michaelis considered the diffuse disease of the bone-marrow as primary.

The Spread of Epidemic Cerebrospinal Meningitis: JÄGER (Königsberg i. Pr., who is high in rank as a military medical official), reported a recent epidemic of this disease in the German army. He emphasized the importance of the disease and the methods of its diagnosis. He considered certain of the North American States, New York and Massachusetts especially, as the foci where the disease is epidemic, that the United States bears the same relation to this disease that India does to cholera, and that it is to the United States that Germany owes her epidemics of meningitis.

FIFTH SESSION.

Intermittent Hepatic Fever on Urea Formation: MÜNZER (Prag) follows Charcot in considering *fièvre intermittente hépatique* as a distinct disease. In the etiology of some cases *Bacillus coli communis* is possibly important, perhaps in those cases which show no leukocytosis between the paroxysms. The speaker confirms Regnard's observations on the diminution of N excretion in many cases during the febrile paroxysm, but considers it of little importance, and explained by the inanition and retention of the N, since proteid metabolism does not, during the paroxysm, differ essentially from that in the intervals. He denies to the liver any specific urea-forming function. The most of the urea may be formed there, but the function is one possessed probably by all tissue cells. Clinically, in no disease of the liver has a hindrance to the urea formation been proven, hence one is not justified in considering cholemia as the expression of an intoxication by the nonexcreted forerunners of urea.

ROSENSTEIN (Leyden) cannot consider intermittent hepatic fever as a separate disease. Febrile paroxysms occur in many hepatic diseases, among others hypertrophic cirrhosis. By no means should they be considered as indicating a purulent process.

The Operative Treatment of Hypertrophic Liver Cirrhosis: HIRSCHBERG (Frankfurt a/M.). The case reported was that of a man 51 years of age, who for several years suffered from a disease which Hirschberg diagnosed as hypertrophic cirrhosis of the liver. The condition of the patient grew so serious that operation was decided upon, on the ground that it is in this disease the congestion of the liver with bile which produces the destruction of the liver cells, and the fatal outcome. Since the obstruction to flow of bile is in the smaller ducts within the liver, the object of the operation should be to provide the bile with a means of escape through the liver substance. This was accomplished by establishing a biliary fistula by incising the swollen, sensitive right lobe deeply at one point, (an incision the depth and width of the finger), and packing the incision with gauze, which was removed in 5 days. At first a large stream of bile escaped, which gradually diminished till the sinus closed on the thirtieth day. No pus escaped. It is nearly a year since the operation, the patient has gained about 25 pounds and is in good condition.

Discussion.—NAUNYN (Strassburg) does not consider the prognosis in either the atrophic or hypertrophic liver cirrhosis as hopeless. Either may heal spontaneously. According to him there is but one constant physical sign in cirrhosis, and that is the increased consistency of the liver. Since this failed in the above case, Naunyn is inclined to doubt the diagnosis, and considers the case possibly one of infectious cholangitis.

ROSENSTEIN (Leyden) also doubted the correctness of Hirschberg's diagnosis, since jaundice failed and gastric disturbances were present early. He had never seen a healed case. Rosenstein separated sharply the cases of enlarged liver with and without jaundice. For the hypertrophic cirrhosis of the liver described by Hanot, jaundice is an essential symptom. The cases without jaundice result in a contracted liver. Hanot's type not so, and do not show the symptoms of congestion as do the former. The hypertrophic cirrhosis cases all have fever at some time during the disease, but not during the entire course.

HIRSCHBERG replied that he should hold fast to his diagnosis until another was proved correct. He added, in reply to EWALD's question, that only *Bacillus coli communis* grew from the bile in his case.

Acute Myelitis: v. LEYDEN (Berlin) presented the clinical side of the subject. Historically, the clinical picture was known long before the lesions were understood at all well. At first, all cases of paraplegia were attributed to myelomalacia. About the middle of the last century, inflammations without softening were recognized, although the distinction then made has proven too sharp. The present classification is: (1) Inflammatory softening, the result of severe inflammation; (2) hemorrhage (hematomyelia), neither clinically nor anatomically to be separated from the first. The myelitis may be further subdivided into (1) transverse, (2) disseminated, (3) poliomyelitis (which should not include the degenerations following cachexia, diabetes, pernicious anemia, etc.), (4) compression

myelitis following caries of the vertebra, which have clinically a similarity to acute myelitis, which is true also, but in a less degree, of the inflammatory processes accompanying tumors of the cord.

In the etiology infection is most important. Primary infection is proven only in the case of myelitis, and the organisms most important are the Diplococcus intracellularis of Weichselbaum and the Streptococcus. The majority of cases follow such infectious diseases as influenza, typhoid fever, and lesser diseases, as tonsillitis, also puerperal infection and hydrophobia. Some cases recover; some are the starting points of a chronic disease. Another cause is (2) trauma, not so much local as general concussion. Such cases form transitions between myelitis and hematomyelia; the lesions present here are usually disseminated foci; (3) poisons, such as alcohol, lead, arsenic, carbonmonoxide, are rarely causes, and the myelitis usually subsides; (4) fright and anger have also been stated to have caused acute myelitis. In the causation of chronic myelitis tuberculosis, lues and gonorrhoea are important.

The symptoms vary according to the regions affected.

The course varies in different cases. Some cases are so acute as to warrant the name myelitis acutissima, but more often the course is more gradual, reaching its maximum intensity after several days. It may progress upward, presenting the serious picture of acute bulbar paralysis, although even this may subside; or transversely; or downward, causing paralysis of the bladder and rectum, bed sores and even gangrene of the extremities. Some of these cases subside, but leave impaired function.

The treatment of such cases is not as hopeless as was formerly supposed, since it has been proven that such exudates and hemorrhages may be absorbed. Some cases die, some are the starting point of a chronic disease, some—and the cases are not rare—recover. The treatment should be symptomatic, since in the case of lues alone have we a specific remedy.

REDLICH (Vienna) presented the pathologic side of the question. The lesions were classified by Leyden-Goldscheider according to their development as transverse, diffuse, disseminated, and poliomyelitis, but these forms show many transitions between the poliomyelitis and the disseminated form, and between the latter and the transverse and diffuse. The large foci are constantly accompanied by softening, either in the sense of edema or hyperemia; or, on the other hand, of true necrosis. Hence the question is a much more difficult one for the pathologic anatomist.

Poliomyelitis, when fresh, is a true inflammation with the lesions located chiefly in the vessels, especially the anterior and central spinal arteries. In some cases Charcot's idea may be correct, that the process is essentially a degeneration of the bene-cells. Closely allied to this form, and also occurring chiefly in young children, is a form of multiple disseminated myelitis with the foci limited to the gray matter.

In the other forms of acute myelitis, 2 types of histologic lesion predominate. The first is acute degeneration of the nervous elements, swelling of the fibers and axis cylinders, occurring in isolated or multiple foci, or in the periphery of other lesions; the second is necrosis of all the elements except, perhaps, the vessels remain intact. These areas correspond usually to vascular areas. Meningitis may accompany any form of myelitis.

It is hard to define myelitis, since it is not yet decided in the case of the nervous system, just what constitutes an inflammation. Mayer claimed that the essential element was the vascular changes, but this is not supported.

Virehow held the very broad view that the results of an irritation constituted inflammation. Bruns included under the term the results of infection and intoxication of the nervous system. A compromise seems necessary, and hence we assume that the same irritant may cause inflammation or degeneration, either of which may predominate. Without dispute is the inflammatory character of poliomyelitis and the related forms of multiple myelitis. Softening, due to embolus or thrombosis is possible although, as yet, unproven, and in most cases must be considered the consequence of inflammation. All transitions exist between softening and inflammation.

Myelitis, as a rule, accompanies an infectious disease. The truly infectious forms correspond quite closely to those with predominating vascular changes.

Bacteria have only rarely been found in the cord, but when introduced they disappear quickly—within 14 days—hence this may explain the rarity with which they have been found. Lumbar puncture will throw much light on this question. In many cases the causal factor may be the toxins rather than the organisms themselves. This is in accord with the fact that poisons, exposure to cold, and trauma have also been claimed as causes of acute myelitis, also that as a rule the myelitis follows rather than accompanies the infectious disease.

STRÜMPPELL (Erlangen) disagreed with the last speaker's definition of myelitis, which he (Strümpf) defines as the active reaction on the part of the tissues of the cord to overcome, or repair the injury done by an injurious agency, whether bacteria or toxin. The best method of studying the disease is by lumbar puncture, and this is not wholly satisfactory, since we cannot obtain directly the products of the diseased foci.

Myelitis may be produced by bacteria or toxins. He stated a case in which lumbar puncture gave a purulent fluid rich in staphylococci, as evidence of the former method, and one

of acute disseminated myelitis with sterile clear fluid as an illustration of the latter method. In these toxic cases the localization of the lesions is often striking. In one of his cases, following erysipelas, the acute disseminated myelitis was limited quite sharply to the posterior columns. The more chronic the intoxication the sharper the localization and the less evident the inflammatory reaction. Simple degeneration of the nervous elements with secondary proliferation of the connective elements when due to external agency may be spoken of as chronic myelitis, but its inflammatory nature is probable rather than proven. Multiple sclerosis Strümpf does not consider a myelitis, since the evidence would indicate an endogenous rather than an exogenous cause.

Discussion Concerning Acute Myelitis.—SCHULZE (Bonn) emphasized the intimate relation between meningitis and myelitis, especially the purulent variety. In many cases no bacteria have been found, but a more general use of the lumbar puncture is much to be desired. Acute myelitis frequently accompanies caries of the vertebra, but is mistaken for tumor since the neuralgic pains fail because of the paralysis. Hence one should be careful in diagnosis since the prognosis in these cases is so different.

V. KAHLDEN (Freiberg) emphasized the view that in inflammations the degenerative changes in the parenchyma elements are primary, the changes in the vessel walls secondary, and the exudation follows the latter.

ROTHMANN (Berlin) spoke of the results of animal experimentation.

GOLDSCHIEDER (Berlin) reiterated his opinion, which the former speaker had criticized, that the vascular changes were primary, and the disease spread along the vessels as the focal lesions of groups of ganglion cells proved.

BITTER (Berlin) reported 6 cases of myelitis in children following various diseases. The exudate was injected into the vertebral canal of animals where it set up a similar trouble.

REDLICH (Vienna) closed the debate.

[TO BE CONCLUDED.]

AMERICAN SURGICAL ASSOCIATION.

ANNUAL MEETING HELD IN BALTIMORE, MD., MAY 7, 8, AND 9, 1901.

[Specially reported for AMERICAN MEDICINE.]

An unusually large attendance made this a most successful meeting. The first paper on the program was:

Some Phases of the Cancer Question, by Dr. ROSWELL PARK.—Cancer always begins as a local manifestation. Both antemortem and postmortem studies are necessary to determine the course of the disease. Park has held for 15 years that cancer is an infectious disease. The specific cause is believed to be due to a protozoan which is exceedingly polymorphic. All observers have seen the same cells but have called them by different names. He thinks, however, that many organisms may enter into the causation of cancer. The subject must be studied from a biologic and chemic standpoint. This the speaker and his colleagues are attempting to do at the University of Buffalo. The small hyaline bodies which are believed to be the specific cause of cancer have been found plentifully in abdominal ascites of animals suffering from visceral cancer, and in all cancer scrapings. They are lighter than fluid and hence are seen near the glass slide in hang-drop. The speaker said that Dr. Galard could state positively that all sarcomas and carcinomas contain parasites, and that these parasites are not the fungus growths observed by the Italians. He would not say, however, that the fungus growths never produce cancer. The great difficulty arises when attempts are made to cultivate the organisms believed to produce cancer. This must be done in living animals and not in media. In this connection the nature of the vaccine virus has thrown some light on the subject. The experiments of Coplin and Funke with vaccine virus were referred to with approval. The author said fluid containing the supposed germ of cancer was injected into 14 guineapigs, all of which died; the average length of life after injection was 50 days, whereas fluid injected into fresh guineapigs from those already inoculated caused death on the average in 25 days, showing that the virulence increases with inoculation. Animals dead of cancer have the germs in the peripheral blood. In 1 case of Hodgkins disease the germs were found in the peripheral blood 7 days before death. There appear to be 2 forms of the injection: (a) that which attacks the lymph-nodes, and (b) that which attacks the spleen. The organisms may remain in the lymph-nodes after the latter are removed and dried, and may then be used for injection into animals. Spontaneous retrocession of cancer may occur, and this is not inconsistent with the germ theory. In a later discussion Park said all animals that had been artificially inoculated had died. A full report would later be made of all their work.

Early Signs of Carcinoma of the Uterus, by THOMAS S. CULLEN, M.D.—The address was a demonstration of the early

signs of carcinoma uteri. Numerous illustrations were shown by the lantern, and the difficulty of and the necessity for early diagnosis insisted upon. The speaker insisted that cells with large nuclei and abundant chromatin in diseased tissue are pathognomonic of cancer.

Brief Consideration of Cases of Cancer of the Breast Treated at The Johns Hopkins Hospital Since 1889.—W. S. HALSTED explained that in the Johns Hopkins Hospital drawings are made of all cases of cancer, and paintings are made of some. Some 320 cases of cancer of the breast have been operated upon in the above-named hospital since 1889, and about 150 of these during the past 3 years. There have been 450 cases of tumor of the breast since 1889; of these only 3 were sarcoma, and but 1 of these was primary. Adenocarcinoma is not very malignant, but always becomes malignant. Dr. Halsted explained the difficulty of compiling trustworthy statistics. Many hopeless cases were operated upon simply for temporary relief, and these should not be counted in with more hopeful cases. He had divided his cases into 3 groups: (1) those from which the axillary and supraclavicular glands were removed at the primary operation; (2) those from which the supraclavicular glands were not removed until a secondary operation; (3) those from which the supraclavicular glands were not removed at all. Local recurrence occurred in group (1) in 11%, in group (2) in 20% and in group (3) in 9% of cases. In group (1) 45%, in group (2) 33% and in group (3) 43% were cured. Intracanalicular myxomas and fibromas are often spoken of as sarcoma, but they are not such.

Late Results in Inoperable Sarcomas Treated with the Mixed Toxins.—W. B. COLEY, began his experiments about 10 years ago, but in the past 3 years has not changed his technic. The best results are obtained in the spindle-celled sarcoma, which shows cures to occur in 50% of the cases. Only about 3% of cures have been effected in the round-celled sarcoma. The treatment should be tried only in inoperable cases. The injection of the toxins is almost devoid of danger. Out of 600 cases treated, but 2 have been fatal from resulting erysipelas. The treatment is useless after metastasis has occurred. It is likewise useless in melanotic sarcoma, and in lymphosarcoma. The speaker has had 15 cases pass the 3 year limit, of these 8 were of the spindle-cell variety. One case recurred after 8 years, another after 3½ years. Several of these cases had sarcoma of the parotid gland. The treatment may be kept up a year or more without harm to the patient. The mixed toxins appear to inhibit to some extent the growth of carcinoma, but do not effect a cure. The author advises this treatment in all cases of inoperable sarcoma.

The Influence of Mental Depression on the Development of Disease by JOSEPH D. BRYANT. Ambroise Paré was the first to suggest the probability that mental depression aggravates cancer. Various later writers were quoted who supported this view. Velpeau opposed this view and Virchow and Rokitsanski gave qualifying opinions on the subject. Idiots appear to be almost or quite immune to cancer. Depression arises under 3 conditions with reference to cancer: (1) Depression arising without fear of oncoming cancer; (2) depression arising in cases fearing cancer; (3) depression arising after cancer has manifested itself. No special fear predisposes to cancer. Among 402 females and 343 males having melancholia, 1 male and 4 females died of cancer. Mental depression plays a very small part, if any, in predisposing to cancer. Possibly there is some predisposition among females, but it is not significant. Death from cancer among melancholic females is nearly double what it is among males similarly afflicted.

Discussion of papers relating to cancer was opened by WARREN, who referred with approval to the increased attention which cancer is receiving among surgeons and in laboratories. The speaker is the recipient of a trust fund bequeathed to Harvard Medical School for investigations with reference to cancer, and he and his colleagues are now in their second year's work, but so far their results have been negative. To make cultures of the supposed cause of cancer is the great difficulty. He believes germs are responsible for cancer, but insists that Koch's law should be complied with. Proof is wanting in many cases. The speaker referred to experiments by inoculation, but said this procedure is similar to transplantation. The germ is probably a protozoan, but this is not proved as yet. Warren has seen the fat-like bodies in the hanging-drop, referred to by Park and Gaylord, but he finally concluded they were inanimate bodies with Brownian movement. The bodies may be simply a contamination of cancer rather than a cause. The speaker agrees with Halsted in having difficulty in compiling statistics in cases of cancer operated upon. He says a classification by the pathologist is desired. The speaker referred approvingly to Coley's experiments, and said he had received favorable results by using the injections of toxins in post-operative treatment.

Dr. CULLEN's brief paper on the subject of the cancer parasite appears in this issue.

Dr. PARK closed the discussion by saying they had great hopes at the University of Buffalo of making valuable contributions before very long. A complete report would soon be made.

Blood Examination as an Aid in Surgical Diagnosis: J. C. BLOODGOOD (Baltimore). See author's abstract in this issue.

The Clinical Value of Blood Examinations in Appendicitis: J. C. DACOSTA, JR. (Philadelphia) reviewed 118 cases seen in the German Hospital at Philadelphia, the statistics representing the condition of the blood before operation, usually immediately after admission to the hospital. The value of the blood-count as a means of differential diagnosis is greatly limited, since conditions which bear the closest clinical resemblance to appendicitis give rise to blood changes identical to those found in the latter disease. Should the diagnosis be between appendicitis and enteric fever, the former is suggested by a leukocytosis, except in event of intestinal hemorrhage or perforation. In typical cases a leukocytosis is sufficient to exclude noninflammatory conditions, as enteralgia, lead-colic, ovarian neuralgia, etc.

Blood Examination in Relation to Surgical Diagnosis: J. D. BLAKE, J. C. HUNNARD, R. C. CABOT. Blood-counts have been made in 50 cases before administration of ether at the beginning of the operation, and again after the operation. A slight leukocytosis was observed soon after etherization, and a still further increase after operation. The increase persisted for about 7 hours. The greatest was an increase of 10,000 leukocytes, with an average of 2,000 increase per em. Operation alone increases the leukocytes in about ½ of the cases. Fracture causes a slight leukocytosis. Some 32 cases were examined after fracture, and 10 showed an increase to 10,000 per em., and none showed over 12,000 per em. After operation for malignant disease of the breast, the hemoglobin was found increased. In perforation in typhoid fever there is found to be an early wave of leukocytosis, but other conditions cause the same, and it is therefore not pathognomonic. It is unsafe to base a diagnosis of perforation on a wave of leukocytosis—it should be an increase that is constant. The blood of the Marathon runners was examined before and after the race, and it was found there was a marked leukocytosis in all, the polymorphonuclears showing a great increase. There were found no nucleated red cells.

The Effect on the Blood of Ether Used as an Anesthetic.—J. CHALMERS DACOSTA, and J. L. KALTEYER, Philadelphia. See author's abstract in this issue.

Examination of the Blood in Relation to Surgery of Scientific Value, But Too Often of no Practical Value, and May Misguide the Surgeon: JOHN B. DEEVER. Blood-count gives only one physical sign, and its significance should not be allowed to go further. Blood-examination promises much and is valuable, but information so obtained is open to many fallacies, because the opportunities for error are many. Attempts have been made to set a standard degree of anemia, below which operation is contraindicated. The speaker insists that there can be no such standard. He cited 2 cases on which he operated, the hemoglobin in one being 30%, and in the other 22%. Both cases progressed favorably and terminated in recovery. Concentration of the blood from purgation, vomiting, sweating, etc., may give a normal or even higher percentage of hemoglobin, when the total quantity of blood is very deficient. The presence or absence of leukocytosis is the most significant fact to the surgeon which a blood-examination will give. Speaking generally, a high leukocytosis is a favorable sign. It is caused by inflammation, but it usually foreshadows a reaction. The speaker emphasized the fact that leukocytosis is not the rule in malignant disease. Only 19 out of 49 of his cases showed over 10,000 leukocytes to the em., and in only 2 cases was it over 20,000 per em. We cannot depend on a blood-count in appendicitis, for the favorable time for operation is early, before leukocytosis has become marked. In salpingitis even a moderate leukocytosis of from 14,000 to 17,000 per em., as a rule, indicates pus. In obstructive jaundice a leukocytosis usually occurs. Excluding pneumonia, leukemia, etc., a leukocytosis of over 20,000 per em. usually indicates pus. Blood-count is valuable, but it must not be permitted to mask the clinical picture.

Wednesday morning's session was held at the Johns Hopkins Hospital. Dr. OSLER was the first speaker. He explained the methods of instruction given the third and fourth year students in the University, emphasizing the point that almost all instruction in medical diagnosis and treatment are given at the bedside, and didactic lectures are almost entirely dispensed with.

Dr. HOWARD KELLY followed, holding a clinic in which he demonstrated the use of the cystoscope. He catheterized the female ureters and demonstrated his method.

Dr. YOUNG exhibited several instruments devised by various men for catheterizing the male ureters. He successfully catheterized both ureters in a male and demonstrated the manner of collecting the urine. No general anesthetic was given the patient but a 4% solution of cocaine was injected into the bladder to relieve pain.

Dr. WELSH then gave an explanation of the laboratory methods in vogue in Johns Hopkins University and explained how the work is done. He congratulated the profession and students of the United States on the progress which has of late years been witnessed in laboratory facilities and technic. It is no longer necessary, said he, for the student of pathology to study abroad in order to become a pathologist. The laboratories of at least a dozen medical schools in this country offer equally as good advantages as can be had anywhere abroad.

CORRESPONDENCE

SALINE INFUSION IN THE TREATMENT OF PNEUMONIA.—FIRST USED BY DR. F. P. HENRY, OF PHILADELPHIA.

BY

S. SOLIS-COHEN, M.D.,
of Philadelphia.

Referring to the excellent paper by Dr. Wm. Crawford Johnson on the treatment of pneumonia, which appears in your issue of April 27, permit me to correct the author in a historical respect. Credit for the introduction of saline infusion in the treatment of pneumonia belongs to Dr. Frederick P. Henry, of Philadelphia, who practised it at the Philadelphia Hospital at least as early as 1890. In the *Medical News* of August 20, 1892, page 216, this statement will be found in print in an editorial article from my own pen. I have also alluded to the matter, giving credit to Dr. Henry in several clinical lectures and other addresses, among them an address on "Progress in Therapeutics," delivered before the Philadelphia County Medical Society, and printed in its "Transactions," and in the *Therapeutic Gazette* of June 15, 1900. In a signed editorial in the *Philadelphia Polyclinic*, July 20, 1898, on "The Use of Physiologic Salt-solution or Artificial Serum," I make the following statement: "In toxemias, in which class of cases, for example, delirium tremens and pneumonia both find place, preliminary or coincident venesection may usefully be made. We have seen recovery take place in doubtful cases under this form of treatment. In 1 or 2 cases, after a preliminary irrigation, the injection of a pint or a quart of warm saline solution into the colon has seemed to serve a good purpose in connection with deficient excretion of urine, and in pneumonia and uremia to keep up the good effect previously obtained by hypodermoclysis." In the *Philadelphia Polyclinic*, May 28, 1898, Dr. Torrance reports from my service at the Polyclinic Hospital, one of these cases in which venesection and intravenous injection of saline solution were used coincidentally. While I have no desire to claim any priority for myself in this connection, I do desire to place on record definitely the absolute priority of Dr. Henry, because I know that his modesty will prevent him from making any claim for himself.

TO IMPROVE THE HYGIENIC AND PHYSICAL CONDITION OF THE SLUMS.

BY

L. I. BOGEN, M.D.,
of Omaha, Neb.

In the first number of your valuable journal in an editorial on "Heredity and Human Progress," the writer strikes the keynote to the situation, when he says: "It cannot be doubted that modern city life, with its unhygienic, underfed slum population, must inevitably produce some such horrors as Dr. McKim outlines." After reaching such conclusions the remedy would naturally suggest itself, viz.: to improve the hygienic and physical conditions of this underfed slum population, and the cause once removed, the effects will themselves disappear. Instead of it the writer suggests "for those classes who are unquestionably hopelessly depraved," etc., the unsexing of these classes and thus preventing them from producing others of their kind.

The writer's remedy would be consistent and logical if, like Dr. McKim, he would contend that the world's degeneracy is due solely to the survival of bad and weakly people. If, however, modern city life, etc., be the cause of it, then degenerates must always be produced as long as this modern city life with the unhygienic surroundings will continue in existence.

It may not be amiss to remind the writer, as well as Dr. McKim, that about a hundred years ago Robert Owen was confronted with the same problem and he solved it very effectively

and in a very much more humane way than Dr. McKim and the writer suggest.

Robert Owen was manager of a large mill in Scotland employing 2,000 people; 500 were children, and nearly all of them had been taken at the age of 5 or 6 years from charity institutions. He found his workingmen in a most deplorable condition, many of them being hopelessly depraved. Most of the families were living in single rooms, and theft, drunkenness, and other immoralities, together with long hours of factory work, kept respectable people from working in the mill.

Robert Owen reduced the hours of labor, established schools for children and adults, improved their dwellings, sanitarily and otherwise, and he put the sale of intoxicating liquors under the strictest surveillance. In a short time this once demoralized village became the most civilized, industrious, intelligent, happy and prosperous community in Great Britain.

AN EPIDEMIC OF ABDOMINAL INFLUENZA AMONG CHILDREN.

BY

DR. WILLIAM B. YOUNG,
of Bon Air, Tenn.

During the summer months I believe we have more gastrointestinal diseases in Bon Air, Tenn., than any town of the same population in the State, and for the following reasons:

Bon Air is a mining town situated 2000 feet above sea level, just on top of the brow of the Cumberland Mountain, where the land is very poor and the sand rock comes so close to the surface that it renders the soil about most of the residences unfit for cultivation. The population is composed largely of coal miners who take very little interest in gardening. No vegetables are shipped to our town, as we have no market house and but one store. The roads up the mountain are almost impassable for vehicles. For the above reasons our people depend almost wholly for their vegetables and fruits upon trucksters, who carry their "truck" in sacks thrown across mules and horses. This method reminds one of Oriental carriers—donkeys and camels. By the time they reach our homes from the valley below the vegetables have usually undergone more or less decomposition, from pressure in the sacks, the bodily heat of the animal upon which they are borne, the excessive warm weather and the distances they are conveyed. On account of the inconvenience of procuring vegetables and fruits, many of our citizens buy in rather large quantities and too often eat them withered and decomposing. There are no cellars and few refrigerators in our little city. The former we cannot have, as the sand rock is too close to the surface. The latter few are able to possess.

A very large percent of our population is poor and illiterate and does not realize and cannot easily be taught the dangerous results of such methods of marketing. They allow, unless closely watched, all ages to partake freely of this unwholesome diet.

Another avenue of contamination is from the milk, on account of the imperfect methods they have of preserving it pure, cool and wholesome.

During the fall and winter seasons we have had, until this year, no more gastrointestinal troubles than any other town of its size. Possibly not so much, as we get few fruits and vegetables, and live very largely on meats and prepared foods, as vitoes, oatmeal, grapenut, and so on. However, during the past winter and early spring, from January the first to April the first, I treated more cases of gastroenteritis than during the entire spring and summer seasons of any previous year. I have been in Bon Air 14 years, and this is the first epidemic of the kind that ever occurred in the winter months. The symptoms were very similar in each child and for this reason I shall generalize and not record individual cases in this report.

Usually the attacks began abruptly, the child being previously healthy. In quite a few cases the attacks came on at night. The child awaking with abdominal pains would soon vomit and purge. The vomiting preceded the diarrhea in most

all cases. After the vomiting and diarrhea the pains would usually cease. However, possibly in one-third of the children the pains continued for several days. Many, after the initial vomiting, never vomited again, but the diarrhea would continue until convalescence. The vomit consisted of recently ingested food. The discharges from the bowels were usually of a dark, green color. Sometimes I would notice a very thin yellowish discharge, having a very offensive odor. Three or 4 children passed considerable blood from time to time. Some few could not take any food nor even water by the mouth, for from 24 to 48 hours, without immediately ejecting it with considerable abdominal pain.

The attacks lasted in some cases for 6 weeks. Two cases were complicated by pneumonia, from which one died. The pneumonia was ushered in with a violent convulsion in each case, after the vomiting and diarrhea had lasted for 3 or 4 days. Usually there would be only one child in a family attacked at first, then, in from a few hours to a few days, every child in the household would have the same trouble.

I am at a loss to account for such an epidemic, unless it was produced by the germ of influenza. All late authorities, I believe, agree that gastroenteric catarrh is caused from some infection. It seems to me we can exclude the most important factors that bring about a summer diarrhea; for instance, injudicious feeding and excessive heat. One-fourth of the attacks occurred in young infants taking nothing but their mother's milk.

Treatment.—In every case I prescribed at the first visit a laxative, usually a little tablet (one of my hobbies in gastrointestinal troubles) composed of calomel $\frac{1}{2}$ gr., ipecac $\frac{1}{16}$, and soda 1 gr. For the children who could not take food or drink without incurring vomiting I gave dry calomel on the tongue from $\frac{1}{16}$ to $\frac{1}{4}$ gr. repeated every hour, until from 1 to 2 grs., according to age, were given. In all such cases it was beneficial and in some it acted like a charm by allaying the irritability of the stomach. I prohibited all food and drink by the mouth and allayed the thirst by euemas of normal salt solution. After the action of the laxative I usually prescribed subnitrite or subgallate of bismuth and salol; in a few cases I was compelled to resort to hypodermics of morphin to relieve the severe abdominal pain. I irrigated in but few cases as I did not consider the trouble due to injudicious feeding, nor to any foreign material in the alimentary canal. The mortality was very light, only 1 death (complicated by pneumonia) out of over 50 typical cases. Not a single child, up to the present, has had a second attack. This gastrointestinal disorder did not attack the adults. It seemed to be confined to very small children and infants. Many of the children seemed weak and lifeless for some time after the diarrhea ceased and the appetite had returned. For this I prescribed strychnine and whiskey, with rest.

MAY A HOSPITAL STEAL CASES?

BY

DR. A. L. BENEDICT,

of Buffalo, N. Y.

Ap[ro]pos of your extract from the *Cleveland Medical Journal*, entitled "May a Hospital Steal Cases?" the following 2 instances may be of interest: Case 1 was referred by me to a certain hospital to which I had previously sent cases as convenient. Through some personal influence she secured a special rate in a small ward. She was essentially a private case, though a poor woman. After all arrangements were made the superintendent insisted that she should be treated by the ward attendant. A request for a suspension of rules was refused and the patient left the hospital. Case 2 was sent to another hospital and referred to me, under the impression of her family physician that I was consultant at this hospital. On visiting her I found that, in addition to the chronic digestive disturbance for which she had been referred, she had erysipelas. I referred her to the regular attendant for treatment for this intercurrent affection. Telephoning after a few days to learn when I should assume charge, I was informed that I could not take

the case as the patient was in the ward. This patient, I believe, remained in the hospital for some time. One naturally dislikes to argue too strongly in his own behalf, and yet when a patient is referred to a specialist for a definite reason and is sent to a certain place for this very purpose, when in addition the case is referred to another to avoid infringement on established lines of limitation of practice, it seems rather remarkable that any hard and fast rule should be adhered to, to justify an obvious breach of ethics.

In writing this letter, I am influenced by no personal hostility: on the contrary both of the attendants mentioned are personal friends, neither were the cases such as to appeal to one strongly from the mercenary standpoint, though neither was a charity case. I may also state that I am not a "sorehead" or an "anti" in regard to hospital work. There is a good old-fashioned principle recognized both legally and generally by the medical profession, that every patient has the right to select his own physician. If a hospital takes a patient as a matter of out-and-out charity, it certainly has the right to lay down any rules it sees fit. So far as I know, no hospital does extend its own charity to this extent. A man who takes a cheap room at a hotel has precisely the same liberty and rights as the one who occupies the most expensive. Partly as a matter of philanthropy, partly for sound business reasons, hospitals offer patients graduated service at graduated rates. The ward patient does not pay as much as the one in the private room, neither does he enjoy the same privacy, luxury and personal attention. To deny him the choice of physician is a gross infringement of his personal rights, as well as an injustice to the majority of the medical profession. To compel him to accept gratuitous services from physicians whom he may not desire, is an insult to his independence. Such a course leaves no middle course open between pauperism and an expense of \$20.00 or \$30.00 a week. In other words, it forces pauperism on a very large proportion of all persons who require hospital care. Even when the patient is genuinely an object of charity, he is rarely the beneficiary of those who lay down arbitrary rules as to what physician he shall have and what he shall not be allowed to choose. The charity is either charged to the city or county or to a fund obtained by an appeal to public generosity on the ground that a public service is being rendered.

A cast-iron rule that a ward patient must be attended by a certain physician is defensible only on the theory that this physician possesses a higher degree of skill than the one whom the patient might prefer. If this is true, why not protect also the patient in the private room and in his own home? Surely there is no excuse for permitting the man in comfortable circumstances to run the risk of malpractice, and to consider the safety only of the poor. There can be no objection to appointing a staff who shall be placed at the service of patients who have no choice of physician. Personally, I do not believe that it is reasonable to require, as some extremists have suggested, that such appointees should be chosen impartially from a civil service list, open to all qualified physicians. This world is not run on such principles. But why should a man with the prestige to obtain such a position require a compulsory protection against the outside physician? Let him use his merit and his influence to the utmost and accept whatever measure of success he can get, just as in his private practice. Such a policy would do away with the antagonism toward hospitals, manifested by many physicians. The great majority of physicians do not care for a ward service, but simply for the right—which is mutual between patient and physician—to attend such patients as seek their services. To paraphrase an old saying, why compel a man to be wholly a hog or to have nothing?

International Academy.—A congress composed of savants representing 12 nations is being held in Paris. Its aim is to establish a federation of learned investigators in order to secure more systematic efforts in research, and a more rapid interchange of results obtained. It has decided in favor of establishing an international academy to which only the world's most famous physicians, philosophers, and scientists may be elected. Germany has sent 11 delegates, and England, Russia, Switzerland, Scandinavia, and Italy are well represented. Prof. Goodale, of Washington, is the only delegate from the United States.

DISEASE AND DEFORMITY OF THE KNEE: ETIOLOGY, DIAGNOSIS AND TREATMENT.

BY

DANIEL W. MARSTON, M.D.,

of New York.

Instructor Orthopedic Surgery, New York Postgraduate Medical School and Hospital. Visiting Surgeon Dalsey Fields Hospital for Crippled Children, and Randall's Island Hospitals, New York City.

Kneejoint-disease may be either purulent or tuberculous or purulent and tuberculous. It may also be complicated by constitutional disease, as syphilis, and occasionally depends upon some lesion of the central nervous system, as in Charcot's disease. Other names that have been used to describe the same condition are: Tumor albus, chronic purulent synovitis of the knee, chronic tuberculous osteitis of the knee, strumous arthritis, fungous or scrofulous disease of the knee. Statistics of disease of this joint are easily obtained and some were

Fig. 1.—Tuberculous disease of the knee.

compiled in the early history of medicine. Dijou, of France, reports a case of tumor albus treated by cataplasms, vesications, cautery, and finally, by excision. In 1730 the French treated this affection by fomentations and the application of Venice turpentine. At this date the length of treatment for cure of the cases was 10 years. Filkin, of Northwich, in 1762 resected a kneejoint for

white swelling, and the patient lived 20 years. Desgranges* in the 17th century used decoctions of herbs and cataplasms of cowdung, which he said afforded relief. This certainly was heroic treatment. In 1836, the English surgeons began to practise extension and fixation in these cases, after the American line of treatment, prominently advocated at that time by Davis, of Massachusetts, and

Fig. 2.—Characteristic subluxation of tibia in advanced kneejoint-disease, either purulent or tuberculous; no previous treatment.

Sayre and Taylor, of New York. Since then various theories relating to injection of the joint have each had their enthusiastic exponents, and not until recently has it been proved by bacteriologic research and clinical experience that these agents are unavailing.

The etiology of disease of this joint may depend upon infection from any of the sources mentioned. In 90% of the cases the disease is primarily tuberculous, the infection occurring in the same manner as in hip-disease. It is not until a mixed infection occurs, as a rule, that there are found in the joint the pus-producing microbes. When they do exist they are usually staphylococci. Cases dependent upon constitutional conditions are rare. A not uncommon occurrence is an arthritis, or inflammation, of the synovia, due to trauma, which is simply the effort of nature in the normal process of repair, when no inoculation of germ-life has as yet taken place in the area of new cell-proliferation. These cases are analogous to the so-called cases of ephemeral hipjoint-disease, which recover in a few weeks, and are entirely distinct from the typical tuberculous or purulent diseases of joints which are often spoken of under the general term of arthritis.

In cases of kneejoint-disease, the focus of disease may exist in the bone, the synovia, fibrous capsule, ligaments, or cartilages. The invasion, development and progress of disease is practically the same here as in the hip. The most common location of the disease is in the internal condyle of the femur, and next most frequently upon the head of the tibia. We can readily account for the frequency with which the internal condyle is the site of the initial focus of disease. In cases of traumatism, however slight, the internal lateral ligament invariably sustains more or less strain, particularly at its insertion

* Griffith, in Ortho. Trans., 1893.

into the condyle of the femur. It is because of frequency of trauma in this location and the subsequent inflammatory process of repair, offering as it does an excellent culture-medium for the reception and growth

Fig. 3.—Chronic contracture of joint. Suitable ease for tendon resection and forcible reduction of deformity.

Fig. 4.—Showing outward rotation of leg and displacement backward of tibia, as seen in advanced stages of disease.

of tubercle, or pus bacilli, that the primary seat of disease is in the internal condyle.

Sex does not seem to have much bearing upon the etiology. If there are more cases among boys it is readily explained by their greater exposure to traumatism in their sports and out-of-door life.

Pyogenic and tuberculous germs enter the circulation primarily, according to Phelps, through the lymphatics. A child playing in the back yard of a tenement house, in an atmosphere contaminated with germ-life, through beating carpets from an infected room where an individual has died of tuberculosis or osteomyelitis, inhales the spores of the germ. These spores are immediately absorbed by the lymphatics from the mucous membrane of the pharynx and the trachea and carried to the neighboring lymphatic glands. The lymphatic glands are rich with cells and are good soil for the reception and growth of the germs. The cells or phagocytes of the lymphatic glands are at once attacked by the germs and destroyed, until the entire gland is converted into a pus-cavity or tuberculous cavity, depending upon the kind of germ absorbed. These are the large glands seen in the necks of children and called by the older authors "strumous or scrofulous gland." Ulceration now begins in the gland, burrowing takes place in the direction of least resistance. The gland is surrounded by a vascular network of veins and arteries. When perforation of the gland takes place from ulceration, its contents may discharge directly into a vein. Thus it can readily be seen how the circulation becomes contaminated with germ-life from the reservoir which is constantly discharging into it. Now if the child playing in the back yard receives a slight injury of a joint, inflammatory action begins at once at the point of lesion already described. The blood being loaded with germs of infection carries them to the point of injury. The pathogenic germs finding a fit soil

for their reception and growth attack the normal, new inflammatory material and convert it into a *diseased condition*, with a formation of pus or a tuberculous abscess. From this point of local infection the pathogenic germs find their way into adjacent tissues, destroying them as they advance and thus enlarging the diseased area. Should the head of the bone be involved it is soon destroyed, and the diseased cavity discharges into the joint, infecting all the tissues involved in the structure of the joint. If the diseased focus is in the soft parts, the joint becomes infected in the same manner, and the bone is secondarily involved. The entire joint now being involved, the same processes which took place in the lymphatic gland are observed in the joint, viz., ulceration, burrowing, and the formation of tuberculous or pus cavities, together with destruction of all tissues, lying in contact with the disease, by infection. Burrowing always takes place in the direction of least resistance. This accounts for abscesses appearing at different points in joints apparently similarly affected. Tuberculous disease does not, *per se* produce abscess. Fluctuation is not present in cold abscesses. Large tuberculous cavities exist frequently, which are filled with tuberculous debris and partially organized material, but pus is not present until the cavity becomes inoculated with pathogenic germs.

The symptoms of kneejoint-disease are numerous and unmistakable: In addition to the 8 cardinal symptoms of disease in any joint there are present in the majority of cases symptoms characteristic to the joint involved. In every case it is well to examine the patient stripped from the waist down, for in 50% of all the cases

Fig. 5.

of hipjoint-disease the pain is referred to the knee and not infrequently cases of hipjoint-disease are well advanced before the discovery is made that it is not the knee but the hip that has been attacked. If the patient

is a child the examiner should use all the arts at his command to gain the confidence of the little one; without it his examination must be less thoroughly made and is much less satisfactory to all concerned. There are usually present in a typical case:

1. Pain.
2. Heat.
3. Swelling.
4. Pain upon joint-pressure.
5. Limited motion.
6. Muscular spasm.
7. Atrophy.
8. Deformity.

The history of the case will deny or affirm the existence of pain. Careful palpation of the affected joint, as well as its healthy mate, will enable the examiner to ascertain the relative temperature of the parts. Swelling of the joint is detected by observation and by palpation. If the presence of fluid in the joint is suspected, it may be discovered by gently tapping the patella. If there is effusion present the floating patella will rebound from the condyles of the femur when tapped by the examiner's finger-tips. The fourth symptom, pain upon joint-pressure, is of prime importance, and is detected by holding the femur firmly in one hand while with the other the operator *gently* crowds together the articulating surfaces of the femur and tibia. No great amount of force should be exercised here and the presence, or absence, of this symptom should always be ascertained

Fig. 7.—Method of discovering absence, or presence, of pain upon joint-pressure, as described in text.

without causing the patient great suffering. Limited motion in the knee is shown by an effort to flex the leg to a right angle, or, to extend it fully upon the thigh. This is occasioned by an involuntary spasm of the muscles governing the joint. Atrophy, if present, is readily seen, and if of any consequence, can be discovered with sufficient accuracy for all practical purposes without resorting to the use of measuring apparatus. The goniometer will record it with scientific accuracy, but a few degrees more or less in flexion matters nothing in the treatment. The limit of motion and muscular spasm

are in all cases the most reliable symptoms. The usual deformity consists of the leg flexed upon the thigh and the foot rotated slightly outward. The earlier symptoms of limp and night-cries exist, of course, before all others.

Before resorting to treatment, it is of importance that the cause of these symptoms is fully understood. Otherwise there exists a probability that treatment for the disease may not be conducted upon the most practical lines. The pain is caused by pressure upon the terminal nerve-plates of the sensory nerves distributed in the area of disease. Nature, in her efforts to repair the traumatism which invariably precedes these invasions of germ-life, throws out countless numbers of leucocytes in her healing inflammatory process. These form an exudate and it is the pressure of this partially organized material upon the minute terminal nerve-filaments that causes the pain always attendant upon reparative processes. The heat is caused by the same influences that produce heat in any inflammatory condition. The swelling

Fig. 6.—Usual appearance of first stage kneejoint-disease. Suitable for extension "in the line of deformity," as explained in text. Operative measures probably not necessary.

is produced by the inflammatory exudate, the effusion into the joint, and the partial luxation of the tibia. The pain attendant upon joint-pressure is caused by the impinging of the intraarticular surfaces upon each other. The cartilages act as buffers in receiving the shock of traumatism and the jar of walking. Limited motion depends upon muscular spasm, which is in turn produced by the nerve-reflexes, which find their origin in the pain caused by the exudate upon the nerve-terminals. The atrophy is brought about by the nerve-reflexes, long disuse, and the wearing of heavy and constricting braces. The greater atrophy is present when the disease is in the bone, rather than when confined to the soft parts. This is because the inflammatory exudate when produced in the medulla of the bone naturally exerts greater pressure upon the terminal nerve-plates than it does if the inflammatory product is in the soft tissues which are of more yielding and elastic consistency.

It will be seen from this that rapid atrophy is always pathognomonic of bone-disease. The deformity is at first due to the voluntary effort of the patient to relax the intraarticular tension of the joint and thus relieve the pain. This flexion is later augmented by involuntary contraction of muscles in spasm, which increases the deformity by advantage of leverage, due to flexion. The characteristic outward rotation of the leg is caused by spasm of the biceps cruris, after a certain degree of flexion has taken place. This flexion, as noted by

Phelps years ago, causes the lateral and rotatory displacement of the joint. When there are erratic deformities, which exist in disease of all joints, they are due to pathologic destruction of the bone, or soft parts, permitting a change of leverage in the muscles affecting the joint. The night-cries in disease of this joint are of the same etiology as those seen in the first stages of hip-disease. The child while asleep has dreams, in which she makes involuntary movements. During profound slumber the muscular spasm, with which Nature while the child is awake protects the joint, is in some degree relaxed, so

Fig. 8.—Specimen, showing extensive destruction of bones of pelvis; same patient had been operated upon for tuberculosis of kneejoint.

that when the involuntary movement occurs while the little one is in dreamland, the tender and inflamed intra-articular surfaces are suddenly brought together, occasioning pain, almost sufficient to awaken the patient, and invariably severe enough to cause the "cry."

It is of interest in any case to know the precise location of the pathologic lesion. Hold the thigh firmly with one hand, and with the other exert lateral traction upon the tibia outward. This will create tension upon the internal lateral ligaments and, if they are involved by the disease, will cause the patient pain. The same is true of the external lateral ligaments, if the leg is adducted at the knee. This method, together with the one described for ascertaining the presence or absence of pain on joint-pressure, will materially assist in locating the focus of disease. The value of the x-ray in this connection has been overestimated. While it is of great value, it is nevertheless not indispensable in this branch of sur-

gery. It is of more assistance in determining the details of congenital and acquired deformities than in locating the early pathologic lesions of disease. It, however, does

Fig. 9.—Ascertaining location of focus of disease, by adduction and abduction at knee, as advised above.

enable the examiner to follow the course of progressive, destructive processes in the bony structure. I have had better results with radiographs made with a good four-plate static machine than with the fluoroscope.

[TO BE CONCLUDED.]

THE CAUSE OF CANCER.*

BY

THOMAS S. CULLEN, M.D.

of Baltimore, Md.

Being interested in the subject of cancer, I have followed the work in the New York State Laboratory for the last two years and learned with interest the results obtained by Dr. Gaylord and embodied in his lecture at the Johns Hopkins Hospital and in his paper in the *American Journal of the Medical Sciences* for May of this year.

In order to prove conclusively that a given organism is the cause of cancer it is necessary:

- (1) To find or isolate the organism.
- (2) To produce cancer by inoculating the organism into another body.
- (3) To recover the organism from the cancer thus produced.

I have had the opportunity of examining some of Dr. Gaylord's specimens and it is certain that the nodules he

*Remarks made before the American Surgical Association at Baltimore, Md., May 7, 8 and 9, 1901.

produced in the guineapig's lungs are cancer. He, however, used peritoneal fluid and not a pure culture of the organism and hence the first and second requisites are not properly fulfilled. He cannot exclude the possibility of cancer-cells from the patient having been carried over in the fluid to the guineapig, and it is a well established fact that cancer-cells may be transplanted and grow. The third requirement is barely touched upon and no proof of its successful accomplishment is adduced.

On page 511 of the journal above mentioned he speaks of being able to cultivate his germ with "comparative regularity," and we are given the medium upon which it grows. And yet, no word as to its appearance or behavior on the culture medium is mentioned. Nor have we a picture of it, although both Plummer's and Sanfelice's organisms are depicted on plate 7. This omission is difficult to account for. Further, on page 537 a list of his injections into animals is found, and here also we fail to find a single instance where there is conclusive evidence of a pure culture of a germ being employed.

The major portion of the article is taken up with the examination of tissues hardened according to different methods, but, as Professor Welch pointed out at the Hopkins meeting, we might argue indefinitely upon the histologic changes without making an iota of progress. In fact, for years one body of men has been claiming that these peculiar bodies found in carcinoma are due to cell degeneration; the opposite faction, that they are parasites. It is only by cultivating the organism, if there be any, and then producing the disease afresh with this newly-found germ that we can prove the cause of this dread malady. As a matter of fact, Dr. Gaylord has confirmed the results of others but added little or nothing new,* and the cause of cancer is still an unknown factor. It is very unfortunate that the suggestion that cancer parasites were floating around in the blood has led a portion of the daily press to infer that cancer is a blood disease and consequently that the removal of a cancer will be useless, as the disease is sure to appear at another point. Such is certainly erroneous. We know that cancer is not a blood disease, but that in the early stages it is an entirely local process; that it is permanently curable is evidenced by the results in European and, to come nearer home, in our own hospitals, where patients are living and well, years after complete removal of the growth.

Dr. Gaylord and his associates should in no wise be discouraged. Many of the world's most able investigators have been seeking the same goal, and as yet none have reached it. They should be encouraged at every point, as in their love for science they are willing to forego financial prosperity in the hope that they may eventually rid mankind of this scourge. New York State is to be congratulated on its wisdom in establishing a cancer laboratory, and is showing a commendable spirit in increasing instead of diminishing the support accorded its scientific men.

*In justice to Dr. Gaylord, it must be added that the above-mentioned article is a preliminary communication and that the completed work may solve many of the still obscure points.

SLOW PULSE, WITH SPECIAL REFERENCE TO STOKES-ADAMS DISEASE.*

BY

ROBERT T. EDES,
of Boston.

The permanent slow pulse with paroxysms of vertigo and epileptiform or apoplectiform symptoms is by no means a common disease. A very interesting and typical case was shown to this association in 1889 and 1890 by our late associate, D. W. Prentiss, and is doubtless well remembered by many members. Through the kindness of Dr. Prentiss, I had the opportunity of seeing this patient several times during his life and of making a postmortem examination. Since this time I have seen one other quite as typical, and some not quite so well marked but sufficiently important in connection therewith to be worth reporting.

A woman, aged 50, of N. E. birth and parentage, had been an invalid since the birth of a child 25 years ago. After fainting several times, she entered the Boston City Hospital in June, 1897. Her temperature was 101° and her pulse 56. Within a day or two her temperature fell to normal and the pulse to 40 and then 20. From this time until September, during the latter part of which time she was in the Adams Nervine Asylum, her pulse remained slow, occasionally rising to 40 and sometimes falling to 25 or a little below.

The heart's area was not enlarged, its action usually, but not always, regular and the sounds very weak. At times between the pulsations were heard sometimes 1, sometimes 2 or 3 slight sounds as of incomplete beats. At times a soft systolic murmur replaced the first sound at the apex. During this time she had fits of varying degrees of severity, of syncope with apparent loss of consciousness, which was not always complete. In some of these the pulse would go down to 18 or 20, and become extremely weak remaining so for some time after her return to complete consciousness. The attacks became more severe, were attended with more dyspnea and Cheyne-Stokes respiration, and she died September 20.

The early diagnosis in this case had been "hysteria and myocarditis" with an interrogation. Dr. Councilman's report was:

Heart distended, especially the right side, with fluid blood. Valves normal save a slight thickening of the edge of the mitral. Myocardium normal. Coronary arteries normal. The aorta smooth save for a few small plaques of atheroma in the beginning of the thoracic and above bifurcation. Arteries at base of brain normal. Very slight interstitial nephritis.

A man, aged 80, in fair general health, had a normal pulse of about 68 or 70. In April, 1878, he had a slight bronchitis with a pulse of 33. April 21, he fell unconscious and vomited; pulse 36. He had several other attacks more or less severe. In one of them Cheyne-Stokes respiration was noted.† While the breathing was on the decline there were some interpolated weak beats which disappeared during the period of apnea and increase. There was gradual improvement till in June his pulse was 70 and on one occasion after a little exertion 80.

In October of the same year, his pulse was rather quick. About a year later he felt rather weak, and the pulse was 36. In July another series of attacks with slow pulse and Cheyne-Stokes occurred. In November, 1880, he had a cold with cough, and a slow, irregular pulse. An hour or two before he died, his pulse was 44, and regular. The sphygmograms, of which quite a number were taken at different times, show only occasionally faint, if any, indications of the intermediate beats noted in the text.

*Author's abstract of paper read to the Association of American Physicians, Washington, April 30, 1901.

†Two sons of this man died of interstitial nephritis and each had well marked Cheyne-Stokes.

In September, 1890, I saw with Dr. Edson, of Roxbury, a bank cashier, aged about 60, who had been working hard with very little vacation. He had had one severe attack in which he lost consciousness and fell and since then, several severe and many lighter ones. He said that he had some of the latter during my visit, but I could observe nothing, except that after some of the seizures there seemed a little longer interval between the heart beats, and then 2 or 3 closer together. The pulse at the wrist was from 29 to 31, mostly regular and of good force and tension. There were some interpolated beats.

About 1½ years after this first examination, Dr. Edson wrote that "for a year his pulse has kept at 28, and is full and perfectly regular, with none of the faltering it showed when you saw him. His lapses of consciousness grew less frequent until last May, since which date he has had none." I found that he had had not only no lapses of consciousness, but no faintness or dyspnea, unless on going up stairs too fast. He was able to walk about quite briskly and do some light work. I was not quite certain whether in my not very thorough examination I could make out any extra beat, but I thought I saw a slight indication of it in the sphygmogram. His breathing at times in the night, as described by his wife, was very much like Cheyne-Stokes.

Dr. Putnam kindly called my attention to a Polish Jew in the Massachusetts General Hospital, who had had fainting fits with some convulsive movements, and a pulse as low as 25. When I saw him there had been no fits for some time, and the pulse was 38. With the slowest pulse there had been some intermediate slight beats, but I could see no trace of such in the sphygmograms nor detect any by the ear. The interne of the service informed me that he had been unable to hear any recently. The form of the sphygmogram in all these cases closely resembled those given in Prentiss' cases, varying only according to the rapidity.

Although most persons with a slow pulse are not in sound health, it must be admitted that there are some who, so far as any one can tell, are not only being able to live comfortably with care, but even to carry on active occupations. We can hardly avoid calling some of these physiologic. In others, good health is only relative, and they are obliged to restrain their activities within narrow bounds: Among these are to be found some who have suffered with the characteristic symptoms of Stokes-Adams disease and have made a partial recovery. The slow pulse may have lasted many years. A temporary moderately slow pulse is not rare, being met together with a slight fall of temperature in many acute diseases, especially for a few days during convalescence; also in the puerperal condition, and in some instances as one of the symptoms of acute nervous depression from fatigue. It seems, for some unexplained reason, to have a special connection with rheumatism, besides its well-known tendency to valvular disease of the heart. Some physicians have seen in this tendency the foundation for a theory of rheumatism as a nervous disease.

Certain poisons, some of them used in medicine, slow the heart. Among them are digitalis and colchicum. Tobacco in some cases seems to have this effect temporarily, although its usual action is the opposite, and the pulse slowed by tobacco is likely to make a sudden jump to over-rapidity. Tobacco, however, has nothing to do with the development of the permanent slow pulse.

The most interesting and important group of cases, however, are those described and commented on first by Mr. Adams and Dr. Stokes, both of Dublin. In these the pulse is considerably below the average, say in the

neighborhood of 40 all the time, with paroxysms at irregular intervals in which it falls still lower; and certain symptoms, vertigo, syncope and epileptiform or apoplectiform convulsions with more or less complete loss of consciousness marking the failure of the heart to supply blood enough to keep the cerebral functions in activity.

In many, perhaps most, of these cases, when fully developed, the pulse is regular and the slowness depends upon the prolongation of the diastole, the systole being sharp and strong and but little longer than in the normal pulse, being quickened or slowed, according to some authors, in proportion to the square root of the diastole.

In other cases, however, there are to be heard, or felt, or seen in the sphygmogram, pulsations in the interval which represent either abortive systoles of the ventricle reaching the wrist much more feebly than others, or not at all; or else, as seems to be shown by comparing tracings taken at the heart, the wrist, and over the jugular veins, of auricular pulsations which fail to be followed, as normally, by contractions of the ventricle. This condition has been imitated in the horse by a feeble stimulation of the pneumogastric nerve. Some observers caution against mistaking a slow pulse at the wrist for slow beats of the heart, and intimate that many cases of slow pulse are really normal at the heart, but have become apparently slow by the failure of beats to reach the wrist. As has just been said, although this condition may exist, as it does sometimes in mitral stenosis, I do not think, after looking over a large number of reported cases, that its possibility has failed to be recognized; for most authors, directly or by implication, show that they have assured themselves of the correct state of things by listening at the heart as well as by feeling the pulse at the wrist. Even were such mistakes common, however, they would not have great consequence, for an interpolated beat of the heart which fails to make itself perceptible at the wrist is not likely to send much blood to the brain, and is interesting chiefly for purposes of explanation and history.

I have looked over a considerable number of cases, many of which were not included in Dr. Prentiss' paper, and tabulated 35 of Stokes-Adams disease and 21 of slow pulse without the paroxysms, in which autopsies have been made. There are also many more of both classes in which no autopsy was held, which have been consulted and in part tabulated for the sake of convenience of reference.

When we come to the pathologic anatomy of these cases, we are met at once by the lack of data on what seems to me one of the most important grounds, *i. e.*, the intrinsic ganglia of the heart. The defect is due to anatomic difficulties which will certainly prevent for a long time their being objects of routine examination, and cases of the kind we are considering are so rare that the chances of one falling into the hands of a competent and enthusiastic microscopist are few and far between; also, in very few of the cases of slow pulse dependent on lesions of the spinal cord, has a histologic examination been made.

The pathologic histology of the ganglia of the heart has been studied quite thoroughly by several specialists,

many of them Russians, but among them all there is but one instance of this kind. The lesions found are of 2 kinds, which may be very briefly summed up as changes in the bloodvessels of the ganglia, hypertrophy and proliferation of nuclei, not only in the capsules of the ganglia, but of the individual connective tissue sheath which surrounds each cell in all sympathetic ganglia, and degeneration of the cells themselves. In all of Ott's cases, with one exception—and that not a typical one—in which the clinical condition was noted, the pulse had been rapid.

These little ganglia are situated in the interauricular septum and along the sulcus between the auricles and ventricles, not (in man) going below this. Although they can sometimes be found by picking out pieces of nerve or even seen under the pericardium by the naked eye, the routine method in most cases will probably consist in serially sectioning the regions where they are most likely to be found.

The nervous supply of the heart is, as is well known, of 2 kinds, supposed to have their centers near each other in the medulla oblongata or the spinal cord, but which reach the heart by different paths. The pneumogastric passes directly downward to the cardiac plexuses. The accelerator or augmentor fibers pass down the spinal cord, uniting with the sympathetic at various points, the most important being the ganglion stellatum, formed by the union of the lowest cervical and first dorsal, which also send branches to the cardiac plexus. The functions of these 2 systems are well known, the augmentors apparently supplying motor energy to the heart and tending to increase its rate, while the vagus or moderator or inhibitory regulates the rate of expenditure of the energy. The interaction of the 2 forces keeps the balance between the demands upon the heart and its response to them. The exact function of the intrinsic ganglia is not so well known. They have been supposed to be the automotors and sources of independent energy, but it has recently been urged against this theory, or assumption on embryologic grounds, that they are offshoots of the sympathetic and of the posterior spinal ganglia, and hence can be only sensitive. How cogent this argument is I do not undertake to say, but there is good physiologic reason for considering them of importance, if not in supplying energy for each muscular contraction (for which the muscle itself is competent) yet as coordinating reflex centers which hold together the ventricles and auricles and keep them beating harmoniously and, of course, also with the maximum efficiency.

It seems to me that they may be compared to the plexuses of Meissner and Auerbach in the intestinal walls, which pass along the motor impulses from one segment to the next, and cause the peristaltic propulsion of the contents.

There have been several theories as to the relation of the cardiac nerves and muscles to the slow pulse. Many years ago Mr. T. Wilkinson King said that "the only known cause of slow pulse is a lesion of the upper part of the spinal cord," and he was perfectly correct, for he protected himself by the word "known," and distinctly admitted the possibility of other causes. More recently

the tendency has been to look to the muscular and vascular degeneration and similar lesions of the augmentor system on the one hand, and irritative lesions of the vagus on the other. No single lesion can cover all the ground. Irritation of the vagus has existed in a few cases and physiologic considerations point very strongly to its influence in the production of the paroxysms; but an irritative lesion is unlikely to remain constant and active for years, and the vagus in particular is known to be capable of holding down the rate of the mammalian heart for only a few minutes.

Another test which seems almost decisive is found in the action of atropin, which is well known to paralyze the vagus from one end to the other, but which does not raise the rate of the pulse in these cases. This observation was first systematically made and published as a means of diagnosis by Dehio, although atropin has been used on more or less empiric grounds and with results corresponding to his statement.

Injuries to the cervical spinal cord, from the level of the occipital foramen down to the last vertebra, have been frequently followed by slow pulse, and they make a very important group. The stellate ganglia, an important way-station, and the intrinsic ganglia, the terminal of the augmentor system, have not, as already said, been examined often enough in cases of this kind to make them constantly explain the permanent slow pulse, and yet it seems that there we are to look for the causation of the typical and nontraumatic cases of Stokes-Adams disease.

Tabulation shows that a very large number of cases are associated with arteriosclerosis, atheroma or muscular degeneration of the heart. In particular, fatty degeneration of the coronaries has been thought to bear a special relation and it is by no means certain that an extension of degenerative arterial disease to the nutrient vessels of the ganglia may not mark the transition point between the fatty degeneration with the quick pulse and that with the slow. The probable relation of disease of the ganglia to these 2 groups was pointed out by our own Jacobi in the discussion of Prentiss' case.

The introduction of vagus irritation into the explanation of the paroxysms demands for its justification no lesion of that nerve. Its activity is well known to be called out by sensory irritations of various kinds within physiologic limits, and it has been shown that its inhibitory power is much more manifest in an animal in any way weakened or in the case of heart weakened by repeated inhibitions. The case may, it seems to me, be briefly stated as follows:

The permanent slow pulse depends upon a weakening or paresis of the augmentor or accelerator system.

This may take place in any portion of its course. In some very marked cases it is the result of injury to the cervical spinal cord. In the majority of medical cases, it is supposed to be connected with degeneration of the cardiac ganglia, but evidence of this is as yet more physiologic and clinical than anatomic. It is distinctly a symptom indicating weakening of the heart.

The paroxysms are the consequences of reflex excitation of the vagus, perhaps no more than normal, but acting against an antagonist while weakened by

degenerative changes and perhaps also by frequent defects from the same conqueror.

Special and extreme depression of the augmentors, or special and pathologic irritation of the vagus, would of course emphasize all the phenomena, and may perhaps be taken as representative of those cases which have originated through great strain of body or mind, which sometimes recover, and sometimes run on into the chronic condition.

Certain experiments illustrating the results of irritation of the stomach and subsequent depression of the pulse through the vagus are very interesting. The irritation was not produced by chemical means or by cold applied to the mucous membrane, but by electric or mechanical irritation of the muscular walls, and especially by distention of the stomach with a rubber balloon blown up. An attack or exacerbation from digestive disturbances occurring in a person with a slow pulse, might hence take place in one of two ways, either from the absorption of ptomain poison, acting on the vagus center in the bulb, or by distention from flatulence, acting simply as a reflex stimulus.

There is no special etiology for these cases. Tobacco is surely not a cause, and alcohol only so far as it contributes to vascular and muscular degeneration in general. The most frequent cause is overwork and strain. With this is to be considered the great preponderance of the male sex among the reported cases. It is especially interesting to note this etiology in connection with that group of cases of cardiac disease induced by muscular strain, noted by DaCosta, Allbutt, and others, where the pulse is too rapid.

The diagnosis of these cases may make itself, but should be confirmed by a search for all cardiac lesions and for concomitant nervous phenomena, lest there should be other existing causes for the epileptiform attacks than a temporary cutting off of the blood supply. It should also be remembered that there are some cases where the ordinary pulse is not below normal in frequency but where its easy yielding to vagus stimulation and the subsequent paroxysms of a nervous character betray its relationship. There are also cases where the nervous symptoms are so slight that their true nature is overlooked. Such a case may suddenly terminate fatally.

The prognosis has been partly hinted at in the beginning. Setting aside the distinctly acute cases of which the prognosis is quite favorable, it is found that there is no inconsiderable proportion who live for many years, some with but little discomfort and others only with a great deal of care. A computation of the average length of life after the discovery of the slow pulse would have no value in face of the fact that the discovery may only be accidental. Osler gives the history of a patient who was known to have had slow pulse for 30 years; this is one of the longest periods recorded.

There are very few cases in which an acquired slow pulse seems to have become distinctly physiologic. This is difficult to understand unless we admit that the healthy heart is capable of doing an amount of work greatly in excess of what it is ordinarily called upon to do; that is, that the margin is a very wide one and that the physio-

logic estimates of the amount of blood pumped by the heart are maximums which very much more than cover the ordinary and necessary work. There is perhaps in such cases some adjustment of the capacity and elasticity of arteries, making a larger reservoir, so that an extremely slow pulse may give a stream sufficiently steady for practical purposes. The case of Dr. Archibald Hewan is an interesting one. His pulse, from overstudy and from gout and rheumatism, gradually fell from 72 to 38, where it remained, but he never had a fainting fit. He was able to climb a mountain some thousands of feet high, his pulse at the top being 40.

But after excepting these more or less favorable classes and circumstances, the prognosis remains very unfavorable not only as regards recovery but as regards life, the great majority of cases in which the disease has existed long enough to be considered chronic, dying in one of the paroxysms, usually before many years.

The treatment, as regards the general condition, should be rest and tonics. The nitrites have been found efficacious and bromides have given relief. Digitalis, in a few instances, has quickened the pulse instead of slowing it. Atropin has been, in most cases, a distinct failure as regards the permanent condition or the frequency of recurrence of paroxysms. As a means of diagnosis it should be given hypodermically. In a few cases reported by French writers, a milk diet has produced rapid and distinct improvement, upon which fact and the temporary scantiness of urine, a theory of uremia has been built, which one is not obliged to accept however, although admitting the value of the clinical fact.

As regards the paroxysms, the recumbent position, nitrites and other heart stimulants have been found most beneficial. Atropin, in a really efficient form, has singularly enough not been extensively used, but should be given hypodermically in doses of 1 or 2 milligrams.

THE TOXIN OF THE COLON BACILLUS.*

BY

VICTOR C. VAUGHAN, M.D., LL.D.,

of Ann Arbor, Mich.

In our work on the bacteriology of cheese McClymonds and I found that the colon bacillus is present in practically all samples of American green cheese and we also ascertained that cultures of this germ may be boiled without destroying its toxicity.¹ Cooley and I took up this work and have recently reported our results.² It is the purpose of this paper to make a further report on the same subject. Since Dr. Cooley left me I have been ably assisted by Mr. L. M. Gelston.

As has been explained in the article by Cooley and myself, we have attempted to isolate the toxin from the bacterial cell, and have therefore worked with the germ-substance obtained from growths on solid mediums. Generally we have employed a number (50 to 100) of Roux flasks of the largest size. These are prepared with a 2% beef-tea agar and inoculated with a beef-tea cul-

*This paper contains the substance of a talk given before the New York State Medical Society, January 30, 1901, but was written a month later.

ture of the bacillus. The colon bacilli with which we have worked have been obtained from cheese, water and normal feces. As a preliminary step, the virulence of the germ is intensified by passing it through a number of animals. The Roux flasks after inoculation are placed in a warm room or in a large incubator. After a time varying with the growth of the bacillus, the cells are scraped from the surface of the agar and used in the preparation of the toxin.

With the germ-substance obtained in this way numerous experiments have been made and the facts learned may be summed up as follows:

1. The toxin is contained within the germ-cell from which it does not, at least under ordinary conditions, diffuse into the culture-medium.

This is shown by the following experiments: A beef-tea culture which had been grown for 21 days in the incubator was filtered through porcelain. Eight cc. of the clear, sterile filtrate was injected intraabdominally into a guineapig, weighing 435 grams, December 4, 1900. The animal was restless for some time immediately after the injection, probably because of the volume of the fluid used, but gave no other evidence of any effect of the injection and remained well afterwards. As a control to this experiment 0.25 cc. of the same culture unfiltered injected into a guineapig of the same weight killed the animal within 12 hours.

It might be argued that these experiments do not show that the colon toxin is not in solution in the beef-tea culture but that the toxin although in solution will not pass through a porcelain filter. This is shown not to be the case from the following experiment:

An unweighed portion of dried bacterial cells was suspended in water heated in the autoclave to 154° under 2 kilos of pressure and filtered through porcelain. Four cc. of this clear filtrate was injected into the abdominal cavity of a guineapig. In 36 hours this animal died and the postmortem findings were those usually found after death from the toxin. This experiment shows that the toxin of the colon bacillus after being removed from the bacterial cell by means of superheated water may be filtered through porcelain.

2. The toxin is not extracted from the cell by either alcohol or ether.

We have repeatedly extracted the bacterial cells with both of these reagents at different temperatures, evaporated the extracts thus obtained, dissolved the residues in water and injected these aqueous solutions into animals. No effect has been induced by this treatment. These reagents even after prolonged boiling do not produce any visible alteration in the form or tinctorial properties of the germ. Traces of coloring matter and fats are apparently the only substances extracted from the germ cell by alcohol or ether and it is probable that all of the coloring matter and the greater part of the fat come from the agar on which the bacillus has been grown.

3. Very dilute alkalis do not extract the toxin from the cells.

This is shown by the following: 100 milligrams of germ substance in a 0.25% solution of potassium hydrate was boiled in an open test tube for 5 minutes. After

this exposure, the germ-substance was separated from the supernatant fluid in a centrifuge and was found to be still highly toxic while the fluid was inert.

4. The germ-substance may be heated to a high temperature with water without destruction of the toxin.

200 milligrams of germ-substance was placed with 10 cc. of water in a tube which was sealed and heated to 184° for 30 minutes. On opening the tube, the contents was found to be milky and microscopic examination showed a granular mass containing a few unbroken cells. Portions of this heated substance injected into guineapigs caused death, and autopsy showed the lesion usually found in these animals when killed with the colon toxin.

Another portion of the contents of this heated tube was placed in a centrifuge and separated into a deposit and a supernatant milky fluid. Guineapigs were inoculated, some with the deposit and others with the fluid; both sets died. This shows that superheated water breaks up the cell wall.

5. Boiling with a 0.2% solution of hydrochloric acid has but little, if any, effect upon the germ-cell or its contained toxin.

One hundred milligrams of the germ substance was boiled in an open-test tube with 10 cc. of a 0.2% solution of hydrochloric acid. This induced no visible alteration of the bacterial cells as seen through the microscope, and the injection of this germ-substance thus heated, after neutralization, caused death in animals in the usual time and with the usual postmortem findings.

6. Heating the germ-substance for an hour at the temperature of the waterbath, with water containing from 1% to 5% of hydrochloric acid, breaks up the cell wall and lessens, but does not destroy, the toxicity of the cell-content. Prolonged heating may render the toxin inert.

Five hundred milligrams of germ-substance was heated on the waterbath for 1 hour with 500 cc. of a 5% solution of hydrochloric acid, then decanted through a filter. The filtrate was clear and colorless, and gave no precipitate when dropped into absolute alcohol, but that the acid had dissolved some part of the substance is shown by the fact that the filtrate gave the biuret test.

The portion undissolved by the acid was dissolved in 100 cc. of a dilute solution of sodium bicarbonate, and this was injected into guineapigs as follows:

No. 1, weight 275 g.;	received 10 cc.
No. 2, weight 255 g.;	received 9 cc.
No. 3, weight 267 g.;	received 8 cc.
No. 4, weight 250 g.;	received 7 cc.
No. 5, weight 305 g.;	received 6 cc.
No. 6, weight 285 g.;	received 5 cc.
No. 7, weight 300 g.;	received 4 cc.
No. 8, weight 315 g.;	received 3 cc.
No. 9, weight 290 g.;	received 2 cc.
No. 10, weight 250 g.;	received 1 cc.

These injections were made at 6 p. m. February 5. Nos. 1, 2, 5, 6, 7, 8 and 10 were found dead at 7 a. m. February 6; No. 4 on the morning of February 8; No. 3 on the morning of February 9, and No. 9 on the morning of February 11.

7. The toxin as separated from the cell-wall by diges-

tion of the latter with hydrochloric acid and pepsin is markedly active.

I removed the germ-growth from 50 Roux flasks, and extracted it with 96% alcohol at ordinary temperature as long as the alcohol took up coloring matter. The germ-substance was then collected upon a filter and the alcohol allowed to drain away; then the mass of germs was placed in a beaker and 1,000 cc. of a 0.2% solution of hydrochloric acid and 0.5 grams of active pepsin added. The beaker with contents was allowed to stand for 4 days in the incubator, the mixture being occasionally stirred. The undigested portion is found by microscopic examination to be amorphous, but still easily stained with methylene-blue. This was collected on a filter, washed thoroughly with a 96% alcohol, dried to a constant weight at 100° and pulverized. One hundred milligrams of this powder was shaken with 50 cc. of water, with which it formed a colloidal body of acid reaction. On adding enough bicarbonate to render the mixture feebly alkaline, the toxin dissolved to an opalescent fluid. This was sterilized by boiling over the naked flame and was injected into guineapigs:

- No. 1, weight 407 grams, received 16 mg. of toxin.
- No. 2, weight 392 grams, received 12 mg. of toxin.
- No. 3, weight 320 grams, received 10 mg. of toxin.
- No. 4, weight 455 grams, received 8 mg. of toxin.
- No. 5, weight 417 grams, received 6 mg. of toxin.
- No. 6, weight 470 grams, received 4 mg. of toxin.
- No. 7, weight 442 grams, received 2 mg. of toxin.
- No. 8, weight 412 grams, received 1 mg. of toxin.
- No. 9, weight 432 grams, received 1 mg. of toxin.
- No. 10, weight 480 grams, received 2 mg. of toxin.

Nos. 1, 2 and 3 died within 6 hours, Nos. 4, 5, 6, and 10 within 12 hours, and Nos. 3 and 9 within 24 hours. One-fifth of a milligram of this toxin kills guineapigs of 200 grams weight and less.

After death from this toxin there is usually, not always, considerable (from 2 cc. to 10 cc.) of serum in the peritoneal cavity. This is sterile, if removed before postmortem infection takes place, and it has absolutely no germicidal action on the colon bacillus as the following extract from my protocol book shows:

"Every tube of exudate taken from the above-mentioned pigs proved to be sterile. This was shown by making beef-tea inoculations from each tube, all of which remained free from growth. I then tried the germicidal action of one of these exudates on the colon bacillus. A loop of a beef-tea culture of this germ was placed in a tube of beef tea and then a loop of this dilution was added to a tube of the serum and plates made from this at intervals:

"Time, 5 min.	15 min.	30 min.	60 min.
"Colonies, 10	25	28	100

"This test, repeated several times, shows that the serum that collects in the abdominal cavity after fatal poisoning with the toxin of the colon bacillus has no bactericidal action on this organism, but furnishes a medium on which it grows readily.

"This serum is not only without germicidal effect on the colon bacillus but it fails to agglutinate this organism."

There are many interesting problems in connection with this toxin which I do not yet feel able to discuss. If the toxin is confined within the cell wall, how is it set free when the whole germ either living or dead is introduced into the animal? If this is accomplished by phagocytic action, do the phagocytes destroy the toxin when they kill the germ? What is the chemistry of

this toxin? Is it a definite compound or is it composed of the many substances mentioned by Ehrlich in his theory concerning the constitution of toxins? Does the bacterial cell contain both a toxin and an immunizing body, or may the toxin be changed into an immunizing substance either by artificial means or within the animal body? These and other similar questions await further study. Although I have pushed my investigations along the lines here suggested further than is indicated in this paper, I do not feel that the knowledge obtained up to the present time is sufficiently accurate to satisfy myself or others, and I prefer not to indulge in theories. However, the fact that at least one of the bacterial toxins is a remarkably stable body and can be obtained in the dry state and permanent form justifies us in taking a somewhat more optimistic view concerning the probability of ascertaining the chemical constitution of these bodies than that recently expressed by Brieger and accepted by Ehrlich³.

A PLEA FOR UNIFORMITY OF TECHNIC IN WIDAL'S REACTION.

BY

RANDLE C. ROSENBERGER, M.D.,

of Philadelphia.

Demonstrator of Bacteriology and Morbid Anatomy, Jefferson Medical College.

When Widal first gave to the scientific world the procedure now known as "Widal's reaction," it was with specific instructions. But since that time modifications have become very numerous. Take, for example, the proportion of dilution in the blood or serum. This dilution, of course, should be uniform, either 1 to 10, 1 to 20, or 1 to 40. Yet many use a dilution of 1 to 100, 1 to 200, and even 1 to 500. Again, as to the age of the culture: Some use a 12-hour, some an 18-hour, and some a 24-hour culture, while some recommend an incubated and some a non-incubated one. A number of observers claim that a filamentous form of the organism is better than the short bacillary form, and hence employ the former, although the reason why is not clear.

Another point of divergence is the time-limit applied to the reaction. Some observers claim that the reaction should occur inside of 15 minutes, others allow 30 minutes, and still others wait so long as 2 hours before declaring the reaction positive or negative. Two hours (I believe) was the time-limit set by Widal himself. It certainly should be considered typical when an *immediate* reaction takes place, particularly when in connection with it, there is a plain history of typhoid fever. This would be as natural as the finding of tubercle bacilli in a tuberculous process.

Again, if we have a Widal reaction in *progress*, clumps form and cessation of motility ensues, although a few individual bacilli are often seen outside of the clumps retaining their motility. Should this, or should it not constitute a positive reaction? Some observers regard it as positive, others do not. In this

connection also, confusion often results because of the disintegration of many corpuscles, more especially the white, the clumping of their granules being then mistaken for groups of bacilli. This might seem improbable were it not for the fact that the inexperienced repeatedly mistake these granules for microorganisms, exactly as they often mistake the nuclei of pus-cells for gonococci. Of course, the serum should be used in cases where it is possible to obtain it, and in this way very few corpuscles would be present.

Again, as to the way of preparing the dilution. If we are to make a specific dilution, a proper instrument should be devised for the purpose. Most observers employ a platinum loop, and take drops of both serum and culture. But here again it is self-evident that no two drops are ever exactly alike in size, especially where there is no uniformity in the size of the wire or loop.

There is likewise frequent variation in the number of tests made. Certain practitioners make but a single test, and whether the reaction be positive or negative, end the matter there. But a single positive reaction should not be considered pathognomonic, since it has been demonstrated that this may be caused by a very high temperature, while on the other hand, in a moderately afebrile stage the reaction may not occur at all. To be scientific and trustworthy, at least 2 tests should be made in each case of typhoid fever, one early and one in the middle of the attack.

If we could agree on a given diameter of platinum wire and a certain size of loop, something looking toward uniformity would be attained. Some use the leukocyte apparatus, and in this way a fairly accurate dilution is obtained.

All objections to the present methods of employing the Widal test have not been stated, for another point of considerable prominence to whether dried or fresh blood gives the better reaction. Some prefer the former, others the latter, and uncertainty sometimes arises in consequence. The dry method, first practised by Johnson, of Montreal, certainly seems very good when we consider that a positive reaction was obtained after 82 days (DaCosta). But every experienced observer knows, or should know, that fresh blood is by far the best for this test, although where the patient lives at a distance from the laboratory, dried blood must be used, and a positive result may be obtained with gratifying success.

In speaking of the results of a test the term "doubtful" and "pseudo" are not infrequently given. Such statements are unscientific and meaningless. A reaction should always be spoken of as either "positive" or "negative," and never as anything else. If there is cessation of motility and clumping of *all* the bacteria in the field (not some of them), this should be spoken of as a positive reaction. Where clumping without cessation of motility ensues, it should be called negative. In cases where some bacteria are grouped together and motility ceases and at the same time individual bacilli outside of the groups still retain their motility, it is only possible after the agreed time-limit has expired to speak of a negative reaction. In such cases a second test

would be necessary, for we know that diseases and conditions other than that of typhoid fever sometimes give a positive reaction, as, for instance, miliary tuberculosis, acute articular rheumatism, endocarditis, and septiemia. In fact, *normal* blood will sometimes give the reaction. Therefore, when these diseases, and even normal blood, may give the reaction, it is evident that we should employ a definite routine in our testing to minimize these phenomena.

The points which I would emphasize and urge the adoption of are:

1. The use of a uniform dilution.
2. A definite time-limit.
3. An agreement as to what constitutes a positive reaction.
4. The use of a culture of definite age, and a clear statement as to incubation or non-incubation.
5. A decision as to whether dried blood, fresh blood or serum is to be used.
6. A stated number of tests to be made in a given case.
7. To drop the terms "doubtful" and "pseudo" reaction.
8. Use of terms "positive" and "negative" only.

Of course some physicians may say that medicine is not an exact science, and no approximate uniformity can be expected. The object of this paper is not to revolutionize the method, but merely to plead for uniformity and definite technic in using a very important scientific aid to the diagnosis of typhoid fever.

Another aim is to discourage confusing modifications. It is well known that in the production of surgical and gynecologic instruments "modifications" are well nigh endless, each claiming to make the instrument much better than the original. Some of these modifications may be improvements, but when an instrument accomplishes its purpose easily and well, no modifications are needed.

So it is in the application of any scientific principle. After the original method has been devised, and a reasonable number of improvements adopted after satisfactory experience, then further "modification" is detrimental and confusing. The Widal test, properly employed, can be of the highest diagnostic service. An agreement along the lines indicated, would largely obviate inaccuracies in its use. Uniformity, not "modification," is the chief requirement for its successful use at the present time.

International Congress of Physiologists will hold its fifth session at Turin, September 17 to 23, 1901, in the Physiological Institute of the University, directed by Professor Angelo Mosso. The International Organizing Committee invites the attendance of physiologists and their active participation in the work and desires such to notify their acceptance to Dr. Z. Treves, Local Secretary, Corso Raffaello, 30, Turin, Italy, and to give him, by the beginning of August at the latest, the titles of the experiments or communications which they have in view, with a detailed list of apparatus or material necessary for demonstration. The payment of 10 francs paid to Dr. Treves in September ensures a card of membership. In addition to the General Secretaries for the work of preparation towards the fifth congress, Professor Frederic S. Lee (Columbia University, New York), Secretary of the American Physiological Society, kindly consented to discharge secretarial duties in America. American physiologists who intend to be present at the fifth congress are requested to notify him, in addition to communicating with Dr. Treves.

THE EFFECT ON THE BLOOD OF ETHER USED AS AN ANESTHETIC.*

BY
J. CHALMERS DACOSTA, M.D.

AND
J. L. KALTEYER, M.D.,
of Philadelphia.

The authors review the somewhat meager literature on the subject, dwelling particularly upon the writing of Mikulicz, J. Chalmers DaCosta, Von Lerber, Oliver, Dudley Buxton, Hamilton Fish and Bloodgood. They allude to the great difference of opinion that exists as to whether or not ether causes blood destruction. They hold that it does cause blood destruction and that those who affirm the contrary have been misled by the blood concentration which results from the preliminary treatment and which is often added to by sweating during the anesthetic state. This blood concentration may mask the fall of hemoglobin; in fact in some cases will cause an apparent rise. The important facts to note are that the color index practically always falls and that the number of corpuscles increases.

These facts prove marked blood destruction and increased production of corpuscles deficient in hemoglobin, resulting from ether anesthesia. The authors report upon 50 cases in which blood examinations were made, and subdivides these reports into numerous tables for purposes of examination and comparison. In 49 of the cases the color index was lowered. The writers also showed sections of the marrow of a rabbit's femur the animal having been etherized to death. These sections showed marked erythroblastic proliferation. The authors conclude that the hemoglobin is absolutely reduced after the administration of ether, this reduction being manifest in the individual corpuscular hemoglobin value. The increased hemolysis is Nature's effort to rapidly replace destroyed corpuscles, and the regenerated cells are imperfectly supplied with hemoglobin. The authors urge that whenever possible 1 or 2 blood examinations should be made before ether is administered, and these examinations should be made before preparatory treatment is instituted. If less than 50% of hemoglobin is present an anesthetic is dangerous and should only be given as a matter of absolute necessity. In malignant disease a percentage of under 50 contraindicates operation. Mikulicz says no general anesthetic should be given under any circumstances if the hemoglobin is under 30%, we believe that 40% is probably the lowest justifiable limit. If operation must be performed when the hemoglobin is under 40% a local anesthetic should be given, except under stress of absolute necessity. It is true, cases with under 40% of hemoglobin are occasionally etherized (for instance we know of 1 case with only 24%) but such cases are rare and are only justified by the imperative necessities of a vital emergency. Whenever the percentage of hemoglobin is low the administration of the anesthetic should be entrusted only to an experienced man. As little ether as possible should be given. The surgeon should operate quickly and prompt measures should be adopted to bring about reaction and to remove the ether from the lungs and blood.

M. Dussaud, a scientist of Paris, is the inventor of 3 remarkable machines: The first, "a loud-talking telephone," is designed to catch, repeat, and preserve every syllable or word spoken in a room in which it is placed; the second, is a cinematograph, capable of conveying to the blind, ideas of motion in natural objects, as we receive them through the sense of sight; and the third is a microphonograph, which is constructed to convey to the deaf sounds of nature, from the human voice to the whisper of the wind.

*Author's abstract of paper read before the American Surgical Association at Baltimore, May 7, 8 and 9.

BLOOD EXAMINATIONS AS AN AID TO SURGICAL DIAGNOSIS.*

BY
JOSEPH C. BLOODGOOD, M.D.,
of Baltimore, Md.

Shock and Hemorrhage.—Observations have demonstrated that there is a leukocytosis of 15,000 to 24,000 following hemorrhage. This comes on within a few hours as a rule. There are not sufficient observations to demonstrate the relation between the amount of blood lost and the leukocyte-count. We have not sufficient observations yet to clearly determine the exact changes in the number of white blood-cells in shock from injury alone without loss of blood. Following hemorrhage, in addition to the rise in the number of leukocytes, there is a diminution in the number of red blood-cells and the percentage of hemoglobin. In severe hemorrhage a blood-count will indicate to a certain extent the amount of blood lost, but as a rule not until 6 to 10 or more hours have intervened after the hemorrhage.

The examinations of blood after contusion of the abdomen to ascertain, if possible, whether we can distinguish by the changes in the elements of the blood the difference between shock from the injury alone, internal hemorrhages and peritonitis from rupture are not sufficient in number to allow any conclusions.

The Importance of a Careful Blood Examination Preliminary to General Anesthesia.—There are now sufficient observations to demonstrate pretty conclusively that in marked anemia, especially when the hemoglobin percent is low, that general anesthesia especially if prolonged, is dangerous. Some authorities give 50%, others 40%, but the majority agree that 30% of hemoglobin is a danger signal, and if possible the operation should be delayed until appropriate treatment has been used to increase the percentage of hemoglobin and the number of red blood-cells.

Postoperative Leukocytosis.—There is need for much more study on this question. Most authorities agree that following ether there is perhaps a slight increase in the leukocytes, which, however, disappears within 24 and at least 36 hours. In operations with much loss of blood there would, of course, be a temporary rise in the leukocytes, but on the whole in the average operation one should expect the leukocytes to be within the normal limits 24 hours after operation. If this is true a sudden rise in the leukocytes would indicate some post-operative complication. In abdominal surgery it would indicate peritonitis, although if the peritonitis were a very grave infection the leukocytes would soon fall rapidly. Perhaps the leukocyte-count as an aid to the postoperative diagnosis in abdominal surgery is most important in the early recognition of obstruction. Here there is always a rise, usually over 20,000 associated with any obstruction of the intestines. This rise generally takes place within from 8 to 20 hours after the beginning of the obstruction, and in the few cases observed the rise in the leukocytes had been prominent before the clinical symptoms themselves were sufficiently clear to make a positive diagnosis. The number of observations so far have demonstrated that when after laparotomy with general anesthesia the patient develops slight distention or even marked distention with a little nausea and vomiting which seems more or less due to paralysis of the intestines and not to a definite obstruction or peritonitis, the leukocytes do not rise, at least not above 12,000 to 15,000. If these observations are confirmed the counting of the white blood-cells would be a great aid in the differential diagnosis in the first 24 to 48 hours or later after laparotomy between benign abdominal distention and obstruction or peritonitis, for which operative interference would be indicated early.

*Authors' abstract of paper read by invitation before the American Surgical Association at Baltimore, Tuesday, May 7, 1901.

Postoperative Phlebitis.—In a few cases observed there is a rise of the leukocytes varying from 15,000 to 20,000. Such a leukocytosis has been observed frequently in typhoid phlebitis, but on the whole, the observations of the changes in the leukocytes after operation are not well established.

The Importance of the Leukocyte-Count in the Early Recognition of Acute Abdominal Lesions.—In this field there are more observations and they seem to be of great importance.

Leukocytes in Appendicitis.—Observed within 48 hours the number of white blood-cells is in the majority of instances of great value in pointing to the extent of the inflammatory condition of and about the appendix. Cases of recurrent appendicitis, of appendicitis suffering from the first attack, first observed practically at the end of the attack when the clinical symptoms are subsiding, rarely show an increase in the white blood-cells. In a few instances when first observed within 48 hours after the beginning of the attack, but when the symptoms are subsiding, there have been a few leukocyte-counts of 15,000 which have rapidly fallen in a few hours to 10,000 and 7,000.

In the cases admitted within 48 hours with acute symptoms, if on account of the clinical picture, operation has been delayed, we have always observed a falling leukocytosis. These patients have recovered and at a later operation the appendix is found to be the seat of a diffuse inflammation, but there has been no evidence of pus outside the appendix. In one case admitted 16 hours after the beginning of the attack the leukocytes fell in 10 hours from 17,000 to 13,000, and in 24 hours to 11,000 associated with the disappearance of the symptoms. With 1 exception the highest first leukocyte count in this group has been 17,000, falling in a few hours to 12,000, 9,000 or even lower. A patient admitted 20 hours after the beginning of the acute attack had a leukocytosis of 22,000. The clinical symptoms, however, were not very marked. The patient was observed 8 hours; during this period the leukocytes fell to 16,000 and the local symptoms practically disappeared. Within the next 24 hours the leukocytes were 11,000, then 8,000, 7,000, then 6,000. Although this patient with a leukocytosis of 22,000 at the end of 20 hours recovered and there is every reason to believe that the inflammatory condition about the appendix subsided, nevertheless it is an exception to the general rule and it would be safer, I believe, to operate in those cases of acute appendicitis observed within the first 48 hours with a leukocytosis of 20,000.

Acute Diffuse Appendicitis; operation; recovery.—In this group there are a number of counts. In the majority the operation was performed at once a few hours after the first observation more on account of the clinical signs than the leukocyte-count. The average leukocyte-count when first observed has been from 15,000 to 18,000. With 2 exceptions, if further leukocyte-counts have been made, there has been a rising count. With these 2 exceptions, when the second count within 4 hours after the first showed a fall of 3,000 or 4,000, it is a question whether these patients would not have recovered if operation had been delayed. In 1 case observed from the beginning of the attack during the period of 36 hours before operation the leukocytes rose gradually from 8,000 to 18,000. In this case the appendix showed diffuse inflammation with no pus in or outside of the appendix and not much exudate. The highest count in this group, 25,000, 36 hours after the beginning of the attack, exhibited at operation the most intense inflammation and the greatest amount of exudate about the appendix.

Gangrenous Appendicitis; operation; recovery.—In this group of cases as a rule, the leukocytosis is higher and rises more rapidly, and in 3 instances it has been of the greatest importance in the early recognition of a grave inflammatory condition of the appendix which without doubt would have led to general peritonitis and death if

early operation had not been instituted. In 1 case the rapid rise in the leukocytes was practically the only clinical evidence of a grave abdominal condition. The patient, a boy, suffered from an attack of pain and nausea and vomiting following a few hours after taking a good deal of indigestible food. When the stomach relieved itself there was no further pain and no further abdominal symptoms. After 24 hours the leukocytes were 17,000. A leukocytosis of 17,000 in a patient a number of hours after taking food would make one suspicious of an inflammatory lesion. In 30 hours the leukocytes were 17,000, and in 36 hours 35,000. The highest temperature was 100°. There were practically no abdominal symptoms, except the history of a short attack of colic and vomiting following indigestible food. Because of this rapid rise and the high leukocyte-count (35,000), it was considered safer to explore the abdomen. A gangrenous appendix with beginning purulent pelvic peritonitis was found. A second and almost similar case was observed when the leukocytes rose from 13,000 to 24,000 in 20 hours after the beginning of the first colicky pain, the first count being 14 hours after the beginning of the pain. In this case there were in addition marked clinical signs of appendicitis. In a third case with very subacute local signs the leukocytes rose rapidly from 13,000 to 23,000 in 20 hours (first count 16 hours).

Acute Appendicitis Distended with Pus; Operation; Recovery.—The high leukocytosis and the rising leukocytosis in cases with more than 1 count has been observed in this group of cases, and the clinical picture and the leukocytosis corresponds pretty closely with that observed in gangrenous appendicitis. Within the first 48 hours after the beginning of the attack our observations have demonstrated that a high leukocytosis, at least above 20,000, has, in the majority of instances, irrespective of the clinical picture, been associated with an increasing diffuse appendicitis, gangrene or an appendix distended with pus.

ABSCESS VS. PERITONITIS.

Appendicitis Abscess.—So far, in our observations we have but 2 cases of abscess with leukocyte counts observed within 48 hours after the beginning of the attack. In 1 the leukocytosis was 18,000 and there were distinct local signs, although on account of the muscle spasm it was impossible to make out a collection of pus. This patient was operated on 24 hours after the beginning of the attack. A small abscess was found about the perforated appendix, the collection of pus was well walled off, but there was beginning peritonitis demonstrated by cloudy sterile fluid and fibrinous exudate on the intestines about the abscess. The low count, 11,000, 24 hours after the operation is hard to explain. This patient had marked local signs of inflammation but no definite tumor. At operation there was evidence that there had been recurrent attacks, the adhesions about the appendix were very firm but the collection of pus was very small.

Appendicitis, General Peritonitis; Operation.—The correct interpretation of the leukocyte-count in this group of cases is difficult because in the majority of cases it is hard to estimate the duration of the peritonitis. Observations seem to demonstrate that in the early hours of peritonitis there is a rapid rise in the leukocytes which, however, soon falls. Three cases have been grouped according to the duration of the attack and not to the approximate duration of the peritonitis. Five cases have been observed, in each of which the beginning of the attack was within 48 hours. Three cases recovered. One operated on 16 hours after the beginning of the attack with a leukocytosis of 14,000; 1 24 hours with a leukocytosis of 32,000 and 1, 36 hours with a leukocytosis of 36,000. In these 3 cases there were distinct local symptoms, but slight general abdominal symptoms. There was no distention of the intestine;

the exudate was chiefly purulent; in the exudate in the general peritoneal cavity only the colon bacilli were found and no streptococci. In 1 case observed 48 hours after the beginning of the attack and operated on at once, the leukocyte count was 25,000. The general abdominal symptoms masked the local symptoms, the patient was very ill, the intestines were distended, streptococci were present and the patient died. One patient was observed in the hospital. Twenty hours after the beginning of slight abdominal colic localized in the right iliac fossa, the leukocytes were 8,000; 6 hours later or 36 hours after the beginning of the attack, the leukocytes were 20,000. Clinically, the patient was not very ill, but on account of the rise of the leukocytes from 8,000 to 20,000, operation was performed. The appendix was perforated and surrounded by a few drams of purulent material; this pus was not walled off by adhesions; the general peritoneum was slightly injected; it appeared as if there was beginning general peritonitis. After the operation the leukocytes continued to rise for 12 hours up to 26,000; then within the next 12 hours fell to 11,000, the patient dying with clinical picture of peritonitis, which was found at autopsy. In this case the streptococci were present. In 5 cases admitted 3 days after the onset of the symptoms, all showing the clinical picture of peritonitis, the leukocyte-counts in 4 were 11,000, 11,000, 13,000 and 14,000. These 4 cases were fatal. The fifth case whose leukocyte-count was highest (17,000) recovered. The cultures from the peritoneal cavity in this case showed *Bacillus coli communis*. These counts and others not given in this short account seem to demonstrate that within 48 hours after the beginning of an attack, a very high leukocytosis is suggestive—but not at all positive—of beginning peritonitis, and that the leukocyte-count does not help us with regard to prognosis. After the second day, in cases in which the peritonitis has been present longer, we have never observed a recovery with a low leukocyte-count. If the leukocytosis still remains high at this period, the prognosis seems better for the ultimate recovery after operation.

Appendicitis-Abscess.—The leukocytosis in this group of cases seems more difficult to interpret. The majority of cases come in with a history of more than 3 days' illness and in the majority of instances the leukocyte count is high, above 16,000, up to 30,000. A high leukocytosis with a history of illness over 3 days, especially if associated as it is in the majority of cases with the clinical signs of tumor, indicates a collection of pus. There are exceptions to this rule. If clinically the patient is getting better, and the tension of the abscess is subsiding, the leukocytes fall. So it must be distinctly remembered that patients admitted at the end of an attack, clinically getting better, may have a collection of pus with a low leukocyte-count and if one is unable to make out the tumor by abdominal examination it will be impossible to tell previous to operation whether there is an abscess or not.

Leukocytosis in Intestinal Obstruction.—In this group of cases the increase in the number of the white cells associated even with very slight symptoms of intestinal obstruction is of the highest importance in the early recognition of the lesion. We have a large group of cases which have demonstrated that within 12 hours after the beginning of the obstruction the leukocyte count may rise to 20,000. Within the first 12 to 24 hours a few observations would demonstrate that if the leukocyte-count rises above 25,000 or 30,000, the probabilities are that one will find gangrene of the obstructed loop or beginning peritonitis. If observed on the second or third day after the beginning of the symptoms it is difficult to make a differential diagnosis with regard to gangrene or peritonitis. After the third day, in cases in which there is no gangrene and no peritonitis or in whom the autointoxication is not yet

very grave, the leukocytes still remain high, 15,000 to 23,000, according to the degree of obstruction; complete, higher; partial, lower. In the presence of gangrene, peritonitis or grave autointoxication, the leukocytes begin to fall. If the patient is admitted after the third or fourth day with a history of intestinal obstruction, and still has a high leukocyte count, the prognosis is good for operation. If the count is low, and especially if it is below 10,000, the probabilities are that you will find at operation extensive gangrene-peritonitis; or the patient will be so depressed by the autointoxication that reaction does not follow relief of the obstruction.

FRACTURES AND DISLOCATIONS OF THE SPINE.*

BY

DR. STEPHEN H. WEEKS,

of Portland, Me.

The doubt and uncertainty which have hitherto surrounded the treatment of fractures and dislocations of the spine can only be cleared up by a more careful study of the nature of such injuries. Though dislocation of the spine apart from fracture is rare, it nevertheless does sometimes occur. It is almost wholly confined to the cervical region, occurring most frequently in the lower half of the neck.

The dislocation is usually brought about by hyperflexion, which causes the inferior articular processes of the vertebra above to slip forward and upward on the superior articular processes of the vertebra below. This is rendered possible by the tearing or separation of the intervertebral disk and laceration of the surrounding ligaments. The displacement of the upper part of the spine is almost invariably forward.

Aside from positive demonstration by dissection it would seem almost impossible that the vertebrae bound together by numerous articulations, ligaments and cartilages, could be dislocated without being broken. Abernethy denies the possibility of such a dislocation. Though the accident is uncommon, a sufficient number of cases have been observed to establish the existence of this injury beyond a shadow of doubt.

Agnew gives a table of 24 cases of cervical dislocation; 11 of these were verified by a postmortem examination.

In the dorsal and lumbar regions the dislocation is very generally associated with fracture, producing what is more frequently called fracture dislocation. The manner in which these dislocations and fractures occur would seem to show, that for their production it is necessary that great violence should be applied while the spine is in the flexed position, as when a mass of earth falls upon a man while in the stooping posture. In the unilateral or one-sided displacement the force is supposed to act more on one side, the affected side, than on the other, or the luxation may result from the spine being violently twisted.

In addition to the displaced and fractured vertebrae, the laceration of the ligaments and cartilages, the cord itself is very liable to be compressed, contused, crushed, and often completely severed. Blood is also extravasated both within and without the spinal canal.

Symptoms of Dislocation of the Cervical Vertebrae.—Though in many instances there may remain some doubt as to the exact nature of the injury, yet in well marked cases of this luxation the head assumes a certain position, dependent upon the direction of the displacement; that is, it will be flexed upon the breast when the dislocation is backward, extended or carried backward when the luxation is forward, and turned to one side or the other when it is a lateral luxation. A break in the line of the

* Author's abstract of paper read before the American Surgical Association, at Baltimore, May 7, 8, 9, 1901.

spinous processes may also be detected, the dislocated vertebra and all above it being found either in front of, behind, or to one side of those below the seat of injury.

The same want of regularity which is noticed in the position of the spinous processes may be seen to exist to some extent also in the anterior surfaces of the bodies of the vertebrae by examining the posterior wall of the pharynx. Both in dislocation and fracture dislocation of the cervical vertebrae paralysis more or less complete follows the injury, affecting all the parts below the seat of injury. Death, after a lesion of this nature, may follow instantly, especially when the luxation is above the origin of the phrenic nerves; or it may be delayed for a few days, rarely exceeding two. Should the head be found twisted to one side and incapable of rotation, with a bent state of the neck, and if it were known that a sufficient cause of dislocation had been applied, there would be presumptive evidence of a unilateral displacement, provided, however, no deformity could be felt at a lower part of the cervical spine. Unilateral dislocation is sometimes brought about by extreme rotation of the neck. When this occurs the head will be turned toward the opposite side and fixed in that position, while an irregularity in the spines and in the transverse processes will be present. Pressure upon the nerves rising between the displaced vertebrae gives rise to peripheral pain and numbness. Varying degrees of paralysis, both of motion and sensation up to the level of the lesion, will result from compression of the spinal cord, and will depend upon the amount of injury inflicted. When the dislocation is unilateral, the cord may escape injury or the damage to it be but slight. When the paralysis is delayed for days, it will probably be due to an inflammatory effusion of serum or lymph, or to inflammatory softening of the cord.

A REPORT OF ONE OF MY OWN CASES.

August 29, 1900, Mr. C. P., aged 70 years, fell from a ladder a distance of about 12 feet, striking on his right shoulder and right side of the head. He was rendered partially unconscious, and while in this condition was carried into the house, when it soon became apparent that he had sustained some serious lesion somewhere in the cervical region. The head was thrown slightly backward, turned sharply to the right and before operation held firmly in this position. The left upper extremity was paralyzed as to motion; sensation was apparently good. Motion in right upper extremity fairly good, motion in lower extremity fairly good. He was, however, unable to pass his urine, the use of the catheter being required. There was great pain in the left arm and hand. Nine days after the injury I saw him in consultation with the attending physician, and found the condition which I have described above, and also found a deformity in the cervical spine at about the fourth or fifth vertebra. It seemed like a dislocation, and it seemed as if there was a fracture with a fragment of bone pressing upon, or had injured the spinal nerve supply to the left upper extremity. An operation was thought advisable to see if the condition could be improved. The next day, September 8, 1900, I made the operation. The laminae of the fourth and fifth cervical vertebrae were found broken and depressed. These were removed and the cord relieved of all pressure so far as possible, and the wound closed without drainage. The position of the patient during the operation was upon the face. As I was closing the wound the patient became badly cyanosed, and the pulse feeble. He was turned upon the back, $\frac{1}{2}$ of strychnia given hypodermically, and he was soon breathing regularly, and no further trouble was experienced. The seventh day after the operation the patient had a slight chill, became cyanosed with a weak pulse. He complained of numbness of the lower extremities, especially the left side. Strychnin $\frac{1}{2}$ gr. was given subcutaneously and repeated in half an hour. In the afternoon of the same day his temperature was 102.4°, respiration 28, pulse 108. The dressings were removed for the first time and it was found that the wound had healed by first intention. The lower stitches were removed, thinking there might be some retained fluids that had caused the sudden rise in temperature. Some bloody serum escaped from the wound; soon after this the temperature fell to 100.4°. The next day the bowels were freely moved with Hunyadi water, and the temperature became normal. During this attack the left leg became partially paralyzed. Strychnin $\frac{1}{2}$ and quinin 2 grains were given 3 times in the day. The wound was irrigated and dressed every day with a strip of sterilized gauze for drainage. I am satisfied that it would have been better had I put in a gauze drain at the time of the operation, as the man was large and muscular and the wound deep, and hard to close without leaving spaces between the divided tissues. At the end of

the sixth week from the time of the operation the wound was entirely healed. The fourth week the patient had an attack of cystitis. This was relieved by irrigation of the bladder twice a day with normal salt solution with 5 gr. of salol 4 times a day.

The fifth week the patient was able to sit up in a chair 3 or 4 hours each day. There was good motion of the head, lower limbs and right arm, but no motion in the left arm. At the end of the sixth week he was able to sit up from 4 to 6 hours each day, and was able to take a few steps with assistance. At this time had a little motion in the fingers of the left hand. From a letter received from his son and signed by the patient himself, dated November 15, 1900, 2½ months after the injury, I quote the following: "My father's condition now, as compared with that before the operation, is an improvement of 75%. He has a good appetite, can eat anything he wants, has gained a good deal in strength, can walk short distances by being supported on either side. His left leg bothers him some, and both legs are somewhat weak. The right hand and arm are nearly normal. Can write his name legibly. There has been some improvement in motion of left hand and arm, can move forearm some by having it supported. His greatest trouble is pain in his left shoulder, arm and hand. He can support his head and turn it fairly well in either direction, wound in neck entirely healed and lameness in cords and muscles seems to be growing less daily. His head was turned sharply to the right before the operation and firmly held in that position. The action of the bladder is normal."

Treatment.—I believe the surgeon should perform laminectomy in every case, if the condition of the patient is such as to justify any operation, regarding the operation in the first instance as an exploratory one.

When an exploratory laminectomy has been undertaken in fracture dislocation, and such displacement found that the removal of the neural arch does not suffice to relieve the pressure on the cord entirely, the operation can be extended to the articular processes, so that manipulation in the wound, combined with extension and rotation, may succeed in reducing the dislocation and restoring the normal line of the spinal column. In making the operation, resection should not be limited to 1 or 2 arches, but should be a large one, often involving the removal of 5 or 6 arches. The membranes and the cord can be carefully drawn first to one side and then to the other in order to expose the bodies of the vertebrae for examination, and if necessary operation. Mr. Horsley, of London, is definitely in favor of an operation in all cases where there are symptoms which would show pressure upon the cord. The greatest possible care should be taken to have the operation thoroughly aseptic. No operation demands greater care in all its details. The shock of the operation is almost always severe; hence every precaution must be taken to avoid it.

Mr. Horsley has called attention to five special dangers.

1. Hemorrhage, which is always considerable in amount, but by means of hemostatic forceps and by pressure by means of gauze and sponges dipped in hot water it may be easily controlled.

2. Difficulty in exposing the spinal canal. With care and patience this difficulty can be overcome.

3. Physical difficulties in treating the fractured vertebrae. In many cases the vertebrae are hopelessly fractured and displaced, and cannot be dealt with satisfactorily. Unfortunately we are not always, or even often, able to judge of the severity of the fracture until it has been revealed by the operation.

4. The hopeless nature of the injury to the spinal cord. In the majority of cases of fracture-dislocation the cord has been injured beyond the possibility of repair.

5. The danger of specific infection. With the observation of modern aseptic surgery there should not be much danger of septic infection, excepting in compound fractures where infection has taken place before the surgeon sees it, or in those cases in which a fistula results from too long use of the drainage tube.

6. To these dangers Dr. White has very justly added the danger of anesthesia in the prone position, the abdominal muscles being paralyzed. This is a very real danger, and was well illustrated in one of my own cases,

in which the patient stopped breathing and came near dying before the operation was completed. The depressed fragments of bone had been removed, the cord liberated and I was in the act of closing the wound when the respiration suddenly ceased. The wound was immediately covered with sterilized gauze; the patient turned on his side, the tongue pulled forward, and soon respiration was restored. The closing of the wound and the application of the dressings were made with the patient on his side. No further trouble was experienced and my patient made a good recovery. After the arches have been removed, the dura should be carefully examined to see whether it pulsates. If there is no pulsation it is generally due to adhesions, or to some other cause of interference with the continuity of the subdural space. If there is blood within the dura, the membrane will present a bluish or purplish hue; if pus, yellowish; if a tumor is present, or there is any increase in the quantity of cerebrospinal fluid, the increased tension and elasticity of the dura will be perceptible to the touch.

Whether the dura should be opened is a more serious question in the spine than in the brain. It is claimed by most operators that the dura should generally be opened. There are exceptions to this rule. The best result I ever had was in a case of fracture dislocation in the middle cervical region, when I did not open the dura. When the dura is opened and the operation completed, the opening in the dura should be closed if possible with a continuous catgut suture in order to secure immediate union.

If the dura is not opened, we cannot learn the exact condition of the subdural space or the cord itself. Having opened the dura the canal can be explored carefully by an ordinary bent probe. So, too, the extradural space between the dura and the laminae should be explored, in order to determine whether there are any irregularities or obstruction, fracture, dislocation, etc. If the cord has been crushed or injured by accident, any splinters of bone should be removed and any considerable irregularity due to dislocation or fracture of the bodies of the vertebrae should be carefully removed by gauge or chisel.

Attempts have been made by several surgeons to suture the cord itself, but without success. Leckey has even gone so far as to propose to shorten the spine by removing a part or the whole of a vertebra or portions of 2 vertebrae by gauge or drills, a procedure which is only mentioned to be condemned.

Drainage is usually required and a wick of sterilized gauze is the best, which can be removed in 2 or 3 days, or at the time of the first change of dressings. At the subsequent dressings the strictest antisepsis must be observed.

The spine is best supported during the healing process by plaster-of-paris dressings or by sand bags placed on each side of the patient.

The usual precautions as to food and drink must be observed, opiates given for the relief of pain, care in relief of bladder and bowels and the preventing of bed sores.

The University of Leyden (Holland) has offered the chair in pathology to Dr. Hausemann, now prosecutor at the Friederichshain City Hospital, Berlin. Two well-known former teachers at Berlin are already professors at Leyden; Professor Rosenstein of internal medicine; Professor Veit of gynecology.

The Causes of Death Among Sailors.—*The Hamburger Seewarte* has collected exhaustive statistics as to the causes of death among German sailors. In the year 1900, 355 seamen died, or no news of them could be gathered. Of this number 93 had not been heard from for so long that it is probable that they are dead; 127 died from accidents; 27 were murdered or committed suicide, leaving only 108 or less than $\frac{1}{3}$ who died natural deaths. In 48 cases the disease causing death was not known; 12 died from yellow fever and malaria; 13 from the after-effects of sunstroke; 2 died from apoplexy; and the remaining deaths were from various diseases, among which were mentioned typhoid fever, tuberculosis, and dysentery.

PRACTICAL THERAPEUTICS

Under the charge of
A. A. STEVENS,
Assisted by
L. F. APPLEMAN.

Warts and Corns.—Daniel (*Therapist*, February 15, 1901) states that very excellent results are obtained by painting warts and corns with pure formalin morning and evening, or more frequently, allowing the fluid a few minutes to be absorbed. The hardening action of formaldehyde very soon effects shrinkage, and the warts or corns may, after a week or two, be lifted off bodily by some manual inducement.

Honthin.—Frieser (*Therapist*, January 15, 1901), has used this compound (a combination of tannin with albumin and keratin) in 38 cases (26 children, 12 adults) of diarrheal disease with excellent results. He believes that it is half as powerful again as tannalbin, and that, owing to its more intimate chemical combination, a much larger amount of the drug reaches the large intestine unchanged. It is also cheaper than tannalbin. He prescribes the preparation in powders to adults in doses of from 8 to 15 grains, 3 to 4 times a day; in children in single doses of from 4 to 8 grains, 3 times daily. It is quite tasteless and odorless, and in the author's experience was always well borne.

Treatment of Neurasthenia.—Brewer (*Journal of the American Medical Association*, January 26, 1901) emphasizes the following points: (1) Rest, either partial or total, according to the severity of the symptoms, and to be enforced for from 2 to 6 weeks. For business men 1 or 2 hours quiet and rest in a darkened room every afternoon, with absolute relaxation from business. (2) Diet should contain proteid materials in abundance—eggs, milk, beef, and mutton being the basis. Sugar should be used only in small quantity. When dyspepsia is present malted milk, somatose or partially peptonized food is given. In severe cases, where absolute rest in bed is enforced, a cup of malted milk mixed with somatose is given every 2 hours. (3) Galvanism to all the muscles sciatin once daily. The head and neck should also be treated with currents of 1 to 3 milliamperes, using large electrodes, and the abdominal muscles with 5 to 10 milliamperes. (4) Hydrotherapy, sponge bath and the wet pack daily, the last beginning with a temperature of 70° F., and gradually lowered to 50° F., and prolonged about 1 hour. The wet pack promotes tissue metabolism, favors elimination of fatigue products, and promotes sleep. (5) Massage daily practised, the movements at first being gentle and superficial. Little by little the force and extent of the treatment should be increased. As the case progresses towards recovery physical exercises should be added. Outdoor cycling, golfing and horse-riding are also good. (6) Aperient drugs, such as a pill of aloes and strychnin, and an occasional calomel purge prove beneficial. When renal deficiency is present, diuretics such as effervescent potassium citrate are indicated. Neurasthenics are benefitted by drinking water freely. (7) When there is much cerebral irritability sodium bromid in combination with a cardiac tonic—fluid extract of adonis vernalis—is given. When there is anemia Bland's is the best preparation. Phosphates and hypophosphites, especially in the form of the compound syrup of hypophosphites, are excellent.

Cardiovascular Disease of Middle and Advanced Life.—J. Mitchell Bruce (*Lancet*, April 6, 1901) states that a large proportion of the distress, disabilities, and dangers attending degeneration of the heart are due to some extrinsic disturbance—distension of the stomach, constipation, worry or exertion, which alone, not the pathologic condition, calls for therapeutic attention. Many unfavorable influences can be avoided by effort of the will. The toxic effects of tobacco, alcohol, tea, etc., are due to abuse, from thoughtlessness or ignorance, or from indisposition, rather than inability to exercise self-control. Gout, corpulence, and allied metabolic disorders—fruitful causes of atheroma—call for temperance not

only in drinking, but in eating. One bit of advice is always of value—whatever they eat, to eat little. Moderation in amount is, speaking broadly, far more important than avoidance of the theoretic antecedents of uric acid, whether meat or milk or sugar. With observance of this single rule must go attention to free elimination by all the excretory channels and the insurance of sufficient exercise and enjoyment of fresh air. Moderation and due respect for age are the true guides to useful enjoyment of exercise after 40 years of age. Nervous strain, as distinguished from simple hard intellectual work, often must be relaxed if cardiovascular damage is to be prevented. In syphilitic lesions potassium iodide should be given freely; it is a remedy of great value. In simple atheroma, depending upon toxemia and anemia, the obvious indication is to enrich and purify blood, and this must be effected by a thorough reform in every department of personal hygiene. Arsenic and moderate doses of iodides, combined with an excess of alkalies, are calculated to promote the same end. The nutrition and activity of the myocardium can be increased and sustained by means of specific cardiac stimulants and tonics, such as strychnin, ammonia, and the digitalis group of drugs, with hematinics, stomachics, and laxatives to insure an abundant supply of wholesome blood, by the control of nervous influences—one of the conditions of healthy nutrition—and by the employment of the non-medical measures now so extensively used to increase the vigor and benefit the metabolism of the cardiac walls, particularly active and passive exercises and baths. In many instances precordial pain, palpitation, faintness, and small irregular pulse are not due to actual failure of the myocardium, but to an embarrassment of temporary character—indigestible meal, loaded bowels, nervous shock, or passing hardships. In such an event cardiac stimulants are out of place. Complete rest in bed, a carminative draught, calomel and saline purgatives, spare and highly digestible food, reassurance, and a little time are quite sufficient means of treatment. When true failure occurs, manifested by residual dilation, mechanical congestion, and dropsy, the restorative measures are bodily rest, a light solid diet and a definite allowance of alcohol, if required, active purgation with mercurials, salines and jalap, and the exhibition of sufficiently large doses of digitalis or one of its congeners, in combination with saline and other diuretics. A few points should be emphasized: (1) We must not be afraid to purge these patients if necessary every morning; (2) when the appetite flags and flatulence occurs, instead of slops a blue pill or dose of calomel should be given and light solids persevered with; (3) nocturnal restlessness and sleeplessness are to be met unhesitatingly with permission to spend the night in an easy chair by the bedside; (4) acupuncture and drainage succeed perfectly in these senile cases with dropsy, as much as 10 pints or more of serum escaping in the course of 24 hours, to the complete and often lasting relief of the circulation.

Yeast in Diabetes.—Nobécourt (*Semaine Medicale*, No. 2, 1901) states that yeast attacks nascent glucose formed from the conversion of carbohydrates, and that experiments have shown that a quantity of glucose which would produce alimentary glycosuria ceases to do so if a small amount of yeast is administered at the same time. It may therefore be possible by the administration of yeast to permit diabetic patients to take a larger quantity of carbohydrate food. A dose of a tablespoonful may be given after meals.

Formaldehyd in the Treatment of Favus.—Demidoff (*Mercel's Archives*, April, 1901) has used formaldehyd with excellent results in a number of cases of favus. After as many of the crusts as possible have been removed mechanically, the remaining ones are then painted with a 5 to 10 percent solution of formaldehyd. The scalp is then covered with a layer of cotton and gauze to prevent evaporation and to render the action of the formaldehyd more lasting. This application causes redness and burning of the skin. In a patient who had been affected with favus for years and who had become almost completely bald, the applications of formaldehyd effected a perfect cure; the crusts and redness disappeared, and the skin of the scalp resumed its normal appearance.

Treatment of Bronchitis.—Patton (*Clinical Review*, March, 1901) states that in most cases the attack is either mild enough or sufficiently advanced to allow of a prescription containing an expectorant, sedative or demulcent. He recommends the exhibition every 2 hours of the following:

R
 Ammonium chlorid 3 to 5 grains
 Codein $\frac{1}{4}$ to $\frac{1}{2}$ grain
 Solution of ammonium acetate 20 drops
 Syrup of licorice anocolin A sufficient quantity.

He believes that bimeconat of morphin and codein are far more efficient than heroin, dionin and similar preparations. Where there is considerable laryngeal irritation he suggests a combination like the following:

R
 Ammonium chlorid 3 to 5 grains
 Morphin bimeconat $\frac{1}{8}$ of a grain
 Fluid extract of cannabis indica 1 drop
 Syrup of tolu Sufficient quantity.
 To be taken every 2 to 4 hours.

Or when the expectoration is very viscid:

R
 Ammonium chlorid 5 grains
 Codein $\frac{1}{4}$ grain
 Tartar Emetic $\frac{1}{2}$ grain
 Fluid extract of licorice 10 drops
 Glycerin 10 drops
 Syrup Sufficient quantity.
 To be taken every 2 hours.

Ammonium bromid is often very effective in bronchitis in weak, nervous people. In acute bronchitis of influenza alteratives often act better than expectorants. Five grains of sodium

The Treatment of Nasal Syphilis.—Morris (*Medical Age*, xix, No. 4), states that in nasal syphilis local applications to the nose and inunctions of mercury to the body are necessary in addition to internal treatment. The oleate of mercury should be applied to the thinner parts of the skin, in various parts of the body. A half hour should be devoted to clearing the nasal cavity of all contained crusts. These may be softened by soaking with Dobell's solution used by means of a soft rubber bulb syringe or a Birmingham douche, after which they can be removed with angular forceps. After all the large crusts have disappeared, the small crusts and any dried secretion may be removed with a cotton applicator. A careful search for any denuded or loosened bone should then be made. After cocaineizing, probe the nose, detach and extract any loosened bone. Remaining particles of pus are destroyed by hydrogen peroxid applied upon a cotton applicator. The whole ulcerated area should then be touched with a solution of silver nitrat 1 dram, distilled water 1 ounce. This should be followed by an insufflation of the following powder:

R
 Iodoform of each 30 grains
 Tannic acid
 Bismuth subnitrat
 Powdered acacia of each 2 drams
 Morphin sulfat 2 grains

This treatment should be repeated daily for several days and the patient directed to syringe the nose 20 to 30 times a day with Dobell's solution.

The Treatment of Bubo.—Griffith (*New York Medical Journal*, lxxiii, No. 7) considers internal medication often superfluous, beyond keeping the bowels freely open and the observance of general hygienic measures. Iron may be given with good effect. Abortive measures are indicated in the early stages. An ice-bag at bedtime or a flaxseed poultice applied to the bubo, combined with vigorous treatment of the primary source of infection, will prevent further development in about $\frac{1}{3}$ of all cases. The following salve may be applied once daily to soften the tissues:

R
 Mercurial ointment,
 Belladonna ointment,
 Ichthyol of each equal parts.

As soon as fluctuation is present the abscess should be opened and drainage established.

THE WORLD'S LATEST LITERATURE

British Medical Journal.

April 27, 1901. [No. 2104.]

1. Traps and Pitfalls in Special and General Practice. DUNDAS GRANT.
2. Remarks on the Training of Ophthalmic Surgeons. A. FREELAND FERGUS.
3. On the Advisability of the Inclusion of the Study of Anesthetics as a Compulsory Subject in the Medical Curriculum. DUDLEY W. BUXTON.
4. On Certain Practical Applications of Extract of Suprarenal Medulla. E. A. SCHLAFFER.
5. Suprarenal Gland Extract in the Epistaxis of Hemophilia. DAN MCKENZIE.
6. The Dietetic Value of Sugar. H. WILLOUGHBY GARDNER.
7. A Preliminary Note on the Hibernation of Mosquitos. H. E. ANNETT and J. E. DUTTON.

1.—Grant, in a preliminary address on **traps and pitfalls in special and general practice**, discusses the business of practice, infection, specialism, the debt of general medicine to specialism, the debt of specialism to general medicine, physical examination and general observation, consulting and general practice, venesection, pitfalls in general practice, pitfalls in special practice and special and medical education. [A.O.J.K.]

2.—An academic discussion by Fergus of the **requisites of the training of ophthalmic surgeons**. [A.O.J.K.]

3.—A plea by Buxton for the including of the study of **anesthetics as a compulsory subject in the medical curriculum**. [A.O.J.K.]

4.—See editorial page.

5.—McKenzie reports a case of the **epistaxis of hemophilia** occurring in a boy of 13, in which, after various remedial procedures—such as the insufflation of tannin, plugging the nostrils, and calcium chlorid internally—had failed to control permanently the bleeding, the application of a **watery solution of suprarenal gland** was followed by immediate cessation of the hemorrhage. A slight recurrence several hours later was effectually stopped by another application of the suprarenal gland solution. [A.O.J.K.]

6.—Gardner, in an article on the **dietetic value of sugar**, discusses the history of cane sugar and beet sugar, and from a consideration of the results of laboratory experiments, as well as from the experience of mankind, concludes that sugar is an extremely valuable article of diet. He believes that the vitality and stamina possessed by the Anglo-Saxon race, as contrasted with the Russians, are due in large part to the greater amount of sugar consumed by the Anglo-Saxons. Its use is urged in simple marasmus, in tuberculosis, in conditions of malnutrition and in growing boys and girls. It is believed that of itself it does not harm the teeth. Bearing in mind alimentary glycosuria, the urine should be examined if the patients be taking large quantities of sugar. In the cases of children with mucus disease, care must be observed in its administration; the obese must avoid it. Its interdiction in rheumatism is possibly merely a prejudice, but those who suffer from gout must not use it. [A.O.J.K.]

7.—Annett and Dutton refer to the recent communication by Wright (AMERICAN MEDICINE, May 4, page 217) concerning the resistance of the larval mosquito to cold, and consider it truly remarkable that it has been found that larvae may withstand a temperature of 4° C. for 2 weeks. They note briefly their own investigations concerning the **hibernation of mosquitos**, and conclude that there can be no doubt that mosquitos (both Anopheles and Culex) hibernate during the winter months in England, and that it seems certain that not only the adults, but, from Wright's experiments, the larval forms also provide for the continuation of the species during the cold weather. Of the hibernating mosquitos found, there were only females, and these had been fertilized. Kept in a dry cage they quickly died, but kept in a damp cage in the cold they survived some months, preserving their so-called hibernating attitude. When warmed, they soon became active, fed on blood, and deposited eggs on the fifth, sixth, seventh and eighth days. Many of them died after depositing a batch of eggs. [A.O.J.K.]

1. The Sometimes Successful Treatment of Cases of Apparent Incurable Blindness. CHARLES BELL TAYLOR.
2. On 2 Cases Bearing upon the Question of the Limitations of Enterectomy. ARTHUR E. BARKER.
3. On Hourglass Stomach; with List of 6 Cases Operated upon by the Writer, and a Tabulated List of all Cases in which Operations have been Performed. B. G. A. MOYNIHAN.
4. Reversed Pulsus Paradoxus due to Aneurysm of the Aortic Arch. JOHN HAY.
5. Case of a Parasite—"Argas (or Ornithodoros) Mégnini" Dugés—in each Ear. J. CHRISTIAN SIMPSON. With a Note on the Anatomy of the Specimen by E. G. WHEELER.
6. A Case of Belladonna Poisoning; Morphia Used as an Antidote. PETER D. STRACHAN.
7. Dermatitis from Arsenic in Stockings. F. W. TUNNICLIFFE and OTTO ROSENHEIM.
8. Tetanus Puerperalis. KEDARNATH DAS.
9. Mercury and Iodide of Potassium Internally given with Pilocarpine Hypodermically in Disease of the Eyes. G. HERBERT BURNHAM.

1.—Taylor refers to a number of cases of **apparently hopeless blindness** in which success followed persistent treatment. The remedies employed in addition to the usual routine and whatever measures were indicated consisted in electricity, the administration of mercury in large doses alone or in combination with other drugs. Emphasis is laid on the rational method of treating disease by removing the cause, strengthening the vital resistance, and treating symptoms carefully as they arise. [J.W.M.]

2.—Barker reports **2 cases of enterectomy** which have some bearing on the limit of intestinal resection. The first patient, a lady of 58, whose urine contained 6.6% of sugar, suffered from severe pain above the umbilicus, vomiting and obstinate constipation. On operation a carcinoma of the colon producing stricture was found. Four and one-half inches of the bowel were incised and the divided ends united by means of 2 rows of silk sutures. Infection, followed by the discharge of some feces and omental sloughs occurred, but eventually complete recovery resulted. The glycosuria which existed adds additional interest to the case. The second case was that of a lady of 76, who for 2 years had a neutral hernia in an ovariectomy scar. For 3 years she suffered from abdominal pain, vomiting and later some obstruction. On operation strangulated hernia of the small intestine through the omentum was found, and the condition of the intestine was such that a resection of the 5½ feet, followed by an end-to-end anastomosis was performed. Uninterrupted recovery followed. Senn has concluded from experiments on animals that not more than ¼ of the small intestine should be removed. The lower in the intestinal tract the resection is done the better it is tolerated. [J.W.M.]

3.—Moynihan in discussing **hourglass stomach** states the symptoms are usually those of dilation following a chronic gastric ulcer. Characteristic signs are (1) disappearance of fluid introduced into the stomach; (2) after lavage of the stomach a sudden gush of ill-digested food may occur; (3) succussion splash heard in the pyloric cavity after emptying the cardiac; (4) after distending the cardiac pouch it gradually subsides, and at the same time the pyloric distends; (5) when both pouches are inflated a sulcus or constriction may be evident. For the relief of the condition gastroplasty, gastrogastrostomy, gastroenterostomy, and partial gastrectomy have been performed. The operation applicable in each case must be determined after a careful examination at the time of operation. [J.W.M.]

4.—Hay reports a case of **reversed pulsus paradoxus** in aneurysm of the arch of the aorta, caused by pressure of the innominate artery. By the aneurysm behind and the sternum in front, the lumen of the artery was almost obliterated at the end of inspiration, at which time no radial pulse could be felt. The patient was a young man who gave a history of syphilis, strain, and rheumatism; suffered from severe pain between the shoulders, headache, dizziness, suffocation, and pain on

swallowing. The larynx and trachea were displaced to the right, there was fullness of the right side of the neck and engorgement of the veins of the arms. Tracheal tugging was present, and a distinct expansile pulsation could be felt behind the left clavicle. He had a deep, wheezing cough, and the cardiac area was enlarged; 2 murmurs were heard, one systolic heard over the seventh right costal cartilage, the other diastolic, heard best over the lower end of the sternum. Postmortem showed aneurysmal dilation of the entire arch. A projection from the aneurysm was adherent to the anterior surface of the trachea. The heart showed hypertrophy and dilation. [J.W.M.]

5.—Simpson reports the presence of the parasite, *Argas Megnini* in each ear of a patient who, 2 months before, had been camping in Arizona. One came away of its own accord, the other was adherent to the tympanum, and was removed by first inserting into the canal a pledget of cotton saturated with chloroform, thus killing it, and then syringing the canal. The symptoms to which the presence of the parasite gave rise were pain above, and a "rattling" sound in the ear. [J.W.M.]

6.—Strachan reports a case of *belladonna poisoning* occurring in a boy of 5, in which *morphin* was used as an antidote with a successful result. The case illustrates the tolerance of the child for the belladonna, he having taken $\frac{1}{2}$ ounce of the glycerin of belladonna (supposed to contain about 1 grain of the alkaloid hyoscyamin), and having remained untreated for 5 hours. The case illustrates also the efficacy of morphin as an antidote, the drug being used hypodermically in 2 doses of $\frac{1}{4}$ grain each, with an interval of about 10 hours. [A.O.J.K.]

7.—Tunnicliffe and Rosenheim, in an article on *dermatitis from arsenic in stockings*, report several cases of dermatitis traced to the wearing of stockings in which arsenic was demonstrated by chemie investigations. They report also the results of their examination of a number of stockings purchased in the open market, and which revealed the presence of arsenic. The arsenic was ascertained to be used in the process of dyeing, and in stockings examined it was present in much larger quantity than is permitted by the laws of certain countries, such as Germany, Austria, and Sweden, that have adopted regulations governing the use of arsenic in dyestuffs. They suggest that if arsenic mordants cannot be dispensed with in dyeing, their use should at least be supervised. [A.O.J.K.]

8.—Kedernath Das, of Calcutta, reports a case of *tetanus puerperalis* successfully treated. The patient, a Hindu woman, aged 28, was admitted to the hospital 2 weeks after delivery with the jaw completely locked, and the spasms did not entirely cease until 6 weeks after admission. There was administered in this period more than 8 ounces of chloral, as much bromid of potassium, and a quantity of tincture of Indian hemp. She was also given plenty of liquid food, and, in addition, saline injections under the breast. In a rational treatment of this dread disease one must look to the following points: (1) To destroy the bacteria at the seat of infection by thoroughly antisepticizing the parturient canal and by subsequently keeping it aseptic; (2) to eliminate the toxins already absorbed by brisk purgation and intercellular injection (under the breasts) of normal salt solution; (3) to overcome the symptoms induced by the action of toxins, viz., the increased reflex irritability of the higher nerve centers, and this is best accomplished by keeping the patient absolutely quiet in an isolated place, and by chloral in very big doses, given either per os, if possible, or per anum; or hydrobromate, or morphia; and (4) to neutralize the poison already absorbed and to immunize the body after local infection has taken place. In regard to the fourth point, theoretically, antitoxin should be used, but its action is as yet uncertain; and though in other forms of tetanus it has reduced the mortality from 90% to 59%, its use in puerperal tetanus has as yet brought no improvement. [W.K.]

9.—Burnham discusses the value of *mercury and potassium iodid* internally with *pilocarpin* hypodermically in diseases of the eye, and reports 2 cases in which the treatment was employed with gratifying results. The first was a case of sclerokeratitis, which, after 4 months of active treatment, cleared up almost completely, nor is a return feared. The second was a case of sympathetic ophthalmia, in which the

treatment was continued for 8 months, and while the improvement was interrupted the results at the time were all that could be desired, and it was expected that the normal condition of the eye would be restored. The efficacy of the treatment is attributed to its power of arousing to excessive activity the normal physiologic processes in diseased tissue, and thus assisting nature in bringing about a restoration. [J.W.M.]

13. Operating Under X-rays. J. F. BALDWIN.

1.—For diagnosis of injuries of the head it is always desirable and usually necessary to shave the head. Two conditions needing special consideration are the natural irregularities of the skull and homefactions from extracranial effusions. These under certain described conditions may emulate fracture. A careful study of hemorrhages and ethymosis and cleansing of the various cavities, exposing the brain to infection is necessary. In injuries without important local signs or definite focal symptoms the treatment must be nonoperative. Fractures of the vault without wound are considered in 3 classes (1) those with local signs but no focal cerebral symptoms; (2) with both present; (3) localized cerebral symptoms of compression indicating most frequently rupture of the middle meningeal. In the first class, if there is no depression there is no indication for operation. Depression must always be relieved by trephining. When the focal symptoms are on the opposite side, trephine at the site of the lesion; when on the same side, trephine on the opposite side. With facial paralysis on the same side as the lesion and monoplegia or hemiplegia on the opposite side, trephine over the motor area implicated. The prognosis is bad. With complex symptoms without connection with any determinable cranial lesion the treatment must be along the lines indicated in the first category. In hemorrhage whether extra or subdural or intracerebral the clots should be removed and the flow controlled. Fractures of the base may be recovered from. The preventable deaths are due to infection. In fractures of the vault with wound in which there is loss of bony wall, simple aseptic healing after careful approximation of the tissues layer by layer causes the least cortical irritation. Insertion of foreign substances is wholly objectionable. In operating for rupture of the meningeal artery, resection of a large rectangular bone flap is advised and the technic is described. [I.M.]

2.—The bladder and rectum perform their functions without interfering with the position of the uterus. They both collapse with the long diameter anteroposteriorly, thus occupying as much anteroposterior space when empty as full.

The upper wall of the empty bladder is not in contact with the anterior wall of the uterus, the intervening space being occupied with intestine. This is demonstrated in laparatomies. The direction of abdominal pressure in consequence is at all times in line with the uterine axis and therefore equally distributed to all of its supports. The lymphatics, blood and nerve supply and general and local examination described. [H.M.]

3.—Three cases of Kelly's and 1 of Halsted's of stone impacted in the ureter, are reported in detail, the literature of the operation is reviewed and a table of 84 operations is appended. When the stone cannot be felt through vagina, rectum or abdominal wall, diagnosis must be made by catheterizing the ureters with a wax-tipped bougie or by radiography, or by exploratory celiotomy. The points of predilection are from 3 to 6 cm. from the kidney, the point where the urethra crosses the iliac artery, and just above the vesical orifice. If the calculus is in the vesical portion it can be reached by the urethra, vagina, rectum or through perineal incision. Extraperitoneal operation is advised for those higher up. [H.M.]

4.—Vineberg presents several cases with misleading symptoms and discusses the frequency with which ectopic gestation is diagnosed as early uterine abortion, and the advisability, if the latter is not running a natural course, of anesthetizing for rigid examination and proper curettage is indicated. If doubt remains after this, exploratory vaginal incision should follow. The unreliability of the so-called pathognomonic signs and symptoms of ectopic gestation are shown. [H.M.]

5.—Fractures due to metastasis of malignant disease or abnormal fragility of the bones. In the case of subsequent union reported a hard shell of bone was found around the deposit. Union is more likely to occur in deposits of slow growth and the slower the growth the less the pain. The degree of pain therefore affects the prognosis. Nonunion is due to the health of the patient, extensive destruction of the bone or separation of the fragments by the growth and not to any inhibition of ossification by the disease. The case of spontaneous disappearance of carcinoma described is one supposed from the history to be such. [H.M.]

6.—In severe inflammation of the eye it is very important that the patient be at rest. Too often there is neglect to put the patient in bed. The circulatory, respiratory, secretory and excretory functions should be attended to and an active cathartic is generally indicated. Bloodletting is very beneficial in certain acute conditions. Altreatives are more influential than any other drugs. In conjunction with hot baths larger doses of iodids can be borne. Mercury should be used till the hemoglobin begins to decrease. Inunction is preferred. Pilocarpin is the best diaphoretic. Iodin salicylate or aminoform should be used in rheumatic exudates. Hot baths are a valuable adjunct to internal remedies. [H.M.]

8.—The immediate untoward effects which may follow removal of adenoids are hemorrhage, injury to the pharynx, reactionary acute inflammation affecting the pharynx, larynx, tonsils, ear, accessory cavities and sepsis. Among remote effects are subacute disease of the pharynx, chronic diseases of the ear, diseases of the accessory sinuses and tuberculosis. The latter danger has been much overrated. [H.M.]

9.—Six cases verified by the microscope and one not so verified are described. This is followed by a short review of the literature, etiology, bacteriology, pathology and treatment. The conclusions are that actinomycosis is not uncommon, that when pure it is nonsuppurative, afebrile, comparatively painless and slowly progressive; that the signs and symptoms are often pathognomonic; that combined surgical measures and potassium iodid give the best results, the latter administered internally curing a large percentage of cases. Interstitial injections exert a striking influence. [H.M.]

10.—During 1899, 12% of the dysentery cases in the Reserve Hospital at Manila developed abscess of the liver. The part played by Amoeba coli is as yet undetermined. Natives rarely develop it, the frequency among Europeans being due to overeating and drinking and other conditions favoring hepatic engorgement. The right lobe was commonly affected, and the abscesses in most cases multiple. In the diagnosis, symptoms

are of little value, this depending on local signs and aspiration of pus. Dulness was increased greatly above, below and to the left of the median line. There was persistent pain over the whole region, with tenderness in the anterior axillary line just below the ribs. Local bulging, edema, with increased width of the interspaces makes abscesses probable, but aspiration alone establishes the diagnosis. Several punctures should be made. The presence of pus makes operation imperative. [H.M.]

11.—Preventive measures for insanity should come from the State. Brower advises the election of senior students in medicine by competitive examination as internes in hospitals for the insane, and these would act as centers of prophylaxis for the community. Treatment for incipient cases should be provided in every hospital on account of the prejudice against legal commitment to asylums. Heredity is the chief causative factor. Marriage should be regulated and degenerates asexualized. Neurotic mothers should be placed under the most favorable conditions during gestation, a healthy wetnurse provided and the child carefully trained. Public schools are sadly deficient so far as neurotic children are concerned. [H.M.]

12.—The presence of pus in an inguinal tumor, rigidity of the abdominal muscles, a paroxysm of pain, and in late cases edema of the abdominal walls, with distention and progressive inflammation, a rise followed by a fall in temperature, with a weaker and quicker pulse, a chill, are some of the conditions indicating immediate operation in appendicitis. [H.M.]

13.—The operation was for the removal of a bullet in the kneejoint which changed its position constantly with gravity. The bullet and point of the forceps had to be located in 2 planes by rolling the patient back and forth. Operation was difficult owing to darkness, etc., but was successful, ultimate motion being perfect. [H.M.]

Boston Medical and Surgical Journal.

1. Some Reported Cases of Typhoid Fever Attributed to Contaminated Oysters, With Certain Facts Concerning this Means of Infection. CHARLES HARRINGTON.
2. Experience with the Widal Reaction in Typhoid Fever. CHARLES F. WINTINGTON.
3. The Widal Reaction in Typhoid Fever. GEORGE B. SHATTUCK.
4. Means of Infection in Typhoid Fever. E. N. WHITTIER.
5. Early Diagnosis of Typhoid Fever by Isolation of Bacillus Typhosus from Stools: Conclusions of Dr. L. Remy Based on the Use of his Asparagin-Laetose-Carbol Gelatine. CALVIN G. PAGE.
6. The Fevers of the Philippines. A Preliminary Report on the Nature of the Fevers Prevalent in the Philippine Islands, Including Typhoid Fever, Malta Fever, the Malarial Fevers and Undetermined Tropical Fevers. JOSEPH J. CURRY.

1.—The cases are taken from literature published since 1893. The investigations of De Glaxa, in 1889, as to the influence of sea water on pathogenic bacteria is summarized. Foote found typhoid cultures introduced with shells virulent at the end of 48 hours. Polak's conclusions were opposed to those of others who had determined that the organism lives longer in the oyster than in sea water itself. Klein found the bacillus after 4 to 18 days in oysters placed in purposely-infected water. According to Boyce, the organism will not grow in the tissues of the oyster. Danger arises wholly from sewage in water where the oysters are planted or stored. The remedy lies in transferring the beds or in storing contaminated oysters from 7 to 16 days in clear sea water. [H.M.]

2.—Withington reports 4% of failures with Widal test in 253 cases of typhoid at the Boston City Hospital. That the reaction rarely appears before the sixth and often not before the ninth or tenth day lessens its value in early diagnosis. In one case, after 8 failures, it appeared on the twenty-ninth day. The technic is described. [H.M.]

3.—Shattuck reports 62 additional cases with clinical diagnosis of typhoid in which 3 failed to respond to the Widal test; 1 additional doubtful case with a positive reaction, and

another developing a different disease, also positive, but attributed to typhoid 2 years before. During the period of the Spanish-American war soldiers having malaria gave positive reactions, but previous typhoid could not be excluded. The paper begins with a resume of one presented 4 years ago. [H.M.]

4.—Whittier alludes to the virulence of rural typhoid and the many sources of infection, with especial reference to the outbreak at Marion attributed to contaminated oysters.

5.—Colonies appear on Remy's gelatin after 2 days at room temperature. The appearance is not sufficient for diagnosis. Clumping with typhoid serum and the absence of indol and gas bubbles are necessary for differentiation of the typhoid and colon bacilli. Cultures have been obtained as early as the third day. In 3 cases bacilli have been found before the serum reaction or any other sign of typhoid was present. The time required to make a report is at least 3 days. [H.M.]

6.—Typhoid fever in the Philippines has never assumed anything near the epidemic form as in camps in the United States during the late war or as in South Africa. The use of old infected Spanish camps has been the source of much sickness, including typhoid. The disease undoubtedly existed before our occupation. The extent is unknown owing to the worthlessness of Spanish and native records as to causes of death. The death-rate in the First Reserve Hospital has been remarkably low, only 15%. No doubt some deaths among soldiers attributed to dysentery and malaria have been due to typhoid. The adoption of prophylactic inoculation for departing troops is worthy of serious consideration. Sixteen cases of Malta fever came under Curry's observation and he believes the disease is not uncommon there. The symptoms are described. Compared with other tropical countries the malarial fevers are not severe and are the causes of relatively few deaths, but are serious on account of predisposing to other diseases through debility and complicating convalescence. The number of admissions to the above hospital was greater than for any other cause. The estivo-autumnal tertian and quartan types are found, a larger percentage of the tertian are reported than in other tropical countries and it is probably as common as the estivo-autumnal. Mosquitos are very thick and active. Very little has been done in the tropics in systematic scientific examinations but when conditions are on a peace basis valuable work can be done toward identifying the undetermined fevers. Some are of short and others are of long duration of the continued type. Hepatic fever is accompanied by marked jaundice and acute enlargement of the liver and lasts from a few days to weeks. Fatal cases show hyperplasia and hyperemia of the liver. In 1 case there were multiple abscesses without previous dysentery. Examinations were negative for the ameba. [H.M.]

Medical Record.

May 11, 1901. [Vol. 59, No. 19.]

8. Postural Treatment in Threatened Miscarriage. ALICE M. SMITH.

1.—Starr divides neurasthenics into 4 classes, according to the origin of the disease, and considers the cases that are toxic in origin. The symptoms, psychological, circulatory, digestive, etc., are described, the chief characteristic being alternations of feelings and symptoms, the depression curve being lowest from 9 p. m. to 4 a. m., and gradually ascending until noon. That the maximum of distress occurs after sleep shows it is not

due to the wear and tear of exhaustion but to some toxic agent which accumulates in the blood and is counteracted by the activity of the day. As activity of the digestive powers appears to aid elimination the poison is probably manufactured in stomach or intestines. The diet usually best digested by these patients is given, followed by formulas for hepatic stimulants and intestinal antiseptics used by the writer. Hot baths followed by cool sponging, moderate exercise and regular rest are also indicated [H.M.]

2.—Potain presents a method by which accurate knowledge of the deep dulness or real size of the heart may be obtained. Percussion is digital, moderate in force, single and concentric, beginning 3 or 4 cm. beyond the periphery. Differences in pitch and not intensity of sound are noted. The projection on the chest wall is mapped out by 3 lines and angles with a dermatographic pencil, adding a few fixed points, and these markings are traced over on transparent tissue paper. Postmortem verifications are made by placing the paper in position, inserting long needles perpendicularly through the chest at certain points which remain in position during removal of the sternal plate. The results are precise. Tracings thus made at different stages of disease give valuable indications for prognosis. [H.M.]

3.—All specifics have been so far disappointing in pneumonia. The best hope lies in serumtherapy. As a symptomatic remedy hypodermoclysis has proved itself a valuable adjunct. An ordinary rubber syringe and the needle of an antitoxin syringe are all the apparatus needed. The injection is given under the breast. When the usual heart tonics fail from $\frac{1}{2}$ to 1 pint of normal saline solution is injected every 2 to 6 hours. It is a powerful cardiac stimulant, increases secretion, moistens the tongue and skin, lessens delirium. It is contraindicated in pulmonary edema unless due to failing heart. Several cases are reported in detail. [H.M.]

5.—Liell, in discussing surgical anesthesia by means of spinal cocainization emphasizes the importance of the most thorough asepsis. To avoid infection from the skin he introduces the needle through a small scalpel incision in the skin. He uses a gold needle and sterilizes the cocain solution by boiling about 1 minute. When introducing the needle, the patient assumes a sitting posture slightly inclined forward to increase the intervertebral distance. The third or fourth lumbar is usually chosen. The needle is introduced in an upward and inward direction at a point about $\frac{1}{2}$ inch to the right of a line drawn between the spinous processes. Its entrance into the spinal canal is indicated by the escape of cerebrospinal fluid. The cocain solution is then injected and anesthesia usually occurs in 10 minutes. Failures sometimes result from faulty technic, the use of too small a quantity of the solution, idiosyncrasy, or inert cocain. The postoperative symptoms which are not constant are nausea, vomiting, headache, increase of temperature and pulse-rate, vertigo, pallor and prostration. These may be minimized and often prevented by the proper preliminary preparation and the judicious use of drugs. [J.W.M.]

6.—Griffith refers to the development of a keloid upon a vaccination scar, and reports a case. The patient was a young girl, who had been vaccinated 5 months before she came under observation, when the tumor was the size of a lima bean. Its removal under cocain was advised, but was refused. [J.W.M.]

7.—King reports the performance of pylorotomy in a patient in his seventy-fifth year. For 2 years he had suffered from gastric disturbance with later evidence of obstruction and gastric dilation. Examination showed dilation of the stomach, and the presence of a nonadherent tumor the size of a goose egg situated above the umbilicus. Before operation the stomach was irrigated with large quantities of decinormal salt-solution, and the patient stimulated by hypodermic injections of strychnin and rectal enema. On opening the abdomen a carcinoma of the pylorus was found, with no involvement of adjacent structures. Pylorotomy according to Kocher's method was performed. Rectal alimentation was resorted to for 3 weeks. Convalescence was uneventful, and 9 months after the operation the patient was well, and had gained 14 pounds in weight. [J.W.M.]

1. Abdominal Pain In Typhoid Fever. THOMAS McCRAE.
2. Spinal Anesthesia by Cataphoresis. J. LEONARD CORNING.
3. The Pathology and Bacteriology of Ureterointestinal Anastomosis. F. ROBERT ZEIT.
4. The Use of the Suprarenal Capsule In Diseases of the Heart. SAMUEL FLOERSHEIM.
5. The Law and the Inebriate; with Remarks on the Treatment of Inebriety. JOSEPH COLLINS.

1.—After discussing the opinions of various authors regarding abdominal pain in typhoid fever, McCrae of Johns Hopkins gives a brief review of 500 cases which have come under his own observation, classifying them as follows: (1) Those in which there is no pain or tenderness at any period (206 cases or 41%); (2) tenderness only (72 cases or 14%); (3) in which abdominal pain is present (222 cases or 44%). Of these, there was, in 61 cases pain only at the onset, which leaves 161 cases or 32% with pain during the entire course. The latter group of 161 cases he subdivides as follows: (a) Those in which pain is due to conditions apart from any special lesions of the disease, as hysteria, lung conditions, abortion, labor, etc. (15 cases); (b) conditions of the intestinal tract apart from complications as vomiting, constipation, diarrhea, etc. (31 cases); (c) abdominal conditions apart from specific bowel lesions as, appendicitis, liver abscess, painful spleen, phlebitis, peritonitis, etc., (25 cases); (d) specific intestinal complications, hemorrhages and perforation (27 cases); (e) no discoverable cause, this being the largest group with 70 cases. [H.H.C.]

2.—Corning describes a method of inducing spinal anesthesia by cataphoresis and reports a case in which it was applied. An apparatus by means of which the cocain solution is injected between the dura and the vertebral canal and to which the positive pole of a galvanic battery is attached is employed. The negative pole of the battery is applied over the abdomen. In the case in which the method was tried anesthesia was produced, but the time required to produce it militates against the practical value of the method. [J.V.M.]

3.—Zeit, in the first instalment of his paper on the pathology and bacteriology of ureterointestinal anastomosis, treats of the mortality percentage resulting from this operation. Of 127 operations performed on dogs, death occurred in 61% of the unilateral and 68% of the bilateral cases. Of the dogs which recovered, not one proved to have healthy kidneys when killed. In man he observed that the percentage was even greater, reaching almost 71%. The percentage in 36 cases of implantation of the trigonum (Maydl's operation) stood at 19%. He found that during the first 10 days dogs died of peritonitis due to leakage, general sepsis or pyelonephritis. Dogs living a longer time either died of pyelonephritis, pyelonephrosis and pyemia or recovered, but all had contracted kidneys. The colon bacillus was the principal cause of these sequels. He concludes the article by speaking of the excretion of bacteria by the kidneys and states that "bacteria in the blood are excreted by the kidneys and may pass through the normal glomeruli without necessarily producing any anatomic lesions." The bacteria found in these instances include the tubercle bacilli, Staphylococcus albus and Staphylococcus aureus, Bacillus prodigiosus and Bacillus anthracis. [H.H.C.]

4.—In his second paper on the suprarenal capsule Floersheim cites 82 cases of organic heart disease which were benefited by the use of the drug. He finds that it is indicated in organic heart disease with weak, fluttering, intermittent or irregular pulse, in cases in which the peripheral bloodvessels are dilated or contracted, in those in which there exists a high-tension pulse and in all valvular lesions. There are no contraindications. The effect lasts from 5 minutes to 3 hours and it is the most rapid acting heart stimulant. It has no cumulative effect and is not poisonous. He gives the dose as 3 grains of the powdered gland, packed loosely in a gelatin capsule. This

is thoroughly chewed, dissolved in the mouth and swallowed without water. For children an emulsion is better. [H.H.C.]

1. Practical Food Prescribing. FLOYD M. CRANDALL.
2. Studies In the Bacteriology of Typhoid Fever, with Special Reference to Its Pathology, Diagnosis and Hygiene. PHILIP HANSON HISS.
3. Restoration of Useful Vision In a Complicated Case of Acute Inflammatory Glaucoma of 10 Days' Duration with Visual Acuity Reduced to the Perception of Light. C. A. VEASEY.
4. Rupture of the Right Kidney: Nephrectomy: Recovery. G. R. TROWBRIDGE.

1.—It is requisite for a good prescriber of food for infants to have a thorough knowledge of breast milk, of chemical and physical composition of artificial foods, of good cow's milk and how secured, of the difference between cow's and breast milk, of modifying for the individual infant, and of the character of food required in health and disease. Artificial foods are deficient in fat, milk, sugar and proteid and are vegetable in origin. Cow's milk, properly modified, is the best food. There is a close relation between acidity and bacteria. An important detail in handling milk is rapid cooling after milking. Milk should be Pasteurized on the least doubt as to cleanliness, and sterilized only in rare instances. Milk should not be modified according to set formulas but according to the requirements of each case, beginning on a weak mixture and working up to a point of tolerance. Tables are given showing the percentage of fat in increasing numbers of top ounces of milk with a general formula for diluting. This relieves the practitioner of the burden of remembering formulas for various ages. A table for milk sugar is also given. The article concludes with suggestions as to the modifications required in various infantile diseases. [H.M.]

2.—The paper gives a review of the bacteriologic investigations of typhoid fever, with a consideration of the results interpreting the disease process, in aiding diagnosis and prophylaxis. The differing views as to whether the lesions are due to toxins or a true infection are presented and also the difficulties in isolating the bacillus in cultures. Its appearance in spleen, blood, rose-spots, mouth, urine and feces are considered in detail in relation to the different stages of the disease. Attention is called to the author's media for plate and tube cultures, described in a previous paper, which permits a diagnosis in from 36 to 48 hours. The exact portals of entry of the bacilli into the tissues and fluids of the body are not known. The usual site is probably the lower portion of the small intestine. It is not known whether they steadily increase after ingestion in the lumen-producing toxins causing inflammation, or whether they first gain entrance to the lymphatic tissues producing the toxins there. That the bacilli are not usually found in feces the first week points to the lesions and not the lumen as the habitat. They are probably carried by the circulation to the spleen, bone-marrow, rose-spots and urine, but typhoid fever is not a true septicemia, as in only the rarest instances is it likely that the bacilli multiply in the blood itself. The portal vein probably carries the infection to the liver and the lymphatics to the mesenteric glands. The germs may enter the general circulation through the thoracic duct. The presence of the organism in the excretions makes it necessary not only to disinfect the feces during the febrile stage, but also all utensils used about the mouth of the patient, and to sterilize the urine until bacteriologic examination has proved the absence of the bacillus. As it may persist for months in urine, this is a serious source of dissemination of the disease. [H.M.]

4.—Trowbridge reports a case of traumatic rupture of the right kidney. Lumbar nephrectomy was followed by recovery. In cases of trauma of the kidney exploratory operation is advised, as this is the only possible means of learning the extent of the injury. [A.G.E.]

Philadelphia Medical Journal.

May 11, 1901. [Vol. 7, No. 19.]

1. The Doctor's Fee—A Plea for Honorable Dealing. JOHN B. ROBERTS.
2. The Etiology of Arrested Mental Development. PEARCE BAILEY.
3. Cataract Extraction. EDWARD JACKSON.
4. Abscess of the Orbit from Disease of the Ethmoid; Chiselling through the Orbit and Draining through the Nose. GEORGE C. HARLAN.
5. Purulent Choroiditis, Following an Attack of Mumps; Diagnosis, Metastatic Choroiditis, Revised by Study of the Eucleated Eye-Ball JOHN T. CARPENTER.
6. Spontaneous (?) Rupture of the Spleen: Laparotomy: Death: Report of Case. D. C. HOWARD.
7. Ephemeral Insanity, with Report of 2 Cases. CHARLES J. ALDRICH.

1.—Roberts, in an article on the doctor's fee and its mode of collection, delivers a scathing rebuke to the members of the medical profession who resort to dishonest and underhand methods. While the physician is often tempted to depart from the strictly ethical standard by life insurance companies or manufacturers of proprietary medicines or new drugs, he should always remember that to do so is to prostitute his professional ability and good name for a monetary consideration which can never repay him for his loss of self-respect and reputation among his fellow-practitioners. [H.H.C.]

2.—In his article on the etiology of arrested mental development, Bailey considers idiocy, imbecility, and feeble-mindedness as varying degrees of the same condition, and divides their causes into the following groups: (1) Those occurring before birth; (2) those occurring at birth; (3) those occurring during infancy and childhood. Speaking of the first group he says that more than 50% of all cases of idiocy are congenital, and in a large proportion of this number, a defective nervous system on the part of the parents or near relatives is demonstrable. Prominent among the diseases in the parent which may cause idiocy in the child are alcoholism, tuberculosis, and syphilis. In the second group he considers injuries to the brain of the child during birth. The commonest clinical manifestations of such injuries are diplegia and paraplegia. Even when such gross lesions are absent, difficult labor with the attendant compression and asphyxiation, is sometimes the only discoverable cause for feeble-mindedness. The proper use of forceps should be regarded as a means of avoiding these injuries, although their use is never without danger to the head of the child. Under the head of causes acting after birth he considers diseases of the brain and its membranes, scarlet fever, typhoid fever, infantile convulsions, total blindness, total deafness, traumatism, and rachitis. [H.H.C.]

3.—Jackson gives clinical notes of 7 cases of cataract extraction. His experience with ripening operations has been favorable. He states that the possibility of making extraction absolutely aseptic must be disclaimed, yet no other operation shows fewer infections. It seems that the line is yet to be drawn between essentials and nonessentials in the technic of aseptic surgery. [A.G.E.]

4.—The operation for abscess of the orbit was practically that of Jansen for the frontal sinus, except that drainage through the nostril was employed and the wound sutured. The drainage tube was not allowed to project through the wound externally, thus allowing better union. [A.G.E.]

5.—The case of choroiditis reported by Carpenter was supposed to have been due to mumps. Preparation of the eye after enucleation showed the presence of a small bit of iron in the vitreous. [A.G.E.]

6.—Howard gives in detail the clinical history of a soldier in whom operation disclosed a ruptured spleen, there being no history of traumatism. The patient had been drinking immoderately for 2 weeks. There had been some cramp-like pain in the left side for a week. The patient's condition did not allow of removal of the spleen and death followed in 14 hours after the operation. Malarial and typhoid infection were excluded as causes of rupture, and while there may have been a trauma, considering the patient's condition, the absence of such history points to spontaneous rupture. [A.G.E.]

Deutsche medicinische Wochenschrift.

April 4, 1901. [27 Jahrg. No. 14.]

Max v. Pettenkofer, F. ERISMANN.

1. The Proportion of Iron in Chalybeate Waters. C. BINZ.
2. Galvano Caustic Occlusion of Vessels in the Nose as a Preliminary to Intranasal Operation. OSTMANN.
3. Remarks on the Therapy of Lachrymal and Nasal Ailments. ALBRAND.
4. Acute Yellow Atrophy of the Liver: Recovery. ALBU.
5. The Treatment of Fresh Cases of Tropic Dysentery. R. RUGE.
6. The Chemistry of Elastic-Staining and its Application in Sputum Preparations. MICHAELIS.
7. Biologic Reaction upon Albumin in Blood and Urine. ZUELZER.
8. The Detection of Minute Traces of Albumin. PRAUM.

1.—Binz takes up the subject of the iron mineral waters, and presents a number of quantitative analyses to show that after standing for some time the original ferrocyanide contained in the water is precipitated on the sides of the bottles as ferrous oxid, thus causing the water to lose its former medicinal value. [H.H.C.]

2.—Ostermann recommends the application of the galvano-cautery as an introductory step to intranasal operations in order to prevent the excessive hemorrhage likely to occur by the use of the more usual methods. [H.H.C.]

3.—Albrand discusses various prophylactic methods for the prevention of stenosis of the nasolachrymal duct, and advises teaching the patient himself or some relative how to use the sound, thus saving the patient time and money, or the application of a permanent sound—preferably that devised by Vulpius, which may be left in situ for months or even years. [H.H.C.]

4.—Albu reports the cure of a case of acute yellow atrophy of the liver in a man of 36. The case is all the more remarkable in that there was no history nor were there any of the objective signs of syphilis present. [H.H.C.]

5.—From his own experience in dealing with acute cases of tropic dysentery, Ruge finds that the old treatment with ipecac (he gives the infusion, 4.0-100.0, 80 cc., t. i. d.) is preferable to that recommended by Plehn (1898), viz.: small, repeated doses of calomel. [H.H.C.]

6.—After discussing the chemistry of Weigert's method for staining elastic fibers, Michaelis describes his method of applying this technic to sputum in cases of suspected tubercular lesion. A thin spread is made upon a slide, dried, and then placed for ½ hour in a jar containing Weigert's solution. The specimen is then washed in water and treated with 3% acid (HCl) alcohol until colorless, after which it is again dried and finally covered with a thin layer of cedar oil (no cover glass). Examination under a low power shows the elastic fibers stained a dark violet. [H.H.C.]

8.—In order to detect faint traces of albumin in nephritic urine the more readily, Praum adopts the following method: A few cc. of the urine is filtered into a test tube and a few drops of the reagent (sulfosalicylic acid in concentrated solution) added. The whole is then carefully mixed and after some time a few more cc. of the filtered urine is allowed to trickle slowly down the side of the tube. The result is a layer of clear control urine above the faintly opaque test urine, forming a contrast capable of revealing extremely minute quantities of albumin. [H.H.C.]

Wiener klinische Wochenschrift.

March 21, 1901. [14 Jahrg. No. 12.]

1. Poisoning with the Fungus *Agaricus torminosus*. HUGO GOLDMAN.
2. Joint Affections in Scarlet Fever. EDMUND HOMA.
3. Primitive Organs of Vision. THEODOR BEER.

1.—Goldman has observed 11 cases of poisoning with the toadstool *Agaricus torminosus*, 3 of which terminated fatally. The symptoms are primarily those of gastrointestinal irritation,

resemble cholera nostras, and set in 4 or 5 hours after the ingestion of the toadstools. The urine is diminished, and contains albumin and indican; eventually there is anuria. The pupils are dilated. The pulse is not accelerated, except in cases that are going to terminate fatally. The respiration is at first increased; later it becomes irregular and superficial. The temperature does not rise above normal. Delirium, trismus, convulsive twitchings, and finally coma, ensue in fatal cases. The author employed tannic acid in the treatment, washing out the stomach with it, and injecting it into the rectum. Stimulants were also employed. Atropin proved of no value. In order to prevent intoxication by toadstools, the author would have the market police instructed in the recognition of the different kinds of mushrooms and toadstools, and would have the pupils in the public schools taught, by means of charts and blackboard drawings, how to distinguish the harmless from the harmful varieties. [D.R.]

2.—Inflammation of the joints—so-called rheumatoid affections are not rare in scarlet fever. Among 506 cases of this disease 14 (2.8%) presented such joint troubles. Other complications occurred in the following proportions: Nephritis in 196 (38.7%), otitis media 115 (22.7%), bronchitis in 59 (11.7%), pneumonia in 21 (4.13%), pleurisy in 6 (1.2%), uremia in 2 (.39%), parotitis, peritonitis and edema of the lungs each in 1 case (.2%). The joint affection appeared in the first week 5 times; at the beginning of the second week once; at the end of the second week 4 times; in the third week 3 times; in the fourth week once. Swelling of the joints was not always present. Relapses are not uncommon. The wrists were involved 8 times, the elbows 7 times, the kneejoints 5 times, the anklejoints 4 times, and the shoulder and hipjoints each once. Several joints were usually attacked at the same time. In 1 of the 14 cases suppuration took place. The treatment consisted in rest for the joints, the application of wet compresses, and in 4 instances the use of sodium salicylate. All of the 14 cases were of the severe or moderately severe type of scarlet fever. Sodium salicylate did not seem to have any special influence. [D.R.]

1. The Protozoon of Cancer. HARVEY R. GAYLORD.
2. Thoracic Aneurysm. Carcinoma of Superior Maxilla. Cholelithiasis and Suppurative Cholecystitis. Inguinal Hernia of Bladder; Cecum. BERN B. GALLAUDET.
3. The Carbohydrates of the Urine in Diabetes Insipidus. DAVID L. EDSALL.
4. Conclusions Based upon 330 Outbreaks of Infectious Diseases Spread through the Milk-supply. GEORGE M. KOBER.
5. Laryngeal Hemorrhage from an Apparently Normal Larynx. GEORGE M. WOOD.
6. Blastomycetic Dermatitis of the Gluteal Region. FREDERICK G. HARRIS.
7. Subinvolution of the Uterus; 3 Suggestive Cases. L. W. ATLEE.

1.—See editorial, April 20, page 100.

2.—Gallaudet reports: (1) An aneurysm of the thoracic portion of the left common carotid artery, in which at 2 sittings with an interval of 5 days, the artery was ligated above and below the aneurysm, the sac opened, and the clot extracted. Extremely dense adhesions were encountered, the venous oozing was marked, and while extracting the clot a sudden gush of blood occurred from within the sac. This was immediately controlled by clamping the jugular, but the patient died quickly; (2) a carcinoma of the superior maxilla that was removed after preliminary ligating of the external carotid artery, the inserting of a tracheotomy tube through the cricothyroid membrane, and packing the pharynx with a sponge. The patient made a good recovery, and at the time of the report recurrence had not occurred; (3) a case of cholelithiasis and suppurative cholangitis in which operation was performed with complete satisfaction; (4) a case of right inguinal hernia of the bladder; (5) a case of hernia of the cecum. [A.O.J.K.]

3.—Edsall, referring to previous investigations regarding the total urinary carbohydrates (both the fermentable and

the unfermentable) in health and disease, details some personal investigations relative to the carbohydrates of the urine in diabetes insipidus. His researches seemed to indicate the improbability of any marked increase in the urinary carbohydrates in diabetes insipidus. It is believed, however, that some cases of diabetes insipidus may show an increased excretion of urinary carbohydrates; this is to be attributed to the increased diuresis and possibly also to the diet. There seems, however, to be no relation between diabetes insipidus and diabetes mellitus, at least as regards carbohydrate metabolism. It is considered extremely probable that the amount of carbohydrates in the normal urine depends largely upon the diet, and that these carbohydrates are in large part at least derived from the food rather than formed in the body, as has been suggested. There follow some remarks upon the benzoylchlorid method of the estimation of the urinary carbohydrates. [A.O.J.K.]

4.—Kober, in his conclusions based upon 330 outbreaks of infectious diseases spread through the milk-supply, refers to the various circumstances under which milk may be the source of disease, and states that of the 195 epidemics of typhoid fever that he has tabulated there is evidence in 148 of the disease having prevailed at the farm or dairy; of the 99 epidemics of scarlet fever the disease prevailed in 68 instances either at the dairy or milk-farm; and of the 36 outbreaks of diphtheria there is evidence that the disease prevailed at the dairy or farm in 13 instances. He urges stricter supervision of the milk-supply, and while he believes that good results follow legislative enactments, he believes that the best results are to be attained by education of the public. [A.O.J.K.]

5.—Wood reports a case of laryngeal hemorrhage from an apparently normal larynx, occurring in a man of 36, and gives brief notes of 6 similar cases that he has collected from the literature. [A.O.J.K.]

6.—Harris reports a case of blastomycetic dermatitis of the gluteal region, occurring in a woman of 78. Excision of the affected area was followed by satisfactory recovery and no evidence of recurrence. [A.O.J.K.]

7.—Atlee reviews the opinions of various writers of the causation and treatment of subinvolution of the uterus, and cites the histories of 3 suggestive cases from his own experience. The patients were relieved of their diseased condition by daily catharsis by magnesium sulfate, douches of water at a temperature of 110° F., twice daily, Benjean's one-grain pills of ergotin 3 times daily, rest in bed for a time, and wholesome food. [A.O.J.K.]

The American Gynecological and Obstetrical Journal.

March, 1901. [Vol. XVIII, No. 3.]

1. Pus in the Peritoneal Cavity. ROBERT T. MORRIS.
2. The Complications of Gonorrhea in Women and Their Prophylactic Treatment. JOSEPH TABER JOHNSON.
3. Ovarian Organotherapy in Gynecology. WILMER KRUSEN.
4. Pregnancy in Uterus Bicornis. GEORGE H. NOBLE.
5. The Operative Treatment of Cancer of the Uterus. E. E. MONTGOMERY.
6. Anne Murray: The First Trained Nurse. ELY VAN DE WARKER.

1.—In dealing with pus in the peritoneal cavity, Morris believes the best results will be obtained if we operate rapidly, avoid the use of large incisions, of gauze packing, of iodiform, and of extensive handling of the bowel. After making an elaborate study of the subject, he presumes there will be a small proportion of cases in which drainage will be a necessity, hemorrhage cases for instance; but most of the cases that are drained today are drained because the surgeon feels that he ought to assume a responsibility that really belongs to the leukocytes, and for which they are well equipped if the surgeon does not interfere with their production and their work. [F.C.H.]

2.—Johnsen discusses the complications of gonorrhea in women, under the following heads: (1) The importance of these complications; (2) their frequency; (3) their nature and variety; (4) so-called "latent gonorrhea"; (5) their importance from an obstetric and infantile standpoint; (6) treatment. Under

the last heading he offers no new suggestions. The physician should be certain that his patients are absolutely cured beyond the danger of a relapse before they are dismissed from further observation, control and treatment. Female patients should be so vigorously treated as to prevent, if possible, the extension of the disease beyond the vagina and the external parts. The question of "latent, chronic or residual gonorrhoea," and its possible disastrous consequences should be more constantly in mind when we are treating these cases, and our management should be so radical, thorough and complete as to prevent the occurrence of pelvic infection and adnexal complications. [F.C.H.]

3.—After 3 years' exhaustive study of organotherapy in gynecology, Krusen thinks that notwithstanding the many brilliant results referred to in his paper, experience leads to the following conclusions, based upon the use of the American product upon American women: (1) The employment of ovarian extract is practically harmless, as no untoward effects beyond slight nausea have been noted even when full doses have been administered; (2) in the treatment of amenorrhoea and dysmenorrhoea no good results were secured (although in some cases of dysmenorrhoea of obesity remarkable results have been obtained by the use of the thyroid extract); (3) the best results were seen in the second class of cases, for the relief of symptoms of artificial menopause, when in a few instances the congestive and nervous symptoms were apparently ameliorated; (4) no appreciable result was noticed in the use of ovarin in the natural menopause; (5) no definite or exact reliance can be placed on the drug, as it often proved absolutely valueless when most positively indicated; (6) it is extremely problematic whether, in those cases in which relief was noted, the effect was due to mental suggestion rather than to any physiologic action of the drug, since the neurotic type of individual demanding this treatment will often be relieved by any simple remedy; (7) in those instances in which effects were noted increase in dosage seemed to have little influence in maintaining the effect or preventing the patient from becoming accustomed to its use; (8) in conclusion, the theory which suggests the use of this extract seems to be at fault, and the administration of ovarin or ovarian extract is based upon a wrong assumption as to the function of the ovary. In organotherapy the best results have been obtained from the use of the thyroid and adrenal glands, and the ovary in function is in no sense analogous to these organs. Its principal function is ovulation, and if any peculiar product is coincidentally manufactured the isolation of this product has not yet been accomplished. [F.C.H.]

4.—In this case of pregnancy in a bicornate uterus, Noble did not realize that he was dealing with an abnormal condition, until he attempted to expel the placenta by Crède's method. The fetus occupied the right horn of the uterus. The left horn and part of the left fallopian tube contained the placenta. Owing to the development of the placenta partly in the tube, where it was adherent, it was necessary to insert the hand in order to remove it. In addition to the report of this case, Noble enters into an exhaustive study of pregnancies in uterus bicornis, giving statistics, the dangers, differential diagnosis and the treatment. [F.C.H.]

5.—In discussing the operative treatment of cancer of the uterus, Montgomery confines himself to the radical treatment. He prefers vaginal hysterectomy when the disease is plainly confined to the cervix or body, the uterus is not unduly large and freely movable, and the vagina is sufficiently spacious to permit of ready access. The abdominal operation should be elected whenever the favorable conditions which are enumerated as requisite for vaginal hysterectomy do not exist. In extension of the disease beyond the confines of the uterus, the destruction of the vaginal portion of the cervix, in involvement of the vagina, partial infiltration of one or both broad ligaments, when the uterus is large, and the disease is complicated by the presence of uterine fibroids, ovarian growths, or the uterus is fixed by previous inflammatory attacks. It should also be selected in the single or nulliparous woman. He does not advocate the removal of the lymphatic glands as a routine practice, as oftentimes in hopeful cases they are not sufficiently involved to justify the additional dissection and risk. In the considera-

tion of the treatment it should be appreciated: (1) that an operation to afford hope of escape from relapse should be early; (2) the vaginal operation should have the preference whenever the conditions will permit of its performance; (3) every precaution should be exercised to operate in healthy tissue and avoid the possibility of reimplantation; (4) the prognosis is much less favorable in women under 36, quite favorable in women over 50, if an operation is done early. [F.C.H.]

1.—Fenger reports 30 cases of conservative operation for renal retention performed by several surgeons. There were 3 deaths, none of them being due to the operation, *per se*. These cases are considered as firmly establishing the justifiability of the object aimed at, namely, the salvation of the kidney otherwise doomed to removal. They also indicate the general direction in which the different methods of operating must be developed for further perfection. For obstruction located in the kidney causing partial cystonephrosis the operation is bisection of the kidney and division of the partition walls between the sacs and the pelvis. One successful case is reported. Of the 30 operations collected 26 were for obstruction located at the exit of the ureter from the renal pelvis. Various operations—transpelvic and extrapelvic—were employed. Of the transpelvic 9 cases are recorded with 2 deaths, 1 from ileus and 1 from uremia in bilateral disease. Of extrapelvic operations 3 were employed: 1. Resection of ureter and reimplantation in renal pelvis, 6 cases with 1 death from iodoform poisoning. This operation was abandoned for nephrectomy in 2 cases. 2. Operation on ureter and pelvis at the seat of the valve or stricture, 11 cases with no deaths. 3. Pyeloplasty, 1 successful case. For obstruction located in the ureter ureterolysis was successful in 1 case and plastic operation on the ureter 1 case. The latter case demonstrated that an operation for reopening a closed ureter may be successful after an unsuccessful attempt has been made, thus justifying even repeated attempts to reestablish the potency of the ureter and thereby save the kidney from removal. [A.G.E.]

2.—Robinson's article is a detailed record of abdominal inspection in 300 autopsies on male adults and 118 on female adults. In it are recorded observations of the appendix as regards its length, shape, position, meso-appendix in relation to the psoas and other muscles, with especial attention to peri-appendicular adhesions. The average length of the appendix was 3 inches. Two general positions of the appendix are considered: (1) The colonic (benign area of peritonitis); (2) the potential enteronic (dangerous area of peritonitis). The appendix was in contact with the psoas muscle in 52% of the males and 32% of the females. This is important in connection with the effect of trauma by that muscle upon an appendix in a partially devitalized condition. In relation to the psoas muscle 5 positions of the appendix are designated and their frequency given. 1. The pelvic position (females 48%, males 37%). 2. The appendix resting on the psoas (males 46%, females 20%). 3. The retrocecal position (females 35%, males 20%). 4. To the right of the psoas (females 28%, males 18%). 5. The potential position (males 23%, females 20%). In 30 males the appendix possessed peritoneal adhesions in 62% and

in 118 females in 50%. The periappendicular adhesions are in the majority of cases produced by the trauma of the psoas and other muscles. The conclusion is considered inevitable that (psoas) muscular trauma is a vital factor in the etiology of appendicitis. In one of the 418 cases, a female, the appendix was congenitally absent. Some of Robinson's conclusions are: 1. The dangerous appendix is the one in a spiral or kinked shape, within range of traumatic action of the psoas muscle. The size and length of the appendix have no special relation to the frequency of appendicitis. 2. The ratio of appendicitis in man and woman is about 3 to 1, chiefly owing to the fact that man's appendix is more exposed to psoas muscular trauma than that of woman. 3. Almost all postmortem and clinical evidence points to the appendix as the organ which is the most dangerous and treacherous of all abdominal viscera. 4. The frequent peri-appendicular adhesions are not appendicitis but peritonitis. They are important steps toward appendicitis. 5. The appendix varies more in position than any other abdominal viscus. 6. Trauma of the psoas muscle produces appendicitis. [A.G.E.]

3.—A study of 136 suspected cases of renal or ureteral calculi led to the detection of 36 cases, 19 ureteral and 17 renal. In only one of the 100 cases was the negative diagnosis improved, the error resulting from a misplaced plate and defective reading of the negative. From these 136 cases the author draws the following conclusions: (1) that both the negative and positive diagnosis by the Röntgen method are accurate and valuable; (2) ureteral calculus is much more common than has been supposed, or about 50% of all cases of calculus; (3) it is impossible to arrive at as accurate a diagnosis of calculus by other methods; (4) this method is comprehensive, and aids operative intervention by localizing all calculi and excluding calculi from the other kidney; (5) non-operative treatment, without a negative diagnosis by this method, is irrational and dangerous in cases that are at all suspicious; (6) this method is precise, because its results are mechanically produced, but accuracy in its employment and care in reading the results are necessary to the avoidance of error; (7) the data obtained by this method make non-operative, conservative treatment rational in cases of small calculi low down in the ureter that can be expected to pass; (8) the negative diagnosis does not preclude exploratory nephrotomy, but does make unnecessary the actual incision into the kidney in search for calculi; (9) the dilation of the ureter with bougies, as has been practical in the female, may be employed in the male by utilizing a suprapubic cystotomy wound to guide the instruments from the urethra into the ureters.

4.—McArthur writes of those cases of intestinal obstruction which are dependent upon embolism or thrombosis of the arterial or venous circulation of the affected bowel. Embolic ileus due to cardiac vegetations, etc., occasionally occurs. Thrombosis is almost always due to an infective phlebitis having its origin in the intestinal mucosa. When the arterial supply is cut off there is not time for the throwing out of lymph and the bowel has a smooth, steel-blue, black, shiny appearance. Venous thrombosis gives a dark, reddish-black bowel with roughened peritoneum. The 4 most constant symptoms are: (1) Blood seen either in the washings from the bowel, in bowel movements, and in the vomitus, unaccompanied by the tumor of intussusception; (2) colicky-like pains, associated with pains in back and lumbar region; (3) early collapse if the embolism has been sudden or extensive; (4) cardiac disturbance, arrhythmia, great frequency, albuminuria. The notes of a case which had been diagnosed as rheumatic pains in the back and abdominal wall are given. Operation afterward, the patient expiring on the table, revealed an occlusion of the superior mesenteric artery. [A.G.E.]

5.—The symptoms, diagnosis, and treatment of mechanical intestinal obstruction are considered. Opium should never be administered. The forming of an artificial anus is rarely indicated in acute obstruction. In obstruction from neoplasms it is often a valuable preliminary operation to conserve the strength of the patient before undergoing an enterectomy. [A.G.E.]

6.—Ochsner states that his experience with ileus due to

neoplasms has been unsatisfactory. He has had a mortality of nearly 50% and of the cases which lived there were but 2 whose recovery he has not regretted. If the abdomen is greatly distended with gas and fluid, it is best as a preliminary to operation to spray the throat with a 2% solution of cocaine and then perform gastric lavage. By repeating this 2 or 3 times the distention may be reduced to a marked extent. If the intestines are greatly distended when the abdomen is opened a circular purse-string suture of silk should be applied to the convex surface of the intestine, that portion emptied by forcing the contents in either direction, an incision made within the suture, and a long half-inch glass tube inserted. This portion of the operation is usually done too hurriedly and the drainage is not satisfactory. If the growth is in the intestine primarily and no lymphatic glands are involved the intestine should be resected at least 3 inches above and below the tumor. If the lymphatic glands are involved it is best simply to make a short circuit by lateral anastomosis. In cases of resection of the small intestine, the Murphy button or the needle and thread may be used with equally favorable results. If the obstruction is below the ascending colon it is always best to make a temporary colostomy and to postpone the radical operation, unless the patient is in a favorable condition. [A.G.E.]

7.—Beck reports a case of fissure of the head of the radius in a girl of 24. The region of the elbow joint showed considerable swelling and tenderness equally distributed. A skiagraph revealed the presence of the above named lesion. Therapy consisted in the application of a plaster-of-paris dressing in rectangular flexion, the forearm being kept in semipronation. The function of the arm did not become perfect until 3 months after the injury, owing to stiffness. A study of this case shows that wherever skiagraphic observation shows no tendency to displacement, it will be advisable to begin motion after 10 days, in fissure as well as in fracture of the radial head. [A.G.E.]

8.—Horsley reports what he believes to be the first operation for excision of the sympathetic cervical ganglia for exophthalmic goiter. The patient was a woman, aged 26. Chloroform was used. The middle and superior ganglia of the right side were removed. No attempt was made to remove the ganglia of the left side, though this had been the intention, because of the condition of the patient. The pulse varied between 170 and 200 during the operation. Four months after the patient's pulse was 90, and the throbbing and palpitation has not returned since the operation. The exophthalmos has markedly diminished, though there is but little decrease in size of the thyroid gland. The case is recorded as one greatly improved. If favorable progress does not continue, extirpation of the left cervical sympathetic ganglia will be advised. [A.G.E.]

1. Veratrum Viride; Its Undeserved Neglect. E. W. SAUNDERS. (St. Louis Medical Review, March 23, 1901.)
2. To Cut or Crush In Stone of the Urinary Bladder. STUART MCGUIRE. (Charlotte Medical Journal, March, 1901.)
3. Have we a New Treatment for General Septic Infection? VAN TILBURG-HOFMAN. (Charlotte Medical Journal, March, 1901.)
4. The Early Recognition of Malignant Growths. EDGAR A. VANDER VEER. (Albany Medical Annals, April, 1901.)
5. Exstrophy of the Bladder. F. GREGORY CONNELL. (Read before the American Medical Association, June, 1900. Awarded Senn Medal.)

1.—In speaking of *veratrum viride* as a much-neglected drug, Saunders attributes this neglect principally to the fact that European writers are silent upon the subject. In speaking of its physiologic action, he states that the alkaloids jervin, by a depressing action of the heart muscle and the vasomotor centers, and pseudojervin, by stimulating the pneumogastric, produce a marked diminution of the pulse-rate. Ordinarily this is the only effect noticed when a physiologic dose is administered. In larger doses the drug induces vomiting and rarely purging, chiefly by its influence in the nervous center, but also by its local irritating action. It acts as a powerful depressant to the anterior motor-cells of the spinal cord. It has no effect on the

muscles, cerebrum or nerves. The respiratory center is also depressed by large doses. It also reduces the temperature 1 to 3 degrees. To this must be added the fact that, although a very powerful drug, no case of poisoning has ever occurred from its administration. It has no detrimental effect upon the blood, causes no change of oxyhemoglobin into methemoglobin, and there is no effect upon the aneboid movements of the white blood corpuscles, all of which is in direct opposition to the action of the coal-tar products. He also finds that it is preferable to the coal-tar products in the beginning of acute infectious diseases, such as scarlet fever, influenza, meningitis, etc. In the treatment of pneumonia, he cites a number of cases in which he has used *veratrum viride* with great success, and gives the beneficial action of the drug in this particular disease as follows: (1) It diminishes the pulse-rate; (2) it lessens arterial pressure; (3) it diminishes the number and depth of the respirations; (4) it reduces the temperature 1 to 3 degrees; (5) the patient has a feeling of well-being; (6) The urine is increased in quantity; (7) it quiets nervous excitement; (8) hepatization in the lung is precocious and partial. Doses of 2 to 3 minims are given every hour until the pulse becomes normal, then the intervals should be increased or smaller doses given. If consolidation has already taken place, *veratrum viride* is of no account, caffeine, camphor, strychnin and digitalis being then indicated. He has used the drug with great success in spasmodic croup—both catarrhal and membranous—appendicitis, peritonitis, endocarditis and pericarditis. [H. U. C.]

2.—McGuire, in his paper on the advisability of lithotomy or lithotripsy, states that while he does not condemn lithotripsy, he believes that lithotomy should be the operation most frequently employed, and lithotripsy reserved for a few carefully elected cases. He considers that lithotomy has the greatest range of application, but is contraindicated in the following conditions: (1) When the stone is large and cannot be crushed by instruments capable of being used through the urethra; (2) when the stone is large and cannot be grasped by reasonable separation of the jaws of the lithotrite; (3) when the stone is brittle and the resulting fragments sharp and irregular; (4) when the stone is fixed and encysted; (5) when the stone has a foreign body as a nucleus, which cannot be crushed and removed; (6) when the prostate is enlarged, or the bladder contracted, making it difficult to seize the stone; (7) when there is a tight or impassible urethral stricture requiring a long operation to relieve; (8) when there is ankylosis of the hipjoint in a position embarrassing the movements of the lithotrite; (9) when the general condition of the patient is such as to make shock dangerous and rapid work necessary. [H. U. C.]

3.—Van Telburg-Hofman, in his paper on the treatment of general septic infection, includes toxemia (sapremia), septemia and pyemia under one head and cites a number of cases in which he used a hypodermic of oleum terebinthinae in the dose of 15 minims with remarkably good results. He injects the turpentine in the subcutaneous tissues of the thigh or upper arm. It at once causes an abscess to form, which he opens in about a week, drains and dresses antiseptically. [H. U. C.]

4.—Vander Veer gives the following reasons as a plea for the early recognition of malignant growths: (1) The patient not having been debilitated by a long and tedious strain upon the system, can the better withstand the risk of shock and hemorrhage of an operation; (2) the greater probability of a complete removal of the malignant growth, by an early operation, and so the less liability of its return; (3) the growth being small the incision will correspond, and so the avoidance of unsightly scars. He finds that the surest way to arrive at a positive diagnosis is to obtain a thorough history of the patient, the history of malignant growths in the family, and then to watch carefully the growth itself. He believes in regarding all growths as malignant until positively proven to be otherwise. [H. U. C.]

5.—In his monograph on exstrophy of the bladder, Connel, after dealing with the histology and embryology of the organ, states that the most common anomalies of the bladder are: (1) Exstrophy of the bladder; (2) absence of the bladder (3) the opposite condition, that of multiple or supernumerary bladder; (4) imperforate bladder, or atresia of urethra; (5) the posterior wall of the bladder may be the site of the malfor-

mation, the bladder thus communicating with the pelvic cavity, vagina or rectum. The condition of exstrophy of the bladder includes, as a rule, all the cases of gastroschisis in which the fissure is in the lower part of the abdomen. It is seen in different varieties or degrees of the same variety: (1) There may occur no fissure in either abdominal or bladder wall, but an absence of symphysis, with hernia of the bladder.—Mayo. (2) The bladder wall is perfect and protrudes through abdominal fissure or the umbilicus.—Vrolik. To this condition the term "ectopia vesicae" has been applied. (3) The ordinary form is fissure in both abdominal walls. (4) Anterior and posterior walls of the bladder may both contain a fissure, and thus occur in 2 halves, separated by an opening of the intestinal tract. The treatment of exstrophy of the bladder may be divided into palliative and radical: A—PALLIATIVE. I.—Apparatus. II.—Flap. (1) Of skin: *a*, epidermis in (reversed); *b*, epidermis out. (2) Of mucous membrane: *a*, remaining bladder wall of patient; *b*, intestinal wall of patient; *c*, bladder wall of lower animals. III.—Suture of edges of fissure: (1) By direct suture. (2) Preceded by preliminary measures. IV.—Miscellaneous: (1) Dilatation of ureters. (2) Plaster bandage. (3) Catheters in ureters. (4) Fistula in perineum. (5) Ureters inserted into the urethra. (6) Nephrectomy on one side and lumbar ureteral fistula on the other. B—RADICAL. I.—Axial implantation. (1) By sutures. (2) By apparatus. II.—Vesicorectal anastomosis. III.—Implantation of trigonum vesicae. IV.—Implantation in a manner imitating normal insertion into the bladder; or an attempt to make a valve. V.—Miscellaneous. (1) Vesicovaginal fistula, with col-pocleisis. (2) Artificial anus; ureters inserted into rectum. (3) Artificial bladder; *a*, opening into urethra; *b*, opening into intestinal tract. [H. U. C.]

Sundry German.

1. Influence of mechanical irritation of various parts of the body on contractions of the heart. HEITLER (Centrab. für Innere Medizin, March 16, 1901).
2. Concerning a But Little-known Tract on the Periphery of the Anterolateral Zone of the Cervical Spinal Cord. BECHTEREW (Neurologisches Centralb., March 1, 1901).
3. A Further Contribution to Intermittent Claudication. GOLDFLAM (Neurologisches Centralb., March 1, 1901).
4. Dysphagia Amyotactica. ROSSOLIMO (Neurologisches Centralb., March 16, 1901).

1.—Heitler finds that the heart contractions can be reflexly influenced by mechanic irritation of various parts of the body. Particularly efficient is irritation of the precordial and hepatic region; but stimulation of the skin, the bones, the muscles, the mucous membranes, the arteries, and even flexion and extension of the limbs may bring about a change in the pulse. The reflex obtained by stimulation of the precordial region is principally due to irritation of the sternum. Percussion of the sternal end of the clavicle produces an active reflex, while percussion of the acromial end does not do so. The change in the pulse produced by irritation of the hepatic region is due to irritation of the liver. The reflex may be excited in all parts of the hepatic region, but especially over the eleventh and twelfth ribs. Repeated stimulation of a part causes a lessening of the reflex excited at that part. The most marked effects are obtained by stimulation of the liver, the sternum, and the adjacent portions of the ribs. The reflex consists in a lessening of the heart dulness through cardiac contraction, and a strengthening of the pulse. [The thought suggested is that the stimulation indicated, like massage of the precordia, might be useful in acute heart failure. D. R.]

2.—A few remarks concerning the tract of fibers designated by Bechterew as the *olivary bundle* (or, more specifically, the *periolivary bundle*), running in the anterolateral portion of the cervical cord. No definite opinion as to its course is expressed, but Bechterew is inclined to consider it descending, and connected with the lower olive. Degeneration of this tract has, it seems, been observed by Meyer, Reinhold, Spiller and others. [D. R.]

3.—The symptoms of *intermittent claudication* are as follows: The patient, after walking a shorter or longer distance,

experiences pain or paresthesias in the lower limbs, especially in the calves or feet. These phenomena subside after rest, but return again on walking, so that at intervals the patient is compelled to stand still or to sit down. In such a case the arteries of the feet should at once be examined. Absence of pulsation in the dorsalis pedis and tibialis posterior explains the symptoms. In addition to the absence of pulsation, signs of disturbances in the circulation, such as venous distension, coldness, cyanosis, edema, ecchymosis, and sometimes thrombosis, are observed. The arteritis is usually symmetrical. Narrowing or occlusion of the dorsalis pedis is sufficient to produce intermittent claudication, but not to bring about gangrene. The symptoms may persist for years; but, as a rule, they become intensified, and may eventually lead to gangrene. Vasomotor disturbances play a prominent part, in addition to arteritis. Transitory pallor, especially of the toes, is frequently noticed. The vasomotor symptoms may be so pronounced as to suggest Raynaud's disease. Paresthesias of all kinds are almost a constant accompaniment of intermittent claudication. The cause of the endarteritis is not definitely known. There is no generalized arteriosclerosis, as a rule. The patients are usually under 50 years of age. In the author's 24 cases, 3 were between 25 and 30; 11 between 30 and 40; and 6 between 40 and 50; the others older. Diabetes does not play any prominent role, nor does gout. Goldflam's cases were all Hebrews; others have reported cases among Russian Poles and Russians; and Haga claims that the disease is common in Japan. Excess in tobacco seems to play a part. Importance must also be attributed to the neuropathic disposition. Regarding syphilis, the author found among his 24 cases only one that had had the disease. Alcoholism is also without importance. The author suggests the possibility of a congenital hypoplasia of the vascular system. The male sex is more frequently affected than the female. In addition to citing several cases of intermittent claudication, the author reports one resembling Raynaud's disease, in which there was arteritis, but no gangrene. The patient was a woman of 32, who, without apparent cause, developed intense pain in the right ring finger about the nail. There were slight bluish discoloration and extreme tenderness on the inner side of the dorsal surface of that finger, although the palmar surface was insensitive to pressure. The pain radiated from the nail, along the surface of the finger, and up the forearm and upper arm, even to the shoulder. The pain lasted 11 years, until the patient's death from heart disease. Examination of the arteries of the finger showed thickening of the intima. The changes in the nerves were very slight. There was some increase in the nuclei of the endoneurium. [The ease in some respects suggests erythromelalgia.] In some cases of intermittent claudication spontaneous pains, of a burning, stabbing, or boring character, arise, particularly in bed at night. The nerves as a rule are normal; when degenerative processes occur, they are usually secondary. The pains may be due to involvement of the vasa nervorum, although it is possible that endarteritic processes are of themselves capable of exciting pain, owing to involvement of the Pacinian corpuscles found in the vessel walls. Gangrene occurred in 7 out of 27 cases. The treatment is hygienic and dietetic, but does not seem to be very satisfactory. Iodids and antisiphilitic treatment appear to do no good. This is also true of sodium nitrate, nitroglycerin, etc. Warm baths are well borne; sometimes mustard foot-baths and cold applications are useful. Galvanic electricity and high tension currents produce transient improvement. D.R.]

4.—The term **dysphagia amyotactica** is applied to those disturbances of the act of deglutition which are not due to organic changes in the pharynx or esophagus, nor to spasm or paralysis of the esophagus and muscles concerned in swallowing. The condition consists in a disturbance in the rhythm of the function of the higher nerve-centers. A number of cases are cited in which the act of deglutition was inhibited or rendered difficult by psychic conditions. The first case was in a merchant, 42 years of age, who after a half-hearted attempt to commit suicide by choking, was seized with a feeling that he could not swallow solid food. Later he also had difficulty in swallowing liquid food, and lived in constant dread that he might not be able to swallow when he wished to do so. When

swallowing liquid substances a vehement spasm of the pharynx occurred. A touch upon the neck or the introduction of a spoon into the throat produced an intense anxiety and restlessness. There were no hysteric stigmata. Treatment proved unavailing. The second patient was a woman of 42 years, who was more or less nervous on account of a drunken husband. After hearing a minister preach in a very hoarse voice she became afraid that her voice might become hoarse, and soon after had difficulty in swallowing, which gradually became intensified. Case 3 is that of a man 39 years old, of neuropathic ancestry. There were no organic changes in the esophagus or stomach; no hysteric stigmata. On one occasion the food went down the wrong way, and from that time on he always had a sense of fear when swallowing food, either liquid or solid. Case 4 is that of a woman 58 years of age, whose mother, 2 brothers and husband were alcoholics. She had difficulty in swallowing, owing to a constant fear of swallowing the wrong way. There were some hysteric signs. The fifth patient was a woman 29 years of age, who had an alcoholic father and an alcoholic husband. On hearing news of the death of a friend she experienced a globus in the throat, and very soon after began to have fear of swallowing which interfered greatly with the deglutition of both liquid and solid food. Case 6 is that of a woman 38 years of age, who had several phobias, in addition to a disturbance of the act of deglutition. The seventh patient, a woman of 31, distrustful, irritable and depressed, developed pain in the pharynx after a not very agreeable romantic adventure. The pains in the throat interfered with swallowing. Case 8 is that of a man of 26, who had distress in the back of the neck during mastication and deglutition. This distress interfered with swallowing. He ate very little, and consumed chiefly liquid food. Objectively nothing abnormal could be discovered. The author does not think that the symptoms described by him are hysteric. The condition is not a special disease, but belongs in the group of disturbances of automatic and habitual movements and complicated reflexes. There are 3 possible types of dysphagia amyotactica: first, the motor; second, the sensory; and third, the psychic. [D.R.]

1.—Marinesco, of Bucharest, contributes an interesting illustrated article on the **gait of ataxia patients**. He concludes that the troubles of coordination of the movements observed in cases of locomotor ataxia are not to be confounded with the functional disorders produced by the paralysis of muscular and articular sensibility. This independence of locomotor ataxia and of sensory troubles is confirmed by the existence of cases of ataxia with perfect integrity of the different forms of sensibility. To explain the production of locomotor ataxia as the result of tabes necessitates the existence of a special faculty,

which the author calls *muscular consciousness*, by which an intimate relation of the muscles and the brain is established and movements are provoked without sight. This muscular consciousness must not be confused with the sensation which gives the idea of weight or resistance, etc., and which was called muscular sense by Charles Bell, and sensation of muscular activity by Gerdy. This last sensation is the result of muscular contraction, and depends upon articular as much as upon muscular sensibility. The muscular consciousness, however, appears to precede and determine the contraction. [C.S.D.]

2.—Chapot-Prevost of Rio de Janeiro reports a new case of *xiphopagia* in the persons of 2 brothers, Chinese, who are joined by a band extending from the xiphoid to the umbilicus. The children were born in Nankong, January 2, 1887, of a primipara, the labor being without difficulty. The first child offered with head presentation, the other with feet. There was but 1 umbilical cord and 1 placenta. The development of the twins has been normal, and they function independently. [C.S.D.]

3.—Vachide and Vurpas record their observations on an *anencephalic monster*, born at 6 months' term and which lived 30 hours. The principal phenomena noted consisted of lowered temperature (28° C. in the rectum); of Cheyne-Stokes respiration, tachycardia (138 pulsations per minute), cyanosis of the integuments, spasmodic contractions of the limbs, exaggeration of the tendinous reflexes and idiomuscular reaction. The general sensibility was retained, but there was no reaction to sound, light, taste or odor. An attack of Jacksonian epilepsy preceded death, which followed dyspeptic symptoms. [C.S.D.]

4.—Aehard obtained by lumbar puncture, fluid which gave cultures of a bacillus resembling *Bacillus coli* and presenting the peculiarity that milk cultures did not coagulate at even temperatures, but did so upon ebullition. He arrived at the opinion that *zona* is due to a specific infection. [C.S.D.]

5.—Dopter explains the pathogenesis of *peripheral uremic paralysis* by the production of Wallerian degeneration of the sciatic nerve as the result of contact with uremic blood-serum. [C.S.D.]

6.—Vineent describes under the name of "*Angina of Bacillus pusiformis*," an affection which presents diphtheroid characters when the bacillus is present alone and an ulceromembraneous form when the bacillus is associated with a delicate spirillum. The inoculation of *Bacillus pusiformis* into the subcutaneous tissues and muscles gives rise to abscesses. [C.S.D.]

7.—Bedart of Lille finds that the *secretion of milk* may be increased by the application of the static current to the nipples for 10 or 15 minutes every 24 hours. [C.S.D.]

8.—Stassano records his discovery of a flagellate infusorian *parasite in the lymphatic glands and blood of syphilitics*. The monad attaches itself to and destroys the blood corpuscles. It is not to be found except during the exanthematous stages and disappears where amelioration is spontaneous or due to treatment. [C.S.D.]

9.—Milan and Legros have recently had occasion to examine cerebrospinal fluid in a case of *nontraumatic tetanus*, and found that it maintained its usual limpidity and fluidity throughout the duration of the affection. At no time were they able to discover any microbes, either by aerobic or anaerobic cultures. Inoculation of guineapigs with the cerebrospinal fluid gave absolutely negative results. [C.S.D.]

10.—Balz, of Tokio, calls attention to the general wellbeing and capacity for endurance exhibited by the inhabitants of the central mountainous portions of Japan where meat, milk or fish are not available and the diet is in consequence exclusively vegetable. [C.S.D.]

11.—Winternitz has had great success in the treatment of *zona* by the application of compresses of 6 or 8 folds of absorbent gauze wet with absolute alcohol. The compress is covered with some impermeable material and this in turn with a layer of cotton, and the whole firmly bandaged in place. The dressing is renewed in 24 hours. The neuralgic pains ceased immediately or within a few days, and the vesicles disappeared without ulceration. [C.S.D.]

THE PUBLIC SERVICE

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine Hospital-Service, during the week ended May 11, 1901:

SMALLPOX—UNITED STATES AND INSULAR.

		Cases	Deaths
		am'g	Indians
Alaska:	Sitka.....Apr. 9.....	Prevalent	
California:	Los Angeles.....Apr. 20-27.....	5	
	Oakland.....Apr. 6-27.....	2	
	San Francisco.....Apr. 20-27.....	2	
Florida:	Jacksonville.....Apr. 20-27.....	21	1
Illinois:	Chicago.....Apr. 27-May 5.....	5	
	Freeport.....Apr. 27-May 4.....	2	
Indiana:	Evansville.....Apr. 27-May 4.....	2	
	Michigan City.....Apr. 23-May 6.....	5	
Iowa:	Clinton.....Apr. 27-May 4.....	1	
	Ottumwa.....Mar. 30-Apr. 27.....	5	
Kansas:	Wichita.....Apr. 20-May 4.....	71	
Louisiana:	Bossier.....Apr. 1-30.....	1	
	Caddo.....Apr. 1-30.....	7	
	New Orleans.....Apr. 20-May 4.....	23	
	Sabine.....Apr. 1-30.....	1	
Maryland:	Cambridge.....Apr. 1-30.....	5	
Massachusetts:	Fitchburg.....Apr. 20-27.....	2	
	Holyoke.....Apr. 27-May 4.....	1

	Karachi.....Mar. 24-Apr. 7.....	429	383
Japan:	Wakayama Kon.....Apr. 12.....	1	1

Changes in the U. S. Marine-Hospital Service for 7 days ended May 9, 1901:

- AUSTIN, H. W., surgeon, to proceed to Washington, D. C., for special temporary duty—May 9, 1901.
- WOODWARD, R. M., surgeon, granted leave of absence for 10 days from May 7—May 6, 1901.
- STIMPSON, W. G., passed assistant surgeon, to proceed to Coalgate, I. T., for special temporary duty—May 9, 1901.
- CLARK, TALIAFERRO, assistant surgeon, granted 30 days extension of leave of absence, on account of sickness, from April 21—May 6, 1901.
- ROBINSON, D. E., assistant surgeon, to proceed to Port Townsend (Washington) quarantine station, and report to the Medical Officer in Command for special temporary duty—May 8, 1901.
- MOORE, DUNLOP, assistant surgeon, that portion of Bureau order of April 18, 1901, directing Assistant Surgeon Moore to proceed to San Francisco, Cal., revoked—May 6, 1901.
- RYDER, L. W., hospital steward, granted leave of absence for 15 days from May 6—May 7, 1901.

Changes in the Medical Corps of the U. S. Navy, for the week ended May 11, 1901:

- DERR, E. Z., medical director, detached from the Naval Academy and ordered home and to wait orders.
- WIEBER, F. W. F., surgeon, detached from the San Juan Naval Station and ordered to the Naval Academy as relief of Medical Director E. Z. Derr.
- LOWNDES, C. H. T., surgeon, detached from the Lancaster, May 11, and ordered to the San Juan Naval Station, via the Mayflower, as relief of Surgeon F. W. F. Wieber.
- BOBERT, E. S., passed assistant surgeon, ordered to the Laneaster, May 11, as relief of Surgeon C. H. T. Lowndes.
- CURTIS, L. W., surgeon, detached from the Vermont, May 11, ordered home and directed to hold himself in readiness for sea duty.
- PICKRELL, G., surgeon, ordered to the Vermont, May 11, as relief of Surgeon L. W. Curtis.
- TAYLOR, J. S., assistant surgeon, detached from the Manila and ordered to the naval hospital, Yokohama, Japan, for duty, as relief of Assistant Surgeon F. L. Benton, detached from the naval hospital, Yokohama, Japan, and ordered to duty on the Asiatic Station.
- BENTON, F. L., assistant surgeon, detached from the Naval Hospital, Yokohama, and ordered to duty on the Asiatic Station.
- STOKES, C. F., surgeon, detached from the Asiatic Station and ordered home, via mail steamer.

Changes in the Medical Corps of the U. S. Army for the week ended May 11, 1901:

- REAGLES, J., acting assistant surgeon, will proceed from Fort Stevens to Portland, Oreg., on business in connection with the furnishing of the hospital at that post. Upon completion of this duty Acting Assistant Surgeon Reagles will return to his proper station.
- HUTTON, First Lieutenant PAUL C., assistant surgeon, is granted leave for 15 days.
- AMES, Captain ROGER P., assistant surgeon, recently appointed, is relieved from duty in the department of Cuba, to take effect when his services can be spared by the commanding general of that department, and will then proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
- GIRARD, Lieutenant Colonel JOSEPH B., D. S. G., is granted leave for 7 days, from about May 10.
- EBER, Captain ALBERT H., assistant surgeon, leave granted April 11 is extended 14 days.
- BLOCK, Captain WILLIAM H., assistant surgeon, recently appointed, is relieved from duty in the department of Cuba, to take effect when his services can be spared by the commanding general of that department, and will then proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
- DOUGHERTY, JAMES C., contract surgeon, is relieved from duty on the transport McPherson, now near Matanzas, Cuba, and will proceed to New York City and report to the medical superintendent of the Army transport service for assignment to duty.
- MADARA, Captain JAMES W., assistant surgeon, will proceed to Fort McDowell for temporary duty, awaiting transportation to the Philippine Islands.
- CHALMERS, Major THOMAS C., surgeon, will proceed to the Presidio, where he will report to the commanding officer, 28th infantry, U. S. volunteers, for temporary duty until muster out of that regiment. When his services are no longer required with that regiment, Major Chalmers is authorized to take advantage of the leave granted him.
- BOWEN, Major WILLIAM, surgeon, is assigned to temporary duty with troops on the Army transport Lawton, to sail for the Philippine Islands about May 12. Upon arrival of the transport at Manila, Major Bowen will report for assignment to duty.
- SPARRERBERGER, Captain FREDERICK H., assistant surgeon, is granted leave for 1 month.
- WHEATE, Captain JUSTUS M., assistant surgeon, is assigned to temporary duty with troops on the Army transport Lawton, to sail for the Philippine Islands about May 12. Upon arrival of the transport

at Manila, Captain Wheate, assistant surgeon, will report for assignment to duty.

- GRANDY, Major LUTHER B., surgeon, is granted leave for 1 month.
- FOGG, Captain JOHN S., assistant surgeon, is assigned to temporary duty with troops on the Army transport Lawton. Upon arrival of the transport at Manila, Captain Fogg, assistant surgeon, will report for assignment to duty.
- CARLING, Captain JOHN, assistant surgeon, is granted leave for 1 month.
- BYRNE, Colonel CHARLES C., assistant surgeon general, the retirement from active service May 7, 1901, by operation of law, under the provisions of the act of Congress, approved June 30, 1882, is announced.
- SWIFT, Major EUGENE L., surgeon, now at San Francisco, Cal., will repair to Washington, D. C., and report to the surgeon general of the Army for instructions.
- CARDWELL, Major HERBERT W., TURNBULL, Major WILFRID, WINN, Major WILLIAM B., TITUS, Major FRANK H., surgeons, U. S. volunteers, are honorably discharged from the service, to take effect June 30, 1901, their services being no longer required. The officers named will proceed to their homes.
- JONES, Captain PERCY J., assistant surgeon, recently appointed, now at San Francisco, Cal., will report for transportation to Manila, P. I., where he will report for assignment to duty.
- PALMER, Captain FRED W., assistant surgeon, recently appointed, now at Brooklyn, Mich., will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
- WADDELL, RALPH W., contract dental surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
- SMITH, A. B., contract surgeon, leave granted is extended 5 days.
- JONES, JOHN F., contract surgeon, now at Leroy, Ill., will proceed to Fort Washakie for duty.
- FIELD, P. CONOVER, contract surgeon, will proceed from Washington, D. C., to New Brunswick, N. J., for annulment of contract.
- SCHERRER, ELMER A., contract surgeon, is relieved from duty at Fort Grant and will proceed to Denver, Colo., for annulment of contract.

AMERICAN MEDICINE

1321 Walnut Street

Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may begin at any time. Volumes end with the last issues of June and of December.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

"The Microbian Flora of the Human Body"

was the subject of a lecture recently delivered by Dr. Metchnikoff, of the Pasteur Institute, Paris, before the Manchester (England) Literary and Philosophical Society. The child, he said, is born microbe-free, but within a few hours even the intestine is invaded. The digestive organs continue the favorite homes, although the hair-follicles and mucous membranes are also thickly inhabited. Something like thirty species are found in the mouth, 30 more in the stomach, and 45 in the large intestine. Many, of course, are beneficial in function, and as an example Dr. Metchnikoff explained the fact that wounds of the mouth heal more quickly than those of the skin, is due to the presence of microbes which by their secretions attack the white blood-corpuscles, "the scavengers of the body." In the small intestine, also, certain bacterial acids prevent the development of other and injurious bacterial types. The lecturer appeared to think the large intestine is a useless organ, and seemed to suggest that the appendicitis specialist in lessening the number of useless and atrophying organs, "propitious to the growth of microbes," might encourage the rise of another-ectomy man. Is it possible that there is a theory-forming center which, under too active irritation by *Bacillus exhypothesi*, may have to be excised occasionally in the interest of conservative science?

Business Control by the A. M. A. Delegates.—

In response to our suggestion that the business of the American Medical Association should be given over to a reorganized small senate or house of delegates, a protesting query has been sent us, the purport of which is that the Executive Committee is precisely such a body and that its work has proved very satisfactory. We beg leave to differ. It is true that it has been a great improvement over the past wrangling inefficiency and injustice of the general session, but—(1) a reduced and reorganized delegate-body is absolutely required, if real representation as a national society is to be secured; with such a properly constituted house of delegates the work of the Executive Committee necessarily becomes that of the direct representatives, or legislators; (2) the Executive Committee is made up of the ex-chairmen of the sections. This is not direct or democratic representation, but is distinctly the reverse, and subject to the political and other abuses always existing in indirect systems of government; (3) the section-chairmen are necessarily more interested in the scientific than in the

business side of association work. The business aspect is different and requires a different order of talent and interest. It moreover demands the whole time of the legislator during the meeting. This the section-chairmen do not want to give, and, as a result, the meetings of the Executive Committee have been poorly attended. The work of this committee is not and cannot be final, but requires ratification (with debate, also!) by the general body. A limited house of delegates need not refer its decisions to the general session.

The annual money-equivalent for charitable work of the staff of a single hospital is thus calculated by the secretary of the Massachusetts General Hospital. It is based upon the lowest rates charged for similar services in private practice. Such a valuation for the year 1899 is as follows:

2,421 surgical operations at \$25	\$ 60,525
95,265 house visits at \$2	190,530
104,205 out-patients visits at \$2	208,410
Total	\$459,465
Cost of free patients [vide statement]	256,107
Total	\$715,572

In other words, this institution is returning more than 13% (in charitable work) on a beneficent investment of about five and a half million dollars.

Is Diphtheria Quarantinable?—In reference to the cases of diphtheria upon the *Rhynland*, the action of the quarantine and city health officials of Philadelphia in permitting the passengers to land without detention and observation, has been severely criticized. Yet it would seem as if the measures taken were amply adequate to the emergency.

If the disease had been raging aboard ship, owing to improper isolation of those attacked, the case would have been different.

With regard to yellow fever, cholera, and plague, the necessity of strict quarantine, even though there had been but one case on board, cannot be questioned.

These diseases do not exist in the United States, and can surely be kept out, so far at least as their introduction through marine channels is concerned. Smallpox also belongs to a different class from diphtheria. The health authorities recognize this in that they ordinarily would permit variola patients to be treated at home, while the transfer to hospital of diphtheria cases is more or less optional with the doctor and the family.

Diphtheria is not nearly as contagious as is smallpox (for the unvaccinated) and in making sanitary regulations, it must always be assumed that the number of unvaccinated in the country is large.

Quarantine laws in the present state of municipal sanitation should be as mild as is consistent with the protection of the community. It is cruel and inhuman to detain poor ignorant immigrants, arriving after a trying steerage voyage, for a long period, if there are other means of guarding the public health.

Disinfection of the cargo and of the ship is another matter—that is always feasible, and, as a rule, causes no undue suffering to anyone. Experience is a guide in matters of quarantine at sea-boards as well as in cities. If no cases of diphtheria develop in consequence of the action of the health authorities of this port, their action will afford a precedent for the future. We are not prepared to express a definite opinion as to the wisdom of not making diphtheria quarantinable, but are heartily in favor of the most lenient and most humane interpretation and enforcement of the quarantine laws.

Consumptive Aliens Denied Admission at United States Ports.—Such is the ruling of the Acting Commissioner General of Immigration. Pulmonary tuberculosis is a contagious disease, and the law of 1891 is henceforth to be carried out, that aliens with contagious diseases will not be allowed to land. The first effect of the ruling will be to restrict immigration, because it will not only directly exclude those suffering from the disease, but it will make the steamship companies greater expense, and hence will, in the long run, raise fares, create delays, etc. The companies being compelled to return all rejected passengers, will have to conduct rigid examinations at foreign ports, in order to be spared the expense of the double voyage. But it is only by the bacteriologist that the decisive test can be made. By union the expense and trouble of the companies may be somewhat lessened, but at best there seems to be a large measure of injustice to them, and it is possible that commercial interests may render the law ineffectual or may even annul it. But the American stomach, however great its digestive power, has probably a sufficiently large meal to attend to already in the tremendous mass of aliens already landed and unassimilated. When disease is added to the labor, it may help to the decision that restriction of undesirable immigration is ordered by sanitary as well as by commercial considerations.

The American Association of Pathologists and Bacteriologists.—Although nearly every branch of medicine has its national society, it was not until last year that an effort was made to organize a society of pathologists and bacteriologists. That the workers in these departments of scientific medicine were desirous of forming such an organization was demonstrated at the first meeting, held in Boston on April 5 and 6, when a membership of 123 was announced, and over thirty papers were read. This meeting was very successful, over two-thirds of the members, representing nearly all medical centers, being present. The officers of this meeting, who were also reelected for the present year, were:

W. T. Councilman, President; W. T. Howard, Jr., Vice-President; H. C. Ernst, Secretary; E. Hodenpyl, Treasurer; L. Hektoen, S. Flexner, C. F. Martin, Council. The next meeting will be held at Cleveland, Ohio, on the Friday and Saturday before Easter, 1902. The Association has no numerical limit to membership. Any one who has accomplished creditable work in pathology or bacteriology is eligible for membership. Thus also the membership is not limited to professional pathologists and bacteriologists, but is open to any one sufficiently interested in pathology and bacteriology to do research work. To the great body of men interested in these subjects the Association will afford an annual opportunity for presentation of new work, for discussion and closer acquaintance, not offered by any other organization. In this way it cannot but aid greatly the future development of pathology in this country; and it is safe to say that the Transactions to be published annually will become the most important record of this development.

New Medical Laboratories at the University of Pennsylvania.—It is with justifiable pride that the American profession can point to our progress achieved or determined upon in medical education. It is true that buildings and equipment do not constitute education or an educational institution, but we can truly say we also "have the men." These splendid machines will give them the better means of speedily placing the American medical colleges at the head of the teaching institutions of the world, as has been prophesied by one of our greatest physicians. Among the noteworthy evidences of progress is the determination of the University of Pennsylvania to build a great laboratory at a cost of \$500,000, for the use of the departments of physiology, pathology, and pharmacodynamics. For the teaching of students and the carrying out of research work in these branches of medical knowledge the new building with its equipment will afford opportunities unrivaled in this country. The building will be two stories in height, with a central court, thus insuring perfect lighting. The first floor will be devoted to the departments of physiology, pharmacodynamics, and pharmacy; the entire second floor to the department of pathology. The plans include two lecture rooms, with a seating capacity of 400, and two demonstration rooms to accommodate 185 students. In all departments, abundant space has been reserved for advance and research work. In the laboratory of pathology there will be also special laboratories for work in surgical, comparative, and experimental pathology, the pathology of the nervous system, and advanced bacteriology, thus making of this department a pathologic institute, in which opportunity will be afforded for any line of work in pathology or bacteriology. The unusual opportunities for investigation thus offered will undoubtedly have a great influence on the development of medical teaching and knowledge in this country, and will aid in securing for American medicine that scientific prominence which it is so rapidly achieving.

The Reorganization of the Lunacy Commission of New York and the appointment of Dr. Frederick

Peterson as the medical member and president promises most excellent results in many ways. The profession has great confidence that under Dr. Peterson's judgment and guidance there will be the best attainable benefit both to science and to the patients. We are sorry that the salary offered by the State allows him to give but a portion of his time from private practice to the work of the commission, but we are learning that there is no money payment for the services of public-spirited citizens who labor for the communal good. It is gratifying to know that Dr. Peterson has the greatest sympathy for the work heretofore carried on by the Institute under Dr. Van Giesen and that there will soon be a resumption of it under the new commission. It would be a great calamity to science and social progress if a noble cause such as that represented by the Institute were to fail of encouragement. There are few movements more worthy of help than that representing the scientific study, cure and prevention of insanity. A committee of the Neurologic Society last year passed the following resolutions. Dr. Peterson today aims to carry out the policy thus outlined:—

(1) It is to the interest of the State that original research work should be carried on in relation to insanity, in order that the science should be advanced and better methods of prevention, treatment and cure discovered. This is of direct interest to the taxpayers, upon whom falls the burden of the care of the insane.

(2) There should be one central laboratory in the State, wherein the energies of the best scientific men in the various departments of medicine related to insanity should be devoted wholly and exclusively to the prosecution of original research.

(3) Such a laboratory, combining the labors of well-qualified workers in general pathology, psychology, chemistry, anthropology, and any other requisite branches, should be able to produce from year to year results which would be creditable to the State as a patron of science, as well as invaluable in advancing the knowledge of the method of treatment and cure of mental disorders.

(4) Each hospital for the insane should have upon its staff of medical officers one physician whose sole duty it should be to conduct ordinary autopsies and to carry on the routine duties of a clinico-pathologic microscopist.

(5) The central laboratory, or Pathologic Institute, should be freely open to any qualified scientific men for the prosecution of original research work under the direction of the laboratory experts, preference always being given to the qualified men in the State hospitals. But systematic teaching of fundamental principles should not be required from any of the departments of the laboratory. The scientific men in charge of the various departments of the Pathologic Institute should devote all their energies to original investigation, and not be taxed, hampered or interfered with by medical men who are able to obtain instruction in fundamental principles elsewhere, without cost to the State.

(6) The central laboratory for original research should be a part of a reception hospital for the insane, situated on Manhattan island.

Popularizing Medical Science.—There is no work more needed than that of the popularization and realization of the teachings of medical and sanitary science. If the better classes could be aroused to the importance and effectiveness of carrying into execution the known means of lengthening life and making it healthy and happy, how tremendously would our civilization be bettered and hastened. It has been demonstrated that the death rate of great cities (*e. g.* Buffalo) can, in a few years,

be reduced one-third by the labors almost of a single earnest man. If one-hundredth of the money wasted by selfish charity and foolish philanthropy could be wisely spent in teaching the people the value of health and the prevention of disease, there would be accomplished one hundred times the good now derived from misguided endowers. We are moved to these thoughts by the report of a meeting held in South Orange, N. J., at which an entomologist set forth the methods of exterminating the mosquito. "Subscriptions for the proposed war came in with alacrity." The method of draining pools, the film of petroleum on stagnant water, etc., were explained and the success attained elsewhere described. If the property holders of the New Jersey coast would unite to rid the State of the mosquito they would also probably make more money in a short time than in a lifetime of *laissez-faire*. The report to the British Government by Mr. Neville-Rolfe, Consul at Naples, shows the commercial and industrial gains to be got from protection against mosquitos. He holds that the extermination of malaria is Italy's most important social and economic question. The Mediterranean Railway Company has fitted its station-houses with wire blinds and screens, and its agents with mosquito-proof clothing, and has thus demonstrated that absolute immunity is secured to employes who before looked upon life at these places as "a sentence of death."

Vasomotor Nerves in the Brain.—In a recent editorial, in which we called attention to some observations by Dereum and Spiller on the presence of myelinated nerve fibers in the spinal pia, we referred to Obersteiner's and Gulland's discoveries of the existence of nerves in the bloodvessels of the pia. We expressed the belief that these nerves were unquestionably vasomotor, and that the circulation in the central nervous system was not entirely at the mercy of the blood-pressure, but could be influenced by the action of vasoconstrictor nerves, just as the blood-supply of other organs. When writing this editorial we were unaware of the valuable and important studies of Huber, of the University of Michigan, who, by means of the Ehrlich intravital method of staining with methylene blue, was able to demonstrate unequivocally the presence of nerve fibers in the pia mater. These nerve fibers he found to be of two kinds: sensory and vasomotor. The differentiation was based upon the following grounds: The nerves considered sensory were distinctly medullated; they occurred in relatively large bundles, especially when in relation with the vessels at the base of the brain; they anastomosed to form wide-meshed plexuses surrounding the vessels; their neuraxons were larger than those of the sympathetic nerves; they branched and rebranched, and presented the short internodular segments usually observed when the sensory fibers approach their termination; and their terminal branches, which were varicose and nonmedullated, ended in fibrous tissue—the adventitia of vessels—or in the pia; the vasomotor fibers, on the other hand, ended in the muscular coat of vessels. Where the entire ending of the medullary fibers could be made out, the ends resembled the peripheral termination of sensory nerves in other parts of the body. The

vasomotor nerves were nonmedullated and form an interlacing network around the vessels. The fibrils terminated in the muscular coat of the pial vessels, in a manner in every respect identical with that of the vasomotor nerves in other parts of the body.

In order to determine whether the vasomotor nerves are derived from the ganglion cells of the cervical sympathetic ganglia, Huber extirpated the latter and endeavored to demonstrate degenerative changes in the pial nerves; but the results were not very satisfactory. An attempt was also made to find nerve fibers in the choroid plexuses of the ventricles, but without success; nor was it possible to trace nerves along the vessels penetrating from the pia into the brain.

In the dura mater two types of nerves were likewise found, of the same character as those in the pia; namely, sympathetic nerves, forming perivascular plexuses, and medullated sensory nerves terminating in the tissues of the dura.

Physiologists have hitherto denied the existence of vasomotor nerves in the brain, because experiments undertaken to demonstrate their presence have failed; we may, however, with Mosso and Obersteiner, attribute the negative results of these experiments to the probable fact that the vasomotor nerves of the brain are very quickly exhausted, and fail to respond to stimuli when the vasomotor nerves in other parts of the body still react.

Autepartum Examination.—A famous French litterateur once said that "a woman only escaped being sick twelve times a year by having an illness that lasts nine months." While this may be a sweeping statement, yet it clearly indicates the necessity of careful attention being given to the pregnant woman, in order to ameliorate or avert any complication of pregnancy and parturition. Ballantyne (*British Medical Journal*, April 6, 1901) has made a strong plea for the establishment of pro-maternity hospitals, where cases may be admitted early in pregnancy, particularly those patients who have suffered in previous pregnancies from one or more of the complications in which some anomaly of gestation has been diagnosed. More thorough examination and more careful study of the individual case could be made in a hospital; and such an institution would undoubtedly prevent disaster to the mother and lead to the conservation of fetal life. Ayers (*Physical Diagnosis in Obstetrics*) has spoken in eloquent terms of the crying need for improvement in medical practice of antepartum diagnosis in obstetrics, and of the value of pelvimetry, uterometry, and abdominal palpation, so that the best time may be selected for the induction or completion of delivery. Too much attention can not be given to the mensuration of the pelvic cavity, particularly when the general average of contracted pelvis, as given by Williams, is 13.1%. Nearly all of the major operations of labor are necessary because of the failure to recognize the probable causes of dystocia earlier in gestation.

The Consumption of Alcoholic Beverages.—That this subject is of great importance for the future of all countries every one is agreed. Indeed, it seems to

have as much interest for those who do not drink as for those who do. Statistics are constantly being twisted by people interested in one or the other side of the alcohol question to support their own side and an impartial study of the subject rarely appears. Such a study we believe is that of H. Bence-Jones, which appears in the *Journal of the Royal Statistical Society*, 1900, Vol. lxiii, p. 272. Even a mention of the many interesting facts brought out in this paper is impossible in the space allowed in these columns. But one fact will certainly be interesting to all Americans who believe in the importance of temperance: He states that the consumption of drink in Canada is smaller than that of any country of the world for which statistics exist; that in the United States is also small, and he is able to trace a comparative decrease in the consumption of spirits in recent years in both the United States and Canada. In the United States in 1890 the consumption of spirits per head was 1.17 gallons; in 1898 it had fallen to 0.92 of a gallon. There is perhaps a slight increase in the consumption of beer and light wines, but the quantities used are still quite small, as compared with some of the beer drinking countries of the world. In Bavaria the consumption of beer per inhabitant is given at 56 gallons; while in Germany as a whole, it is 27 gallons; in the United Kingdom not quite 32 gallons; in the United States 13 gallons per inhabitant. However, the consumption of beer does not indicate the entire consumption of alcoholic beverages. For in North Germany, for example, very little beer is drunk, the consumption of the inhabitants of those parts being spirits rather than beer. Thus, also, there is comparatively little beer consumed in Scotland and Ireland, while the consumption of spirits is proportionately larger.

The question of the desirability of drinks is not discussed, the question being as to what is drunk in the civilized countries of the world rather than whether it should be drunk or otherwise. As to the latter question there can be no doubt but that alcoholic beverages have their important uses in disease and whatever the tectotalers may believe with regard to the use of alcohol in a state of health, they cannot afford to deny its value as medicine. As to the hygienic side of the question it is certain that alcohol is not needed ordinarily by persons in a state of health, but it is also equally true that a large proportion of the people of civilized countries will consume a certain amount of alcohol quite regardless of this fact. If alcoholic drinks are to be used at all it is important that a pure article should be sold which will do as little damage as possible. The increase in the use of beers and light wines is encouraging rather than otherwise; for it is the experience of the countries in which they are most generally used that they are not as commonly adulterated and that drunkenness, poverty and disease are caused less often by them than by spirituous liquors.

A decrease in the amount of alcoholic beverages used is no doubt very desirable, but this will certainly not be brought about by the efforts of fanatics. We may be sure that the decrease in the use of alcoholic beverages in the United States is due to an increased intelligence of its people as a whole and this is highly encouraging.

Temperance in all things and not teetotalism is what is needed.

The Psychology of the Consumptive.—“The effect of bodily disease on the mind” says the editor of the *British Medical Journal*, “is a comparatively unexplored region of psychology. We, indeed, believe in a general way that long-continued severe pain may derange the reason; that cutaneous irritation may give rise to a kind of frenzy; that gout engenders an almost savage irascibility; that dyspepsia obfuscates the intellect and engenders spiritual gloom; that a disordered liver breeds melancholy; that a loaded colon disables the judgment; that fissures or fistula of the anus causes a peculiar irritability of temper. These facts suggest that every organic lesion, and, indeed, every pathologic condition, may reflect itself in a corresponding mental disturbance, so as to supply a scientific basis for the charitable maxim, ‘*Tout comprendre c'est tout pardonner.*’”

An interesting contribution to this field of clinical research has been made by Dr. Maurice Letulle, who in a recent number of the *Archives Generales de Médecine* gives the result of an investigation which he has lately carried out as to the psychology of tuberculosis. Mental energy, he says, and possibly a hyperexcitability characterize the early stages, but when ulceration begins there is lassitude and intellectual neurasthenia. M. Letulle thinks that in the last stages of illness there is none of the illusion as to recovery commonly supposed, except in medical men, who strangely enough, he says, are full of hope. As a rule defects of soul are exaggerated, but “melancholy is the badge of all the tribe of consumptives”—melancholy and egoism. For all are said to be selfish and exacting, thoughtless of the rights and sacrifices of others, and even spiteful, and vindictive. The editor of the *British Medical Journal* holds that M. Letulle's view is entirely too gloomy, and we would even go farther and say it is untrue. Is it not a question, partly, of race and of racial characteristics? According to M. Letulle's own expression psychic defects are exaggerated, not only in the tuberculous, but, as we think, in all diseases. When we are ill we indulge ourselves more than ever in the universal weakness of self-pity, and in chronic illness this indulgence is increased by the habit of being spared, of being waited upon, and coddled by everybody. Then, alas, it is a horrid thing to stare death in the face, to know that one's just chance at life has been denied, and all through no fault of one's self. It is wonderful so many patients do preserve the kindness and sweetness of which all physicians know.

Prize-Essays for Public Instruction—A Suggestion.—The close observer of medical superstition and abuses has constantly borne in upon his mind that these flourish because of popular ignorance. This ignorance is of course well supplemented by that egotism which usually accompanies lack of knowledge and perhaps is even better fortified by the greed of the money-getter. But at the bottom is the conditioning basis of utter ignorance of and scorn for the world's past or present experience. The mobs of the antis have the shallow enthusiasms which make them rush into print with the millions of

pamphlets, books, and journals of their propagandic literature, all filled with fallacies and untruths easily detected by the expert, but bringing conviction to the foolish. Against this torrent of folly and nonsense we have nothing of a popular kind to offer. What, for example, has the physician to give his rabid neighbors and patients that shall enlighten them as to the real facts of the antivaccination or the antivivisection literatures and controversies. For a philanthropist we can imagine no more beneficent and fruitful way of spending money than to offer prizes for the best essays on these and a hundred other subjects, and to place the pamphlets in the hands of every physician for free distribution. It is a work which AMERICAN MEDICINE would like to undertake or to act as the medium of, if such a measure of success should come to us as to enable us to do it. Could not your rich patient be incited to act in the meantime?

Since the foregoing was in print we have learned that the Colorado State Medical Society offers a prize of \$25.00 for the best essay, if deemed worthy of the prize, pointing out the dangers to public health and morals, especially to young persons, from quackery as promulgated by public advertisements. Essays should be sent to the Literature Committee, Room 315, McPhee Building, Denver, Colorado.

The Influence of Smoking in the Causation of Epithelioma of the Tongue.—The question of the influence of smoking in the production of epithelioma of the lip has often been raised and there is a general belief among surgeons that the use of tobacco is an important factor. Carcinoma of the tongue is fortunately a much rarer disease and the influence of smoking in its production has not been as frequently considered. In his latest edition of “Diseases of the Tongue,” Henry T. Butlin states that he feels justified in speaking much more strongly on this subject than he ventured to do some years ago at the time of the appearance of the former edition of his work. He believes that smoking is a decided factor in the causation of cancer, not so much directly as indirectly, rather by producing or tending to produce those conditions of the surface of the tongue which predispose to carcinoma than by immediately leading to the development of carcinoma in such tongues. He states that he does not rely so much on the statistics in support of this view as his personal experience with individuals suffering from precancerous conditions of the tongue and actual carcinoma. Thus Whitehead found only 61 smokers among 104 persons suffering from carcinoma of the tongue, which seems almost a small proportion, but the common history which we receive of much smoking, the great frequency with which carcinoma of the tongue is preceded by chronic inflammation of the surface of the tongue which has occurred in smokers and has been maintained by smoking and the much greater liability of males to the disease than females, leads to this view. Further confirmation of this belief is found in the fact that up to the present century little attention was paid to the diseases of the tongue. The introduction of tobacco into Europe at the end of the Middle Ages is thought to have had a great influence in the production of this increase.

Whatever influence tobacco may have in the production of carcinoma of the lips or tongue, it is exceedingly improbable that this fact will have much influence in preventing the habit of smoking. But as Butlin suggests it is probably more the irritation than any specific injurious quality in the tobacco itself. Hence smokers who would be wise should avoid the use of the stronger grades of tobacco, those forms of tobacco which to give aroma are mixed with various chemical and other substances which may be irritating, and the use of short stemmed pipes, and they should discontinue smoking the stubs of their cigars and cigarettes until they burn the lips and tongue. Those who have sufficient belief in the influence of tobacco as a specific factor in producing carcinoma can hardly have any other resort than to discontinue the habit.

Ovarian Transplantation.—The work of Morris, Knauer, and Gregorieff in experimental transplantation of the ovary has been attended with surprising and gratifying results. Knauer successfully transplanted ovaries from one rabbit to another, and the transplanted organs continued their functional activity, and many animals became impregnated subsequently. But it has remained for an American investigator, Dr. Robert T. Morris, to secure the interesting result of having successfully transplanted ovarian tissue from a healthy woman to a castrated one, with a subsequent pregnancy. The possibility of gestation following such transplantation presents some perplexing problems. The old query, which is the mother of the chick, the hen or the incubator, may be revived. With the greater dangers and possibilities lurking in artificial impregnation, some French writer may soon be basing a novel on the fact that neither reputed parent is the real one. May the medical forum become the scene of animated discussion upon the possibility of disease being transmitted by a fragment of foreign tissue? May the progeny of a healthy and innocent mother thus inherit tuberculosis, syphilis, or other horrible disease? May a thrifty traffic in healthy ovaries develop? Even the rehabilitation of an effete aristocracy is thus rendered possible, and the introduction of fresh energy assured without diluting the cerulean sanguinary fluid or compromising family traditions by unwelcome mesalliances. When sterility exists, due to ovarian disease, a remedy is at hand, and Napoleon might have been spared a disgraceful divorce had this procedure been adopted earlier. Advocates of female suffrage refer to the period when eminent English jurists discussed the profound subject whether a woman was related to her own child, and it is barely possible that American jurists of the twentieth century may have to decide whether a woman who supplies a diseased ovary is liable to a suit for damages, if a diseased child is born.

Atropin in Intestinal Obstruction.—The treatment of intestinal obstruction by medical means is often unsuccessful. Operation, although often indicated, cannot always be undertaken: in the first place, because of the age of the patient, many cases of intestinal obstruction occurring in advanced life; in the second, because, owing to delay for the purpose of trying medical meas-

ures, the patient has been brought to so low a state that the outlook for an operation is almost hopeless. It would seem, therefore, that a remedy which gives promise of cure should be most welcome. The German papers have recently contained numerous articles upon the use of atropin sulfate in intestinal obstruction, and, so far as can be learned, the treatment has frequently been successful. Large, almost poisonous doses, are necessary. The majority of writers recommend from 2 to 3 milligrams ($\frac{3}{8}$ to $\frac{1}{4}$ of a grain) at a dose, hypodermically. Toxic symptoms, such as delirium and restlessness, or stupor and unconsciousness, generally follow the use of such large doses; but, at the same time, these doses bring about movement of the bowels and the passage of gas. In an unsuccessful case reported by Höchtlén, autopsy showed that the obstruction was due to constriction of the intestines at two points by peritonitic adhesions. In such a case, atropin, could not, of course, be expected to give any results.

Extremism in the Antispitting Crusade is a danger which we should not run. The passage of an ordinance by the New Orleans Council against spitting, not only upon floors and cars, but upon sidewalks as well, seems very likely to defeat the object in view. It will probably result in utter indifference to the law. People will balk at such extremism and the world will go on as it did before the reform was started. It is useless to enact laws and attempt reforms too far in advance of public sentiment, and which will not be executed. In the prohibition State of Vermont, for instance, it is found that the sale of liquor for medicinal, mechanical or chemical purposes is as great as in other States for all purposes. In one town, Bradford, this reached the enormous sum of an average of \$3.89 for every man, woman and child. A little real progress is better than a failed attempt at impossible greater things.

EDITORIAL ECHOES

Immunity to Typhoid Fever.—Comparison of the results obtained by many observers seems to show that, while immunity is not constant after one attack of typhoid, it appears to be established for an extremely variable period in many cases. The results obtained among the British troops in South Africa and India apparently justify the idea that inoculation confers immunity frequently enough and of sufficient duration to lead to further use of this procedure, at least in cases where large bodies of men are exposed to the disease under unfavorable circumstances.—[*Medical News.*]

The Need of Pipe Galleries in New York.—The condition of the multitude of pipes uncovered in the excavations for New York's underground railway should arouse an overwhelming demand for a system of pipe galleries. Such a system would be a civic economy and a conservator of health. It would place all pipes where they could be rigidly inspected at frequent intervals. They would be accessible in case of leak or break. There would thus be no opportunity for the contents of the pipes to percolate through the soil and jeopardize the health of those living near. There would be no interference with traffic or with business along the line of any pipe route. Thus money would be saved and health conserved.—[*North American Journal of Homeopathy.*]

BOOK REVIEWS

A Compend of Human Physiology.—Especially adapted for the use of medical students. By Albert P. Brubaker, A.M., M.D., adjunct professor of physiology and hygiene in the Jefferson Medical College, etc., etc. Tenth edition, revised and enlarged, with illustrations and a table of physiologic constants. Philadelphia: P. Blakiston's Son & Co., 1900. Pp. 270. Price 80c. net.

To say that any book has passed through 9 editions and warrants a tenth, now issued revised and enlarged, is praise enough. Of all the admirable quiz-compendis issued by this firm none have enjoyed a greater continuous popularity than this by Dr. Brubaker.

Tuberculosis as a Disease of the Masses, and How to Combat It.—Prize Essay, Berlin, 1899. S. A. KNORF, M.D. Price, 25 cents; cloth, 50 cents. M. Firestack, 200 West 96th street, New York.

This excellent monograph was written for the laity, but the general practitioner will find it suggestive and its practical details helpful in cases in which he is obliged to give instruction to those suffering with or exposed to the disease. It should be widely circulated.

Anomalies and Curiosities of Medicine, being an Encyclopedic Collection of Rare and Extraordinary Cases, and of the Most Striking Instances of Abnormality in all Branches of Medicine and Surgery, Derived from an Exhaustive Research of Medical Literature from its Origin to the Present Day, Abstracted, Classified, Annotated and Indexed by GEORGE M. GOULD, A.M., M.D., and WALTER L. PYLE, A.M., M.D., with 295 illustrations in the text, and 12 half-tone and colored plates.

The popular edition of this work is offered 5 years after the first edition, forming a handsome imperial octavo volume of 968 pages. It appears to be the first attempt to briefly summarize and to arrange in order the records of the most curious, bizarre and abnormal cases that are found in medical literature of all ages and of all languages, and is a work of the greatest interest to the physician, physiologist and psychologist. To know extremes gives directly some knowledge of means and by implication and inference it frequently does more. A glance at the bibliographic index shows that several years of exhaustive research have been spent in the great medical libraries in the United States and Europe in collecting the material presented. Complete references are given to those facts that are comparatively unknown or unique or that are worthy of particular interest or further investigation. A complete general index is also added in which may be found not only the subjects under consideration and numerous cross-references, but also the names of the authors and most important reports.

Sexual Debility in Man, by F. R. Sturgis, M.D., formerly Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York, etc., etc. E. B. Treat & Co., Publishers, 241 and 243 West Twenty-third street, New York City. 1900. Price \$3.00.

The singularly naïve acknowledgment in the dedication of this book would lead us to expect something worth while in its subsequent pages. Nor are we disappointed. The candor evident in the preface, where the author disclaims any desire to fill a "long felt want," is certainly refreshing. He frankly states that his object is to promulgate certain opinions on these matters which are at variance with the usual teaching. He first takes up the anatomy and physiology of the organs under consideration, then proceeds to discuss the various phases of debility and impotence, their causes and curative treatment. The views expressed are often novel, particularly with respect to cause and effect in many diseases of the male, but his conclusions are so fairly stated and based upon observations so keen and illustrations so plain that we are almost compelled to accept them. Good wholesome common sense is the chief characteristic of the book throughout. Occasional lapses from a high moral plane are evident which are deplorable, but as the work is scientific and not ethical these may be condoned. It is eminently candid and truthful throughout, free from prudery on the one hand and devoid of pruriency on the other.

Chloroform. A Manual for Students and Practitioners. By Edward Lawrie, M.B., Edin., M.R.C.S., Eng. Residency Surgeon Hyderabad, Lieutenant-Colonel I.M.S., etc. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co.

This manual is exceptionally well written, and incorporates the results of the experiments which were performed by the Hyderabad Chloroform Commission. The physiologic action of chloroform is fully described, and the method of its administration is detailed. The manual is of inestimable value to the student of medicine, the practitioner, and to the anesthesia specialist. Lawrie has done much to eliminate the universal fear of the employment of this anesthetic, and has formulated definite rules, which if adhered to, will obviate to a great extent untoward results.

A Textbook of Pathology. By ALFRED STENGEL, M.D., Professor of Clinical Medicine in the University of Pennsylvania, etc. With 272 illustrations, 873 pages. Third edition, revised. W. B. Saunders & Co., Philadelphia and London, 1900. Price, net, cloth, \$5.00; half morocco, \$6.00.

The final end of medicine, surgery, gynecology and obstetrics is the direct application of the physician's knowledge to the patient's condition. But the doctor who hopes to avoid the dangers of empiricism must keep alive his interest in the causes and conditions underlying disease processes. Where can the knowledge desired be better found than in a good general pathology? He will not need a volume filled with laboratory technique, nor containing methods for original research, but one in which he can find stated the essential pathologic facts relating to each class of diseases and region of the body. Moreover, these facts should be so stated that the clinical features of each disease may be elucidated. The efficiency of such a work will depend upon the breadth and reliability of the author's knowledge, his skill in selecting essentials, the arrangement of the subject-matter and his skill in presenting these materials in a manner which shall insure their assimilation by the seeker after truth. Such is the object of the present volume, and, after a careful perusal and a comparison with other textbooks, we do not hesitate to say that it fulfills the requirements. The field is well covered. It is thoroughly abreast of the latest conclusions. It is enriched by the wide observation and experience of the author. Moreover, being primarily written for the use of students, it is so plainly couched that its meaning is never obscured. No controversial matters are admitted, except an occasional reference to explain the author's position.

In the first division of the book, or General Pathology, the chapter on Bacteria and Bacterial Diseases is the most noteworthy. Nearly a hundred pages are devoted to this topic. This evinces the author's wisdom, since it is along this line that so much new truth has entered the domain of pathology. Here, too, a clear description of ground already won may prepare the way for advances.

In the second division, or Special Pathology, the chapter on Diseases of the Blood is worthy of special mention. We may also note in passing that the obstetrical field is not neglected. The entire subject of Nervous Pathology is carefully treated. An admirable 6-page epitome is inserted, covering the embryology, histology, anatomy and physiology of the nervous system, with a statement of the neuron theory. This little interpolation will be especially valuable to men who cannot consult more extended works.

The book is beautifully illustrated and well indexed. The paper, type and binding are all that could be desired.

Food for the Sick; How to Prepare It. Food for the Baby, by EDWIN CHARLES FRENCH, M.D. Pp. 171. Price \$1.00, postpaid. Louisville: John P. Morton & Co., 1900.

There seems to be just enough therapeutics in this little book to make it undesirable to put into the hands of the laity. In diarrhea milk is *not* always the best diet—it is sometimes rank poison, as in the enterocolitis of infants. Nor is it much safer to prescribe milk (whether predigested or otherwise) as the final word on the diet of dysenteries. It is often nearly the last thing which the patient can digest. The cooking recipes are clear, and generally practical.

Atlas and Epitome of Labor and Operative Obstetrics.—By Dr. Oskar Schaeffer, Privatdocent in Obstetrics and Gynecology in the University of Heidelberg. Authorized translation from the fifth revised German edition, edited by J. Clifton Edgar, Professor of Obstetrics in Cornell University Medical College, etc., with 14 lithographic plates in colors and 139 other illustrations. Philadelphia and London: W. B. Saunders & Co., 1901.

This work is an excellent example of that class of textbooks which aim to set forth concisely primary principles and tested methods, knowledge that can be "snatched," rather than to elaborate and exhaust the subject. The classification of fetal positions, at discord with the usual American one, is somewhat confusing. Fetal presentations which are rare and more rarely diagnosed, are given undue prominence; and simplification of the multitude of references to figures and plates would be an improvement. The general classification, however, is simple, clear and logical. The method of presenting obstetric operations is admirable. The conservative, least dangerous, and, therefore, usually the best methods, are emphasized. The drawings, representing original work, have the commendable merit of illustrating instead of confusing. It would be difficult to find 100 pages in better form or containing more practical points for students or practitioners of obstetrics.

The Students' Manual of Venereal Diseases.—By F. R. Sturgis, M.D., sometime Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York; formerly one of the Visiting Surgeons to Charity Hospital, B. I., Department of Venereal Diseases; Member of the American Association of Genitourinary Surgeons, etc. Seventh edition, revised and in part rewritten by F. R. Sturgis, M.D., and Follen Cabot, M.D., Instructor in Genitourinary and Venereal Diseases in the Cornell University Medical College; Genitourinary Surgeon to Bellevue Hospital, Outpatients' Department; Visiting Dermatologist to the New York City (Charity) Hospital; Lecturer on Venereal and Genitourinary Diseases in the University of Vermont. Pp. 216; price, \$1.25 net.

A careful, and at the same time condensed, description of the commoner forms of venereal diseases which the average young practitioner will be called upon to treat, together with the most appropriate remedies, is offered in this work. It is concise and at the same time thoroughly practical, the mooted points in venereal medicine having been omitted.

A Manual of Practical Hygiene for Students, Physicians and Medical Officers.—By Charles Harrington, M.D., Assistant Professor of Hygiene in the Medical School of Harvard University. Illustrated with 12 plates and 105 engravings; 8vo. Pp. 72. Cloth, \$4.75 net. Lea Brothers & Co. Philadelphia and New York, 1901.

In the 17 chapters of this work are considered the following general topics: Foods, Air, The Soil, Water, Habitations, Schools, etc., Disposal of Sewage, Disposal of Garbage, Disinfectants and Disinfection, Quarantine, Military Hygiene, Naval and Marine Hygiene, Tropical Hygiene, Hygiene of Occupation, Vital Statistics, Personal Hygiene, Vaccination, Disposal of the Dead. Notwithstanding the necessity for conciseness in an attempt to cover so extensive a field, the author has succeeded in bringing together a vast fund of information, and in presenting the same in a most attractive and interesting manner. The chapter on foods is particularly interesting, incorporating as it does the results of the extensive investigations concerning American food materials carried on under the auspices of the U. S. Department of Agriculture. Many readers will probably be surprised to learn of the extent to which dogs are slaughtered for food in the large cities of Germany, *e. g.*, in Dessau an average of 251 yearly. The thorough treatment of the subject of food adulterations and their detection would, in itself, render the book of permanent value; but the same may be said of the chapters on Water, the Disposal of Sewage and the Disposal of Garbage. The book should be placed in the hands of every official in every large city of the land; it is truly a "Practical Hygiene," better fitted for the use of those controlling public works, city officials, builders, plumbers, teachers, and of physicians than any book available. The illustrations are good, but the index is not altogether satisfactory.

Nursing Ethics, by ISABEL HAMPTON ROBB, Graduate of the New York Training School for Nurses attached to Bellevue Hospital; late Superintendent of Nurses and Principal of the Training School for Nurses, Johns Hopkins Hospital, Baltimore, Md.; late Superintendent of Nurses, Illinois Training School for Nurses, Chicago, Ill.; Member of the Board of Lady Managers, Lakeside Hospital, Cleveland, Ohio; Honorary Member of the Matrons' Council, London, England. Pp. 273. Price Cleveland: J. B. Savage, 90-92 Wood street, 1901.

This little book contains many words of wisdom, and should be in the hands of every nurse. It has long been needed. The advice given is sound and practical. Mrs. Robb emphasizes the fact that no set of rules can alone make a perfect nurse or even a fairly good one; and that 2 or 3 years in a hospital cannot supply the lack of home training, a good general education, and the early implantation of ideals which lead to love of the "beauty of holiness," of truth, honesty, and consideration of others. But in many ways this unpretending volume is a finger post on the road to that "perfect conduct" which Herbert Spencer defines as "Ethics."

Manual of the Diseases of the Eye.—For Students and General Practitioners. With 243 original illustrations, including 12 colored figures. CHAS. H. MAY, M.D., Chief of Clinic and Instructor in Ophthalmology, Eye Department College of Physicians and Surgeons, Medical Department, Columbia University, New York. Price, \$2.00. Wm. Wood & Co.

The manual is clearly written and the necessary condensation is judiciously done. Philadelphia refractionists will not agree with the statement that we may assume the absence of astigmatism when the patient reads 20-20, and will find the teaching on the use of mydriatics unsatisfactory, and would change the emphasis somewhat in the treatment of muscular anomalies. The illustrations on the whole are good, although many of those for diseases of the eye are too diagrammatic. The volume is attractively bound and printed.

A Manual of Syphilis and the Venereal Diseases.—By JAMES NEVINS HYDE, A.M., M.D., Professor of Skin, Genitourinary and Venereal Diseases, Rush Medical College, Chicago; Dermatologist to Presbyterian, Michael Reese, and Angustana Hospitals, of Chicago; Consulting Dermatologist to the Chicago Hospital Society for Women and Children, and to the Chicago Orphan Asylum; and FRANK HUGH MONTGOMERY, M.D., Associate Professor of Skin, Genitourinary and Venereal Diseases, Rush Medical College, Chicago; Professor of Skin and Venereal Diseases, Chicago Clinical School; Dermatologist to St. Elizabeth's Hospital, Chicago. Second Edition, Revised and Enlarged.

We notice with pleasure the appearance of the second edition, revised and enlarged, of Hyde and Montgomery's "Syphilis and the Venereal Diseases." The work consists of a volume of 594 pages and contains 58 illustrations and 19 full-page lithographic plates. The authors state that the work is intended for students and practitioners rather than specialists. For this purpose it is well adapted, constituting as it does a convenient medium between the ordinary compend and the voluminous "American Textbook of Genitourinary Diseases." The discussion on syphilis is full, comprising rather more than one-half the volume, and leaving little in addition to be desired. Besides syphilis the authors have discussed chancreoid, diseases not invariably venereal, hypochondriasis, acute urethritis, chronic urethritis, complications of urethritis, stricture of the urethra and gonorrhoea in women. The discussion on gonorrhoea is fully up to date and coincides in pathology and treatment with the teaching of the most advanced genitourinary specialists. Throughout the work, useless theories and controversial matter have been wisely omitted, and a practical common sense pervades the whole. The treatment recommended for the various disorders appears to be that fully approved by the best practitioners, though less exhaustive than that in more voluminous works. The work is written in clear, concise and easily comprehended English. There is a place even in the very crowded and exhaustive medical literature for this work, and it will doubtless be received by the profession in the spirit hoped for by the authors.

AMERICAN NEWS AND NOTES

GENERAL.

Correction.—In AMERICAN MEDICINE, May 11, page 247, the election of officers for the Gastroenterological Association should read: President, Dr. John C. Hemmeter, Baltimore; first vice-president, Dr. W. D. Booker, Baltimore; second vice-president, Dr. S. J. Meltzer, New York; secretary and treasurer, Dr. Charles D. Aaron, Detroit.

The National Confederation of State Medical Examining and Licensing Boards will hold its next meeting at St. Paul, Minn., June 3, 1901. A cordial invitation is extended to members and exmembers of State Medical Examining Boards, physicians and educators interested in the cause of higher medical education. There will be a discussion of the question—What should be the legal definition of the practice of medicine?—following a paper on that subject by Dr. Henry Beates, Jr., of Philadelphia. Also a discussion following the report of the Committee on Interstate Reciprocity and Uniform Legislation.

Smallpox.—In Massachusetts, 6 cases of a mild type, at first thought to be chickenpox, have been diagnosed at Roxbury; 2 cases in a family at Adams, a member of which had been at Cohoes, N. Y., and at Pownal, Vt., where the disease has prevailed; 2 more cases at Leominster, and 2 cases at Southbridge, and 1 case is in the isolated ward in the Marine Hospital at Chelsea.

The New York Board of Health denies that the disease has been more prevalent in that city this winter than in other parts of the country. From December 28, 1900, to May 3, 1901, there were 723 cases there out of a total in all the States and Territories of 22,344. In the northwestern section of Philadelphia 2 new cases were reported May 17, and on the same day, in Chester, 7 cases, 6 of which were in 1 family, were reported. The authorities have ordered the vaccination of all the school children.

At Camden, N. J., another case is reported and measures to prevent its spread are being considered by the Board of Health. Two more persons suffering from smallpox have been removed to the Isolation Hospital, at Paterson, N. J.

The patients and suspects quarantined at Salisbury, Md., have all been discharged. Compulsory vaccination has been declared imperative in Washington county, Md., owing to the importation of colored labor from infected districts. Smallpox exists in many localities in Canada, and has broken out again in Kentville, Nova Scotia.

In Detroit, Mich., 60 cases of a mild form of smallpox have been found in the St. Francis Polish Convent, and several cases of it and a great number of exposures are reported from Wild Rose, Wis., and in Sheboygan there is consternation in its discovery in the family of a man who conducts a milk route in that city. At Chippewa Falls, Wis., the lower rooms of the public and parochial schools and the public library have been closed, owing to the prevalence of smallpox and scarlet fever. Near Warsaw, Ind., 10 cases are quarantined and an epidemic is reported among the white people of the town of Rolla, N. D.

Prompt vaccination has prevented a spread of the disease in the Institution for the Deaf, Dumb and Blind, in Berkeley, Cal. Two steamers from Naples and 1 from Hamburg have each had a case of smallpox among the steerage passengers. Official reports from Merida, Mexico, report the epidemic there as diminishing, and from Ponce, Porto Rico, April 29, a slow improvement in the situation.

Preliminary Report of the Committee on Organization of the American Medical Association.—The following embody the recommendations which will be incorporated in the Constitution and By-Laws to be submitted at the St. Paul meeting:

1. The delegate body shall hereafter be known as the "House of Delegates of the American Medical Association."
2. The House of Delegates shall consist of not more than 150 members and shall be created as follows: (a) 1 delegate for every 500 members or fraction thereof of the State and Territorial societies recognized by the American Medical Association; (b) 1 delegate from each of the Sections of the American Medical Association, to be elected as are other officers of the Section; (c) 1 representative each from the U. S. Army, the U. S. Navy, and the U. S. Marine-Hospital Service.
3. Delegates representing the State societies shall serve for 2 years, $\frac{1}{2}$, or as near as may be, of such delegates to be elected the first year for 1 year only.
4. Whenever the number of delegates exceeds 150 there shall be such a reapportionment among the affiliated State societies as will bring the total membership of the House of Delegates below that number.
5. The House of Delegates—as the Sections—shall hold its sessions daily, from 9 a. m. to 12 m., and from 2 p. m. to 5 p. m., or so much of such time as may be necessary, provided that it shall hold no session on the morning of the first day of the annual meeting, nor during the time of the General Sessions.
6. The General Sessions of the American Medical Association shall be composed of members and delegates who may be in attendance at the annual meeting, and the time of meeting

shall be 11 a. m. on the first day of the annual meeting, 7.30 p. m. on the first 3 days of the annual meeting, and 12 noon (or such other hour as may be agreed upon) on the last day of the meeting, which session shall be for the installation of the officers for the ensuing year and other concluding exercises.

7. All the officers of the Association shall be elected by the House of Delegates, but no member of the House of Delegates shall be eligible to any office whose incumbent is elected by that body.

8. No one shall be elected a member of the House of Delegates who has not been a permanent member of the American Medical Association for at least 2 years.

9. The election shall take place on the morning of the fourth day of each annual meeting.

10. No one shall be elected to any office who is not present at the annual meeting at which the election occurs.

11. The officers elected shall be installed at 12 o'clock on the last day of the annual meeting.

12. The membership of the Association, in addition to the delegates, shall be composed of permanent members, honorary members, and associate members.

While the Committee fully appreciates the fact that its duties do not extend below the American Medical Association, nevertheless it has in the interest of a complete organization considered the State and local societies, and to complete this urgently required organization of the regular medical profession, offers the following recommendations to the various State and territorial medical societies:

(a) That each State society shall at the earliest possible moment appoint a "Committee on Organization," to which shall be referred, with the Association's endorsement, the report of your Committee, and especially that part which refers to State and county societies.

(b) That each State society immediately raise funds and employ an organizer to organize the profession in its territory.

(c) That the State societies unitedly agree to federate themselves in the American Medical Association, and as a preliminary to this adopt a uniform organic law in regard to certain fundamental principles: viz., to divide their annual meeting into 2 branches, legislative and scientific; the legislative branch to be as small as is compatible with representation from all the county societies, and to be composed of delegates elected by the county societies.

(d) That membership in the county or district societies shall constitute membership in the respective State society without further dues, and that no one be admitted to membership in the State society except through county or regular district societies.

(e) That funds to meet the expenses of the State society be raised by a per capita assessment on the county and district societies.

(f) That a united effort be made to influence special societies to limit their membership to those who support the regular organization, and the seminational and miscellaneous societies to encourage systematic organization, by covering a definite territory and also by limiting their membership to supporters of the regular organization.

(g) That each State society create a permanent committee and a fund for the purpose of enforcing all medical laws in every part of its territory.

(h) That each State society cooperate with the American Medical Association and with the other State societies in solving the problem now before the profession relating to medical education, medical legislation, reciprocity, licensing, etc.

Your Committee further recommends that a committee of 3 be appointed at the St. Paul meeting to continue, in behalf of the American Medical Association, the plans authorized in this report, and to act in conjunction with the large Committee to be appointed by the various State societies. Your Committee also presents herewith supplementary arguments in favor of organization, all of which is respectfully submitted.

[Signed:]

J. N. McCORMACK, Bowling Green, Ky.
P. MAXWELL FOSHAY, Cleveland, Ohio.
GEORGE H. SIMMONS, Chicago.

NEW YORK.

Dr. Nathaniel D. McDowell has been appointed optical surgeon of the State Industrial School.

Harriet E. Blach, of Amityville, has been appointed physician in the Long Island State Hospital.

Dr. Louis Fisher has been appointed a visiting physician to the Willard Parker and Reception Hospitals of New York City.

L. Emmett Holt has been appointed clinical professor of diseases of children at the College of Physicians and Surgeons, New York.

New Lunacy Commissioner.—Dr. Frederic Peterson of New York City has been appointed medical member of the New York State Lunacy Commission, to succeed Dr. Wise. Dr. Peterson has made nervous and mental diseases a special study for a number of years.

An **Emergency Hospital** has been established at Buffalo, for the use of the public at the Pan-American Exposition. It comprises 2 male and 1 female wards, accommodating in all 26 beds, and is supplied with all modern medical and surgical appliances. Dr. Roswell Park is the head of the staff of 3 physicians.

Hospital Appointments.—Drs. Frederick Zingsheim and Paul O. Lendeke have been appointed medical internes in the German Hospital of Buffalo. Drs. Tripp and Leonard of the University of Buffalo, class of 1901, have been appointed resident physicians of the Buffalo General Hospital.

PHILADELPHIA, PENNSYLVANIA, ETC.

The Children's Seashore House at Atlantic City opens June 1 and during the month of June will receive free, as far as accommodations allow, sick or convalescent children from the various city hospitals.

The University of Pennsylvania will soon erect a new medical laboratory at a cost of at least \$500,000. The authorities are also contemplating the construction of a new medical hall, anatomical building, and auxiliary buildings. These buildings will adjoin the new laboratory about to be erected.

Honors to a Philadelphia Physician.—Dr. Joseph Leidy has received from the French Government the decoration of Chevalier of the Legion of Honor and the decoration of "Officier Instruction Publique." These have been bestowed for services rendered the French Government during the Paris Exposition as member of the International Jury on Hygiene.

The Western University of Pennsylvania, at Pittsburg, has appointed a committee to appear before the Appropriations Committee of the State Legislature demanding why the institution should be neglected in the State appropriations. A number of physicians, members of the school faculty, were recently summarily dismissed from the staff of the West Penn Hospital. The committee will likewise demand an explanation for this.

WESTERN STATES.

Compulsory Vaccination.—Governor La Follette, of Wisconsin, vetoed the Collins Compulsory Vaccination Bill as he did not believe the emergency existed which required a law that was so bitterly opposed by many of the citizens.

American Medical Association's members are invited to avail themselves of the headquarters secured by the *St. Paul Medical Journal* in a room adjacent to the general exhibits, during the St. Paul meeting, for writing, reading, smoking, and general lounging.

Carl Krueger, whose stomach was removed 3 weeks ago by Dr. B. B. Eads, of the Illinois Medical College, is reported to be fully recovered. He is able to partake of vegetable foods and predigested meats. A similar case in San Francisco, performed successfully 2 years ago, was the first of its kind in this country.

Cats Stricken with Diphtheria.—The cats in a certain district of Chicago are afflicted with a throat disease which many claim is diphtheria. The felines are dying by wholesale, but so far there has not been a case reported in which the disease has been communicated to the persons who feed and caress the animals.

The Ohio Hospital for Epileptics held a meeting of the Board of Trustees May 17. Dr. H. C. Rutter, manager, formally tendered his resignation, which had been requested by Governor Nash. At this time an effort was made by Dr. Rutter to obtain the support of the trustees in his discharge of the director of the Pathologic Laboratory, Dr. A. P. Ohlmacher, but a letter from the Governor to the Board of Trustees was read expressly forbidding this action.

Hospital Investigation.—A special committee of 9 members, composed of representative citizens from civic clubs and associations, and 3 county commissioners, of Chicago, chosen to make an impartial investigation of charges of cruelty and neglect made against officials of the County hospital by discharged patients, found the nurses in the main faithful, conscientious and able but overworked, and an increased force was recommended also an improvement in the quality of the food and the manner of serving it.

Hospital Insufficiently Heated.—Patients who have been recently dismissed from the Cook County hospital, Illinois, complained that the institution was not properly heated and that the sick wards suffered from the low temperature. Commissioner Beer, a member of the hospital committee, when questioned stated that this condition of affairs had existed for 20 years, the temperature running anywhere from 15° to 20° below what it should be for the sick. The remedy of the introduction of a new heating plant is strongly recommended by a committee of investigation, and in the future that the warden, chief engineer and the Board of County Commissioners should jointly and severally be held responsible for any negligence in this department.

FOREIGN NEWS AND NOTES

GENERAL.

Treatment of Tuberculosis.—Dr. Brunon, Director of the Rouen School of Medicine, says the English method of fighting tuberculosis with beefsteak and tennis is more efficacious than the sanatorium system observed throughout Germany.

Soda Water Sparklets are proved to have explosive propertics as illustrated in the case of a young Boer girl in South Africa who picked up a sparklet and in attempting to open it with a nail it exploded blowing off the distal and second phalanges of the 3 fingers and wounding the palm and little fingers.

In the Interest of Public Health the Mayor of Lyons has issued an order, authorized by a statute of 1880, forbidding the establishment of all new public houses within 250 yards of a cemetery, school, church, or other religious building. The reason for the law is to stop the increase of alcoholism by preventing the creation of new public houses.

Obituary.—JOHN PENN HARTREE of Cambridge, England, aged 57. WILLIAM BEALE WALLIS of Colchester, England, May 6, aged 71. EARNEST HENRY RICHMOND WATTS of Kensington, England, May 5, aged 41. W. LANGFORD, at Kyneton, Australia, March 21. THOMAS ALEXANDER PAPILLON of St. Leonards-on-Sea, England, April 2, aged 42. HENRI NAPIAS of Paris, April 28, aged 59. Dr. GEORG ASP, professor of anatomy at the University of Helsingfors, April 25, 1901, aged 67.

Human influence on weather conditions is involuntary, says Dr. Trabert, of the Paris Meteorological Society. The change in the weather he attributes to deforestation and the extensive burning and incomplete combustion of coal. The dust being scattered through the air forms a basis for condensation, and this tends to produce rain. He rejects the theory that the abundant production of steam increases the number of storms, stating that in Germany, which has many large industrial plants, the evaporation would scarcely be $\frac{1}{4}$ inch to the square mile.

GREAT BRITAIN.

Smallpox in Glasgow continues to decline. Since the beginning of the year, 302,000 of the citizens have been vaccinated.

Scientific Disposal of Sewage.—An investigation of a number of the larger cities of Great Britain shows that in nearly all of them a scientific disposal of all sewage is made, either by filtration or precipitation or irrigation on sewage farms.

Glass Particles in Candy.—The *Lancet* calls attention to the dangerous ingredient of finely crushed glass splinters added to some high grade candy to give it a sparkling appearance, and supposed to be adopted to compensate for the absence of any crystalline appearance in glucose which is used so largely as a substitute for cane sugar in confectionery. When the candy is dissolved in warm water, the splinters fall to the bottom of the tumbler in a tiny heap of broken glass. Two children who ate of this candy shortly afterwards suffered from severe abdominal pain, in the one case in the region of the appendix. The pain persisted for several days.

Dietetic Value of Sugar.—Dr. Gardiner, of England, in his researches on this subject finds that sugar is a potent creator of energy and maintainer of stamina, and in confirmation of his laboratory experiments cites the endurance of the date-eating Arabs, the fine health of the sugarcane-eating negroes, and the results achieved by mountain climbers, explorers, athletes, and soldiers who were fed on this diet. He attributes in great measure the increased height and weight, and better health of the English people in the last century to the increased consumption of sugar, which in England has trebled per head in the last 40 years.

CONTINENTAL EUROPE.

Support of Paupers.—France is said to maintain its paupers by means of a tax of 10% on all theater tickets sold.

The Saccharine Bill has been passed by the Reichstag Committee. It is a measure designed to prohibit the sale of saccharine under the name of sugar.

Turf wadding used as absorbent bandages for men and animals in cases of wounds, padding for splints, etc., was first spun from turf fiber by Zsehorer, a civil engineer of Vienna. Karl Geige, of Düsseldorf, improved it by getting from turf a finer material and by action of chemicals and washing has removed all impurities, so that the turf wool consists of almost pure cellulose, is soft and elastic and from it clothing and rugs are also largely manufactured.

SOCIETY REPORTS

AMERICAN SURGICAL ASSOCIATION.

ANNUAL MEETING HELD IN BALTIMORE, MD., MAY 7, 8, AND 9, 1901.

[Specially reported for AMERICAN MEDICINE.]

[Concluded from page 291.]

Demonstration of Fractures of the Pelvis: OSCAR H. ALLIS, M.D. The speaker, by extensive apparatus, demonstrated how fractures of the pelvis may be made. The demonstration was upon the cadaver, and by applying force, by means of a lever, to the femur, it was demonstrated how different luxations and fractures are produced. One marked feature was resisting strength and solidity of the pelvis of the cadaver; another was the remarkable resiliency of the green femur, stripped of all supporting muscles.

Pancreatitis: MAYO ROBSON (Leeds, England) said all diseases of the pancreas except those producing gross organic changes have been practically overlooked, notwithstanding the proof evinced by observation and experience that the pancreatic ducts share in the same inflammatory processes as the bile ducts, and he regretted that there is as yet no reliable signs to aid in the diagnosis of occlusion of the pancreatic ducts. In the near future he has grounds for hope that an examination of the urine, blood and feces will give this diagnostic aid. The frequent association of gallstones with chronic pancreatitis, found in his own experience, and the theory deduced that pancreatitis and gallstone troubles are intimately related, is confirmed by cases cited from literature. The condition giving rise to fat necrosis he does not regard as essentially a pancreatitis, as has been suggested. The ill effects of the recognized hemorrhagic condition, coexisting with carcinoma of the head of the pancreas, he overcomes by the administration of 30-60 grains of calcium chloride, twice daily, from 24 to 48 hours previous to operation. He pointed out the possibility that glycerin set free in the tissues by the fat necrosis may be the true cause of the local hemorrhagic tendency in pancreatic disorders. He classified pancreatitis as acute, subacute and chronic, and gave indications, treatment and illustrative cases.

Treatment of Chronic Ulcer of the Stomach: A. W. MAYO ROBSON, F.R.C.S., Leeds, England. Medical treatment, said the speaker, is the first to be applied in chronic ulcer of the stomach; this is successful in most cases. But we should operate earlier than has been the practice. Chronic gastric ulcer is more serious than is usually supposed, and treatment, medical or surgical, as indicated, should be urged, and that early. The diagnosis, as a result of late investigations and experiments, is comparatively easy. Under proper surgical treatment the mortality is now not more than 5% or 10%, though formerly it was much higher. There had been but 188 operations for gastric ulcer up to 1890. The number of operations has increased greatly since then. Even when immediate operation is not demanded the elaborate previous preparation of the patient by continued lavage is unnecessary. The previous preparation may be limited to making the mouth surgically clean, giving aseptic food, and lavage with sterile water for 2 days. The last meal should be given 12 hours before the operation, enemas being used thereafter. A suit of cotton-wool should be worn, and a grain of strichnia given previous to operation. Exploratory gastrotony may be necessary for diagnosis. Excision of the ulcer is not always necessary. Pylorotomy is simply a form of excision. The speaker has had the lowest mortality in the posterior operation, it being but 5% in 40 cases.

Treatment of the Arteriovenous Aneurysms of the Subclavian Vessels: R. MATAS (New Orleans) reported a case of bullet injury occurring in a man aged 24 years, in whom the right subclavian artery and vein had been perforated through the scalenus anticus. The bullet had also injured the brachial plexus, causing paralysis of the corresponding upper extremity. The operation was performed 10 days after the injury. An osteoplastic resection of the clavicle with disarticulation at the sternoclavicular joint was made under local infiltration. Anesthesia with eucaïn B., and a temporary traction loop of silk was applied under the first portion of an anomalous subclavian artery, the innominate being absent. The vein was provisionally compressed above and below the anastomotic orifice. Notwithstanding complete control of the subclavian at its origin, profuse hemorrhage took place from the anastomotic orifice when the vein was detached from the artery, the bleeding stopping when double ligatures were applied above and below the perforation in the artery. The bleeding indirectly came from the vertebral and internal mammary. After dividing the artery between the ligatures, the orifice in the vein was closed by lateral suture, and the venous circulation was reestablished. A bullet, undeformed, 38 caliber, was extracted. Shock followed, but patient was restored by saline infusion. Recovery with partial loss of hand and forearm from mortification caused by arterial ischemia and insufficient collateral circulation. Primary healing of operative wound. In reviewing the literature of the subject, the author referred to 15 cases of this rare injury which had been recorded since 1829, when Larrey described the first case. Of these, only 4 had been operated

upon. The indications for intervention, the prognosis and details of the operative technic closed the paper.

Operative Intervention of Tumors of the Liver, with a Report of Cases: W. G. MACDONALD (Albany). This paper will appear in a future number of AMERICAN MEDICINE.

Subtrochanteric Osteotomy: E. H. BRADFORD (Boston). This paper will appear in a future number of AMERICAN MEDICINE.

Phlebitis Following Abdominal Operations: A. VANDER VEER (Albany). This paper will appear in a future number of AMERICAN MEDICINE.

An Operation for the Radical Cure of Umbilical Hernia: Dr. W. J. MAYO makes a transverse elliptical incision at the base of the hernial tumor, entirely through the peritoneum. The sac is loosened from the surrounding tissues and opened. If the hernia consists of omentum it is ligated in sections and removed, if of bowel the latter is returned. The aponeurosis both above and below the incision is exposed. The lower flap of the aponeurosis and peritoneum is slid upward about $\frac{3}{4}$ of an inch, between the upper margin of the aponeurosis and the peritoneum. The wound edges are held in this position by 2 rows of buried sutures. The author has had better results by this method of treatment than by any other.

The Prevention and Cure of Postoperative Hernia: JAMES E. MOORE (Minneapolis).—This paper will appear in a future number of AMERICAN MEDICINE.

Fractures and Dislocations of the Spine: Dr. S. H. WEEKS (Portland). See Author's Abstract in this issue.

Radical Cure of Inguinal and Femoral Hernia, with a Report of 800 Cases Operated Upon from 1891-1901: Dr. W. B. COLEY (New York) says the mortality now in inguinal hernia is not more than $\frac{1}{3}$ %. Since he has been using rubber gloves he has had but 1 case of infection following operation. He prefers not to use the buried silver suture, for though a sinus may occur rarely, it is of sufficient frequency to lead him to prefer not to use it. A sinus may even occur after primary union has taken place. An undescended testicle in an inguinal hernia can almost always be brought into the scrotum.

The above paper was discussed by WARREN, of Boston, and by HALSTED, of Baltimore. The latter does not now transplant the cord as formerly, but is particular to remove any enlarged veins of the cord, thus diminishing the tendency to recurrence. He still uses the buried silver sutures and is satisfied with the results so obtained. Out of 520 cases sutured with wire there were but 25 cases of suppuration, and in only 2 cases did sutures have to be removed, while in the hospital, and in 3 cases after leaving the hospital. But 1 suture was removed for fancied cause of pain in a neurasthenic patient. There was but 1 secondary stitch-abscess.

Resection of a Large Part of the Chest Wall for Sarcoma; use of Fell's Apparatus for Artificial Respiration; Late Continuous Fever due to Staphylococcus Blood-infection; Successful use of the Antistreptococcal Serum; Complete Recovery: Dr. W. W. KEEN. The case of a colored woman, aged 26, was cited. A fall injured her left side 2 years ago, later a tumor appeared at the lower angle of the right scapula, and had continued to grow. Operation was performed in the Jefferson Hospital and the tumor, which had become very large, was removed. It measured 15 cm. vertically, 26 cm. horizontally and was elevated 7 cm. above the general level of the chest. A horseshoe-shaped incision was made, beginning at the outer border of the right breast, thence down to the eleventh rib and backward and upward near the spinous processes as far as the level of the inferior angle of the scapula. A skinflap was turned up. The tumor being adherent to the ribs it was gradually peeled away. The fifth, sixth, seventh and eighth ribs were found involved. A portion of each of these was resected and the underlying pleura found diseased. A portion of the pleura 18 cm. by 12 cm. was quickly cut away. The lung at once collapsed but the Fell apparatus was used to induce artificial respiration. Deep sutures of catgut were carried through the lung tissue and the edge of the wound to prevent complete collapse. The patient at first progressed well but later there was a continued and persistent rise in the patient's temperature. An examination revealed the streptococcus in the blood. Injections of antistreptococcal serum were used, and the temperature gradually went to normal. The patient made a good recovery from the operation. A microscopic examination proved the tumors to be a spindle-cell sarcoma. Attention is called to the following points: First, the method of separating the tumor from the chest-wall so as to determine more exactly the limits of the disease and lessen the size of the opening to be made in the chest. Second, the division of the ribs anteriorly and posteriorly prior to opening the pleural cavity, thus diminishing the period of danger in collapse of the lung. Third, the use of Fell's apparatus, which was not satisfactory in this case and for which the speaker would prefer to substitute the apparatus of Bloom or that of Matas, of New Orleans. (These were demonstrated to the Fellows.) Fourth, the suture of the lung to the chest-wall. This was followed by no untoward surgical results, and it diminished very greatly the postoperative pneumothorax, almost abolishing it. Fifth, whether the use of the antistreptococcal serum was the cause of the fall in the temperature, one can hardly say, but the results were striking. Sixth, the examination of the blood was of great value as showing the reason for the continued high temperature, and led to what is believed to

have been the proper treatment for the condition. Seventh, it is too early to determine what the future of the patient will be, but after nearly 7 months her condition is eminently satisfactory.

Artificial Respiration in Medical and Surgical Practice by Means of an Air Pump Attached to a Modified O'Dwyer Cannula: R. MATAS (New Orleans). This apparatus was exhibited and its uses demonstrated on a larynx connected with rubber balloons which acted as artificial lungs. He referred to his previous contributions on the subject of intralaryngeal insufflation in preventing and correcting acute traumatic pneumothorax and on the value of the Fell-O'Dwyer apparatus in treating other conditions of asphyxia. The instrument which he now presented he regards as an improvement on the bellows used in the Fell-O'Dwyer apparatus, not only because it exactly measures the quantity of air injected into the lungs, but also because the pressure under which air is insufflated is accurately measured by the mercurial manometer which is attached to the apparatus. The quantity of air injected with each stroke of the piston can not only be measured but is accurately regulated by a simple device connected with the accessory piston which controls the automatic cutoff. This pump had the great advantage over other appliances used for the same purpose in so far that it was accurate and could be regulated with the precision required of an instrument for physiologic research.

The Use of Silver Wire and Electricity in the Treatment of Aneurysms. Report of Cases: LEONARD FREEMAN, M.D. (Denver) reported 2 cases of his own in which he used the silver wire and electricity. He stated that most operators have advised the use of finely drawn silver wire, about No. 27 in size, and that about 20 feet of wire is all that should be used. He, however, is of opinion that the soft silver wire is better and he prefers to use a greater number of feet of it than is commonly used. The soft wire is better because it springs less and thus has less tendency to rebound when introduced into the sac, and also less tendency to suddenly change position in the sac and break up the newly formed clot. The glass-flask experiments and illustrations are misleading because the inside of the flask is smooth and regular, while that of the aneurysmal sac is not. A turnip hollowed out and wire introduced is a more trustworthy experiment. The author illustrated this and showed why he preferred the soft silver wire and plenty of it, to the smaller quantity of finely drawn silver wire. Up to the present time 87 cases have been wired, the most of them having not more than 20 feet of wire introduced. One case had 78 feet, another 72 feet of wire introduced.

Discussion.—FINNEY, of Baltimore, said there had been 2 cases of apparent cure by wiring in the Johns Hopkins Hospital, but the patients eventually died. He had wired 1 case 3 times, the tumor bulging at a new point after each operation. Temporary relief was obtained after each operation, but the patient finally died. In 2 cases wired death was hastened.

MATAS insisted on determining the indications for wiring, and said in the past there had been indiscriminate wiring. He called attention to the fact that wiring an aneurysm of the abdominal aorta was attended by great danger because the orifices of important arterial branches are likely to be occluded. This occurring, the organs supplied by these vessels are apt to become gangrenous. This is not a fancied danger because about 50% of abdominal aneurysms are in the vicinity of the celiac axis. He said several conditions should exist before wiring an abdominal aneurysm is safe: It should be sacular, should have strong walls, the lumen should be small, the patient's vessels should be in a fair condition, it should be low down in abdomen, or on the posterior wall if in the region of the celiac axis. Since these things cannot be predetermined the operation is a perilous one in abdominal cases.

Movable Kidney; its Cause and Treatment: M. L. HARRIS dealt largely with figures and measurements and his paper is not well adapted to abstract. The speaker insisted that body form is responsible for movable kidney. He has arranged a scheme of measurements whereby he states the presence or absence of movable kidney may be determined without palpation. This was too intricate for abstract. Repeated pregnancies and trauma, he concludes, have little or nothing to do with producing movable kidney. Treatment was considered only from an operative standpoint. The practice with most operators is to fix the kidney too high up in the abdominal cavity. Here the cavity is usually too small for it and pain results. We must take into consideration the body form.

Two Cases of Abdominal Contusion; (1) Fracture of the Spleen—Splenectomy—Recovery; (2) Fracture of the Kidney—Nephrectomy—Recovery: S. J. MIXTER, M.D. The paper was very short, detailing a case of rupture of the spleen by traumatism from machinery. The patient went into collapse. Operation was done early and the spleen removed. The patient made a good recovery. In the second case a girl of 10 was run over by an express wagon. There was great shock but no external sign of injury. She soon passed bloody urine. On opening the abdominal cavity the kidney was found fractured. The 2 fragments were removed and the child made a good recovery. These 2 cases, the speaker said, show the importance of early operation in cases of abdominal injury.

Nephrolithotomy on Both Kidneys: S. J. MIXTER. The case of a young man was recited. From his seventeenth to his twentieth year he had several attacks of colic, and often passed gravel in his urine. The x-ray picture showed concretions in

both kidneys. During September operation was performed, and 2 stones, together weighing 1,020 grains were removed from the left kidney. During February following, the right kidney was operated upon, and again 2 stones removed. The patient made a good recovery. The case illustrates the value of the x-ray, and shows that large stones may exist in the kidney and give rise to only mild symptoms.

Discussion.—HUNNER reported a case in which the x-ray showed a stone in the right kidney. Operation showed the kidney in such condition that its removal was deemed wise. The patient secreted no urine after the operation, and death occurred. Necropsy showed a double ureter on the left side. A stone had completely occluded the opening at the bifurcation, and only $\frac{1}{2}$ of the kidney was functioning.

The Management of the More Malignant Forms of Rodent Ulcer: J. COLLINS WARREN. This paper will appear in a future number of AMERICAN MEDICINE.

New Method of Closing Defect Following Thorough Removal of the Breast: S. J. MIXTER. The method advocated cannot be well illustrated except by diagram. The skin incision begins well above the axilla of the affected side and is carried down on the external aspect of the diseased breast, thence across chest below the border of both breasts and up on external aspect of the sound breast to near axilla of sound side. The diseased breast and underlying muscles are removed, and the sound breast loosened and shifted to the center of chest. By this means the entire wound may be closed.

Discussion.—WARREN thought many women would object to this deformity for cosmetic reasons.

CARMALT, of New Haven, reported a case treated similarly to those of Mixter with good results.

Congenital Sacrococcygeal Tumor of Large Size, by CHARLES A. POWERS, M.D. (Denver.) Read by Title.

Vicious Circle After Gastroenterostomy: THEODORE A. MCGRAW, M.D. (Detroit.) This paper will appear in a later number of AMERICAN MEDICINE.

A Case of Splenectomy for Myelogenous Leukemia: M. H. RICHARDSON, M.D. (Boston.) This paper will appear in a future number of this journal.

Congenital Anterior Dislocation of the Tibia Treated by Arthrotoomy: JOHN B. ROBERTS, M.D. (Philadelphia.) Read by Title.

Pneumotomy, with Exhibition of the Patient: W. JOSEPH HEARN, M.D. (Philadelphia.) This paper will appear in a future number of AMERICAN MEDICINE.

XIX GERMAN MEDICAL CONGRESS.*

HELD AT BERLIN, APRIL 16, 17, 18 AND 19, 1901.

[Continued from page 288.]

SIXTH SESSION.

Uric Acid Formation in the Animal Body: WIENER (Prag) fed hens on various nitrogen free substances containing a chain of 3 carbon atoms, and at the same time injected urea. Among the substances used were glycerin, lactic, oxybutyric, glycuronic, tartaric, malic, et al., acids. After the use of all but a few exceptions, butyric, propionic et al., there followed an increased uric acid excretion, which was most marked when a dibasic acid was used. Similar but less marked results followed the same experiments on men. These same substances, however, when fed the isolated mammalian liver produced no increased uric acid formation, but did an increase of tartaric and dialuric acids. He concludes that in birds, and in a less degree in mammals, there is a synthetic formation of uric acid; that there is first the production of a dibasic acid with 3 carbon atoms, from which is built tartaric acid. The next step is the addition of a urea group, giving dialuric acid, which when another urea group is added gives uric acid. In men this synthesis is not very important normally, but may be in case of gout and other pathologic conditions.

Experimental Study of the Metabolism of Sugar in the Body: MAYER (Karlsbad). This paper has previously been published. Mayer points out the necessity of studying the metabolism in diabetes. He has proven glycuronic acid to be the first oxidation product of sugar. This acid may be excreted in considerable quantities in diabetes. An increase of glycuronic acid in the urine is an expression of imperfect oxidation of sugar and may be the first symptom of latent diabetes.

ROSIN (Berlin) then reported his observations (already published) on the quantitative relation between the sugar of the blood and the urine in diabetes.

Chronic Pentosuria: BIAL (Kissingen) gave a careful historic review of the subject, and then reported the experiments performed in conjunction with Blumenthal. The conclusion is that pentosuria is a disease totally distinct from glycosuria, since glucose is well used by a patient with pentosuria. Phloridzin produces a similar glycosuria as in a normal person, and the dextrose content of the blood is normal. Neither does it arise from albumin katabolism since feeding thymus does not

*Specially reported for AMERICAN MEDICINE by Dr. CHAS. P. EMBSON with grateful acknowledgment of indebtedness to Prof. EWALD, editor of the *Berliner Klinische Wochenschrift*, for his assistance in the preparation of this report.

increase it. Patients with pentosuria have normal oxidation power of the tissues. It is present in the blood, but beyond that its source is unknown.

The Physiologic Relations of the Three Arabinoses: WOHLGEMUTH and NEUBERG (Berlin). This was a report of a series of experiments to determine the physiologic relations of substances which differ alone in the arrangement of their atoms. The result showed that the configuration of the molecule, in the case of the 3 carbohydrates, is important from a physiologic point of view.

The Influence of Lesions of the Kidney on the Course of Pancreatic Diabetes of a Dog: ELLINGER and SEELING (Königsberg). A dog was first made diabetic by the extirpation of its pancreas, and then an acute nephritis produced by cantharides. The sugar in the urine diminished, both the percent and absolute amount, but also the quotient between sugar and nitrogen (D: N) in the urine became smaller. The effect on the sugar excretion is more transitory than that on the nitrogen. If acute nephritis develop spontaneously in a dog with pancreatic diabetes the sugar in the urine diminishes, even disappears, but since it increases in the blood its disappearance from the urine is due to diminished excretion, hence the renal lesion has not diminished the essential symptom of diabetes, the hyperglykemia.

NAUNYN (Strassburg) maintained that these experiments are not in accord with observations on patients and cannot be used (as the authors wished) to explain the latter. He had seen glycosuria disappear in cachectic conditions (lung tuberculosis *e. g.*) when there was no trace of a renal lesion.

The Analysis of Tremors, and Disturbances of Movement: SOMMER (Giessen), professor of Psychiatry at the University of Giessen, demonstrated several pieces of apparatus designed to analyze tremors of the hands, feet, acipito frontalis muscle, etc., by recording the components of the tremor, *i. e.*, the amount of motion in each of the 3 directions, also instruments for measuring the pupils of the eye, and for studying the kneekick. These instruments of the psychologic laboratory are useful in the study of various nervous and mental disorders, and have proved valuable in the differential diagnosis between hysteria and various nervous diseases.

SEVENTH SESSION.

Experimental Lesions of the Medulla Oblongata: ROTHMANN (Berlin) studied the effects of experimental lesions of the pyramidal and Monakow's tracts in the medulla of the dog and monkey. The paths were destroyed by as local a lesion as possible with a needle. In the dog, when the pyramidal path at the decussation, or Monakow's tract, was destroyed, in either case there was a perfect restitution of function. If, however, both were at the same time destroyed, there resulted spastic paralysis of the extremity of the corresponding side, and electrical stimulation of the motor cortex of the other side was without effect. If in monkeys the pyramidal decussation was cut, in a few weeks perfect restitution of function occurred.

HERING (Prague) considered the motor function of the pyramidal tracts proven beyond doubt, but admitted the justice of Rothmann's criticism of the modern view concerning their mode of function.

Porencephalia: v. KAHLDEN (Freiburg). The speaker pointed out that whereas it was admitted that cavities in the brain could result from embolism or thrombosis of an artery, resulting in a funnel-shaped cavity, yet neither of these processes had ever been observed in porencephalia of congenital origin, and yet were commonly assumed to explain the latter cases. Neither was there evidence of congenital lues in these cases. He believes that trauma (concussion) without fracture may explain these cases since it evidently was the cause of the process in the case of a 1-year-old child who fell from a table and died 14 days later, at whose section were found 2 such cavities.

BENDA (Berlin) remarked that much was in favor of the former view and doubted that Kahlden could explain all cases.

A Rare Cause of Rupture of the Aorta: v. KAHLDEN (Freiburg). The case was of a man of 30 in which the sequence was acute articular rheumatism, purulent pericarditis, which extended to the aorta and rupture of the latter.

Further Observations on the Etiology of Acute Articular Rheumatism: SINGER (Vienna) reported more cases in favor of his previously published opinion that acute articular rheumatism is a mild form of septicemia caused by the ordinary pus organisms. During the past 2 years he has had opportunity to study 5 cases of fatal acute articular rheumatism and 2 cases of chorea, which cases were reported at length. In all except 1 case of chorea were found in the various organs by cultures, fresh cover slip preparations, and in the sections of the tissues, *Streptococcus pyogenes*. The other case showed *Staphylococcus pyogenes albus*. The speaker then at length answers the criticisms made of his previous communication, and himself criticized the work of Wassermann and Meyer. He emphasized the points that between acute articular rheumatism and cryptogenic septicemias one sees clinically many transitions, that the streptococci show so many variations that it would be difficult to prove an organism specific with only slight differences from those ordinarily found, and that animal experiments have little value in this case since streptococci can in them easily produce joint inflammation.

The Bacteriology of Acute Articular Rheumatism: F. MEYER, (Berlin) whose work had received the particular

attention of the previous speaker, then read an already published paper. His work would tend to show that the cause of this disease is a specific organism, a diplococcus. This organism has been grown from exudate of the tonsils in 12 cases of tonsillitis, which disease, according to Meyer, is very intimately associated with acute articular rheumatism. The serous exudates in the joints in cases of rheumatism he has invariably found sterile. He has grown the organism once from the heart valves in a case with endocarditis. Cultures of this organism injected subcutaneously into animals in a few days will produce an inflammation of the joints with serous exudate such as occurs in rheumatism. This fluid at first contained the organism but later was sterile. In one case it produced endocarditis. In all cases in which he had produced inflammation of the joints by streptococci the fluid been purulent. He doubts much that his is an attenuated streptococcus.

Discussion.—Menzer (Berlin) supported Meyer in his opinion. He denied that the disease under discussion was a pyemia. He referred to the experiment performed by Meyer and himself by which a rabbit was infected in the tonsil with Meyer's organism and developed multiple arthritis and endocarditis.

GLASER (Berlin) supported Meyer and also reported experiments showing the possibility of producing by streptococci in animals an affection similar to polyarthritis without producing sepsis.

MICHAELIS (Berlin) reviewed the work done on the subject in v. Leyden's clinic and supported the claims of Meyer that the disease in question was a specific infection.

SINGER at this point read the opinion of Michaelis expressed in 1897, at which time Michaelis denied any specificity to the disease.

v. LEYDEN defended the work done in his clinic by Meyer and Michaelis. He considered the already mentioned production of polyarthritis and endocarditis from inoculation into the tonsil as evidence of great value.

The Development of Surgery of the Lung: GLUCK (Berlin) reviewed the work extending over the past 37 years on the surgery of the lung. He mentioned his experiments showing the possibility of in animals, removing the most of one lung, and then reported his cases, exhibiting a few of them in which he had removed several ribs and freely opened the lung, in some cases removing much of a lung. He has operated 14 times, 7 of which were for abscess, all recovering, some for bronchiectasis.

A Rare Cause of Unilateral Paralysis of the Recurrent Nerve. The Symptoms and Diagnosis of Patent Ductus Botalli: SCHRÖTTER (Vienna) first mentioned the 2 cases of Ortner in which the nerve was compressed by a left auricle dilated by mitral stenosis. In his own case the compression was produced by the dilated ductus botalli. The diagnosis of persistence of the ductus botalli can be made by the skiagraph, its shadows being seen in the second left intercostal space.

Paralysis of the Left Recurrent Laryngeal Nerve in Mitral Stenosis: KRAUS (Graz). In this case there was considerable dilation of the right ventricle and left auricle in consequence of which the relations between the pulmonary artery, ligamentum arteriosum and aorta were altered. The left recurrent laryngeal nerve was compressed in the angle between the left pulmonary artery and ligamentum arteriosum, and not at all by the enlarged left auricle which Ortner considered the cause in such cases.

Centralization of the Work on Brain Anatomy: VOGT (Berlin) discussed the advantages of a central place for the study of brain anatomy where the work could be done according to uniform methods.

The Pneumonia Mortality in Hospitals: HAMPELN (Riga) explains the high mortality of pneumonia as not due so the disease as such as to injury received (exposure, etc.), during transportation to hospital; hence the mortality among those treated in their own homes is lower than in the hospitals. The remedy is better means of transportation.

S. MEYER (Berlin) replied that that did not apply to Germany where the facilities for transporting the sick were excellent.

Fatty Degeneration of Organs: ROSENFELD (Breslau) Rosenfeld believes the prevalent ideas concerning fatty degeneration to be erroneous. According to his view in phosphorus, et al., poisoning the preformed fat from the various fat depots of the body goes to the liver to cover the glycogen deficit. His reasons are, that a glycogen deficit is always present in cases of phosphorus, et al., poisoning; that the fat disappears from the cells and is replaced by glycogen if the dog is allowed to hunger or more rapidly if the dog is well fed; and the fatty "degeneration" is prevented if the liver is not allowed to lose its glycogen, hence fatty liver is not common in man since our food furnishes plenty of glycogen. Also, only a healthy cell can become thus filled with fat; neither in the necrotic tissue of infants nor in coagulative necrosis does one find fatty degeneration. Hence there is no "fatty degeneration" since (1) the fat can be proven to have been deposited there; (2) a degenerated cell does not become fatty.

A Comparison of the Results Obtained in Determining the Size of the Heart by the Orthoröntgenographic Method and by Percussion: MORITZ (Munich). Moritz has tested these 2 methods of determining the size of the heart in a series of 89 cases. On the same patient the heart outline was percussed and then determined by the speaker's apparatus by

means of which the outline of the heart in its true dimensions may be determined (by means of x-rays.) In 68% of the cases the outlines agreed. The lines did not correspond in the remaining cases, sometimes the right border, about as often as the left, and in 4% of the cases, neither. Moritz uses only his fingers in percussion, holding the pleximeter finger firmly against the chest and striking it in such a manner as to use the sense of touch to the utmost. He pointed out the errors made determining the position of the apex beat of an enlarged heart; often the measurement includes the thickness of the chest wall.

Discussion by EDELFSEN (Kiel), KARFUNKEL (Leipzig), CRIGERN (Leipzig), LEROY DORN (Berlin), PÄSSLER (Leipzig), brought out no new points on the subject.

After a short address by the president of the Congress, Professor SENATOR (Berlin), in which he thanked the committee for its very efficient aid, and the reply by Professor NAUNYN (Strassburg) on the part of the committee, the Congress adjourned.

IOWA STATE MEDICAL ASSOCIATION.

[Specially reported for AMERICAN MEDICINE.]

The semicentennial meeting was held at Davenport, May, 15, 16, and 17, 1901, under the Presidency of Dr. R. E. CONNIFF, of Sioux City.

The sessions were well attended; the papers were short, practical, and instructive, and the discussions spirited.

In his address, the president gave a retrospective view of the advances that have been made in medicine and surgery within the last few years. Among other things, he urged the establishment of a State sanatorium for the treatment of the indigent consumptive poor, and suggested that action be taken to influence the State Legislature to appropriate sufficient money for the construction and maintenance of said sanatorium. He also recommended the enactment of a law to regulate marriage among the defective classes.

Dr. IRA K. GARDNER, Chairman of the Committee on Constitution and By-Laws, read the report of the Committee, and asked that action on it be deferred until the next annual meeting, for the reason that at the St. Paul meeting of the American Medical Association a report is to be made looking toward the reorganization of that Association, and in case the report was adopted, such changes would be made in the Constitution and By-Laws of the Iowa State Medical Society as to conform with those of the American Medical Association. He outlined the salient features of the report of the Committee on Reorganization of the American Medical Association, and urged the Iowa delegates to go to St. Paul and do everything in their power towards its adoption.

Dr. R. L. CLEAVES, of Cherokee, in a paper on **puerperal infection, discussed the varieties and causes.** He narrated the report of a case of pyemia and septicemia, and then gave his conclusions drawn from a long experience, and made a plea for asepsis in the lying-in room.

Dr. G. C. COTTAM, of Rock Rapids, discussed **puerperal infection from a surgical standpoint.** He detailed a series of cases illustrating the various forms of puerperal sepsis, with deductions as to sources and prevention of infection. The utility of temporizing measures was dwelt upon, and the manifest advantages of radical treatment at the onset of symptoms pointed out.

Dr. D. C. BROCKMAN, of Ottumwa, spoke on the **early diagnosis of mammary and uterine cancer.** Statistics show that $\frac{2}{3}$ of cancers begin in the uterus or breast. Primarily they are local, and curable, if operated upon early. The diagnosis is not always feasible; if it were, many patients might be saved who now die. The cardinal symptoms were pointed out. Doubtful cases should be considered malignant until they are proved to be benign. He urged the importance of examining thoroughly a specimen of the growth. The symptoms of uterine cancer, either of the os cervix or body, were defined.

Dr. C. E. RUTH, of Keokuk, in a paper on the **treatment of uterine and mammary cancer,** stated that the growth is primarily local. There is a tendency to speedy death from exhaustion. Recurrence of the disease is certain if a portion of it be left. Metastasis took place through the lymph channels, and not by the fascia. Serumtherapy and other medication were unpromising. Surgical treatment, while uncertain, gives the only hope in such cases. It was exceedingly difficult, if not impossible, to tell where normal tissue begins and where carcinoma ends. He referred to drainage, dressing and hysterectomy when and when not indicated. He also discussed the vaginal and suprapubic routes. Sloughing is a contraindication against hysterectomy.

Dr. H. A. LEIPSIGER, of Burlington, dwelt on **ovarian cysts and malignant sequelae.** He referred to the best available means of differentiating benign from malignant growths in the early stages. Do apparently benign ovarian cysts contain foci of malignancy? He reported 2 cases in support of an answer in the affirmative.

Dr. WILLIAM L. ALLEN, of Davenport, reported a case of **ovarian tumor in a child 12 years of age.** The tumor was first noticed when the child was 12 years and 6 months old. The growth appeared at that time to be the size of a coconut. Operation was done 10 months later, a simple unadherent cyst of the right ovary being removed, weighing about 12 pounds. Rapid and complete recovery followed.

Dr. DONALD MACREA, JR., of Council Bluffs, gave a brief review of the work done in cases of **kidney stone, the diagnosis and treatment.** He alluded to the importance of the x-ray as a positive means of diagnosis, and showed numerous skiagraphs. He emphasized the importance of thoroughly clearing the ureter.

Dr. D. S. FAIRCHILD, of Clinton, considered **ulcer of the duodenum from a surgical standpoint.** Conditions were compared with those of ulcer of the stomach. The importance of making a diagnosis before perforation was dwelt upon, as well as the difficulty attending diagnosis. He discussed the methods which may be employed before and after perforation, reported a case, and briefly reviewed other cases.

Dr. A. L. WRIGHT, of Carroll, gave a brief history of the **surgery of the gall-bladder.** He pointed out the indications demanding such surgery, and the methods used in determining such indications. He dwelt on the most suitable time for the performance of such operation. Should it always be done whenever gallbladder pathology exists? He considered the technic of the operation, as well as the immediate and remote results.

The following officers were elected for the ensuing year: President, Dr. J. R. Guthrie, Dubuque; first vice-president, Dr. S. Bailey, Mount Ayr; second vice-president, Dr. J. H. Kulp, Davenport; secretary, Dr. V. L. Treynor, Council Bluffs; treasurer, Dr. George L. Skinner, Cedar Rapids. Des Moines was selected as the place for holding the next annual meeting.

CONGRESS OF CHARITIES AND CORRECTION AND THE NATIONAL ASSOCIATION FOR THE STUDY OF EPILEPSY.

ANNUAL MEETING HELD AT WASHINGTON, D. C., MAY 7, 8 AND 9, 1901.

[From Our Special Correspondent.]

The extent to which the community should endeavor to modify and regulate the laws of nature, and particularly those which provide for the propagation of the species and the survival of the fittest, has been discussed from many points of view at the meetings held here within the past week under the auspices of the Congress of Charities and Corrections. Sociologists, philanthropists, ministers of religion, persons having charge of asylums and reformatories and medical experts of one kind and another have all taken part with equal zest in the various symposiums; and if the net result does not go far towards supporting the theory that in the multitude of counselors there is wisdom, it is none the less true that it showed the existence throughout the country of a large amount of benevolent intention, which has only to be properly directed to be fruitful of very excellent results. With a great deal of wild theory, moreover, it was gratifying to observe that there was a considerable admixture of practical suggestion, based on actual experience and kept within bounds by eminently sane judgment. The tendency on the part of some of the enthusiasts was of course to run to extremes, and those accustomed to such gatherings will not be surprised to learn that among those who aired their views most earnestly were men and women who would have society conducted after the pattern of a model stud farm. Such a driving home of the issue to its apparently logical conclusion is perhaps unavoidable at meetings of the kind, but it is none the less to be regretted, as the inevitable effect is to bring the proceedings of the body generally into disrepute, if not to make them the subject of ridicule.

For example, one of the questions most keenly debated was the old one whether **individuals suffering from physical or mental defects should be allowed to marry.** Undoubtedly there is much to be said in favor of the imposition of further restrictions in this respect than now exist. The difficulty is to know where to draw the line. Most people will agree that it would hardly do to act upon the suggestion put forward by several speakers that every epileptic subject should be prohibited from contracting a matrimonial alliance. For, on the one hand, it might be asked why stop epileptics? Why not place similar restrictions giving evidences of degenerative tendencies—upon the alcoholic, the tuberculous, the immoral, the criminal, the weak-minded of every shade and description? And, on the other hand, there would arise the question, Who are to be considered epileptics? Medical authorities are far from agreed as to what constitutes the difference between true epilepsy and other nervous attacks which simulate that disease. Julius Cæsar and Napoleon, as was remarked, might both be included in the category of epileptics, even without a very strict method of classification, and it is well known, as was also pointed out, that many men who have occasional epileptic seizures, say once or twice a year, are unusually capable and even brilliant members of the community—men having charge of large business concerns, authors, scientific investigators, lawyers, and what not. Are all these to be debarred from matrimony because of the epileptic taint? And if so, does it not follow that they should be debarred likewise from illicit connections, the fruits of which are much more likely to become a charge upon the State or municipality than children of such parentage who might be born in regular wedlock. Then would follow another needful step, that of placing all such persons under strict and constant surveillance—altogether too ridiculous a measure to be seriously

considered. Several of the speakers did admit that this would be an unpardonable interference with the liberty of the individual; but even they were ready for the most part to concur in the proposition that unfortunates who become wards of the public have no rights which call for recognition, at least in so far as regards the exercise of sexual function. As will be seen the whole subject bristles with problems as delicate as they are difficult, and they are only hinted at here to emphasize the importance of paying heed to the warning uttered by Dr. Bullard, of the Massachusetts State Hospital for Epileptics, and proceed with extreme caution in everything having the form of legislative enactment, or tending to impose restraints against which the common sense of the public will revolt. It is evidently a matter in regard to which we should act upon the principle of the old English seer who said "Let us take our time in order that we may get to an end the sooner."

The National Association for the Study of Epilepsy and the Care and Treatment of Epileptics, which held its first annual meeting in connection with the congress, is a body that will commend itself to medical men no less than to sociologists and philanthropists. Its work, while not free from the troublesome problems above alluded to, will in the main be decidedly practical in character, its objects, as set forth in the circular calling the meeting, being: (1) To promote the general welfare of sufferers from epilepsy. (2) To stimulate the study of the causes and methods of cure of this disease. (3) To assist the various States in America in establishing a uniform system of care for epileptics, and (4) to advocate the care of epileptics in institutions designed for their special needs, where they may (a) receive a common school education, (b) acquire trades, and (c) be treated by the best medical skill for their malady. The president of the association is the Hon. William Pryor Letchworth, LL.D., of New York State; the vice-presidents, Dr. Frederick Peterson, New York, and Professor Osler, Baltimore, and the secretary, Dr. William P. Spratling, of the Craig Colony for Epileptics, Sonyea, N. Y. To the last-mentioned gentleman, who is widely known because of the active part he has long taken in the study of this particular branch of medical science, it is largely due that the association has been started on a solid basis, and that the proceedings of its first annual meeting presented such an interestingly varied program. The Secretary of State, Mr. Hay, willingly gave his aid to secure the cooperation of the consular staff in foreign countries to gather information as to what is being done abroad in the way of providing homes for sufferers from epilepsy and checking the development of the disease, the consequence being the receipt of a number of more or less valuable contributions to the current literature on the subject. It may be considered gratifying from a purely patriotic point of view, though otherwise unsatisfactory, to be able to reflect that those communications did not show any superiority on the part of foreign methods of dealing with the difficult problem. In fact, it seems that the United States is in the lead in this class of medico-charitable work.

Even here only a beginning has admittedly been made; but the success which has attended various State enterprises, and particularly the Craig Colony in New York, is sufficient to warrant much further effort in the same direction. Dr. Spratling has frequently told in print, as well as verbally at medical meetings, the story of the inception and growth of that institution and of the excellent work it is doing. But it is a story that cannot be told too often, so remarkable are the results which have there been achieved. The general plan of the method pursued is to give the patients change of occupation, putting them as far as possible to congenial tasks, and getting their minds interested at the same time that their physical faculties are exercised. The surroundings are agreeable, the colony being situated in a picturesque part of the State, and the grounds and cottages being made as attractive as art can make them. Strict attention is paid to the diet of the patients, and every effort is put forth to render the life of the little community as cheerful as it is wholesome. Moreover, there is an entire absence of restraint, which is found to work well, the instances being altogether exceptional in which the colonists have strayed from their homes, and there being hardly a case on record in which they have not found their way back. Altogether the system known as the cottage colony has come to be recognized as an ideal solution of the problem of how to deal with a class of unfortunates whose woes were described by Lucretius (in some powerful lines which were quoted in one of the papers read at the gathering), but in regard to whose physical or mental ailment but little progress has been made until now since the days of Hippocrates.

From a purely medical point of view, it was perhaps to be regretted that too little time was available for the discussion of the causes of epilepsy, and also as to the part that medicines play in the treatment of the disease. The tendency on the part of Dr. Spratling and others is to resort to bromids and other sedatives as little as possible, though their efficacy in mitigating the severity of attacks and possibly postponing if not averting them was acknowledged. One medical man from Chicago asserted his ability to cure the disease, but he did not fully explain the method by which he did so, the fact that he is to read a paper on the subject before the American Medical Association at its forthcoming meeting at St. Paul, evidently making him think that his views would more properly fall within the scope of a purely medical gathering.

CORRESPONDENCE

SENILE MENSTRUATION?

BY

R. G. BARCKLEY, M.D.,
of Milford, Pa.

I wish to report a rare case coming under my observation recently:

Mrs. W. was aged 90 last March. Without appearance of disease, a discharge resembling that of menstruation appeared last month (April), and continued for 8 days, without any pain or discomfort. It ceased for 2 weeks, and returned. Her general health is good. She has never worked very hard, and has had pleasant surroundings.

PROPER MEDICAL LEGISLATION.

BY

H. D. YOUNG, M.D.,
of Burlington, Iowa.

The report of the autopsy upon the Minnesota Medical Bill, which you have reprinted from the *St. Paul Medical Journal*, should prove interesting to everyone who has the good of the profession at heart, and particularly those who see so much good to be done by proper medical legislation.

We have in Iowa a supposedly good medical law: A diploma showing 4 years of study, and an examination by the State Board, are the essential requirements. The practice of medicine is defined, and severe penalties are inflicted for practising without a license. Yet there are good men in the profession who ask "Cui bono?" They point to the fact that in order to get such a law enacted, we have to admit in public, after long denial in private, the claims of the homeopaths and eclectics to scientific standing. They point to the fact that osteopathy (whatever it is) has been able to secure practically as good a standing. They declare that when an attempt is made to enforce the penalties for infraction, the law is openly condemned by the press and public, and frequently lacks the sympathy of the court.

Against criticisms such as these it is difficult to make headway. I have wondered if more might not be accomplished by a change of base.

For instance, why not bend our energies to secure legislation along the following lines:

- (1) A broad and scrupulously exact definition of what constitutes the practice of medicine.
- (2) The title of doctor, and the right to collect fees for medical services, to belong only to those who have fulfilled the following requirements:
 - (a) Four years of study in a medical college (diploma not essential).
 - (b) An examination by the State Board on anatomy, physiology, chemistry, materia medica, pathology, the principles of surgery and the principles of obstetrics.
 - (c) Evidence of good character and the age of 21 years.
- (3) Registration, the register to be posted in a conspicuous place in the court house of the county of residence.
- (4) Adequate penalties for illegal practitioners on the basis of cheating by false pretense.

Legislation of this character may not cover so many points as that which has heretofore been desired, but it seems to me would largely disarm the critics. It makes no mention of the practice of medicine as a subject for examination for two reasons, namely: It is reasonable to infer that a person who has sufficient knowledge to pass the examination in the other subjects would be able to make proper application of this knowledge (no two doctors practise alike anyway); and reference to the regular, the homeopathic, the eclectic and all the *isms* in medicine would thereby be avoided. It is worthy of note that legislation, naming the different schools to be recognized, is not wholly free from the charge of unconstitutionality on the ground of class legislation. It is also possible that avoidance of these names might serve to relieve the public mind of any suspicion that there could be a combination of the schools for the sake of revenue. Let us strive for something that everybody can respect, or abandon the question entirely.

POSTINFLUENZAL MELANCHOLIA.

BY

B. C. LOVELAND, M.D.,
of Syracuse, N. Y.

Your editorial of April 20 on "Postinfluenzal Melancholia" suggests to me that my views on the subject, briefly expressed, may not be amiss.

I believe that melancholia as a rule depends to a great extent on toxemia or autointoxication of a type identical with or similar to the lithemic state. It has been my lot to care for influenza in a large number of neurotics and lithemics, and I have almost constantly noted a marked increase in the uric acid symptoms following such attacks.

As a result of this observation some years ago I began from the first days of the disease to use what may be called an alkaline treatment for influenza, *i. e.*, meet indications in regard to cough, pain or heart and use 5 grains each of soda salicylate and soda benzoate in a full glass of hot water 3 or 4 times in a day. From this time I had more rapid recoveries, less depression and fewer sequels generally.

DISINFECTION OF TYPHOID URINE.

BY

MARK W. RICHARDSON, M.D.,
of Boston, Mass.

In AMERICAN MEDICINE for May 11, there appeared an editorial upon "urotropin and its use in typhoid fever." To one of the statements made in that editorial I must take exception: That typhoid bacilli are found in the urine in less than $\frac{1}{4}$ of the cases; that when present they are not always provocative of harm to the patient. That urotropin is not always effective in removing the bacilli is perfectly true. It is, moreover, very important to disinfect the urine after it is voided, whether urotropin is given or not. The writer of the editorial, however, misses completely the most important point of all, namely, that the bacilli frequently persist for weeks, months, or even years in the urines of persons who have passed through an attack of typhoid fever. No amount of disinfection outside of the body will remove the bacilli from the bladder, and there is no doubt in my mind that patients are being turned loose constantly who, through their urines, spread typhoid fever broadcast. Now, urotropin has been found to sterilize these urines, in the great majority of cases, permanently. Therefore, let me express again my opinion that, inasmuch as bacteriologic examination alone can determine whether or not a urine contains typhoid bacilli, all typhoid patients should be given urotropin, 30 grains daily, for 10 days as convalescence approaches. A few cases will escape even then, but the great majority at least will be rendered innocuous.

CASE OF FIBROMYOMAS.

BY

LEO. H. BERND, M.D.,
of Philadelphia.

Through courtesy of Dr. Munroe I recently saw a case of considerable interest as follows:

Mrs. L. C., age 22, Russian, was admitted to Jewish Maternity March 4, 1901. Her pelvic measurements, were, Cr. I., 28 $\frac{1}{2}$; Sp. 28; bandloques 20 $\frac{1}{2}$; bilitrochanteric 31; vertex L. O. A. Fetal heart sounds 120. On the 5th she began to have contractions, but they were slow and there was not much dilation. This kept up until the 9th, when dilation was complete. About 3 p. m. forceps were applied and although there was no difficulty in the application it was impossible to draw the head down.

I saw the patient at 7 p. m. and found the head in a perfectly normal position and forceps were again applied. The result was the same. As the head felt proportionately small enough to pass through the pelvis, podalic version was done. No difficulty was experienced in finding the feet and the child was delivered up to the head. So far as we could judge something seemed to retard the head.

Forceps were applied to the after-coming head and although we got it through the pelvis the soft parts seemed to hold it. There was a marked vaginismus but a slight tear obviated that.

By inserting two fingers in the rectum I was able to hook them over what felt to be a most peculiar shaped head and by traction on the body we delivered the child. The placenta followed almost immediately with slight bleeding.

There was a slight tear of perineum. The cervix had a bilateral tear and was somewhat dense. In the posterior wall of the uterus, flattened out about the size of an orange was a hard mass. It seemed to be in the muscular portion. The tears in the cervix extended into the edges of this mass. Had it been a hematoma of course it would have vanished at once. We therefore made a diagnosis of fibromyoma.

The woman made a good recovery and on examination when discharged the tumor had entirely vanished. She gave no history of any trouble during pregnancy nor before. The time it took to dilate the cervix is readily understood. The child lived 11 hours.

AN INTERESTING ANOMALY.

BY

W. M. WEAVER, M.D.,
of Hartford, Conn.

Permit me to report through the columns of AMERICAN MEDICINE an anomaly, revealed by a postmortem examination held on April 7, last:

The subject, a female infant, weighing 6 pounds, died on that date after living 13 days. During this time it presented symptoms of irregularities in the circulatory and respiratory systems. The child cried vigorously enough at its birth and, to all outward appearances, seemed normal, but was unable to nurse well. It slept a great deal. Its body was cold and its cry weak and moaning. On the tenth day the child ceased nursing. On the afternoon of that day the following conditions were noted: There was a slight discharge from the nose. The body was cold and there was a slight tendency to cyanosis. The rectal temperature was 96.8°, the respirations were 50, and the pulse was very feeble. There were no abnormal breathing sounds, but the heart was heard beating most distinctly to the right of the sternum. A more thorough examination on the next day seemed to verify the supposition that the heart was on the right side. Respirations at this time were 80, temperature 101°, and the pulse probably between 170 and 180. Rales were heard over both lungs, for the most part loud and musical. There was a slight cough, and at each attack of coughing the child became very cyanotic and struggled for breath. It died while the mother was asleep, death, it is fair to presume, occurring in an attack of coughing.

The postmortem examination was conducted in the presence of Drs. J. W. Felty and J. H. Standish, neighboring practitioners. The heart was found enlarged and was placed obliquely in the chest, with its base directed upward, backward and to the left, corresponding to the fifth dorsal vertebra. The apex was directed downward, forward and to the right, corresponding to the lower border of the sixth rib on the right side, just outside the nipple line. The chamber, which assumed the functions of the right ventricle, was in front, lying from left to right, and completely covered the left ventricle which was on the right side. The right auricle was to the front and on the left side beneath the second intercostal space. It was enlarged and covered the left auricle. The chamber of the right ventricle was twice the size of the left ventricle and was filled with blood. The right auricle was also filled with blood. The valves of the heart were normal as to number and formation, but the foramen ovale and the ductus arteriosus were not completely closed. The foramen ovale gradually closes about the tenth day, we are told, but a slit-like opening sometimes persists during life without any inconvenience. In this case, however, there was considerable opening remaining where the valvular fold, which closes in the foramen, had failed to join its upper margin. The arch of the aorta was directed to the right instead of the left and the descending aorta was on the right side of the spinal column. Correspondingly the inferior vena cava was on the left side. The large bloodvessels given off from the aortic arch did not share in the transposition, for the left common carotid and the left subclavian arteries were given off separately, as in the normal body.

The lungs were peculiar in that the right lung had 2 lobes and the left 3. There were some reddish and blue-brown spots in the base of the right lung which were airless and the bronchioles contained considerable mucus, but there was no marked inflammatory involvement of the substance of either lung. The stomach was normal in size, but was placed on the right side, the pylorus being directed from the right to the left where it joined the duodenum. The large lobe of the liver, which is usually on the right side, was on the left and the other lobes were correspondingly reversed. The spleen was on the right side occupying the same relative position as it does when normally placed on the left side. The pancreas extended from the spleen to the concavity of the duodenum, which was to the left of the median line. The intestines were placed in reverse order. The cecum, with appendix, was on the left side and the sigmoid flexure on the right.

ORIGINAL ARTICLES

APOPLEXY AND HEMIPLEGIA.*

BY

HAROLD N. MOYER, M.D.,

of Chicago, Ill.

I invite attention to a brief consideration of apoplexy and hemiplegia, not with the hope of presenting anything new, but rather with the idea of directing attention to some common misconceptions in the diagnosis and treatment of these conditions. Notwithstanding all that has been written regarding the term apoplexy, it retains its place in the nomenclature of medicine and is very loosely used even by the best writers. During the last two decades this faulty use of the term has been pointed out repeatedly. If used in the original Greek sense, meaning literally, to strike down, one can take no exception to the use of the term. By many it has come to be the equivalent of cerebral hemorrhage, and if I may judge from a considerable consultation practice, I should say that the conception in the minds of the profession is almost invariably that apoplexy means a cerebral hemorrhage. It is not difficult to see how this error has grown. For hundreds of years apoplexy was a nosologic entity until postmortem examinations began to be performed with some frequency, when it was found that a large proportion of those who died very soon after an apoplectic stroke had a rupture of the bloodvessels of the brain. As a matter of fact, those who had a stroke resulting from embolism or thrombosis to a large extent recovered; hence, they did not figure in the postmortem tables, but were nevertheless classed as cases of cerebral hemorrhage which recovered. At the outset of my remarks, I would say that apoplexy from thrombosis, in my judgment, is very much more frequent than that from cerebral hemorrhage, but very much less fatal.

So strongly has the idea of arterial rupture and hemorrhage been associated with the word apoplexy that it has been applied to these conditions when they occur in other organs than the brain. Thus, we have the term pulmonary apoplexy, a condition which is described in most of our standard textbooks; not infrequently, apoplexy of the liver and of other internal organs is spoken of. Strictly speaking, but one condition of the lungs merits the term apoplexy—that of pulmonary thrombosis in which the patient is stricken suddenly; a hemorrhage should be spoken of as such or as an extravasation.

There is a prevalent misconception as to the relation of cerebral arterial disease to sudden death. In a recent investigation, I asked a number of physicians as to the causes of sudden death. Out of 20, 19 stated among the causes apoplexy and heart-disease, about one-half of them placing apoplexy first, and the other half, heart-disease in the order of frequency. The twentieth physician, who happened to be a pathologist, said that cerebral hemorrhage was very rarely a cause of sudden death; that is, of death taking place within a few

hours—it was only when hemorrhage took place into the medulla involving directly the cardiac and respiratory centers, that we had the phenomena of sudden death. This latter view is correct, though I believe that it is directly contrary to the prevalent opinion.

To distinguish hemorrhage from thrombosis and embolism is of some importance, especially from the standpoint of treatment. Practically there is little distinction between thrombosis and embolism, as an embolus becomes a thrombus as soon as it is arrested in the artery. The secondary or remote consequence of hemorrhage, thrombosis, and embolism is practically the same.

The problem to be determined when summoned to a patient who has had a stroke, is to determine whether it is due to a thrombosis or hemorrhage of the brain. In the absence of a history, this may not be easy, as acute alcoholism, uremia, epilepsy, the initial stage of general paralysis as well as diabetic coma simulate very closely the stroke accompanying cerebral vascular involvement. As a rule, we can determine later by the presence of hemiplegia, and this fact can be ascertained even in states of profound coma, if the paralysis is very marked. As a rule, the slighter degrees of paralysis are not accompanied by coma; hence, a profound and prolonged loss of consciousness due to hemorrhage or to thrombosis is almost certain to be accompanied by a very marked hemiplegia. This can commonly be ascertained by a careful examination of the patient's arms. The side which is not paralyzed, if raised from the bed and held in different positions, will be noted to have a certain amount of resistance, and occasionally slight involuntary movements will be noted in the muscles. Upon the paralyzed side, the arm will slip through the fingers something like a piece of wet rope or other inanimate object. If held for a considerable time, it will not present the involuntary movements noted on the side which has escaped. Another symptom almost always present early in severe cases is the turning of the eyes toward the side of the lesion. In right hemiplegia the patient looks toward the left, the side of the lesion in the brain; in left hemiplegia the direction of the eyes is reversed.

Once you have determined the fact of hemiplegia associated with coma, there is no question but that you have to deal either with hemorrhage or thrombosis of the brain. Which of these may be present may be a difficult decision, but it is of considerable importance from the standpoint of treatment. In cerebral hemorrhage you are dealing with a ruptured bloodvessel and your effort is to secure as quickly as possible coagulation and an occlusion of the ruptured artery preventing a pouring out of blood and further damage. In thrombosis you are dealing with a very different condition of affairs. There has been set up a sudden anemia in the region supplied by the occluded vessel, which will result in softening. In this last you have a process which calls for stimulation and the maintaining of vascular pressure and of nutrition. In the former you desire to reduce the circulation to the lowest possible limits. In the treatment of cerebral hemorrhage you would have the head raised, while in thrombosis it should be lowered.

* Read before the Tri-State Medical Society, Keokuk, Iowa, April 2, 1901.

In hemorrhage, bleeding is indicated; while in thrombosis it is not. As a matter of fact, a diagnosis between these two conditions is in many cases impossible, so that the treatment should not be too vigorous upon any one line, unless clear indications are present. It is a fact that in most cases of thrombosis there is a very marked reaction, and that while bleeding and reducing measures may be contraindicated, there are still a certain number of cases which may receive benefit from those measures which are useful in cerebral hemorrhage. When in doubt, treat the case carefully, avoiding those active measures which often do more harm than good. In any event, the patient should be kept quiet, preferably placed upon the side rather than upon the back, the bowels should be opened, and, if you are sure you are dealing with a case of hemorrhage, by all means give nitroglycerin. We do not know that this will do harm in cases of embolism, but it will certainly be of great benefit in case you are dealing with a ruptured bloodvessel. Very much the same effect may be secured by bleeding the patient—namely, a lowering of vascular pressure which favors coagulation in the ruptured vessel. In one of my cases of hemorrhage, marked benefit was obtained by a thorough bleeding and a subsequent injection of a normal salt solution. Should another similar opportunity offer, I would certainly add to the salt solution .5% of gelatin in the hope of favoring coagulation in the ruptured vessel. I cannot condemn too strongly the administration of strychnin and ergot. Useful as strychnin is in heart-failure, it should have no place in the therapeutics of thrombosis or hemorrhage into the brain. Cases of this kind prove fatal from respiratory failure due to direct pressure in the cranial cavity, and the strychnin is of no sort of value, except to increase the vascular tension and so precipitate the very condition which it is destined to relieve. The same is true of ergot. It is of no value in controlling hemorrhage into the brain, but, on the contrary, directly favors it, because it increases vascular tension. Ergot is only of value in postpartum hemorrhages, and there it is of use because it contracts a hollow muscular organ and so mechanically occludes the vessel. It has no influence in hemorrhages into cysts or any organs in which no such muscular structure exists.

The diagnosis between hemorrhage, thrombosis and embolism depends largely upon the previous history. In embolism the stroke is always sudden without premonitory symptoms, but usually the patient has been in more or less ill health and frequently a cardiac lesion or advanced disease of the kidneys are present. The prognosis in hemiplegia, due to embolism, is graver than in other forms because the underlying conditions, predisposing toward embolism, are in themselves of great gravity. In thrombosis we have the constitutional states of syphilis, gout, and rheumatism to guide us, and there are usually some premonitory symptoms. A patient will complain for weeks or months of a tingling or numbness in the fingers, which will gradually increase until some morning the patient wakes to find one side paralyzed. Such a warning should be given its full significance in a patient who has syphilis and antisiphilitic treatment instituted. In patients past middle life such subjective

symptoms upon one side of the body are strongly suggestive premonitory signs of an apoplectic seizure, probably thrombotic in origin. The early recognition of these and prompt treatment of the underlying constitutional states will serve to postpone, if not altogether prevent, the development of a hemiplegia.

The treatment of the secondary consequences is exactly the same, whether it is due to hemorrhage or thrombosis. As soon as the patient regains consciousness a careful estimate should be made as to the amount of damage which has been done. As a rule, it will be found that the arm is more paralyzed than the leg, and the face least of all. While the face upon the paralyzed side is somewhat smoother than upon the opposite, it is the lower part of the face that is principally affected, the patient not having lost the power to close the eyes, as they do in peripheral facial palsy. Very soon after the effects of the stroke have passed the patient begins to regain some power in the paralyzed side and this should be encouraged. Several times a day the patient should make a conscious effort to move the paralyzed side, first commanding him to move the well arm and then both arms. These early efforts at movements undoubtedly bring into action certain damaged nerve-cells and tracts which, if allowed to remain out of use for a considerable time, might undergo degeneration. In most cases it will be found that there is more or less loss of sensation, even in cases in which the paralysis is not very marked. Careful testing will show a certain amount of impairment, and the peculiarity is that it is most impaired in the hand and foot, less in the arm and thigh, while the trunk is comparatively little involved. Sometimes the paralysis is slight and the loss of sensation considerable, and again it is reversed; but as a rule the loss of sensation follows the same distribution as the motor impairment, and this is exceedingly valuable from the standpoint of diagnosis as it is characteristic of the organic hemiplegic lesions.

In the treatment of secondary consequences of hemiplegia, we must ever bear in mind the possibility of the development of late rigidity, which is a thing most to be avoided. This is accomplished by massage and the passive movements. A fixing of the extremities by contractures is always accompanied by more or less general involvement; hence the articulations should receive very careful attention. Even with the best of treatment, in many cases rigidity and uselessness, particularly of the upper extremity, is marked, but even when the result is so unfavorable, it is certain that careful attention to this detail will result, in the majority of cases, in a more useful extremity than will be obtained without it.

Another point in reference to hemiplegia is the much more severe character of the lesions when the hemiplegia affects the right side and the lesion is upon the left side of the brain. It is in these cases that we have aphasia and they are always accompanied by more intellectual disturbance than those in which the accident occurs with the right brain.

During the Examination.—*Professor:* "How would you treat postpartum hemorrhage?"

Candidate: "If it were a severe case I would ligate the postpartum artery."

A CASE OF INTERMITTENT CLAUDICATION.*

BY

DAVID RIESMAN, M.D.,

of Philadelphia.

Professor of Clinical Medicine, Philadelphia Polyclinic; Instructor in Clinical Medicine, University of Pennsylvania; Visiting Physician to the Philadelphia Hospital.

In 1858, Charcot¹ read a paper before the Société de Biologie, in which he reported the following interesting case: A man, aged 54, who had early in life received a bullet wound in the right flank, complained of a peculiar difficulty in walking. After walking for more than a quarter of an hour he would experience throughout the entire right leg a feeling of weakness and numbness; and if he continued on his way, pain and tingling began in the penis and extended to the right thigh and down the left leg to the foot. Finally, cramps and stiffness supervened and rendered the limb useless. After a few moments' rest he could continue his walk, but for only a short time; in 20 minutes the symptoms described returned, and again arrested his progress. Death ensued from gastrointestinal hemorrhage. At the autopsy the right common iliac artery was found to be the seat of an aneurysm in its upper two-thirds. The lower portion was obliterated and converted into a fibrous cord.

Charcot attributed the functional disturbances in the right leg to an ischemia or anemia of that member, produced by the arterial obstruction, and termed the condition intermittent claudication or intermittent limping. The expression was borrowed from veterinary medicine, in which it was employed to designate an intermittent painful limping or paralysis occurring in horses. Bouley², in 1831, was the first to point out the equine form of the affection, and attributed it, as did Charcot afterward, to arterial obstruction.

Charcot's paper, although classic in the clearness of its diction and reasoning, remained almost unnoticed both in France and elsewhere, and it was not until he had on several occasions recurred to his original observation and had recorded others, that cognizance was taken of the disease. The most elaborate studies have since been made by Erb³ and by Goldflam⁴. As the former has but recently reviewed the literature, I would refer to his masterly paper for an historic account of the affection.

The cardinal symptoms of intermittent claudication are as follows: The patient starts out to walk, and does so for a short distance with perfect or almost perfect ease. Then he begins to experience pain and numbness, often a distinct cramp, in one or both legs, usually in the calves or in the feet. Further walking becomes difficult or impossible, and he is compelled to rest. After a few minutes, however, locomotion can be resumed, only to be again interrupted by a return of the pain and cramp in the legs. The patient thus becomes intermittently limping, or rather lame. In horses the objective symptoms are similar. The animal starts out well, but after a short trot of a quarter of an hour or less it begins to limp, and if spurred on, the hind legs become stiff and rigid, and it falls to the ground in evident pain. After a short rest it can go on, but the

same symptoms recur within a few minutes, and the animal becomes useless for service.

Examination of human beings suffering from intermittent claudication has shown as a very characteristic objective feature an absence of pulsation in the arteries of the feet—chiefly the dorsalis pedis, often also the posterior tibial, in rare instances the popliteal and the femoral. Pulsation of the dorsalis pedis is practically never absent in health; nor in disease, except in conditions such as edema, elephantiasis, and analogous affections which interfere with the satisfactory palpation of the artery, and in arteriosclerosis of marked degree. Erb examined a large number of hospital patients, and found pulsation present in 99%. In 1% it was absent, by reason of the causes just mentioned. Goldflam found pulsation of the artery absent in 9 out of 200 heterogeneous cases examined by him. None of these 9 showed symptoms of intermittent claudication. This indicates that obliteration of the pulse may occur without intermittent claudication; but Goldflam's and Erb's cases of the disease show that intermittent claudication very seldom exists in the absence of obliteration of the pulse in the dorsalis pedis artery. Thus, in 24 cases observed by Goldflam, the pulse in either one or both dorsalis pedis arteries was absent in all but 1 case; the posterior tibial did not pulsate in either leg in 7, and in 4 each the right and the left were pulseless. In Erb's 12 cases the arteries of the feet were examined in 11; and of these 8 showed absence of pulsation in 1 or more of the arteries in question—the dorsalis pedis and the posterior tibial behind the inner malleolus. In 1 case no pulsation could be detected in the popliteal; this artery is, however, so deeply placed that, as Goldflam remarks, a negative result is of but little value.

Aside from the intermittent hindrance to walking, there are, as a rule, no other motor symptoms in intermittent claudication. Sensation is also normal—objectively, at least; subjectively, the patient often experiences various paresthesias—formication and numbness, as well as pain and coldness. Vasomotor symptoms are common, and consist of pallor, coldness, and dryness of the skin; at times there is a peculiar bluish mottling, and rarely signs of local syncope, in the shape of pallid, anemic areas, like the "dead fingers" of Raynaud's disease, are manifested.

That it is important to recognize the disease, is shown by the fact that gangrene occurred 7 times in Goldflam's 24 cases. It is very probable, moreover, that a number of instances of spontaneous gangrene reported by surgeons were really cases of intermittent claudication.

The majority of the patients are men; 11 of Erb's 12, and all of Goldflam's 24. The interesting case reported by Gordon⁵, in which the disease was associated with paresthetic meralgia, occurred also in a man.

Regarding the age, Erb's patients varied from 32 to 60 years; of Goldflam's 24, 14 were under 40; my own patient is a man of 39 years.

From the point of view of pathologic anatomy, the most important lesion is an obliterative endarteritis of the peripheral arteries. This endarteritis is associated with hypertrophy of the muscular coat, and often with corresponding alterations in the veins. The changes are

* Read at a meeting of the Philadelphia Neurological Society, April 22, 1901.

similar to those found by Mitchell and Spiller^d in the arteries of the toe from a case of erythromelalgia, which is likewise a very painful affection of the distal parts of the limbs, and may in some respects be considered as belonging in the same category as intermittent claudication. The digital nerves in Mitchell and Spiller's case were decidedly diseased, but in the cases of intermittent claudication hitherto studied, either at autopsy or after amputation of a gangrenous limb, no changes were found in the nerves. In 1 case Marinesco noted peculiar alterations in the muscles, the interpretation of which is not entirely clear.

The etiology of the disease coincides in a large measure with that of arteriosclerosis, which, as I have stated, is the principal anatomic lesion found in the disease. Syphilis, alcohol, exposure, tobacco, and perhaps diabetes, play a role. Regarding syphilis, it is interesting to note the contrast between the cases of Erb and those of Goldflam. The former found 4 out of 9 (44.4%) patients to be syphilitic, while only 1 of Goldflam's 24 had had the disease.

As arteriosclerosis is common and intermittent claudication rare, it is necessary to assume that other factors contribute to bring about the latter affection. These factors presumably are vasomotor disturbances, which may in turn be connected with endarteritic changes in the vasa nervorum.

When we come to explain the symptoms, it is very natural to attribute the various functional disturbances to the anemia and stasis produced by the arterial obstruction. This latter is in part organic—due to the endarteritic process; in part it is dependent upon vasomotor spasm. "The cry of the nerves for blood" expresses itself in pain; the muscles, on the other hand, seem to respond to the same privation with a painful contraction or a cramp. Charcot inclined to the belief that the muscles lost their irritability, and possibly suffered a change analogous to cadaveric rigidity—such as, for instance, is produced by occlusion of the abdominal aorta in the well-known Stannius' experiment. Whether the arterial spasm is in itself painful—by stimulation either of sensory nerves or of touch corpuscles in the vessel-walls—is a mooted point. There is abundant evidence that acute arterial obstruction is excessively painful, and some have attributed the pain to such a form of irritation.

The intermittent character of the symptoms is not surprising; during repose the amount of blood supplied is sufficient for the functional demands, but during the use of the limbs in walking the supply becomes inadequate; as soon as the patient rests the waste products are removed, and the parts again receive their needed share of blood.

It is an interesting fact that the majority of patients with intermittent claudication have been excessive users of tobacco and have been of the Hebrew race. Both of these statements apply to my patient, whose case I now proceed to relate:

Mr. D. A. G., a native of Iowa, 39 years old and married, is the head of a large manufacturing establishment. He denies having had syphilis. He worked hard for many years as a traveling salesman, and while thus engaged was much exposed

to cold and wet. His mother was a diabetic, but died of an accident; his father died of apoplexy; a sister died of diabetes. Three brothers and several sisters are living and well. His wife has had 1 miscarriage, and has borne 1 child, now 11 years of age, who has had St. Vitus' dance. All his life, the patient has used tobacco to excess, both in chewing and in smoking.

Fourteen months ago he had an attack which was by one surgeon diagnosed as appendicitis, and by another as muscular rheumatism. He was in bed 10 days, and, for reasons that the history fails to reveal, lost in the next 3 weeks 35 pounds in weight. A blood-examination was made by a microscopist for the physician in attendance, and the patient was told that he had malaria.

One day about this time, while walking on Chestnut street, he suddenly had a sensation as if water were running down the left leg, and experienced a sharp pain in the sole of the left foot. So severe was this that he had to take a cab to go to his office. Ever since then he finds that although his legs feel natural when he starts, as soon as he walks a few squares he has pain in the calves, especially the left, and the legs feel, to use his own words, as if they weighed 100 pounds. After resting a few minutes he is able to resume his walk, but the pain and heaviness quickly return. These annoying occurrences have caused him to form the habit of riding in the street-cars for even the shortest distances; he will thus take a car to cover 2 blocks.

One afternoon about 2 weeks ago I visited him at his factory, which is on Arch street, between Third and Fourth streets. He told me that he had gone for luncheon to the Bullitt Building—only about 2½ squares away. When he got as far as Fourth and Market streets he could scarcely lift his feet on account of pain and a sense of weight; and he was compelled to rest for a few moments before proceeding to his destination.

A very curious feature is that while in his factory he walks about a great deal with scarcely any trouble. I attribute this largely to the fact that his mind is intensely centered upon his business, and this gives him no time to think of his ailment. Possibly, also, the greater resilience of a wooden floor, as compared with asphalt or stone pavement, may be a factor.

The patient's feet often feel cold, and perspire profusely when he is walking. There is, however, no numbness and no formication, but occasionally he has a feeling as of pins and needles in his fingertips. The pain is not influenced by atmospheric changes or by excitement. Last summer he was much benefited by a sojourn in the Pocono Mountains. Before going there he had a good deal of pain, but after a short stay he was much relieved, and was able to walk 4 or 5 miles without suffering.

There is also a distressing shortness of breath on slight exertion, and he has to be very careful of his diet on account of a sensitive stomach. It was the dyspnea and the trouble with his legs that first caused him to consult me last November. I should also state that in June, 1900, he had a peculiar attack, during which he lost speech, and power in the right arm; the leg and face were unaffected, and consciousness was not impaired. After 2 weeks' treatment, apparently with the iodids, he recovered.

On examination I found the patient to look at least 10 years older than his actual age. He had a sallow complexion and dark rings under the eyes. The heart-sounds at the apex were weak; the second pulmonic sound was accentuated, but the second aortic was not increased in loudness. After walking up and down the office a few times, the first sound at the apex became reduplicated. The radial arteries were thickened. The pulse was 100 to the minute; this rapidity of beat was noted in a number of examinations. The pulse was small, and the tension increased. The temperature was normal. The knee-jerks were present, but feeble. Tactile sensation was good over the lower limbs, and there was no disturbance of the heat-and-cold sense. He did not have Romberg's symptom nor the Argyll Robertson pupil. Examination of the arteries of the feet showed that *pulsation was entirely absent in both dorsalis pedis vessels*. The posterior tibials pulsated, the left less strongly than the right. This is interesting, as the left leg was the worse. The popliteal vessels could not be felt; but as I have already stated, this is no criterion, since they may be deeply situated.

There was no swelling and no discoloration of the limbs. The urine, of which the patient passes about 35 ounces a day, contained a trace of albumin, but no tube casts, and was free from sugar; it had a specific gravity of 1,008, and a strongly acid reaction. Fehling's solution was turned green and a precipitate of phosphates formed.

Treatment directed to the relief of the trouble in the patient's legs proved for a long time unavailing. Nitroglycerin and the iodids (the latter in the form of iodalbacid) wrought no change; neither did massage produce any material improvement. Lately, however, benefit was secured by a combination of iodids and mercury—the so-called mixed treatment. The relief, however, has been but temporary. He is now taking bromids and nitroglycerin, which have seemed to help him more than anything previously given. When I last saw him, April 16, he was better than he had been for months, and could walk 4 or 5 squares without a return of the pain. Following a suggestion of Erb's, I shall add strophanthus to the treatment. This strengthens the heart, without contracting the vessels, as does digitalis, and thus sends more blood to the lower limbs. It goes without saying that the patient has been instructed to lessen his indulgence in tobacco; but he is so addicted to its use that he has been unable to carry out my wish for an entire discontinuance.

To complete the discussion of the treatment of intermittent claudication, I shall add a few words regarding diet, exercise, etc. The diet should be that suited to arteriosclerosis in general; namely, one largely vegetable. Red meats, alcohol, tea and coffee, and rich foods, should be excluded. The alkaline mineral waters are helpful. With regard to exercise, the advice of Erb that great moderation be used is certainly judicious. If the nature of the affection is not appreciated, the temptation to urge the patient to practise walking at all hazards might easily arise. This would be a serious mistake, in the light of the pathology of the affection. Fatigue should always be carefully avoided. The patient should—to quote Erb—walk with the watch in hand. He should also protect himself carefully from cold and dampness. Massage may prove beneficial; my own patient was not, however, helped much by it. Galvanism is useful, the feet being placed in separate buckets of salt water, in which the electrodes are also immersed. The current is passed first in the one and then in the other direction, for a period of from 3 to 6 minutes.

The iodids and nitroglycerin are indicated; so are cardiac stimulants of the strophanthus order. As has already been mentioned, my patient was benefited by the bromids and nitroglycerin.

The case I have reported is, I think, a typical one of intermittent claudication on an arteriosclerotic basis. The shortness of breath on exertion, the transient aphasia, and the gastric symptoms are probably likewise connected with arterial changes. The only ascertainable factors are tobacco and exposure, together with much mental strain. Whether the man is in danger of that most deplorable complication, gangrene, I cannot say; it is to be hoped that he will be spared this terrible calamity.

DISEASE AND DEFORMITY OF THE KNEE; ETIOLOGY, DIAGNOSIS AND TREATMENT.

BY

DANIEL W. MARSTON, M.D.,

of New York.

Instructor Orthopedic Surgery, New York Postgraduate Medical School and Hospital. Visiting Surgeon Daisy Fields Hospital for Crippled Children, and Randall's Island Hospitals, New York City.

[Concluded from page 295.]

It should in all these cases be our first duty to save the life of the patient, by whatever means necessary; and second, to preserve the limb with as little deformity and as near normal function as possible.

Constitutional treatment should consist of careful attention to the diet, and the use of general tonics, as codliver-oil and creasote, such as each case seems to

Fig. 10.—First incision.

need. Nourishing food in unlimited allowance is in my opinion of as much importance as treatment with drugs. Good steaks, eggs, plenty of cream, and sufficient farinaceous food, will, when combined with good air, out-of-door life and cheerful environment, work wonderful results in even advanced cases. I have noticed in the cases operated upon in the Postgraduate Hospital, coming from the old and densely populated sections of the city, that if these children are returned to their homes, they are soon seen again in the out-patient department, candidates for further operative measures. If on the other hand these little folks are sent to our country hospital for such cases, their improvement is rapid, and their cures made more permanent. Together with hygienic and dietetic precaution, mechanical protection

is, as a rule, indicated in the very inception of the disease and not infrequently supersedes the necessity for operation. The inviolable law in all cases of joint-disease is extension for the relief of intraarticular pressure, and immobilization to prevent the trauma of motion.

The knee is no exception to this rule. Upon detection of disease the joint should at once be put completely at rest. If there is deformity due to spasm of muscle it should be overcome by proper extension-apparatus. The ordinary Buck's extension (Fig. 9) applied as far as the joint is as good as any. It is best put in with moleskin

sure. To prevent this it is necessary to employ traction in the line of the deformity. Place a wide bandage behind the calf of the leg near the knee, and attach this to a hook in the ceiling over the bed. By so doing the head of the tibia is lifted upward and forward and the intraarticular pressure is relieved instead of augmented. Place pillows around the knee to avoid any slight jar to the joint. When the limb is straight a protective apparatus should be applied, one that will continue extension is best. Plaster-of-paris is excellent as an immobilizing agent, but does not furnish adequate extension. It is furthermore cumbersome and heavy. No brace is better adapted to the many requirements of such a case than that devised by Thomas, of Liverpool. (Fig. 10) This is practically an ischiatic crutch, allowing the patient to take the weight-bearing point upon the tuberosity of the ischium, which also affords the counter-extension. Thomas of

Fig. 12.—The patella and capsule of joint removed.

straps and a muslin roller bandage. The buckles at the end of the straps should be 1 inch above the malleoli and should be on a level with each other, in order that even traction may be exerted on both sides. The usual weight-and-pulley accompaniment is used. The weight may be supplied by a bottle of shot, a sandbag, or anything which permits the regulation of weight.

Traction must always be exerted in the line of deformity. If when the leg is flexed upon the thigh at an angle of say 20° extension is applied and the weight put over the foot of the bed as in the treatment of fracture of the femur, the patient will seldom gain relief. On the contrary, the pain is usually increased. This is because with the hamstring tendons as a fulcrum and the tibia for a lever, you are producing intraarticular pres-

Liverpool did not teach the theory of intraarticular pressure and the extension modification of his knee-brace was not original with him. The shoe of the opposite side should have a cork elevation of 2 inches. If the best possible results may be obtained in the use of this brace, it is essential that careful attention should be given to the adjustment of the circumferential bands just above and below the knee. The one above the knee holds well back the lower end of the femur. The band below the joint keeps well forward the head of the tibia, thus preventing any tendency that may exist toward subluxation of that bone. It is a bad result when these cases recover with genu-recurvatum.

In convalescent cases, or when the ligaments of the knee have been strained, it is not always necessary to

resort to extension, although a stout support is needed for the joint, while in use. For such cases there is nothing more simple and yet effective than the lock-joint knee-brace, used in our Postgraduate Clinic. (Fig. 17) It allows the patient to walk with a stiff knee. By a lever-joint the knee can be unlocked to enable the patient to bend the leg while sitting, and when standing it will lock again automatically. The apparatus is adjustable to any shoe by a sliding socket fastened to the sole of the shoe.

In advanced cases, when suppuration has taken place and there are present destructive changes either in the bone, or in the soft parts, operative measures should be adopted.

Every abscess, purulent or tuberculous, should be opened as soon as the condition is diagnosed, or even suspected. The presence, or the size, of an abscess, is no criterion by which to judge the destruction that may have taken place. The largest abscesses are sometimes

necrotic tissue when the abscess present is not large enough to excite unusual suspicion.

Incise all suspected abscesses at once. If no abscess is

Fig. 14.—Bone resected.

present no harm will have been done, and the intelligent exploration of the joint with his finger will give the surgeon knowledge otherwise unobtainable.

Excision of the kneejoint in children must not be performed if any other treatment can be substituted, because of the interference with the normal growth of the limb. In adults excision is not only advisable, but is the rule usually followed. In children under 15, it is better surgical practice to perform a scraping operation. The Volkman scoop well used can usually remove all necrotic tissue. The joint should then be irrigated with pure carbolic acid, allowed to remain for 1 minute in contact with the tissues. The corroding effect of the acid is neutralized by the thorough use of absolute alcohol, and then the whole is flushed with a mercuric chlorid solution. The wound is best drained with the glass speculum drainage-tube, which should be kept in place until the granulating surface fills in from the bottom. It is well to protect these joints for at least a year after the operation with some suitable brace.

In adults and adolescents in whom the growth of the limb is, or is nearly, complete, and the bones have acquired so firm a texture that after the operation they readily undergo an unyielding synostosis, the procedure that has afforded us the best results is the Phelps' rapid excision. As Plimpton aptly says in an article on this subject in the April (1897) issue of the *Postgraduate Journal*:

"In determining what operation for excision of the knee best subserves the requirements, it may be said that the method which allows of the most complete removal of all diseased tissue,

Fig. 13.—Articular surfaces exposed.

and gives perfect drainage, retains the part in best apposition, and fixes the bones without the use of pins or wire, and last, but not least, the one that can be

accompanied with but little destruction of the adjacent bony tissues, while too, the entire articulating surfaces may be denuded of cartilage and the joint filled with

done with the greatest ease and rapidity, is to be preferred." Without entering into a discussion of the merits and demerits of the operations devised and performed by different surgeons, I believe that Fenwick's section of the bone (see Fig. 14), with Phelps' method of removing diseased soft parts together with bone, as described below, fulfills all the requirements mentioned above, with a few exceptions. When the head of the femur is destroyed, precluding the section according to Fenwick, Dr. Phelps has devised a

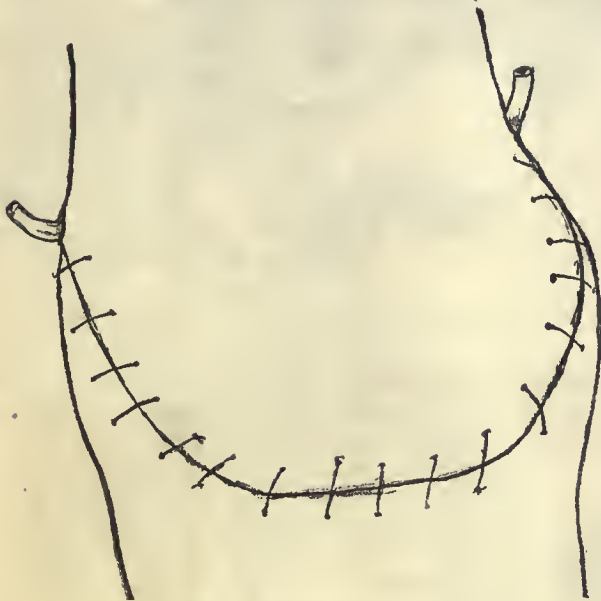

Fig. 15.—Wound closed.

method to meet this condition by sawing a wedge-shape at the end of the femur and a V in the tibia for its reception. The essential feature in Fenwick's operation is the sawing of the bone in a line parallel to the articular surfaces, so that when placed in apposition the convex surface of the femur fits the concavity in the head of the tibia. The bones are so locked that there is little or no chance of their slipping and no tendency to rotate outward in the dressing. No pins or wires are needed to keep the bones in contact. This is greatly in the patient's favor, since the necessary period of anesthesia

Fig. 16.

is shortened by 10 or 15 minutes. When wire and pins are used, they occasionally give trouble later.

The length of time taken for excision of the knee has an important lesson for us in the statistics respecting the mortality of the operation. Mr. A. G. Miller, of Edinburgh, in a report on incision, advised against it in certain feeble patients (otherwise suitable cases), recommending the amputation because it could be done in a

much shorter time, remarking that while in either operation the shock was about the same, the effect of the longer period of anesthesia was to lessen greatly the patient's chance of life. There is a vast difference in the ether-shock, whether the patient is under its influence 20 minutes or 2 hours. This point is clearly set forth and proved in a series of clinical lectures by Dr. William H. Porter on anesthesia, delivered before the class of the New York Postgraduate Medical School and Hospital.

The shock of the operation in excision of the knee must of necessity be profound. Add to this the shock produced by ether in an operation lasting from 1 to 2 hours instead of 20 minutes, and the chance of saving the patient's life is greatly reduced. Except in extreme cases, no surgeon ought, after he is familiar with the operation here recommended, to take more than 15 to 20 minutes to operate and apply the dressing. If the steps of the operation, which I will recount, are followed, I think you will be convinced that it can be performed within the time specified.

Fig. 17.

Fig. 18.

Entering the knife a little posterior to and above one of the condyles of the femur, a curved incision is made, extending sufficiently below the patella to expose the margin of the head of the tibia, terminating at a corresponding point on the opposite condyle (see Fig. 10). This incision opens the joint more extensively than any other. Dissect the flap well up, as in Fig. 11. A curved incision above the patella removes nearly the entire synovial sac, together with the patella (see Fig. 12). Instead of picking at the diseased parts with forceps and scissors before going further, thus consuming valuable time, with consequent danger to the patient, the lateral and crucial ligaments are divided and the knee is flexed as in Fig. 13. With a saw proceed at once to resect the bones, at the same time sawing out a large portion of the diseased soft parts as well as bone (see Fig. 14). This done, the entire joint is removed with nearly all of the disease. With seissors and a Volkmann spoon the remaining disease is quickly cleared away. This concludes the cutting part of the operation. Ligate the 3 or 4

arteries if necessary. A continuous suture closes the incision, drainage at the same time being introduced (see Fig. 15). The dressing is the usual gauze and cotton, with plaster-of-paris extending from the toes to the groin. Still, quoting Plimpton, it is due more to the method than the skill of the surgeon that the operation is so quickly performed.

The statistics as compiled by Prof. Plimpton, of 102 excisions of the knee performed by the visiting staff of the orthopedic department of the Postgraduate Hospital in that institution, the New York City Hospital and the Mary Fletcher Hospital, and in private practice, are summarized herewith:

- Average shortening, 0.88 inch.
- Least shortening, 0.5 inch.
- Greatest shortening, 3 inches.
- Average time in hospital, 7.7 weeks.

No wiring was done except in the first cases. No amputations occurred. Bony ankylosis resulted in 4 months to a year in all cases.

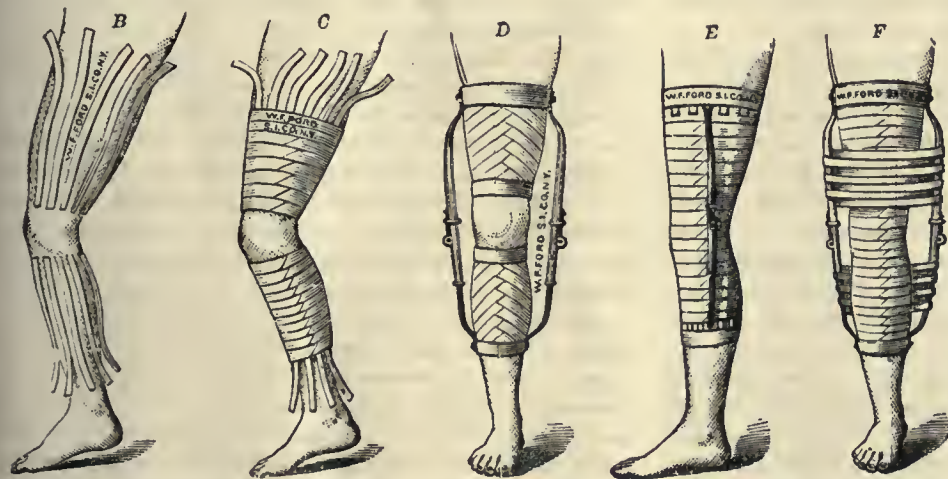

Fig. 19.—Showing method of applying knee-brace with moleskin straps.

OTHER AFFECTIONS OF THE KNEE.

Rheumatic knee is always due to a constitutional condition and is usually associated with a similar condition in one, or more, other joints. Rheumatic joints are, as a rule, multiple. A single joint, as the knee, is never involved, excepting it is preceded by an injury. The treatment of such cases is therefore, in addition to the mechanical and operative, constitutional. The mechanical treatment is of as much importance as in tuberculous and purulent joints, but will avail more if combined with the time-honored salicylates and other classic antirheumatic remedies.

Bursitis, or housemaid's knee, is a simple serous effusion into the prepatellar bursas. The treatment is the evacuation of the fluid, thorough scarification of the inner walls of the sac with a short tenotome, and the careful strapping of the joint with a basketwork of adhesive plaster straps, which neatly maintain compressions of the walls of the cavity.

Synovitis, acute or chronic, may depend upon traumatism uncomplicated, or may be associated with gonorrheal infection. The former condition is a simple inflammatory condition of the synovia and will usually yield

to rest and fomentations. The gonorrheal joint is due to specific infection at a time when the process of repair, the normal inflammatory process, is going on in some part of the synovia, following some traumatism, slight or otherwise. These joints should be treated as purulent and thoroughly irrigated. Immobilization is there combined with extension. Later on, hot air, massage baths, compression and electricity are all included in the routine treatment. The chronic form naturally follows the acute and is treated in much the same manner. The strapping, as recommended in bursitis, is excellent treatment here, and has, in my hands, often given most gratifying results. Here also incision and drainage should be kept in mind.

The etiology and pathology, as well as subsequent treatment of arthritis deformans are largely matters of neurologic interest.

The absence of objective symptoms, the history of the case, and the extraordinary prominence of subjective symptoms will place the doctor upon his guard in cases of

Fig. 20.—Typical bending following joint excision, which was not properly protected after operation.

hysterical knee, also called functional disease, neuromimetic knee. Porter reports a case of hysterical hipjoint-disease perfectly cured by the careful administration of a bitter tonic. Similar cures may doubtless be made by treatment along the same lines in hysterical knee.

Complete inability to extend the leg upon the thigh is caused by rupture of the quadriceps extensor. It is most satisfactorily treated by suture of the torn ends of the muscle and the application of a posterior knee-splint, to be worn for some weeks. The wounded limb is hardly ever as strong as before the injury.

Nine-tenths of the cases in which either dislocated semilunar cartilages or loose bodies in the joints are present occur in the knee. Potent factors in the etiology may be traumatism or the previous existence of fluid in the joint. The presence of "so-called" rice bodies is due

Fig. 21.—Result following excision.

to tuberculous infection. Incision and removal of the offending particles, large or small, is the only treatment that offers any reasonable hope of permanent cure.

I am indebted for many of the electrotypes used in illustrating the text, to Prof. A. M. Phelps, through the courtesy of whom and of Prof. W. O. Plimpton it has alone been possible to present much that may be found interesting in the above.

CHRONIC HEART DISEASE IN CHILDREN RELIEVED BY SYSTEMATIC MOVEMENTS.

BY

JOHN MADISON TAYLOR, A.M., M.D.,

of Philadelphia.

This paper is a presentation of views reached by experience and observation in dealing with the disordered conditions in the hearts of children.

Although some attention has been given to the relief of long-standing disorders of the heart and circulation by systematic exercises, as much of the literature on the subject as could be reviewed by the writer seems unsystematic and mainly suggestive. Nowhere are the principles outlined with sufficient clearness which should govern us in the selection of the measures to fit the different conditions met. Among the standard textbooks the subject is usually disposed of briefly, if alluded to at all, and in a vague and general way. The excellent papers on the subject of mechanical measures for disorders of the heart from such sources as the physicians of Nauheim and Aix les Bains, deal chiefly with certain aspects or routine procedures. Advocates of physical culture have occasionally entered claims which met with little or timid encouragement, or with opposition, the reason being probably that physicians fail to study the subject in a practical manner. In recent journal-articles the matter is referred to more encouragingly.

It is well known that a fair proportion of the sufferers from serious cardiac diseases pass through a long and active life, and at the end perish from diverse maladies not necessarily dependent upon, though perhaps modified by, the cardiac disability. One instance to which I may refer is that of a relative of my own, a most active and industrious member of the profession of medicine, who now, at the age of 72 years, still enjoys excellent health. Another is a clergyman, whose work lay for 40 years or more, on the frontier of one of our wildest sections, who did all that a sound man could do, and is still active at 70. Both these gentlemen had serious valvular disease in their early manhood, and both had advice at that age, from foremost European authorities, and were told unreservedly that they must speedily die, and yet they lived more than an ordinary lifetime since, of the severest activity, mental and physical.

These typical instances will serve to illustrate the fact, well established, that great and prolonged activity and usefulness is entirely compatible with what is often regarded as irretrievably damaged hearts. Similar

instances are cited by Samson, Balfour, Lauder Brunton, etc.

In the past 20 years it has been my privilege to release or modify the embargo laid on many people who, because of pronounced cardiac defects, had resigned themselves to a life of enforced quiet, or gravely modified usefulness and happiness, imposed on them by eminent authorities, thus far with no mishaps. Nor was this done recklessly, as can now be safely stated, but on principles carefully computed. It is an instructive study to search in these histories and formulate the grounds on which success and sustained activity were reached, whether accidental or scientifically earned. Some day it shall be my privilege to present them, but the present proposition is to outline the reasons for and the forms of exercise which, in my experience, have proven suited to children disabled in their circulatory machinery. Again, it may be said that a fair proportion of the untoward results of strains are due to indiscretions on the part of the patient, who may or may not have been adequately informed of the possibilities of his case. In the repair of damaged conditions of the heart, freedom from nervous and mental strains are of equal importance with physical quietude. In estimating the injuries due to enfeebled hearts by undue activities, we must not lose sight of the fact that oftentimes the real injury resulted rather from fictitious and emotional stimulation applied and continued; this, moreover, upon an organism which had at no time the benefits of a most necessary training under skilled direction which should fit the heart for as much work as its normal condition would warrant. All physicians familiar with athletics appreciate how much can be done to reinforce cardiac capacity, be it inherently much or little, if wisely directed; and again how serious is the resulting disturbance upon perfectly sound hearts in those who compete when inadequately trained. The heart is capable of and certainly deserves most important training. When physicians realize this, and when they are encouraged to exercise supervision not only over all athletic competitors, but of growing children in their homes, our young men will become not only more formidable competitors, but we will hear less of those (really rare) instances of break down under strains which serve as lurid texts for the diatribes of the sedentary. When the organs of circulation have had, by accident or by design and judicious direction, acquired normal development anatomically and functionally, that individual is better fitted to endure the strains and exigencies of a busy life, and he is enabled to tide over in safety many hard places, and this contributes largely to bring him to a green and happy old age. If this is true of boys it is even more important for girls who have need of the fullest cardiac competency, since theirs is a complex circulatory apparatus, which during the period of gestation is gravely taxed to do a double duty.

One word here as to hypertrophy of the heart-muscle. A heart hypertrophies in proportion to the amount of work it is called upon to do, regardless of what that work may be. This is a perfectly physiologic condition, and is to be desired and not feared if it comes from normal healthy stimulation, with no pathologic obstacle or

incompetence in or out of the heart, to be overcome. If this obstacle exists it is liable to be perpetual, and the compensatory muscle increase proceeds till such time as it is no longer capable of balancing the defect, when dilation results. If the organs of nutrition and elimination are maintained in a normal state (and for this, activities of many kinds are essential) the period of degeneration will be far distant, and only at the end of a long and useful life. If not, and ptomaines and other toxins accumulate, all the tissues suffer, of which the ceaselessly busy heart, already defective, is the first to feel the strain. Again, the strain may be due to defects in the vasomotor mechanism and then the condition of the peripheral bloodvessels needs faithful attention. This comes about through vasocontrol medicines or agencies. Measures which help to regulate the caliber of, hence resistance in, the peripheral arteries are of vital importance. Of these, baths and surface applications come first, but mild exercises are of even greater importance because more far-reaching and permanent. To obtain the undoubted advantages which follow upon muscular exercises, with the resulting blood purification, the increased breathing capacity and greater oxygenation, it is not necessary that we should have in mind, nor employ the ordinary concepts of exercise which prevail among the laity and profession alike. Physicians should make themselves familiar with the physiology as well as the practical principles of exercise. They are curiously ignorant or indifferent, usually giving far worse advice to patients than can be had from experienced trainers and professors of physical culture, even when they have themselves taken some part in athletics. Their conception of exercise too often is the crude belief that this means a series of active movements which involve muscular contractions and flexions more or less violent, ignoring the far greater value of extensions, tensions and counter-extensions, posturings and relaxations. They usually cherish the belief that active voluntary motion producing quickened cardiac action and more or less breathlessness is harmful for such patients, as indeed is quite true in some cases. Very salutary effects are obtained by passive movements, manipulations, stretchings, rotations and the like, gradually supplemented by voluntary acts, deep breathing, and finally, graduated active movements of the limbs, neck and trunk. In the cardiac cases it is seldom necessary to proceed to resisted movements for a long time, certainly not until it is shown by careful observation that the individual is capable of enduring them.

Exercise, in the sense employed in this paper, is both the passive and intentional, yet systematic use of the machinery of motion for the purpose of maintaining and improving health. When the mechanism of circulation is itself damaged, along with the organs of vitality, it is customary for medical advisers to content themselves with merely counseling restriction of activities, and modifications of the environment in as advantageous a fashion as is consistent with the possibilities enjoyed by the individual. As a consequence the patient falls into a complex condition of passive organic disturbances because the circulatory movement is stagnated, and this produces many far-reaching effects some of which are most serious. It is true some children suffer amazingly

little from this, spontaneous and conservative adjustments coming to the rescue, but in the majority there are sooner or later evidences of passive congestions, particularly in the liver, kidneys, lungs, and indeed in the nervous system, which assuredly demand relief. When this is omitted, life is shortened, and more conspicuously, living is rendered much less enjoyable. A cleaner blood supplied to the brain enables the bedridden one to enter into much more of the passing events of his environment, to be far more cheerful, to read and acquire many intellectual as well as physical pleasures.

Congestion of the liver has a wide influence upon the conservation of energy. If the blood sluggishly circulates repeatedly through this great laboratory, unsupplied by those elements which favor its healthy metabolism, unrelieved of those powerful poisons which are here secreted, then both mind and body must suffer marked depression. The liver should produce an adequate amount of bile, the natural primitive laxative. Its retention produces jaundice, and many depressing states. Laxatives can accomplish only a part of what is required. The kidneys when long congested, are liable to become functionally inert, and to suffer structural change, retaining toxins and permitting the escape of albumin.

The lungs, if never encouraged to full activity, lose their elasticity, especially at their apices; the pulmonary circulation, deficient as it is in vasomotor nerves, stands in peril from slight infections or congestions, and pneumonias, infective or passive, easily arise and are then most difficult to resolve.

The skin, the great defender of the body, becomes inelastic, the surface nerves and bloodvessels lose their tone, the peripheral vasomotor mechanism ceases to guard the organs from surface chill, leaving them vulnerable to slight variations in temperature, and atmospheric or other changes.

And lastly, to complete the sketch, the nervous structures suffer, and above all, the brain, though longest to resist, at last succumbs to this abuse of the vital organs. Not only the intellectual forces wane, but the disposition is impaired, and that inestimable boon, the joy of living, fails little by little. Death is far more often dependent upon emotional depression, discouragement, and the apathy which comes of increasing disappointments, of which one of the most recognizable factors is the gradual realization, conscious or unconscious, that a life like that of others is impossible for them, not only preventing them from sharing the activities of those about, which could be endured, but a realization of the inability to share their reasonable animal pleasures is denied because the organs of sense are obtunded by the retained products of tissue waste.

All this can be modified, and most of these discomforts are capable of amelioration, by supplying in some form and to some degree, the normal activities or their equivalents. And this again can be done by keeping the importance of the matter constantly in mind, and adapting our measures to the capabilities of the individual.

I am fully in sympathy with those who would treat cases of marked cardiac disorder by rest in bed for long periods. My contention is that during this time a great deal can also be done to mitigate the evils of

enforced rest by passive movements and graduated activities. As the condition improves, as acute states pass away, as compensation becomes established, there will usually be found a time when it is not only permissible, but wise to direct greater activities, always watching the effects with practised eye, and permitting of no indiscretions—for therein the danger lies, not in the regulated movements. Finally there comes a third stage, when the patient is prepared either to take the matter into his own hands if he be of a resolute nature, and recklessly throw off the irksome restrictions imposed upon him for months or years, or on the other hand, to accept the embargo as laid upon his normal impulses and fall into hypochondriasis or invalidism. Here, more than ever, is the wisdom of the medical adviser tested.

It will be conceded that organic functioning is dependent in a great measure upon the maintenance of the normal anatomic interrelationships of the viscera. This is eminently true of the lungs, when rachitis or other cause has produced deformities of the thorax. Long protracted illness of any sort tends to induce faulty attitudes, and the growing bones and ligaments lose their normal adjustments. Disuse and inactivities emphasize this further. The heart and great vessels must share equally in the disability. Jacobi reports a case in which the aorta, by dislocation of the lungs, was bent upon itself, and the circulation thus seriously embarrassed. The narrowing of the thorax in rachitic children causes a crowding downward of all the abdominal organs, the liver and spleen are engorged, the kidneys frequently dislocated, and in consequence, readily diseased. Even in the absence of structural deformities, prolonged and enforced rest induces similar results.

So much for the picture, readily enlarged by each, of the need of symmetrical adjustment to secure full organic interrelations. This brings me to the first point to be striven for. By regaining the normal attitudes of the body the figure becomes well set up, the skeletal muscles and ligaments, when in good tone, hold and maintain the organs in such positions as will enable them to do their best work. Damaging contractures sometimes arise, not only in the ligaments, but also in the muscular coverings and intermuscular septa, in the connective tissues generally, and even in the skin and subcutaneous structures; these must be released and a greater flexibility secured. My experience, gained as a lecturer on massage and regulated exercises, for years past, has brought me in contact with a large number of highly intelligent operators and exponents of physical culture methods, and I am increasingly impressed by the remarkable results obtained by no other means through passive flexions, rotations and extensions and counterextensions, in not only improving tissue, but in repairing changes in the whole nervous system. In many conditions the lesser forms of central change seem thus distinctly benefited. Much larger improvement is to be expected from this than from the lighter forms of massage. General massage done in a massive and hurried fashion is capable of producing harm in conditions of acute or graver forms of heart disease. The form of massage to be recommended is a slow, gentle kneading, constantly supplemented by a picking up of

the tissues and separating them from contiguous structures increasingly. In dealing with the abdominal viscera this is a rule for constant observance.

In beginning with a case of heart disease of subsiding acuteness, while absolute rest lying down is still required, no harm can result and much good come, by employing the systematic procedures to be outlined. For a few minutes twice a day let the physician himself or a thoroughly trustworthy assistant direct the child to lie flat on the back without a pillow and hold itself very straight or horizontally erect, if the term be permissible, and with the arms extended like a cross, submit to gentle passive movements by the operator, one hand for counterextension on the trunk, the operator to pull outward the limb, gently rotating and revolving and vibrating; later, manipulating the tissues about the shoulders, hips and larger joints, and finally making some strokings inward, etc. By this means I have had repeatedly not only good immediate effects on digestive and other organs and on sleep, but tendencies to minor deformities are thus overcome. The circulation is thereby made more active in the muscles, the blood is invited to change in the viscera and move in a more complete cycle throughout the body.

As the condition of the heart improves gentle massage may be given to the limbs, and later to the trunk also, always slowly and gently and for a short period, preferably twice or thrice a day, with an increasing degree of force employed in the passive exercises. Then comes the time when forced breathing is of value, teaching the child to take long, slow breaths filling the lungs and giving exercise to the diaphragm. The diaphragm is a most important muscle, and can be taught to be used voluntarily. By its contraction the thoracic viscera are raised and lowered, and the abdominal ones moved as well. The effort at costal breathing produces many useful effects. The diaphragm along with the muscles of the abdominal walls can be trained to act as flexors as well as extensors, and compression as well as passive support can be exerted upon the organs. The act of forced costal breathing is of value in many directions, by expediting the oxygenation of the blood and the maintenance of the elasticity of the visceral structures, and is itself an exercise refreshing and of much efficacy. This is proved by those, such as singers and others, who practise it in lieu of greater muscle movements. I am told a sect in India allow themselves little other activity than deep costal breathing, and by this acquire not only much vigor, but a very handsome and symmetrical thoracic development. Certain it is, as clinical results show, that these and other voluntary movements of the abdomen result in improved cellular conditions.

To secure the best form of breathing it is important to teach the child to lift the shoulders and make them flexible by placing the clasped hands on top of the head and making repeated efforts at raising and lowering the scapular muscles. This draws up the ribs and the serratus muscles as well as bringing the long abdominal and dorsal muscles into play, and it is surprising how rigid these tissues will often be found even in such young subjects; in older persons it requires a long time to acquire freedom of action.

While still lying on the back active extensions of the limbs may be made in different directions, best with the hands extended firmly on the arm, as far out as possible, shoulders level, up and in front; the feet are next similarly extended until the heel reaches as nearly as possible in front. This produces a strain on the tendons which makes for flexibility not only all along the limb, but far into the tissues of the shoulders and the hips which if disused so rapidly grow inelastic. As the condition of the circulation improves the operator may meet these extensions by a certain amount of resistance and increasingly, always watching the effect on pulse and respiration, neither of which should be made to hurry. It is gratifying to note how much of this form of exercise may be employed without inducing hurried breathing or pulse rate, only both are amplified in volume most comfortably, and a sense of immediate wellbeing follows.

After a few weeks of these measures, and when the child is fit to be allowed up and to walk about a little, the exercises may be continued and varied in the sitting posture, which must be maintained a long time. The important movements are still the extensions and rotations, always slowly and firmly. The movements should involve little or no thrusting upward of the arms nor drawing of them back beyond the vertical line of the body, nor lowering or raising of the trunk. All movements should be natural postures in natural and usual directions but always accurately performed.

Many movements can be made with the neck to great advantage. Neck exercises seem simple and profitless to an active child, but much can be accomplished for healthful circulation of the head, brain and thorax by this means alone. Especially is this true where there is disturbed sleep. A hanging down of the head, with slow rotations first one way from 5 to 10 times, and then the other way the same number; a forward and backward thrust likewise repeated, and finally the rather difficult accomplishment of a side to side movement maintaining the vertical line of the face. All these tend to amuse a bedridden child of suppressed activities, and redistributes the stagnant blood in areas anatomically of the largest importance. Later a mild resistance can be offered with advantage to the head during the neck movements. Soon the eye will become brighter, the face cheerier, and living will become more tolerable and sleep deeper and sweeter.

In all conditions of weak heart and lungs, attention should be given to the muscles of the upper thigh and hips, where large muscular power resides, hence large oxygenation takes place, and these can be exercised cautiously, yet fully, without disturbing the respiratory or circulatory balance. These, in form, are first passive, then active, widening and contracting of the thighs either while lying or sitting, the feet resting on the ground and later resistance can be offered to a pronounced degree in perfect safety.

Finally it is feasible to proceed to more complex coordinating movements suitable for vigorous children, which it is needless to describe here.

In conclusion let me call attention to the fact that a close study of the suitability of such simple yet carefully estimated procedures will repay the physician, and the

patient may thereby escape a disabling degree of invalidism which too often results from degenerative changes in vital tissues during the progress of a life of enforced passivity.

PERIPHERAL VENOUS THROMBOSIS IN CARDIAC DISEASE, WITH REPORT OF A CASE.

BY

J. A. MacGREGOR, M.D.,
of Minden, Nebraska.

In his article on "Thrombosis and Embolism," in "Allbutt's System of Medicine," published in 1899, Dr. William H. Welch called attention to the association of thrombosis of the peripheral veins with disease of the heart, and in a paper entitled "Venous Thrombosis in Cardiac Disease," published in May, 1900, in the Transactions of the Association of American Physicians, he has considered the subject more fully. Of the 28 cases, including 5 previously unpublished, reported in the latter paper, all but 4 were instances of thrombosis of the veins of the neck, arm and chest, the affection being in the vast majority of cases on the left side. It is this peculiar localization, in such marked contrast to the usual seats of venous thrombosis, as well as certain clinical and etiologic features, which lend especial interest to this subject.

Inasmuch as before the appearance of Dr. Welch's papers, this subject had received but little attention, and as the number of cases hitherto recorded is small, it is believed that the report of the following typical case will be of interest:

C. H. M., male, aged 46, has been for the past 10 years a saloonkeeper, and previously was a miner. There is no history of rheumatism or of venereal disease. Twelve years ago he had an attack of rightsided hemiplegia without aphasia, the onset of the paralysis being gradual during 24 to 36 hours. He was treated for this in a hospital in San Francisco, where he completely recovered in 4 months.

Before the attack of hemiplegia and since his recovery therefrom, he has enjoyed excellent health up to October, 1900, when he began to suffer from shortness of breath and slight puffiness of the ankles. He was treated, according to his statement, for "liver and kidney trouble," but with no improvement.

On February 3, 1901, he came under my professional care, complaining of symptoms referable to heart disease. His general nutrition was fair. The shortness of breath had increased to orthopnea and there was well-marked lividity. The dropsical swelling of the lower extremities extended above the knees and later there was edema of the genitals, the buttock and the abdominal walls. The abdominal cavity became so distended with serum as to embarrass the circulation and the respiration, and to necessitate relief by tapping. The appetite was capricious, the bowels irregular and the urine scanty, high-colored and slightly albuminous, without casts. No abnormality was detected in the liver or spleen.

There was no precordial bulging and the area of cardiac dulness was not markedly increased. There was a well-marked thrill perceptible on palpation at the apex, and a rough, presystolic murmur was audible, most distinct over the third left interspace, close to the sternum. Obstructive disease of the mitral valve was diagnosed.

The pulse varied between 96 and 112, being at times intermittent and at times irregular. The arteries were fairly well filled and elastic, without increased tension. The superficial veins of the upper abdomen, chest and neck were dilated.

There was a harassing cough, but physical examination of the lungs gave only negative results. There were frequent attacks of epistaxis, which at times was profuse. The temperature ranged between 98° and 98.6° F. Sleep was much broken, and at times there was mild delirium.

Six weeks before death there appeared the evidences of thrombosis of the left axillary, subclavian and internal jugular veins, with a possible extension of the thrombus into the left innominate veins. The onset of this complication was manifested by severe pain in the left arm, shoulder and supraclavicular region, accompanied by much edematous swelling in these situations. The swelling extended from the fingers to the shoulder and to the side of the neck on the left side. The skin here became livid, tense and shining, the superficial veins were dilated and areas of capillary stasis were present. The sense of touch was impaired. Motion, either active or passive, gave rise to excruciating pain. There was marked tenderness on pressure over the course of the axillary, the subclavian and the internal jugular veins.

The condition of the patient remained about as described for one week, when the symptoms referable to the thrombosis began to abate, and in the course of a month the improvement progressed to nearly entire disappearance of the edema of the arm and of the pain, only a slight tenderness remaining over the course of the plugged veins. The capillary circulation became good, although the superficial veins remained prominent.

During the whole course of the thrombotic attack the pulse-rate was not altered from its previous condition, and the temperature was not increased.

Notwithstanding this local improvement, the heart became increasingly incompetent, and on April 3 there was unusual weakness of the pulse, which was also intermittent and irregular. Edema of the lungs supervened, and the patient died 24 hours after the onset of these more severe symptoms. During the last 4 to 6 hours there was marked twitching of the left arm and leg. No other cerebral symptoms were noted. An autopsy could not be secured.

In its main features the case above described corresponds to the prevailing type of peripheral venous thrombosis in heart disease as described by Welch. The valvular lesion was mitral stenosis; the thrombosis appeared during broken compensation, and the location was the usual one—on the left side in the veins conveying blood from the arm and the neck. There was not only no association with rheumatism at or near the attack, but no history of rheumatism at any period. It is probable that the cardiac lesion was of long standing, as the attack of hemiplegia, 12 years before the final illness, seems to have been of an embolic character, although, of course, this is not certain. If the lesion dated so far back, it had evidently been well compensated for many years. The age and the sex of the patient are perhaps worth noting, as the majority of the cases analyzed by Welch were at a later period of life and of young women in whom mitral stenosis is more common than in men.

As there appears to be some diversity in the symptoms referable to this form of thrombosis in different cases, attention may be drawn to the severity of the pain and tenderness at the beginning and to the extent of the edematous swelling.

Undoubtedly the most interesting feature of the present case is the recovery from the symptoms referable to the thrombosis. This must have been attributable to the establishment of a sufficient collateral circulation, in spite of the great disturbance of the general circulation caused by the disease of the heart. Only 4 of the 24 cases reported and collected by Welch recovered, but he doubtless correctly attributes the gravity of the prognosis not

so much to the disturbance created by the thrombus as to the condition of the heart usually present when the thrombus makes its appearance. It is certainly of interest that a collateral circulation could be established under such unfavorable circulatory conditions as existed in my patient.

The twitching of the arm and leg which was noted during several hours just before death is perhaps attributable to the jugular thrombosis. In one of Poynton's cases, cited by Welch, there were cerebral symptoms and at autopsy cerebral edema, which were referred to the jugular thrombus. It may be that in the present case there was an extension of the thrombus at the last, or that with the rather sudden, extreme failure of the heart the cerebral circulation became so feeble that the preexisting plug without any further extension sufficed to set up cerebral edema or some local disturbance of the venous flow in the brain.

The questions concerned in the causation of this form of thrombosis have been discussed by Welch, and there appears to be nothing revealed by the present case which sheds additional light upon this aspect of the subject.

A HITHERTO UNDESCRIBED REACTION FOLLOWING THE INOCULATION OF VACCINE VIRUS. A PRELIMINARY REPORT.*

BY

HEINRICH STERN, PH.D., M.D.,
of New York City.

CASE I.—Mr. O. W., aged 50, German, was a sufferer from uricacidemia for a number of years. The paroxysmal attacks caused him great suffering and he underwent treatment by almost a score of physicians. He was referred to me by his last medical adviser on August 16, 1900. Learning that patient held a position in a brewery, I at once interdicted the use of beer and of other alcoholici, and prescribed for him, after repeated analyses of his blood and urine, an antilithemic diet and medicinal agents as potassium iodid and colchicum. One week's treatment ameliorated the patient's condition to a great extent, demonstrated not only by the absence of pain and the disappearance of the bloatedness so common in habitual beer drinkers but also by the increased blood alkalinity and the occurrence of uric acid in the normal ratio in the urine. He remained free from pain as long as he took the medicines. Discontinuance of the latter, even for but 2 or 3 days, although patient had meanwhile strictly adhered to the prescribed diet, inevitably brought back the gouty pains. In course of time it proved that colchicum alone would abate the attacks; finally colchicin in small doses was ordered and continued almost without interruption.

In December, 1900, on the occasion of the outbreak of variola in Manhattan, every employé of the brewery who had not been vaccinated for 5 years had to submit to vaccination by the brewery's own physician. Mr. O. was vaccinated (tertiary vaccination) with effect. On the seventh day, when he had moderate fever and felt himself quite indisposed, he dispensed with the administration of colchicin. The fever continued somewhat longer than normally, for about 4 days. For some reason or other the patient did not again start with the colchicin. In January, 1901, about 5 weeks after the vaccine inoculation, Mr. O. called on me and stated that he had not taken any medicine for a month past, and that he had since felt entirely free from pain. He also expressed the opinion that there seemed to be a relationship between his vaccination and the cessation of the lithemic phenomenon.

*Read at the meeting of the Manhattan Clinical Society, April 5, 1901.

This incident induced me to observe whether similar effects had taken place as a result of vaccination in other cases of lithemia and in kindred affections.

CASE II.—Mr. J. D. M., aged 50, American, who is under treatment for chronic interstitial nephritis, was for a time affected with severe paroxysmal pains of a neuralgic character in the region of the psoas and glutei muscles. Since his revaccination which was accompanied with considerable swelling of the axillary glands, in December last, he experienced no pain on any occasion.

CASE III.—Mrs. A. R., aged 48, American, is afflicted with diabetes mellitus. Various disorders of the peripheral nerves, especially spasmodic contractions of the muscles of the calves accompanied the underlying affection. She was vaccinated (secondary vaccination) in the beginning of December 1900; the vaccination took, but moderately; the patient, however, has not been troubled with cramps in the calves since that time.

CASE IV.—Mr. I. R., aged 43, American, has diabetes mellitus for the past year. The exclusive meat-fat diet to which he was subjected for almost 3 months caused uricacidemia or a kindred condition which was most marked in the ankles and toes. The subsequent diminution of the daily quantity of albumin- ingesta and the substitution therefor of carbohydrates was not followed by a cessation of the pains. These only subsided after patient had been successfully vaccinated (tertiary vaccination) in December, 1900. He experiences now occasional, but very slight contractions in the calves. These contractions are not troubling him at all; they are a concomitant symptom of the diabetic state and bear no relation to the pains prior to vaccination, which were of a decided gouty character.

CASE V.—Mrs. S. M., aged 45, German, diabetic, is subjected to chronic lithemia. In December, 1900, she was vaccinated with effect. Soon after the inoculation she felt herself free from pain and in spite of her obese condition could walk 3 or 4 miles without feeling tired. The gouty exacerbations have not recurred.

CASE VI.—Mrs. S. S., aged 26, American, obese, complained of distressing sensations in the muscles of the back, and of an intense tired feeling in the lower extremities. She was vaccinated (tertiary vaccination) in December, 1900. The vaccine process ran a somewhat anomalous course. On the ninth day after inoculation her body-temperature rose to 40.5° C. During the febrile period, lasting for almost a week, in which time she became much prostrated and suffered intense pain, radiating from the point of inoculation, the urine possessed characteristic pyrexia features with very high degrees of density. Before the complete abatement of the acute phenomena, the original muscular pains and the languor had already vanished. Mrs. S. had no distressing sensations since, and without exerting herself, is able to walk 4 or 6 miles daily, which she finds necessary to keep down her embonpoint.

CASE VII.—Mr. H. W., aged 32, German, obese, was affected with an unusually pronounced languor during the months of October and November, 1900. The condition seemed to be due to the hyperingestion of fruit, principally of apples and grapes. The large amounts of malic and tartaric acids thus introduced into the system did not appear to oxidize as readily as smaller quantities usually do. A lithemic or pseudo lithemic state was the result, of which the aforementioned lassitude was but a manifestation. He was vaccinated with effect in December, whereupon the lithemic symptoms were promptly dispersed.

CASE VIII.—Mr. A. M., aged 40, colored, suffered from muscular rheumatism upward of 4 months, when he was vaccinated late in December, 1900. The inoculation was successful. When a week later he remarked without being questioned that he was now cured of rheumatism. After another week the patient had gained in body-weight, and followed his usual occupation.

CASE IX.—Miss B. P., aged 38, Irish, was affected with arthritis for about 5 months. She was treated with salicylates and acids, and was ordered antilithemic diet; but, however, on account of the dampness of her place of employment, these means were of little avail. In January, 1901, she submitted to vaccination; the reaction ensued; at the same time the arthritic

pains had ceased almost abruptly. Two weeks later the pains had not returned.

CASE X.—Mrs. A. O. C., aged 54, colored, very obese, is subject to gouty diathesis. The exacerbations became so violent on different occasions that she had to resort to morphin. During her last paroxysm she was visited by a board of health vaccinator who compelled her to be vaccinated. The pains left her almost instantly and she feels very comfortable at the present day.

Prompted by the foregoing and some other similar observations, I tried to investigate whether the disappearance of gouty and kindred phenomena after vaccination in my cases was but an accidental occurrence, or whether vaccinia exerts a certain definite influence upon uricacidemia or other blood anomalies. For this purpose I vaccinated 2 male sufferers from lithemia. It is true, neither individual had undergone previous treatment for his affection, and it is quite probable that a rational therapy would have brought about cessation of the gouty manifestations. As so many were vaccinated during last winter's smallpox scare, the 2 young men had no objection to submit to the inoculation.

FIRST EXPERIMENTAL INOCULATION.

Mr. R. A., aged 32, German, complained of "jumping" pains in back and arms, of headaches, pain in thighs and on urinating. The experimental vaccination (revaccination) was effective; fever moderate; pains disappeared during the first week. He feels quite well at the present time. Occasionally he is troubled with slight cephalalgia, but this seems to be due to overwork and little sleep.

SECOND EXPERIMENTAL INOCULATION.

Mr. L. F. L., aged 24, suffered from pains in lower extremities, particularly in the ankles, and from occasional attacks of coccygodynia. Experimental vaccination (revaccination) was effected; elevation of temperature was not observed. The distressing sensations vanished completely. Patient feels comfortable now, but is affected with acne.

My experience as to the nature of the vaccinia reaction upon metabolic disorders, as uricacidemia, so-called, is as yet too limited to warrant any positive statements in this respect. That there occurs a reaction there seems to be no doubt; however, the literature on vaccination which I consulted does not dwell upon this or a similar action of the virus. It abounds, on the other hand, in the influences of intercurring acute and chronic maladies upon the process of vaccination and in anomalies which may be subsequent to the inoculation.

I have reported the foregoing cases in the order in which they came under my observation. No attempt was made to classify them according to their apparent underlying cause. Clinically speaking, the cases were such of uricacidemia, rheumatism and neuralgia. However, they all had one symptom in common—*pain*.

Inasmuch as the pain was relieved in every instance, we may assume that this amelioration was due to one and the same reaction, and we may further assume, that one and the same cause stands at the foundation of many affections, which are clinically differentiated between as gout, rheumatism and neuralgia. Thus the vaccine virus, or a modification of it, may become a factor in positive diagnosis.

The normal constituents of vaccine lymph hardly possess solvent or specific eliminating properties, and it seems that the reaction is a secondary or an indirect one.

The system in its endeavor to rid itself of the virus, develops increased oxidizing qualities. The diminished formation of incompletely oxidized meta- and catabolic products may be the consequence of the augmented internal combustion.

However, the direct causes of the painful conditions in my cases might not have been of metabolic origin after all. The same factors which had called forth the condition of uricacidemia may have prepared a proper soil for the development and propagation of *ectogenous* pain producers. If such is the case, that is, if the more acute manifestations are due to bacterial activity, then the reaction may be due to the influence of cytorhyctes variolae, the variola-vaccina sporozoa.

It does not seem probable that vaccination will afford relief of all pains simulating the gouty or rheumatic type. Besides, I cannot state whether the inoculation of the attenuated virus immunizes the organism but temporarily against the exacerbations of lithemia and kindred affections. As far as I could learn, pain and languor have not returned in a single instance. The patients are now free from aches and discomfort for from 3 weeks to almost 4 months.

The virus used in every instance, as far as I could ascertain, was manufactured by the Department of Health, of New York City. The reaction, which awaits confirmation by other observers, may afford us an insight into the genesis of at least *one* pathologic state.

In closing these remarks I wish to emphasize that there is certainly no intention on my part to introduce vaccination as a "specific" for all kinds of muscular and other pains, for it is not; neither is it my aim to recommend it as a prophylactic or a therapeutic measure against gout, rheumatism and affections of this category.

PREGNANCY COMPLICATED BY FIBROID TUMORS. CESAREAN HYSTERECTOMY AT EIGHTH MONTH.

BY
MARY ALMIRA SMITH, M.D.,
of Boston, Mass.

Surgeon to the New England Hospital for Women and Children.

Operations upon the pregnant uterus (aside from Cesarean section) have only within the last few years been considered justifiable. Since the days of aseptic surgery these operations have become more common, and it seems wise, for the present, that all such cases should be published in order that the profession may arrive at just conclusions regarding this new branch of surgery. The following case might be called a Baer-Cesarean operation, since Baer's method of performing hysterectomy immediately followed removal of the child by Cesarean section.

L. H., age 33, born in North Carolina, colored. Her family history showed nothing of special note, except that one sister died of "quick consumption" at childbirth. She had been feeble as a child. Menses established at 18, and were regular and fair in amount, but she always had pain. Her last period occurred January 3 to 9, 1900. She had malarial fever at 18 years of age, and has had 2 attacks of grip since. In December, 1899, she first noticed a lump in left side of abdomen. This is the first pregnancy. She felt life in April, 1900. In May she

made an unsuccessful attempt to procure an abortion and was sick for a week with suppression of urine and cramps in lower abdomen. From the beginning of pregnancy she frequently had pain in right iliac fossa, increasing in severity of late. Digestion was fair, and bowels regular, but she says she feels very weak and has some palpitation. Limbs have never been swollen.

On physical examination these points were noted: Patient is tall and thin. Mucous membranes of good color. Cervical glands in posterior triangle enlarged. Respiratory murmur good. Heart: Apex beat in fifth interspace fairly regular, first sound booming and slightly roughened in quality; second sound accentuated. Breasts large and pendulous, nipples well developed, no colostrum. Abdomen irregularly distended by a tumor extending to a point midway between the umbilicus and the ensiform cartilage. The umbilical depression was effaced. Numerous hard masses could be felt, but it was impossible to distinguish the fetal parts with certainty. Fetal heartbeat heard on right side near umbilicus, strong, 150 per minute. No fluctuation could be found; percussion note dull over tumor. Uterus somewhat movable, especially in transverse direction.

Measurements.—Circumference at umbilicus, 84 cm.; circumference at iliac crests, 84 cm.; from symphysis pubis to umbilicus, 15 cm.; from umbilicus to ensiform cartilage, 18

cm.; between anterior superior spines, 22 cm.; between crests of ilia, 24 cm.; bi-trochanteric, 29 cm.; external conjugate, 20 cm. Vagina moist; no varicosities. Cervix uteri cannot be felt. A hard mass like a fibroid tumor in the posterior wall of the uterus filled the pelvic cavity.

Urinalysis.—September 11, 1900. Amount in 24 hours, 1,800 cc.; color, yellow; slight cloudiness; reaction neutral; specific gravity 1,008; no sugar; small quantity of albumin; urea, 22. Microscopically, epithelial cells, leukocytes and a few casts.

Diagnosis.—Pregnancy at about 8 months, complicated with multiple fibromyoma, so situated that a delivery of the child by the vagina was impossible.

Prognosis was of course grave, but there being no alternative, abdominal delivery was advised. The patient was kept under observation, and meantime, her general condition improved, as far as possible; but pain and increasing weakness soon rendered interference necessary.

Operation at N. E. Hospital, September 13, 1900. After the usual aseptic preparations, the patient was etherized, and an incision made in the abdominal wall from the symphysis upward about 20 cm. extending to the left of the umbilicus. The uterus was brought out through the incision, and gauze pads packed around it to protect the intestines. An incision was made in the anterior uterine wall from the fundus down, a little to the right of the median line in order to avoid a large fibroid on the left side. The child was grasped by the feet and lifted out; the cord was quickly clamped and cut, and the baby, cry-

ing lustily, was given to an assistant. The placenta and membranes were removed, and the uterus failing to contract properly on account of the numerous fibroids, an elastic ligature was applied around the cervix to control the hemorrhage. Further examination showed that there was no hope of saving any part of the uterus, and it was therefore at once removed, following Baer's method of supravaginal hysterectomy. There was no further hemorrhage, and after flushing the abdominal cavity with normal salt solution, the abdominal walls were united with layer sutures and the usual sterilized dressings applied.

The child was a male, well formed and developed, weight 5 pounds. In the beginning its temperature was low, but this soon improved after being wrapped in cotton and an electric pad placed in its bed. From the first it was fed artificially, but seemed to thrive well, and was later discharged in good condition.

Examination of Specimen.—Placenta weighed 1 pound, and was attached to the right side of uterine cavity. Cord 37 cm. long. Uterus with both tubes and ovaries attached weighed 7 pounds. Largest circumference 65 cm. Diameter of cervix at point of separation from fundus 3 cm. In anterior wall of uterus an incision 20 cm. long just avoiding a large fibroid tumor which occupied the entire left side of the uterus, and was 15 cm. in diameter. Thickness of uterine wall in upper part 6 cm.; in lower part very thin, only 1 mm. Right side of the uterus contains several small tumors from size of English walnut to that of a large orange. One in the lower segment of this side specially prominent is 8 cm. in diameter. Attached to the left round ligament is a small tumor the size of an English walnut. All the tissues are very edematous. The cavity of the uterus was very small, hardly admitting a fist. The fallopian tubes and ovaries were apparently normal. Microscopically all the tumors are made up of fibrous and muscular tissue.

After-treatment.—The patient recovered from ether without nausea or any special signs of shock. Her first and only complaint was of severe pain in region of the heart. This was very persistent, and only yielded to repeated hypodermic injections of morphin. On September 14, the patient said she had slept very little last night owing to the pain in precordial region. The pulse is irregular, from 100 to 120 beats per minute. Digitalin and strychnia continued. Bowels moved freely after calomel and salts. Morning temperature 100°, evening 103°. On September 15 the patient was very restless and the cardiac pain still required the hypodermic use of morphin. Stimulants were used freely, but in spite of them the pulse is of bad quality, 140 to 160 per minute. Temperature is now normal. Considerable dyspnea. Normal salt solution was administered by hypodermoclysis. The next day the condition was about the same but the patient was very apprehensive. The temperature at 6 a. m. was 98.4°. On September 17 the patient was somewhat apathetic; the extremities were cold at intervals through the day. Pulse responds more slowly to stimulants. At 10.45 p. m. she became delirious and passed away on September 18.

Autopsy.—Body long and slim; rigor mortis marked. Medium layer of fat. Incision in median line of abdomen 20 cm. long, united by silk-wormgut sutures. Walls of wound well agglutinated; no signs of suppuration. Opening the abdomen the omentum was found covering small intestines, which were but slightly distended; a few drops only of serous fluid in abdominal and pelvic cavities. Peritoneum smooth, not injected; intestines free, and serous coat smooth. Stumps of broad ligaments and uterus covered by peritoneum, and sewed with fine silk sutures; no suppuration. Spleen small, surface smooth, cut surface normal. Liver not enlarged. Cut surface apparently normal. Left kidney small; capsule easily detected, cortex normal; right kidney same, except that capsule was adherent in one small spot. Stomach slightly enlarged; contained about 30 cc. of milky fluid. Intestinal m. m. smooth, not injected; contained small amount of same milky fluid as stomach. Lungs retracted, left apex attached by light adhesions, which were easily detached; 25 cc. bloody serous fluid in left pleural cavity. Surface of lungs smooth; upper lobes glued together. Pressure on cut surface gives exit to pinkish froth. No spots of induration in either lung. Bronchi empty. Mucous membrane smooth. In pericardial cavity small quan-

ties of bloody serum. Pericardial surface smooth. Heart not markedly enlarged. On removal of heart, blood emptied from the vessels. Mitral valves thickened, 1 of them shortened. Walls of left ventricle hypertrophied. One papillary muscle size of lead-pencil. Aortic valves soft. Right ventricle wall 2 mm. in thickness. Tricuspid valves thickened; 1 papillary muscle absent; cordae tendinae attached to wall of ventricle. Walls of right atrium not hypertrophied. Pulmonary valves smooth.

In reviewing the case one is naturally impressed by the important role played by the heart in the unfavorable result. The autopsy revealed the presence of an old endocarditis, and yet the compensation had been so good that I had laid no special stress upon the heart symptoms, even though there was a slight roughening of the first sound. The booming character of the pulse also was attributed more to the pregnancy being complicated by the fibroid tumors than to any special cardiac disease. We are so accustomed to meeting disturbed conditions of the heart in nearly all cases of fibroid tumors, sooner or later, that perhaps we do not give them the attention such symptoms deserve. Nevertheless, this patient was kept under observation for some time, and

special attention was given to improving her digestion and general condition. The bowels were regulated, the kidneys flushed and the diet carefully regulated. There was probably much less blood lost at the operation than during a normal confinement, as the rubber ligature applied to the cervix entirely prevented any bleeding, except during the very brief period of the extraction of the child. Neither was the ether narcosis unduly prolonged. However, the circulation was enough disturbed, together with the seemingly slight shock, to entirely derange the cardiac equilibrium, and it was this organ that gave us all the trouble afterwards. The bowels and kidneys were acting freely, there was no sepsis and the autopsy showed that all the other organs were healthy. The patient was not married and had no wish to live, and this fact may have helped on the general depression.

Imitation of Lemonade.—Judgment, with a penalty, was brought against William Park, of New York, for selling "Eiffel Tower Lemonade" under pretence that it was manufactured from concentrated lemon juice. Chemical investigation showed that the concoction was but a simulation of lemonade, containing 49% of tartaric acid, 44% of cane sugar, 2% of water, and 5% of coloring matter and oil of lemon, the latter being the only portion of the mixture that actually came from the fruit.

ON THE USE OF ALCOHOL IN TREATMENT OF CARBOLIC ACID BURNS AND POISONING.

BY

F. PIRKNER, M.D.,

of Union Hill, New Jersey.

Author's Abstract of a paper read before the North Hudson County Medical Society, February 21, 1901.

The first experiments by which it was shown that the local caustic action of carbolic acid was arrested or prevented by prompt application of alcohol were made by S. D. Powell and A. M. Phelps, of New York. Powell¹ in 1894 ascertained that in 95% alcohol he had an antidote to carbolic acid and he since used it in treatment of carbolic acid burns. Powell reports also a case (loc. cit.) where alcohol was used internally in carbolic acid poisoning. He demonstrated his discovery in front of his class, filling his mouth with pure carbolic acid and allowing it to remain 30 seconds; he then filled his mouth with pure alcohol, and suffered no bad results whatever. I have made a similar experiment with the same good result, taking 1 drachm of a 25% solution of carbolic acid into my mouth and waiting 30 seconds for the acid to burn. The pain was instantly relieved by 80% alcohol; no symptoms of any kind remained, but the carbolic acid taste. Even with a magnifying mirror I could not see any anatomical changes. Desirous to convince myself also of the practical virtue of alcohol in more intensive burns, I rubbed some *pure* carbolic acid with the glass-stopper of the bottle into the skin of the dorsal part of my right hand, being sure to cause at least a local dermatitis. *Two minutes* afterward I bathed the injured skin with 80% alcohol, which relieved the pain immediately, leaving, however, a hyperaemia of the hypodermic capillaries. I applied the alcohol again 5 minutes later, and once more 10 minutes after the second application, by which time the burning sensation had all gone and there was only a reddish color of the injured skin left to indicate a very slight inflammation. I may also mention the fact that I have always had a personal idiosyncrasy against carbolic acid.

A personal experience is also reported by George W. Sargent, of Seneca Castle, N. Y.² Mistaking the bottles, he poured carbolic acid instead of alcohol over his hands previously cleansed, but remedied the mishap at once with alcohol. Phelps states positively³ that we have in alcohol an absolutely safe and sure specific against the escharotic action of pure carbolic acid. A revision of the literature convinces me that this fact is better known than the power of alcohol as an antidote to carbolic acid poisoning, which is well worth recommending, as proved by the following few cases, the only ones reported in literature.

D. H. Galloway: "Strong carbolic acid, used by mistake as a throat spray," relieved and cured by alcohol and water.⁴ Herman Klein, of Chicago,⁵ besides two other cases of external application of carbolic acid, reports one case of poisoning (young woman swallowed 2 ounces of carbolic acid) treated and cured by large doses of alcohol. The *first report* of a case in which alcohol was tried as an antidote *internally*, and which proves beyond

any doubt the life-saving action of the latter, was made by H. Rodman.⁶ The case occurred in New York as long ago as December, 1899, to a woman 60 years old, who swallowed about 2 ounces of pure carbolic acid, and very shortly afterward was given by H. Rodman 4 ounces of strong alcohol, 3 minutes later the contents of the stomach being washed out with warm water. The washing was then repeated with diluted alcohol and the usual methods were employed for combating shock. Under this treatment the patient, although of extremely low vitality, had in an hour and a half been relieved of all urgent symptoms. Magnesium sulfate was then ordered, to be given every 4 hours, and mucilaginous drinks constantly. On the fifth day the patient was again in her normal condition. From his observation Rodman draws the conclusion that alcohol exerts a specific action in overcoming the physiologic effect of carbolic acid.

Aroused by Rodman's splendid results, I made use of the first accident case that came under my observation to try the "new treatment," having had many disappointing experiences with the old method.

December 31, 1900, at 8 o'clock a. m., I was called in a great hurry to see Anna K., 3½ years old, who had been given a table-spoonful of pure carbolic acid instead of medicine, swallowing at least 2 drams of the poison, the mistake not being noticed until the most alarming symptoms set in. When I arrived, about half an hour after the accident had happened, I found the child completely unconscious, no conjunctival reflex, etc. No vomiting had occurred. Breathing stertorous, pulse feeble, thready. Temperature apparently normal (no thermometer was used). Lips cyanotic, extremities cold. No burns in the internal mouth, only an eschar on the lower lip and chin. By means of a stomach tube I introduced 3½ ounces of absolute alcohol. While a hot bath (100°) was being prepared, I administered strychnin, 1-60 grain, twice hypodermically. The patient was then bathed for a quarter of an hour, the water being kept at 100°, and cold water compresses being placed on her heart at regular intervals.

This treatment was followed by a noticeable improvement immediately, the conjunctival reflex returning and feeble sounds being muttered each time when the cold compress touched the skin. Breathing grew clearer, the heart's action stronger. I then had the child brought to bed and hot water bottles put at her feet. At 12 o'clock, the time of my next visit, I found little change, the alcohol apparently having done its work and thrown the child into a regular stupor. Consciousness had not returned; the pulse, however, had become rapid, fuller and more frequent. The child had had 2 convulsions. Milk had been forced into her throat against my warning not to feed her. I made an infusion, hypodermically, of 1 pint of physiologic salt solution.

At 3 p. m. the child regained some consciousness, and called, "Mama," her eyes seeking for the mother. I prescribed milk of magnesia, directing the nurse to give very carefully 1 table-spoonful every half hour. At 5 o'clock, when I returned, the temperature had risen to 104°, the pulse to 136. The child talked in a delirium and was a little restless. Breathing stertorous. At 7 o'clock, temperature 106°; pulse, 150; respiration, 44. Prognosis letalis.* Child died at 11 o'clock p. m.

The case cited and all the cases known corroborate the fact that alcohol is a specific against the escharotic action of pure carbolic acid. Comparing my case of poisoning with the few cases reported in literature the question arises: Why did I fail to save the life of my patient? I arrived too late. Twenty-five to 30 minutes had been

* According to the best information, "letalis" is spelled without an h, being derived from the latin form "letum"—death, and not from "ἄλγηθῆ"—oblivion.

ample time for the carbolic acid to be almost all absorbed and introduced into the circulation. I have seen a 29-year-old patient die within 15 minutes after a rectal injection, by mistake, of 1 quart of a 2.5% solution of carbolic acid—equal to 25 cc., or about 1 ounce of pure carbolic acid—without having the slightest chance to prevent the fatal termination. Had I then known of the antidotal action of alcohol I might have saved my patient's life, although the mistake had not been noticed before alarming symptoms set in. Such an experience will explain the impulse that prompted me to embrace the only possible opportunity toward a successful treatment in the case I reported.

The conclusions from my case are: Although the amount of carbolic acid left in the stomach and intestine when the alcohol came in contact with it was rendered harmless, and the general action of the already absorbed poison was checked immediately, enough carbolic acid had already been allowed to exert a disastrous action. Further experience must show if in such cases, where the pathologic effect of the absorbed acid cannot be (*sit venia verbo*) "neutralized" any more, an excess of alcohol might not be a new danger for the patient. I would advise under similar conditions not to repeat the doses of alcohol if it has no chance to exert its specific action, by lack of a corresponding quantity of chemically unchanged carbolic acid in circulation.

Rabies in Berlin.—In Berlin no case of rabies has been known since 1873, when a law was passed requiring the compulsory muzzling of all dogs during the entire year. This was done because experience showed that the decrease of danger during the winter months was not sufficient to warrant a relaxation of the law, as January furnished as many cases of rabies among animals as August.

Smoking Rendered Harmless.—A surgeon General of the German Army is reported to have treated tobacco leaves with tannin and a decoction of *Origanum Vulgare* before they were made into cigars, and by this means so transformed the contained nicotine as to render it harmless to the human system. Experiments were made upon persons having aversion to tobacco in any form and these smoked 3 cigars in succession without experiencing any inconvenience, without alteration in pulse, breathing or temperature.

Method of Preparing Virus in the Berlin Pasteur Institute is described by Joseph B. Greene, of the United States Marine-Hospital Service. "The virus is prepared by inoculating rabbits subdurally with virus. At the end of the eighth day of the disease the rabbit is killed and the spinal cord secured under the strictest aseptic precautions. A small piece is always placed in bouillon to test its sterility in case the animal should be infected with tubercle bacilli or other dangerous organisms. Then the spinal marrow is suspended by strings in closed jars containing potassium hydroxid for the purpose of drying. The longer it is allowed to remain in the desiccating jar at a temperature (20° to 23° C.) the less virulent becomes the marrow. Pasteur considered that after 14 days' drying, the marrow became avirulent. Treatment as a rule begins with the attenuated virus and increasing its virulence till the termination of the treatment, which continues for 19 to 21 days, depending on the severity of the case. The head cases are always considered the most serious, and bites occurring under protected clothing are the least serious. A piece of the spinal cord 5 cm. in length is emulsified in a mortar, and from his 2 cm. is administered hypodermically. As a rule, 1 dose is given daily, though when it is urgent to get the patient immunized as soon as possible, it is administered twice daily."

SPECIAL ARTICLE

THE MISSION OF A MEDICAL COLLEGE.*

BY

WILLIAM W. KEEN, M.D., LL.D., F.R.C.S. (HON.),
of Philadelphia.

Professor of the Principles of Surgery and of Clinical Surgery.

Twelve years ago I had the honor of delivering the introductory address at the opening of the session of the Jefferson Medical College. I took as my topic the "New Era in Medicine, and its Demands upon the Profession and the College." In it I pointed out the demands which this new era in medicine made on our medical colleges. Today I purpose supplementing that address by considering an allied topic, "The Mission of a Medical College."

A mission is defined as "that with which a messenger or agent is charged," and I find in Webster an apt illustrative quotation from Milton:

"How to begin, how to accomplish best,
His end of being on earth and mission high."

There are missions for individuals, as for Columbus, Washington and Lincoln, and in medicine for a Vesalius, a Jenner and a Lister. There are missions for nations, as for the Hebrews in religion, the Greeks in art, the Romans in law, England and America in civil and religious liberty. But there are also missions for institutions, especially for institutions of learning, such as the Universities of Bologna, of Oxford, Edinburgh, Harvard, etc. Has not the Medical College a mission? If so, what is its nature and how is it being accomplished?

The mission of institutions of learning, among which may be classed the medical school, is threefold: First and foremost the development of the character of its students; secondly, the education of its students, and, thirdly, the encouragement of original research.

First, the development of character; that is "the sum of the moral and mental qualities which distinguish an individual viewed as a homogeneous whole." The school which instructs the intellect, but does not develop the moral character of its students, fails in its most important duty. "Intellect alone is cold, heartless and selfish; it must be lighted up by moral and spiritual principles to reveal its beauty or fulfil its high mission."

Character is partly the result of heredity and of environment. Those who are so fortunate as to possess parents to whom they can look up with reverence, even after they have passed away, are most happy. They have had a training which nothing else can supplement. The environment which they have had at home and the subtle influences of the family life will influence their whole subsequent career. The preliminary education which they have had, the physical health with which they have been endowed, the mental stimulus that they have received from their parents, all these count for much. Then there are undoubtedly individual differences; for example, the slothful, the vicious, the brave, intelligent, hard-working and virtuous. It would be a trite saying to assert that the last are those who will win the prizes in the struggle of life.

But when a young man has left his home and enters the medical school, he comes under a different set of influences, partly from his fellow-students, but chiefly from his teachers. He is moved by their example, observes their industry, acknowledges their ability and recognizes their success in life as due to a sturdy character which in turn develops the character of the student. The College is a center for those projectile moral forces, which once set in action, prolong their effects for many years afterward in well-nigh every student. We can

*Address delivered at the Seventy-sixth Commencement of the Jefferson Medical College of Philadelphia, May 15, 1901.

point for example in this school to the splendid and forceful lives of a McClellan, a Duglison, a Gross, a Pancoast and a Da Costa, whose influence on the character of hundreds and even thousands of men all over the world tells for the best and the highest ideals in medicine.

Not that which one learns in a medical school or in any other educational institution is of the most value. The *methods* he learns rather than the *facts* which he acquires; the high ideals which are instilled into him rather than the low cravings for a mere sordid success—these are the things which are of value and develop most the character. To do one's level best every day with every patient and in many cases without hope of fee or reward save the sense of duty done, the inspiring influence of success in the constant and irrepressible conflict between good and evil, life and death, this is what is of more value to the student of this and every other college than the mere information which he has acquired. It is not given to everyone to occupy a conspicuous place, but every one of you in your sphere, humble though it may be, can do your daily duty faithfully and truly, and if you do this, if you develop a high and noble character, even though your sphere be humble, when you lay down life's burdens the Great Master may well say to you, "Well done, good and faithful servant." Character depends not on the sphere, but on the person, not on the greatness of the opportunity, but on how the opportunity is met. Let me quote a portion of the justly-celebrated oath of Hippocrates to show you away back in the fifth century before the Christian era how well the Father of Medicine met his opportunity and set us an example we will may follow:

I will "reckon him who taught me this Art equally dear to me as my parents, to share my substance with him, and relieve his necessities if required; to look upon his offspring on the same footing as my own brothers, and to teach them this art, if they shall wish to learn it, without fee or stipulation; and that by precept, lecture, and every other mode of instruction, I will impart a knowledge of the Art to my own sons, and those of my teachers, and to disciples bound by a stipulation and oath according to the law of medicine, but to none others. I will follow that system of regimen which, according to my ability and judgment, I consider for the benefit of my patients, and abstain from whatever is deleterious and mischievous. I will give no deadly medicine to anyone if asked, nor suggest any such counsel. . . . With purity and with holiness I will pass my life and practise my Art. . . . Into whatever house I enter, I will go into them for the benefit of the sick, and will abstain from every voluntary act of mischief and corruption. . . . Whatever, in connection with my professional practice, or not in connection with it, I see or hear, in the life of men, which ought not to be spoken of abroad, I will not divulge, as reckoning that all such should be kept secret. While I continue to keep this oath unviolated, may it be granted to me to enjoy life and the practice of the Art, respected by all men in all times! But should I trespass and violate this oath, may the reverse be my lot!"

The second mission of a medical school is education. In the address already alluded to, I pointed out in considerable detail the enormous and rapid strides which had been made in medical education in the last 30 years. It is especially gratifying that the progress made has not been only in medicine proper, but largely in the preliminary education which is required of medical students of to-day. The better educated men you are at starting, the better educated men you will be at the finish, and, as a rule, the greater your success. But along with this better preliminary education in order to meet the enormously increased demands of a modern medical education, a college must furnish facilities which were not in existence 30 years ago, but are absolutely indis-

pensable now. Let us see how the demand has been met:

The former methods were limited to lectures and textbooks. The spoken word, in my opinion, is of the greatest importance. Fresh from his everyday contact with disease and death, an impressive, ardent lecturer exerts a powerful influence which nothing else equals. His flaming words awaken enthusiasm and stamp his ideas on his students. But this alone is quite insufficient for our purpose. It must be supplemented by your textbooks. In them is garnered the knowledge of the past and the present. This is indispensable as a starting point. As there were brave men before Agamemnon, so there were great surgeons before Gross. They were men with few of our artificial helps, but they had eyes and ears and fingers to observe with and common sense and sharp intellects to utilize their stores of accumulated facts.

But the knowledge of other men which one reads about is with difficulty made part and parcel of our intellectual bone and muscle. We must do more than this. We must develop individual observation and individual, personal knowledge. This is done in the modern medical school in 2 ways relatively new.

The most striking change in modern medical education is the introduction of the laboratory. There the medical student has his powers of observation developed by his teachers in approved directions and trained and filed to a fineness by careful personal investigations. There he learns not what others have done, but what he himself has done and sees the results that he himself has accomplished. Yet, when I began the study of medicine in 1860, there was absolutely no laboratory connected with the Jefferson, or any other medical college, with the exception of the dissecting room, that is the laboratory of anatomy. Now we have eleven laboratories, through each of which every student passes, and there learns to observe for himself and think for himself. That was a very brief, but pregnant reply of Huxley to a querulous correspondent, a reply which epitomizes the value of knowledge acquired for one's self by actual personal investigation. "Take a cockroach and dissect it."

The other relatively new method is the clinical; that is to say, each individual student is not taught as formerly only didactically the symptoms of disease which he must memorize, and the treatment which, very likely, he will forget, but in small ward classes he is made to examine as many patients as possible for himself, elicit the family and the personal history, institute a physical examination, percuss, auscult, palpate, and by the most approved clinical methods discover the nature of the existing ailment, understand its pathology, comprehend its symptoms, and suggest the proper treatment, all by the exercise of his own brains. Contrasting the exclusively didactic methods when I was a student with those of today, which are so personal and individual, the difference is almost that of darkness and of light. Surely, the Jefferson Medical College, which has tripled the length of its course of instruction and quadrupled the means and the thoroughness of instruction, is fulfilling its mission.

Yet, any medical school which is content with its present methods of fulfilling its mission, has at once fallen from its high estate. If it does not advance to newer methods, to better methods, to more exact methods, it is left behind in the march of progress. The whole history of the wellnigh fourscore years that the Jefferson Medical College has existed shows that it has constantly made progress to these better and better methods. That the next half century will witness a still greater progress, who can doubt?

The third mission of a medical college is to encourage original research. Teaching existing knowledge is very well and for the student is the chief end or final cause for which a medical college exists. But the medical

school owes a duty to the profession, to the public and to the cause of science. This duty is constantly to add to our present knowledge, to solve the riddles of disease, to answer the questions which are ever arising in the human mind as to our animal existence, with all its disorders and accidents and our mental capacity and its disturbances, and persistently and intelligently to improve our means and methods of treating these deviations from the normal. We must restlessly and continually enlarge the boundaries of knowledge if we desire to make progress—and where in the quest for additional knowledge, should investigation and original research be so likely to find a congenial home as in the very institutions where the present state of knowledge is exhibited from day to day, where teacher and pupil, conscious alike of the limitations of our knowledge, long for a better and a wider view?

The characteristic of the past century, which Wallace has so well described as the "Wonderful Century," is that of original research and the consequent growth of every department of human knowledge. Witness the enormous progress in our means of transportation on land and water for social and commercial purposes; witness the wonderful development of our manufactures from the invention of the steam engine, the sewing machine, the cotton gin, the various electric devices, such as the telegraph, the telephone, the trolley car, and the dynamo; the fast printing press, the improved processes for making iron and steel, and a hundred other instances which occur to you in a moment.

All these, mark you well, are the result of the searching, persistent careful work of the scientific student in the laboratory. They are not accidents, they have followed in the wake of the discovery of the laws of dynamics, of electricity, of chemistry. First came that which was pure theory, then the practical application for the welfare of the world.

Nor has medicine lacked during this wonderful century. We have seen the introduction of vaccination, of anesthetics, of antiseptics, which three, as with a besom, have swept into oblivion a large part of the disfigurements, pain and death which ravaged the race in former centuries; of the serum treatment of disease, which has gone so far to put an end to the hecatombs of the victims of diphtheria and its congeners. Pharmacology has given us so many new drugs that our prescriptions differ as the antipodes from those of 100 years ago. Bacteriology has revealed the actual causes of many diseases and still better, has shown us how to protect mankind from their invasion. Chemistry has given us new and efficient methods of sanitation, which have wonderfully prolonged human life. The microscope has laid bare to us the processes of disease; the blood has yielded up at least some of its secrets; the examination of the secretions now warns of unsuspected dangers. We can see the spectral forms of the bones and even the beating of the heart and other viscera by the x-rays, and instruments of precision have enabled us accurately to weigh and to measure, where before we only vaguely guessed.

In view of this enormous progress, it may be asked whether there is anything left to be discovered. To this it may be replied, that, if, starting with their poor equipment, our sturdy fathers made such immense forward strides, shame upon us, their degenerate sons, if, with our rich inheritance, we cannot outdo them and solve many of the enticing problems by which disease beckons us onward into the realms of the unknown; if there are not among us other Jenners, and other Listers, and other Röntgens, to make the twentieth the most illustrious of the centuries.

What a boon will be conferred upon humanity who discovers the cause and the means of cure of those curses of the race—cancer, sarcoma and other tumors, of syphilis, typhus fever, rheumatism and gout, scarlet fever, mea-

sles and even who can tell?—a panacea for old age and all its present evils!

Other triumphs, too, in wholly unknown and unsuspected realms await the patient, persistent investigator. These triumphs will be won by close observation at the bedside and by indefatigable investigations in the laboratory. To me the most encouraging sign of the times in medicine is the enthusiasm with which the laboratory has been welcomed, not to replace, but to be the handmaid of the clinician.

In this country our medical schools have not been wanting in their duty. I need but to point to the many laboratories now in actual daily use, not only in facilitating the instruction of the student, but in training up skilled assistants who, within the next few years, will be in the van in making new discoveries of the utmost importance to the well-being of mankind.

But all this means more buildings, enlarged equipment, more men, more money. Whence are all these to come? The student cannot pay increased fees at all commensurate with the increased expense of his education. The older methods, where 1 man lectured to 200, 400, or 500 men at once have been replaced by a method of instruction which requires the training of small classes of 20, 15, 10, or even 1 or 2 men by a single teacher. In other words, our modern methods have wholly changed from general instruction given to large classes, to individual instruction of smaller classes and often even of single students. As Harvard, Yale, Princeton, Brown and all other universities are clamoring for increased endowments for just such enlarged work and are getting them, just so the medical school must have increased funds for providing facilities for instruction and research, and especially must have endowments by which these hitherto unknown expenses can be met.

I have indicated the mission of the medical school and have shown that it is being splendidly fulfilled. Is there no corresponding mission also for the community? Shall it be, can it be, that these ardent teachers and these faithful students shall valiantly struggle on in the endeavor to solve the problem how to transmute sickness into health, how to avert the dire effects of accident, how to say to death, "thus far and no farther," and the community stand aloof, apathetic and indifferent, absorbed in business, forgetful that sickness and sorrow will sometime inevitably come to them? Remember that sickness and sorrow can only be averted by the highest skill, the greatest learning, the wisest judgment, all founded upon knowledge gained in these expensive laboratories and in these great hospitals which train the men who are to minister to you in the time of peril.

Citizens of Philadelphia, to you we must appeal. Yonder College and Hospital, as I have told you, are fulfilling their "mission high," but are sorely hampered for want of larger means. Every week we have to refuse worthy sufferers for want of a larger number of beds in a constantly crowded hospital. You can give them to us. We need endowments for Professorships, for Fellowships and Scholarships. You can give them to us. By your gifts and your bequests you may make possible the fine ideals which we hope to realize. We have the men, men of brains, of education, of industry, who are longing only for the opportunity. If you but knew as I know how earnest, how intense, how consuming is the longing in these very young men before you to do their level best, if you only give them the chance! Must we Americans, we Philadelphians, say them nay for want of such encouragement and of such gifts? I do not believe it. As in your hours of sickness you trust implicitly to us, so in your hours of health and wealth we trust implicitly to you, and I know we shall not trust in vain.

The New York State Hospital for the care of crippled and deformed children was opened May 17.

PRACTICAL THERAPEUTICS

Under the charge of

A. A. STEVENS,

Assisted by

L. F. APPLEMAN.

Treatment of Dysentery.—Potilor (*Les Nouveaux Remèdes*, xvii, No. 2) recommends ichthyol enemas in the treatment of dysentery. A dose of castor oil should be taken at the start, and injections, consisting of 6 drams of ichthyol, dissolved in about 27 ounces of water, are then given every other day. The liquid must be made to reach as high up in the intestine as possible. The pains disappear very rapidly under this treatment, and all other symptoms disappear.

Alcohol as a Disinfectant.—Bertarelli (*Revue d'Hygiène*, January, 1901) has found that the best results are obtained with alcohol as a disinfectant. When it is used in 50% strength, its power diminishing with either weaker or stronger solutions. A 20% strength was more active than 25% strength, and both than 99%. The drug has practically no effect on spores. Alcoholic solutions of corrosive sublimate, carbolic acid and zinc sulphocarbolate were more effective the less the amount of alcohol in them.

Diabetes.—Van Noorden (*Deutsche Praxis*, No. 1, 1901) believes that jambul is of some value as a general remedy. In some cases when it is necessary to increase the amount of carbohydrates in the diet the glycosuria may be held in control or even diminished by the use of sodium salicylate or aspirin. Carlsbad water, especially warm, acts favorably, particularly on the dyspeptic symptoms. The salicylic compounds exert a favorable influence on the pruritus, bronchitis on the nervous phenomena—insomnia and palpitation. Opium should be given when severe neurotic symptoms develop from the enforced diet. Antipyrin is efficacious in diabetic neuralgia. Bismuth is useful when there are intestinal disturbances. Salicylates, particularly thioform, have given the best results.

Iodin in Tuberculosis.—Flick (proceedings of the Philadelphia County Medical Society, March, 1901) states that foremost among the drugs which empirically have been found to be useful in tuberculosis are the iodine compounds. He believes that inunction with a solution of some of the rich iodine compounds has increased his power to deal successfully with tuberculosis fully 50%. The iodine compounds which may be used by inunctions are iodoform, europhen, iodol, and aristol. All of them are soluble in olive oil and cod-liver oil, and all break down readily, thus giving off their iodine. The richest of them is iodol, which contains 89% of iodine, but unfortunately it breaks down very readily, and is apt to decompose before it can be used by the patient. After considerable trial he has discarded it for europhen, which in solution will hold together for some weeks. He uses these iodine compounds by inunction because they give in this way an even, continuous effect, without deranging digestion.

Treatment of Tuberculosis by Sodium Cinnamate.—Mann (*Philadelphia Medical Journal*, December 1, 1900) uses intravenous injections of solutions of sodium cinnamate in tuberculosis with encouraging results. The healing processes are quickened when they are sluggish or totally inactive in some, though not all, of the cases. The beginning dose is $\frac{1}{16}$ to $\frac{1}{8}$ of a grain, which may be gradually increased to $\frac{1}{4}$ or $\frac{1}{2}$ of a grain, but this should rarely be exceeded. Under careful aseptic precautions the author has not had the slightest infection in over 800 injections. Marked drowsiness has been noticed after its use in a number of patients. This does not appear until 10 or 12 hours after the injection and usually disappears in 24 to 30 hours when moderate doses have been given. After generous doses, in severe and febrile cases, a slight rise in temperature has occurred within 24 hours. In the author's experience it has usually not exceeded a degree or a degree and a half.

Treatment of Acute Dysentery.—Cruikshank (*Journal of the American Medical Association*, January 5, 1901) believes that magnesium sulfate is as nearly a specific for dysentery as quinin is in malaria, or mercury and potassium iodide are in syphilis. It should be given in dram doses every 2 hours, dissolved in a very little water and mixed with a little aromatic sulphuric acid. This should be continued from the beginning of the attack until there is a subsidence of the symptoms. When the stools have become nearly normal the medication may be gradually withdrawn. The average duration of the disease under this treatment is from 3 to 7 days. The writer's conclusions are: (1) Dysentery is a disease of great gravity; (2) it is both contagious and infectious; (3) it is caused by the introduction into the system through food and drink, and also through the air, of a specific microorganism the identity of which seems still in doubt; (4) dysentery is one disease in whatever latitude it is found, and the only varieties are those based on the intensity of the morbid process; (5) the therapeutic agents suggested for the treatment of acute dysentery are useless and harmful. Magnesium sulfate acts as a specific.

Local Use of Guaiacol in the Treatment of Frequent Painful Urination.—Hawes (*Journal of the American Medical Association*, December 29, 1900), recommends guaiacol for the treatment of painful urination in those cases in which the cause of the symptom is located in the extreme inner portion of the urethra, usually in a space $\frac{3}{4}$ to $1\frac{1}{2}$ inches external to the urethrovesical orifice. The author believes that disease of the deep urethra is usually mistaken for cystitis or "irritable bladder" and a careful diagnosis should be made. An ordinary urethral speculum should be passed through the deep urethra; any mucous or blood should be mopped away with absorbent cotton on the end of an applicator, until the mucous membrane is dry, after which guaiacol is applied to the area by means of another applicator tipped with cotton. Guaiacol acts as an anesthetic and mild stimulant. It gives rise to much less pain than the usual local application. No strangury results, and the urine will often be retained for hours after the application. The perineal and suprapubic discomfort is lessened after a few hours, in many cases, and when this application has been made at intervals of from 5 to 10 days, it has given more satisfaction than any remedy previously used. Twenty per cent. of the author's patients have been cured. About 70% are markedly improved. Some cases which would seem to fall within our field have not improved. If applied every day or 2 it will produce local tumefaction which causes a diminution in the size of the urinary stream; this tumefaction passes away in a few days.

The Antiseptic and Serum Treatment of Pernicious Anemia.—W. Hunter (*Medical Press and Circular*, April 3, 1901) reports the following case. The patient was a man, aged 37, suffering from anemia of 2 years' standing. On admission he was very anemic, fairly well nourished, the skin being of a lemon color. The teeth were markedly carious. The urine contained urobilin. The red blood-cells were altered in size and shape, numerous nucleated corpuscles were present. The hemoglobin was reduced to 35% and the corpuscles were reduced to 1,500,000 per cmm. The treatment consisted of an antiseptic mouth wash, 30 minims of the solution of mercury perchlorid as an intestinal antiseptic, with ammonium carbonate (gr. 3) and tincture of digitalis (mx 5) as a stimulant, and 4 injections (within 3 weeks) of 10 cc. of antistreptococcal serum. After 5 weeks' treatment there was an increase of 40% of red cells and 37% of hemoglobin. Six months subsequently he looked in robust health, and the red corpuscles numbered 4,550,000. The author believes that pernicious anemia is a chronic infective disease of septic origin, and that it is the result of a special infection of the mucosa of the digestive tract, especially of the stomach, frequently also of the mouth and of the intestine.

In their order of importance the following are the lines of treatment to be followed out: (1) Oral antiseptics. Complete in its character, both with regard to diseased teeth, irrespective of any absence of pain or discomfort such teeth may be causing,

and to the special lesions of the tongue; (2) gastric and intestinal antiseptics, in effecting which removal of the oral sepsis is one of the most important measures to be carried out; (3) arsenical treatment, of whose great value there cannot be a doubt. For the improved prognosis with regard to the disease—the average duration being now in my experience some 3 years—the use of arsenic deserves, in my judgment, the credit. It is no less certain, however, in my experience, that arsenic alone cannot permanently arrest the disease; (4) antitoxic treatment, with the hope of thereby antagonizing the poisons within the blood responsible for the hemolysis.

Treatment of Infantile Eczema.—Kistler (*La Médecine Moderne*, January 30, 1901) employs the following ointment to relieve the itching of infantile eczema:

R	
Salicylic acid	15 grains
Bismuth subnitrat	4 drams
Powdered starch	1½ drams
Cold cream	2 ounces

Calomel, in the dose of 1 or 2 grains, is indicated from 1 to 3 times a week, to aid in the elimination of pathologic products.

Vaginal Douching in Obstetrics.—Wadsworth (*American Journal of Obstetrics*, April, 1901) advises the avoidance of douching in obstetrics unless it is particularly indicated. Antepartum douches frequently fail to remove pathogenic bacteria when they are present; they destroy the natural protection of the vagina; they are liable to cause slight injuries to the vaginal wall through which infecting bacteria may gain entrance into the body; and finally, pathogenic bacteria may be introduced by these manipulations. The routine management of cases should be freed as far as possible from all procedures which interfere with the natural resources of the body; for these, in the vast majority of cases, are sufficient protection against the invasion of pathogenic bacteria. In the few exceptional cases requiring interference, this should be determined by the bacterial examination.

Lupus Vulgaris Successfully Treated with Ethyl Chlorid.—Dethlefsen (*Treatment*, April, 1901) reports the following case: The patient was a girl, aged 29, suffering from lupus of 12 years' duration. The ulceration involved a large part of the nose and left cheek. The treatment consisted in a thorough freezing of the affected parts, but without previous scraping. During the first week the freezing was done daily; later every second or third day; and toward the end of the treatment once or twice a week. Each freezing was followed by a great rush of blood toward the affected part. Serous transudation followed and formed a crust. This crust was removed before the next freezing, but only so far as it could be done without lacerating the parts. After 10 weeks' treatment there was complete restoration of the skin without the slightest loss of substance.

Guaiaicol Therapy of Gonorrhoeal Epididymitis.—Goldberg (*Centralblatt f. inner Medicin*, April 6, 1901) has used guaiaicol with satisfaction in 25 cases of gonorrhoeal epididymitis. An ointment consisting of guaiaicol, 5 grams (75 grains); lanolin and resorcin, 10 grams (150 grains) is applied every 12 hours until the whole quantity is used in the course of 3 or 4 days. Before the first use of the ointment the patient takes a cleansing sitz bath. The ointment is then applied to the painful part and covered with a linen rag, absorbent cotton, and waxed paper, the whole being held in place by a suspensory. In addition, from 3 to 4 grams (45 to 60 grains) of salol are given per day. The patient's general condition decides whether he is to go to bed or to be allowed to stay up and to follow his usual vocation. More than 3 or 4 days' rest in bed is not necessary. Of 22 patients treated by the guaiaicol method, 15 were sick less than 3 days; and all did not have to interrupt their daily work. The local effects were: A prompt removal of the pain, if the case was seen in the acute stages; prevention of the swelling, if the case was seen immediately after the onset of symptoms; or an arrest of the swelling, if it was already present. No bad effects upon the heart or lungs were noted.

1.—Rennie, in a clinical lecture on functional nerve disease, recognizes 4 types of functional nerve disease, as follows: (1) Feigned disease; (2) hysteria in its varied manifestations; (3) neurasthenia; and (4) functional disease concomitant with and dependent upon organic disease. He refers briefly to some of the manifestations of each form of disease and to certain differential diagnostic signs. [A.O.J.K.]

2.—Waller, writing of the centralization of medical education by the University of London, discusses the 3 stages into which medical education naturally falls: (1) Preliminary scientific—chemistry, physics, biology; (2) early medical—anatomy, physiology; (3) medical proper—medicine, surgery. He then details the essential points in a scheme for the centralization of medical education by the University of London. [A.O.J.K.]

3.—Ogilvie, in some remarks on the inheritance of acquired immunity, discusses critically various facts and hypotheses regarding the transmissibility of acquired characters, especially Weismann's and Hertwig's opinions, and, diverting to the domain of pathology, refers to the hereditary transmission of acquired immunity, mentioning especially the work of Tizzoni, Ehrlich, Hübener, Vallard, Wernicke, Roux and Calmette. It is believed that there exists no proof to show that parental immunity is ever transmitted by the germinal cells to the next generation; the offspring, however, may derive immunity from its mother by either the blood or the milk—this is, by the placental circulation or by suckling. It is believed that the accumulation theory as an explanation of racial immunity is an unsubstantial hypothesis. [A.O.J.K.]

4.—Wright, in a note on the results obtained by antityphoid inoculations in Egypt and Cyprus during the year 1900, gives the following statistics: Average annual strength of the British troops—uninoculated, 2,669 inoculated, 720; number of cases of typhoid fever—uninoculated, 68, inoculated, 1; number of deaths from typhoid fever—uninoculated, 10, inoculated, 1; percentage of cases calculated on average annual strength—uninoculated, 2.50; inoculated, 0.14; percentage of deaths calculated on the same basis—uninoculated, 0.40, inoculated, 0.14. These figures testify to a nineteenfold reduction in the number of attacks of typhoid fever, and to a threefold reduction in the number of deaths from that disease among the inoculated. [A.O.J.K.]

5.—Edgecombe reports a case of secondary anemia becoming pernicious, occurring in a woman of 38. When first seen examination of the blood revealed: hemoglobin, 23%; erythrocytes 475,000 (color index, 2.40); leukocytes 1,4000. After the lapse of 4 months the blood condition was as follows: hemoglobin, 85%; erythrocytes, 3,250,000 (color index 1.30); leukocytes, 5,200. Three days prior to the death of the patient (8

months after first observation), the blood condition was as follows: hemaglobin, 8%; erythrocytes, 485,000 (color index 0.84); leukocytes, 9,100. Another interesting feature of the case was the preponderance of megaloblasts over normoblasts. The case is believed to be one of anemia secondary to repeated hemorrhages from the nose gradually passing into the condition designated pernicious anemia. [A.O.J.K.]

6.—Thin reports the treatment of 2 cases of nerve leprosy in which recovery took place. The treatment of the first case consisted of chaulmoogra oil internally and externally for more than 2 years; that of the second case, of pyrogallie acid externally, gurjun oil internally regularly, and arsenic internally intermittently. [A.O.J.K.]

7.—Harris refers to the question of operating on patients suffering from exophthalmic goiter and mentions a case in which a lady patient who had a large exophthalmic goiter was operated upon for the removal of a cystic tumor of the breast. Ether was taken badly and the patient died 68 hours after. In such conditions it is best to avoid operation and when it is imperative to precede it with a course of cardiac stimulants. [J.W.M.]

8.—Rowden reports a case of descending Landry's paralysis in a child of 10, terminating fatally in 4 days. The clinical features of the case were progressive, symmetrical motor paralysis affecting first the muscles of the neck, then the arms, forearms, chest, legs, etc.; absence of disturbances of sensation until a few hours prior to death, when slight impairment was noted; absence of rigidity, twitching, pain, or spasm; preservation of mental functions and of control over the emunctories. [A.O.J.K.]

9.—Higgins reports 2 cases of severe frontal herpes, occurring in women of 45 and 49 respectively. [A.O.J.K.]

11.—Payne reports a case of whooping-cough cured by irrigation of the nares with 10 to 20 ounces of carbolic lotion (1 to 40) 3 times daily. The injection was performed by means of a syringe, the lotion being allowed to go up one nostril and down the other. At first the irrigation caused a good deal of sneezing and coughing, and a considerable amount of gelatinous mucus, some of which was of a greenish color, was ejected. Soon, however, the irrigations caused less discomfort and the patient, at first refractory, began to look forward to them for relief from his sufferings. It is believed that other antiseptics will answer as well as carbolic acid. [A.O.J.K.]

1.—Morris, in a clinical lecture on eczema in relation to age, discusses eczema of the infant, eczema of the young child, eczema of the age of puberty, eczema in the adult, eczema in the adult woman at the change of life, and eczema in the aged. He describes in appropriate detail the etiology, clinical features, and treatment of each form of eczema. [A.O.J.K.]

2.—Brunton, discussing the action of arsenic as observed during the recent epidemic of arsenic poisoning, mentions the manifestations of arsenic when introduced into the body in

physiologic and toxic doses. The amount of beer consumed by some of the sufferers during the epidemic was so small as to raise the question whether the neuritis could be due to the arsenic alone, even though its action may have been directed to the nerves by the alcohol or hops, or whether some other poison besides arsenic was present in the beer, or whether the arsenic was present in such a combination as to have a much more deleterious action than that of pure arsenic itself. The evidence nevertheless points to the conclusion that the symptoms were due chiefly, if not entirely, to the arsenic. The contamination of the beer was brought about through the use of glucose and invert sugar made by one particular firm that had been supplied by sulphuric acid, containing a very large quantity of arsenic. It is suggested that some of the cases of alcoholic neuritis may in reality be due to arsenic in contaminated beer. [A.O.J.K.]

3.—Poynton and Paine, detailing the results of some further investigations upon rheumatic fever, describe the researches they have undertaken to establish a certain diplococcus as a cause of this disease. They have succeeded in demonstrating the organisms in 2 more nodules; and they have grown them in pure culture in the nodular tissue outside the body; they have produced by intravenous inoculation into lower animals a condition they believe to be acute rheumatism—polyarthrititis, pericarditis, and multiple valvulitis; and from the joints of the animal after death they have isolated the organisms. As the nodule is looked upon as a highly characteristic manifestation of rheumatic fever they conclude that their investigations lend strong support to the contention that this diplococcus is the cause of rheumatic fever. In addition they believe that the actual commencement of chorea in rheumatism is usually associated with the presence of the diplococcus in the brain. By centrifugalizing the pericardial exudate from a case of acute rheumatic pericarditis they have succeeded in demonstrating the presence of these organisms in the polymorphonuclear leucocytes. Finally they bring forward some facts that suggest that fever may be a primary phenomenon of rheumatism, and then discuss the experimental production of disease of the heart. [A.O.J.K.]

4.—Bowlby and Steedman report a case of gastric ulcer in which perforation was followed by rigors. The patient was a female of 27, who for 2 years previous had suffered from gastric disturbance, and had since suffered from anemia. She was suddenly seized with severe pain in the left side, and vomiting. The next day she was comparatively comfortable. The second day she had 2 rigors, and the abdomen was tender and tympanitic. On operation a gastric perforation was found and sutured. The abdomen contained but little infected material, which was removed by sponging. The gastrohepatic pouch was drained for 3 days, and the patient did fairly well for 4 weeks, when there occurred severe abdominal pain with vomiting and collapse. The abdomen became distended, tender, and tympanitic. Liver dulness was almost obliterated. Temperature was 100°; the pulse ranged from 88 to 100, and was growing irregular and feeble. A second operation was performed and a volvulus of the small intestine found with about a quart of dark fluid in the abdomen. The bowel was untwisted and punctured to evacuate the gas so that its restoration to the abdomen might be accomplished. The subsequent progress of the case was uninterrupted, and the recovery complete. The second condition illustrates the unreliability of the pulse in abdominal conditions. [J.W.M.]

5.—Kirk, writing of serous vaccinia in connection with cretinism and rickets, reports several cases of serous vaccinia and the subsequent occurrence of cretinism, and expresses his belief that the thyroid is concerned in the production of serous vaccinia and serous types of other affection. It is thought that the condition of the gland is such that it is prone to atrophy from exciting causes that would otherwise prove inefficient. It is believed that we ought to recognize the existence of a serous diathesis as emphatically as we do that of a hemorrhagic diathesis, and that it is probable that the two are intimately related to each other, while it is evident that both are associated with great vulnerability of tissue by various morbid agents. Referring to the fact that the thyroid has an antitoxic action on certain toxic substances resulting from the

digestion of albuminous bodies, he asks: "Is it possibly concerned also in defending the organism against the germs of some zymotic diseases?" He suggests that vaccination and perhaps experiments on vesication should be performed on calves and a few other animals after expiration of the thyroid. It is thought probable that the greater viscosity of calf lymph, as compared with human lymph, may be due to the greater energy of the thyroïdal function. [A.O.J.K.]

6.—**Sarcoma of the uterus** is a comparatively rare disease. Williams in an analysis of 2,649 cases of primary uterine neoplasms found only 2 cases of sarcoma to 1,571 of cancer. Croft reports 3 cases of sarcoma of the uterus. In the first the malignancy of the disease only asserted itself a few months after confinement and was not discovered until secondary growths rendered operation impossible. The second was a diffuse sarcoma of the connective tissue of the mucosa and the patient died of peritonitis. In the third, the uterus was removed and the patient, a woman of 30, continued in good health 2 years after operation. [W.K.]

7.—**Combo** reports a case in which recovery followed operation for diffuse peritonitis from perforative appendicitis. The symptoms at the onset were pain referred to the region of the appendix, followed by vomiting and abdominal distention, and edema in the neighborhood of McBurney's point. Temperature ranged from 102°-104°, pulse 132, respiration 36. Four days after the onset of the symptoms operation was performed and an abscess extending up toward the liver and down to the pelvis was found and evacuated. A large quantity of brown-tinted blood was sponged from the pelvis. Drainage was established by carrying one tube into the subhepatic pouch and another down into the pelvis. Complete recovery followed. [J.W.M.]

8.—**Broadway** reports his results with the use of diphtheria antitoxin. Of 24 patients treated with the antitoxin but 1 died, whereas of 6 treated along ordinary lines, 2 died and 2 developed postdiphtheritic paralysis. [A.O.J.K.]

9.—**Aikman**, writing of the respiratory movements of the precordial area in health and in disease, directs attention to certain modifications of the chest movements that, he believes, indicate acute and chronic disease, and also forecast the advent of it. He points out that in health the left third intercostal space rises and falls at its sternal end during the respiratory act to an appreciably less extent than the right. This he speaks of as "the comparatively still area." He has found during the course of acute rheumatism that a marked diminution of the movement in the third left intercostal space precedes the stethoscopic signs of pericarditis by a period varying from 1 to 4 days. In a much shorter period the limitation of movement extends to the second, and even to the first, intercostal space, and increases, less markedly, to the left. The variations of chest movement that prognosticate and evidence endocarditis are less in degree; in many cases of old-standing cardiac diseases, however, the precordial stillness is wider than normal [A.O.J.K.]

1.—A history of the **Wyeth method of operation** and of the various methods used to control hemorrhage is given. Digital compression of the aorta and common iliae and gradual dissection is described and objections stated. The included tables of operations for malignant neoplasms, septic infections and injuries show a mortality of 19.8%. This takes in deaths from intercurrent disease. The statistics of other methods follow, and it is acknowledged that asepsis must share with improved hemostasis the credit of the diminished mortality. [H.M.]

2.—Two classes of **intra-nasal lesions** are considered. The first includes chronic lesions of the anterior region of the middle meatus. Often most careful search must be made before focal suppuration of mucosa or air-cells is discovered. The **ocular reflex** may be either injection of the vessels of the ocular conjunctiva and those of the museles, with passive edema of the retrotarsal folds, or neuralgic pains along the inner upper aspect orbital wall. The latter is excited by any mechanical or nervous irritation of the nasal mucosa, and is not relieved by any treatment directed to the eyes. The second group includes lesions of the inferior meatus and adjacent cells causing suppuration, fistula and granular degeneration of the tear sac. An operation for radical extirpation of the sac with free drainage into the nose is described. [H.M.]

3.—**Purulent and secondary atrophic rhinitis** may often be traced to a **sinusitis**. The latter is also associated with **nasal polyps** and deviated septum. Obstruction is caused by these, and also by thickening of the mucosa or small granulations, or even inspissated mucus at the openings of the sinuses. The obstruction may be permanent or intermittent and the result may be either congestion or inflammation. There may be retention of gases in some cases and rarefaction of the air in others. Pain is more or less continuous, frequently worse upon arising and wearing off later, is increased by stooping, dull and boring, increased by colds and exposure, and accompanied by heat in the face, and is localized according to the sinus involved. Discharge may be present or absent. Transillumination is valuable, but not always reliable. Drainage and treatment of the lining membrane are necessary. Artificial openings tend to close more quickly than the natural ones. All obstructions must be removed. The hot air treatment in many cases gives quick and permanent relief. The technic is described. [H.M.]

4.—The **bath** is indicated whenever the **temperature** is 102° or 102.5° F. The patient is placed on a blanket, covered with one layer of surgical gauze which should fit the skin perfectly when moistened and this is sprinkled with water at 115° F. and the patient is constantly fanned. As rapidity of **evaporation** depends on the condition of the atmosphere, the guide for each bath is the amount of water evaporated and not the time consumed. In the cases reported 1 quart was used, the time being 15 to 20 minutes. The average fall of temperature was 1.9° F. The principles of the method were tested on bottles of hot water and the results of the experiment are given at length. [H.M.]

5.—The much higher mortality from invasion of the peritoneal cavity by **Streptococcus pyogenes** than from the gonococcus makes it important to distinguish between these infections. In making a diagnosis the history is very important, the great majority of cases being due to infection in labor or miscarriage. The lesion is generally a parametritis and most investigators have failed to find the gonococcus in the latter. The situation of the mass is also characteristic. It lies in the connective tissue surrounding the uterus and vagina and beneath the peritoneum. The tendency of the infection is to follow the layers of connective tissue and fascia and not invade adjacent layers. When the peritoneal cavity is approached it is protected by adhesions of omentum, tubes, ovaries and intes-

tines. The mass is nearly always asymmetrical. This is in marked contrast to gonorrhoeal infection, which is also more superficial. The consistency is of bone-like hardness as a rule, and there is an intimate connection between the uterus and pelvic wall. The streptococcus is very long-lived and the same precautions must be taken in old as in recent infections to protect the peritoneal cavity. Early operation, before suppuration, is advised. The incision should be extraperitoneal and the mass thoroughly broken up by blunt dissection, so as to evacuate any abscess cavities, and drainage established. [H.M.]

6.—Bachmann criticizes Burnett's position in regard to **Ménière's disease**, believing he has confused the deafness, tinnitus and vertigo of middle ear affections with it. Certain physiologic experiments are described, which explain how immobilization of the stapes in the sound window in middle ear disease may cause the above symptoms. The etiology and symptomatology are reviewed. To differentiate it from middle ear disease with vertigo it should be remembered that the latter has visible lesions, in its purulent form a discharge, and a different history. Ménière's disease yields to nonsurgical treatment directed to the original cause. [H.M.]

7.—On account of faulty business methods there are more financial failures among medical men than any other class. There should be a more fraternal spirit, a uniform fee-bill; companies and corporations should guarantee payment for services to injured employees, and public authorities should give just compensation for services. Physicians of every community should organize for mutual protection from dead-beats, etc., and to enforce the same recognition given to other classes and prevent unfavorable discrimination by public authorities, as in the settlement of estates and services to paupers. [H.M.]

8.—Stoner briefly reviews the uric acid and suboxidation theories of **rheumatism** and considers atavistic possibilities in connection with the uric acid diathesis. From his study of rheumatism he draws the conclusions that it is due to an infectious germ, the symptoms varying with their position and attenuation, that these germs may complicate other diseases; that their nidus may be the joints, heart or muscles; that uric and lactic acid are the product not the cause of the disease and are not pathognomonic; that hereditary tendency exists in the large majority of cases, and that grip and rheumatism belong to the same family of diatheses. [H.M.]

9.—The physical characteristics, reactions, method of preparation, physiologic effects and method of using **paraphenylene diamine** are described, together with the character of the eruption caused by it. The suddenness of the onset, enormous swelling of the lids and metamorphosis of the physiognomy help to differentiate it from acute eczema. The usual calmative agents for the latter disease are indicated and in grave forms the hair must be sacrificed. [H.M.]

10.—With both ether and chloroform cessation of respiration may either precede or succeed cessation of the heart's action. Blood-pressure is lowered by both. Respiratory difficulties may be spasmodic, asphyxial or paralytic. The 2 former occur more frequently with ether. The points to be noted before and during the administration of the anesthetic are given in detail. Treatment is given for the milder and graver forms of heart or respiratory failure. Mechanical means are used first, as cardiac stimulants are useless till there is a circulation to carry them. Massage of the heart has given startling results. This is accompanied by rhythmic tractions of the tongue and followed by artificial respiration. Then come cardiac stimulants. Acupuncture of the heart has been tried as a last resort with encouraging result. The after-effects on kidneys and lungs are considered. Silk's table giving indications for the choice of an anesthetic concludes the article. [H.M.]

11.—There are many cases in which the **vesicular murmur** is entirely absent, except in forced inspiration. This may be the result of light clothing or lazy breathing, sedentary occupation, underfeeding, overwork, or worry. An incomplete pulmonary function produces bloodstasis and exudation into bronchi, intercellular spaces and upon the surface of the pleura. These are noninflammatory and when stirred by respiration produce rales which are diagnosed as from bronchitis but more properly from bronchial catarrh—a passive rather than an active

condition. The apices are most frequently affected, the "mucous click" being diagnosed as tubercular. It is simply the prepared soil and all these sounds will disappear with systematic expansion. In examining the chest our attention should be directed not so much to abnormal as to the lack of normal sounds. After pleurisy and pneumonia the closest attention should be given to anatomic recovery by exercises aided by cold friction baths, general hygiene and tonics. [H.M.]

12.—The various theories as to the origin of stone are briefly reviewed and 7 cases of infection of the **renal pelvis or substance** associated with stone are analyzed. The symptoms pointed in all but 1 to unilateral involvement and this was subsequently verified by bacteriologic, chemie and microscopic examination of the urine obtained from the 2 ureters separately. In the alkaline urine were found *Bacillus proteus vulgaris* and a white *Staphylococcus* associated with stones made up of phosphates and carbonates of calcium and magnesium. A consideration of the findings warrants the belief that the nucleus of the stone was a zooglear mass made up of the **microorganisms** causing the infection, while the constant alkalinity caused by the urea-decomposing power of the microorganism furnished the salts necessary for the formation of the stone. In the one case with acid urine examined, the infection was due to *Bacillus coli communis*. The stone was a mixture of uric acid and urates. The cases show a definite relationship between the variety of germ and the chemical composition of the calculus. [H.M.]

13.—This is the eleventh recorded case of **strangulated hernia** in which the bladder alone was involved. [H.M.]

Boston Medical and Surgical Journal.

May 10, 1901. [Vol. CXLIV, No. 20.]

1. The Treatment of Psoas Abscess by Incision. ROBERT W. LOVETT.
2. Infantile Scorbutus. JOHN LOVETT MORSE.
3. Neuritis Recurring after Atrophy of both Optic Nerves in a Case of Brain Tumor. EDWARD R. WILLIAMS.
4. A Case of Accidental Inoculation of Cancer in a Fresh Wound. A. T. CABOT.

1.—Lovett reports the result in the treatment of **psaos abscess** at the Children's Hospital, covering a period of 10 years, from 1890 to 1900. During this time 49 cases of psaos abscess were operated upon, and the present condition of 43 of these is known. Of the 49 cases operated upon, 17 died, 26 were known to be still living and the result in 6 cases was unknown. The author makes a general conclusion from the facts set forth as follows: That fever is not necessarily an accompaniment of psaos abscess formation; that where it does occur, the prognosis is not so good as where it is absent; that the best method of operation is by a lumbar or iliac incision, one or the other, and preferably the latter. It seems desirable, on general principles, to avoid recumbency for long periods, which makes drainage by an iliac incision almost impossible. It seems best to put on a plaster jacket almost immediately after operation to enable the patient to sit erect and to enable the abscess to drain almost from the first. In this way the writer has obtained better results than by any other method. [A.B.C.]

2.—**Infantile scorbutus** was first described in 1883. It is uncommon under 6 months and after 2 years. Six cases are reported typical and atypical. The symptoms are anemia; malnutrition; pain on handling; an expression of terror when approached; pyriform swellings at the ends of the diaphyses which are tender, sometimes red, but never hot, and are due to subperiosteal hemorrhage; swelling, sponginess and ulceration of the gums, which are purple and often hemorrhagic; cutaneous, nasal, gastric, intestinal, orbital or other hemorrhages. The diagnosis is given between it and rheumatism, purpura, rickets, syphilis, Pott's disease, infantile paralysis and injury. It is caused by some error in diet, the majority of cases occurring in those fed on proprietary foods, though it has accompanied the uses of breast or raw cow's milk, etc. Treatment consists in regulation of the diet and the administration of lemon or orange juice. During convalescence iron may be indicated. In severe cases, recumbency on a Bradford frame or light splints on the

limbs may afford relief. Recovery occurs in 2 or 3 weeks. [H.M.]

3.—But 2 similar cases of **recurring neuritis after atrophy** have been reported, and these are reviewed. Williams' case when first seen presented a typical picture of retinitis albuminuria. A number of other cases of brain tumor, showing the same oenlar picture, are cited, and reference is made to cases of chronic nephritis causing simple neuritis attributed to brain tumor. [H.M.]

4.—Cabot relates a case of **autoinoculation of cancer** in a male patient of 55. There was a cancer high up on the anterior rectal wall. This was removed by the Kraske operation. During the manipulation the juicy cancerous growth was rubbed about in contact with the wound made by the Kraske operation. The operation was done in March, 1897, and the tumor was examined microscopically and found to be adenocarcinoma. There has been no recurrence at the original site of disease. Two months after the first operation another was done to close the posterior opening in the rectum. During the summer of 1899 there was observed a hardening of the tissue behind the rectum. This was removed—a mass the size of a hen's egg. It extended from the mucosa of the rectum backward along the sacrum to which it was firmly attached. The scar in which the recurrence took place was separated by an interval of 5 to 6 inches from the original site of the disease. A microscopic examination showed it to be adenocarcinoma with colloid degeneration. The author is of opinion that this was clearly a case of autoinoculation. [A.B.C.]

Medical Record.

May 18, 1901. [Vol. 59, No. 20.]

1. The Recent Buffalo Investigations Regarding the Nature of Cancer. ROSWELL PARK.
2. Contracture of the Neck of the Bladder. CHARLES H. CHETWOOD.

1.—Continued study of **cancer** leads to the conviction that on its inception it is purely local and that the process of generalization is relatively slow save in rare instances. Park firmly believes in its infectious nature, the parasite being extremely polymorphic. The same forms are described and figured by Italians as blastomycetes, by French as protozoa, and Germans as products of cell degeneration. The length of time over which the apparent infection extends is no argument against the theory since the time in which syphilis and leprosy kill is measured in years. All other metastatic diseases are considered parasitic. Cancer-like pus may possibly be produced by various organisms. Statistics show that it probably is not transmissible, but several instances of its autoinoculability are given, including those through operation wounds, indicating great care in removal of the tumor. The work of Dr. Gaylord at the State laboratory connected with the University of Buffalo is epitomized. Death seems to come by terminal hematogenous infection. Cachexia is produced by varied causes. The Italian view has not been sustained or disproved by **Buffalo investigations**. The characteristic bodies are hyaline, resembling fat droplets, which in suspension oscillate. These develop into larger forms with pseudopodia and later into sacs containing spores which are highly refractive. The best culture medium is bouillon made with *Fucus crispus*. Nearly all fixatives cause the disappearance of spore sacs and most of the developed organisms. The more resistant are 2 small forms described by Russell. The organisms are found in the blood and all organs of patients dying of epithelioma and sarcoma; they are not found where cancer does not exist and may, as in one instance cited, produce other than characteristic lesions. The work of investigators upon the role of unicellular animal life as a disease-producing agent is briefly reviewed with especial reference to that of Pfeiffer who also made a study of endemic cancer. That the organisms are found in lymphnodes ahead of epithelial deposits is an argument against the infectivity of the latter. The success of splenectomy in Banti's disease and its failure in other morbid conditions of the spleen is explained by the fact that the protozoan infection is still local in the former. Analogously if the cancerous growth is removed before general

infection has occurred cure is promising. Later operations simply palliate by removing the largest supply-depot. Just as there are 3 types of malarial parasites so may there be more than 1 cancer organism, causing in one case carcinoma, in another sarcoma. There is nothing in the protozoan theory of cancer to make belief in the spontaneous disappearance of malignant growths less plausible. [H.M.]

2.—Chetwood insists that many of the so-called cases of hypertrophy of the prostate are in reality **contraction of the neck of the bladder**. The author discusses the cause, saying it is due to some prolonged pathologic condition causing chronic inflammation in the region of the trigone or in the prostatic sinus. This condition and prostatic hypertrophy may coexist. Treatment is considered at length. The author has devised an instrument which is inserted into the bladder through a perineal incision. The instrument has a cutting or cauterizing blade after the manner of the Bottini instrument. The electric current is turned on and the cauterizing or cutting is done by sight and touch. The author has operated on 16 cases by his method, with 1 death from a pyelonephritis 5 weeks after operation. Seven patients were entirely cured and most of the others improved. He considers this method of procedure superior to the Bottini in several particulars, especially in the far fewer after-complications. Several illustrations accompany the article. [A.B.C.]

New York Medical Journal.

May 11, 1901. [Vol. LXXIII, No. 19.]

1. Atonia Gastrica and a New Method of Treatment. A. ROSE.
2. What Constitutes Sexual Intemperance. W. J. S. STEWART.
3. The Pathology, Diagnosis, Special Prophylaxis and Treatment of Tuberculosis of the Skin. JOHN A. FORDYCE.
4. Primary Chanere of the Septum of the Nose. W. FREUDENTHAL.
5. Syphilis of the Nervous System. B. ONUF (ONUFROWICZ).
6. Acute Strangulated Femoral Hernia on a Puerto Rican Hillside. P. R. EGAN.

1.—Rose discusses **Gastroptosis** and mentions a new method of treatment. The essential factor in the production of the condition which may exist alone or may be a part of a general prolapse of abdominal organs is most often manifest in persons of tuberculous tendencies or those suffering from anemia, chlorosis or acquired rachitic changes. Other contributory conditions may be gastric motor insufficiency, pyloric tumor, relaxation of the abdominal muscles following childbearing or obesity, the use of the corset, and skirt strings. The condition may exist for a time without giving rise to symptoms due to a compensatory propulsive force; later this fails and symptoms of gastric dilation become evident. As regards treatment general tonics are indicated. The following means of strengthening the abdominal muscles are mentioned, viz: bandaging, massage, electricity, gymnastics and hydrotherapy. The treatment most satisfactory to the writer has been strapping the abdomen by means of wide strips of zinc rubber plaster applied one horizontally over the upper portion of the abdomen and one obliquely on each side over the iliac crests overlapping in the median line. [J.W.M.]

3.—Fordyce discusses **tuberculous dermatitis as regards pathology, diagnosis, prophylaxis and treatment**. The different varieties are given and the importance of the recognition of each emphasized. The typical lesion of lupus is a brownish-red nodule deeply seated in the skin. It destroys the invaded parts by ulceration or atrophy. General tuberculosis and secondary infection occasionally occur. The process may be attended with excessive development of fibrous tissue by means of which the process is arrested, by the formation of a pseudo-**elephantiasis** due to extensive lymphatic infection or by the development of epithelioma. Lupus must be distinguished from syphilis, epithelioma, glanders, actinomycosis, streptococcus and staphylococcus infections. As regards prophylaxis the usual hygienic precautions should be observed and early manifestations treated radically. As to treatment, anatomic tubercles should be removed. Other methods are palliative treatment in which iodoform is valuable, the use of caustics, the curet, concentrated light and the x-rays. [J.W.M.]

4.—Freudenthal discusses extragenital syphilis, and reports a case of chancre of the nasal septum, in which the diagnosis was obscure until the appearance of unmistakable manifestations. It was rendered so by its occurrence during the prevalence of influenza, in which there occurred glandular enlargement and other symptoms resembling those of syphilis. The patient was a physician, and the infection arose from picking his nose after having made a vaginal examination of a woman who afterwards proved to be syphilitic. [J.W.M.]

5.—Onut, in his paper on syphilis of the central nervous system, distinguishes the following forms: (1) Meningitis, which is usually basal; (2) cerebral tumor; (3) multiple focal affection of the cerebrospinal axis; (4) hemiplegia; (5) diffuse brain lesions simulating progressive paresis; (6) pseudotabes or syphilitic tabes; (7) spastic paraplegia; (8) anterior poliomyelitis; (9) syringomyelia; (10) diseases of the peripheral nerves. [H.H.C.]

6.—Egan reports a case of acute strangulated femoral hernia which occurred under circumstances unfavorable for operation, and which was reduced under anesthesia by persistent taxis. [J.W.M.]

Medical News.

1. On the Modern Treatment of Acute Gonorrhoea. GEORGE KNOWLES SWINBURNE.
2. Chronic Gonorrhoea. JOHN VAN DER POEL.
3. On Gonorrhoeal Conjunctivitis. WARD A. HOLDEN.
4. Treatment of Gonorrhoeal Stricture of the Urethra. JAMES R. HAYDEN.
5. The Treatment of the Complications of Acute Gonorrhoeal Posterior Urethritis. JAMES PEDERSEN.

1.—Swinburne prefers to begin active treatment for acute gonorrhoea early. He begins with hot irrigations of a weak solution of potassium permanganate. Irrigations must be copious and frequent, and applied by the physician himself, beginning at a temperature of 105° F. and gradually ascending to 120° F. The germicide used is protargol. A urethral syringe is half filled with a 2% solution of cocain, then the remainder with a 2% solution of protargol. At each successive visit the cocain is diminished until finally the protargol only is given. The anterior urethra is treated only while it is affected. If the case is seen early the treatment is given twice daily for 3 or 4 days; this may be longer or shorter, depending on the progress of the patient. The rest of the first week the treatment is once daily. During the second week the treatment is every other day; during the third week twice, and the fourth week but once. At the end of the fifth week if there be no gonococci in the discharge, the patient is given the beet test and the germs again sought. He insists that the patient return in 4 to 6 weeks for a final examination. The author advocates this form of treatment at any time in the acute stage at which the patient presents himself. He has long ceased to use copaiba and eubebs. He advocates irrigating into the bladder without a catheter if it can be done without causing discomfort. He condemns the hydrostatic method of overcoming the compressor muscle. All that is usually necessary is to have the cooperation of the patient, and when an injection is made have him attempt the act of micturition, thus relaxing the compressor muscle and permitting the fluid to enter the bladder. This, of course, after the anterior urethra is irrigated thoroughly. Protargol is of great use in the posterior urethra. This is instilled by means of a No. 12 French catheter and a syringe, $\frac{1}{2}$ to 1 ounce of a protargol solution (gradually increasing to 2 $\frac{1}{2}$) is slowly instilled, being shortly after urinated out. A final examination at the end of say 6 weeks, is very important. [A.B.C.]

2.—Van Der Poel says in the diagnosis of chronic gonorrhoea there are several important points to be cleared up before treatment is commenced: (1) As to the character of the discharge; (2) its origin; and (3) the pathologic conditions that cause it. No hard and fast rule can be laid down in the treatment of this condition. In general the hygienic treatment is the same as in acute gonorrhoea, except greater freedom may be permitted in diet and exercise. Internal treatment is simi-

lar to that in the acute stage; alkalies and diluents in case of scalding, if reinfection is present; oleoresins when this has subsided, and later the antiseptics such as salol and urotropin. In the local treatment the general rules to be observed are: (1) Care and conservatism in all procedures; (2) avoidance of over-instrumentation and injuries to the mucosa; (3) sufficient rest after passing through one system of treatment before beginning another, should another be necessary; (5) surgical cleanliness, and sterilization of all instruments. Protargol in the strength of $\frac{1}{2}$ to 1 $\frac{1}{2}$ %, used by irrigation, is the best treatment for the anterior urethra. The same in strength of $\frac{1}{2}$ to 1%, is used in posterior urethritis. To irrigate the posterior urethra spasm of the cut-off muscle is prevented by the use of cocain, 10 to 15 grams of a 1-150 solution held in the anterior urethra for 4 or 5 minutes. Injecticus in the anterior or posterior urethra are made daily, and are most effectual when combined with a hand injection by the patient himself, of a weak solution of bichlorid, 1-30,000 or 1-15,000. [A.B.C.]

3.—The usual course of untreated gonorrhoeal conjunctivitis is described, including swelling of the lids, discharge, sloughing or ulceration of the cornea, and papillary hypertrophy of the conjunctiva. A suspected discharge should be examined at once microscopically. A single application at the beginning of silver nitrate, 2%, or protargol, 40%, may modify favorably the subsequent course. The chief medication is cold from compresses that have lain on a lump of ice. The secretion should be washed away every few minutes with a warm solution of boric acid or potassium permanganate, 1 to 2,000. Infants can bear less cold than adults. The cornea in all cases must be inspected daily and cold decreased or heat substituted, if haziness appears. The other eye must be protected by an impenetrable covering. Recent statistics show that protargol in varying solutions cures the disease more quickly and with less discomfort than silver nitrate. Ulcers should be touched with iodin, carbolic or the cautery. The patient requires nursing day and night. If hospital facilities are adequate the enormous expense of supporting the neglected in blind asylums would be much curtailed. Economically, proper treatment of the eyes of the newborn is even more desirable. [H.M.]

4.—Hayden gives a general review of the treatment of gonorrhoeal stricture of the urethra. The ordinary treatment employed by most genitourinary specialists is advocated for stricture of the urethra in various situations. Perineal urethrotomy is discussed at some length and the operation described in detail. Divulsion and electrolysis are condemned. [A.B.C.]

5.—Pedersen in discussing the treatment of the complications of acute gonorrhoeal posterior urethritis subdivides the complications into local and general. The former include urethrocystitis, cystitis, ureteritis, pyelitis, pyonephrosis, funiculitis, epididymitis, prostatitis and seminal vesiculitis; while the general complications include arthritis, endocarditis, pericarditis, pleuritis, meningitis, etc. The author recites the treatment for the several local complications. Hygienic treatment is common to all. In urethrocystitis the chief indication is a bland and antiseptic urine. This is met by a milk diet, water and the urinary antiseptics. Anodynes may be necessary. Cystitis is not a frequent complication. Fever, larger area of hypogastric pain and tenderness differentiate it from urethrocystitis. In addition to the treatment for the latter condition we may use antipyretics, sedatives, anodynes, fomentations and counterirritants. Instillation and irrigation may be necessary. For this purpose protargol is recommended. The treatment for the other complications is discussed at some length. Gonorrhoeal arthritis is discussed and the ordinary treatment advocated. [A.B.C.]

Philadelphia Medical Journal.

8. Anisometropia. NÖRBURNE B. JENKINS.

1.—See page 194, Vol. I, No. 5, AMERICAN MEDICINE.

2.—Tyson makes a further report of a case of **presystolic murmur** as associated with pregnancy, admitted to the hospital the second time, suffering from faintness and syncopal attacks with distinct systolic heart murmurs; relieved and admitted the third time nearly a year later with the complication of grip. Her cardiac condition was much improved and she recovered rapidly. The case is of interest as showing different stages of returning compensation and also illustrating typically the changing physical signs of mitral stenosis. [W.K.]

3.—Kelsey reports the case of a man of 24, born with an **imperforate anus**, and in whom there had been a free communication between the bladder and rectum since an artificial anus was made in infancy. The patient often went for 3 months without fecal evacuation. An incision for colostomy revealed a large muscular pouch spreading over the small intestine and reaching from the anus to the diaphragm. The wall of the gut was greatly hypertrophied and contained enormous veins. At the ordinary point of junction of the transverse and descending colon this pouch suddenly narrowed to the size of a normal large bowel though the muscularis was still greatly thickened. An artificial anus was made at that point. [A.G.E.]

4.—Thompson, in his paper on the **relations of the public to the medical profession**, first considers the estimation in which the profession is held by the public. He says that in general the public regards the medical profession as a mere trade, the members of which look upon it solely as a means of obtaining a livelihood; that it is a close corporation, strongly dominated by class feeling and that it aims to monopolize, to its exclusive profit, the whole field of the treatment of disease, wherein it is very jealous of all competitors. He then speaks of the willingness with which the public receives and welcomes any prophet or prophetess hailing from realms unknown, and that the more mysterious their ideas the higher their position in the estimation of the public. As one such class of impostors he speaks of the Christian Scientists and of the danger to the community from their teaching and treatment, particularly of contagious diseases. To impress the public with the complexity of the human body and the foolishness of trying to cure disease by the aid of these fakirs, he advocates the teaching of anatomy and physiology in the public schools. For the protection of the public against the spreading of contagious diseases by these same people, he advocates appropriate legislation, but remarks that the starting of such legislation must be by some other body than the medical profession, as any movement thus started would be construed by the laity as mere jealousy. [H.H.C.]

5.—In his paper on **gastric tetany**, Morgan, after reviewing the etiology, pathology, symptomatology, etc., of the disease, cites 2 cases which came under his supervision. These he treated with Strontium bromid, in 5-grain doses, given before meals, and a suitable diet, finding that as long as this treatment was continued a marked improvement in the condition of the patient was apparent. [H.H.C.]

6.—Ballenger, in a very comprehensive and lengthy paper on the **functional tests of hearing**, explains the various tests and gives their range of usefulness in the various forms of aural disease. [H.H.C.]

Berliner klinische Wochenschrift.

April 15, 1901. [38 Jahrg., No. 15.]

1. Hyperesthesia of Nasal Mucosa. B. FRÄNKEL.
2. Glycogen Formation after Ingestion of Albumin. F. BLUMENTHAL and WOHLGEMUTH.
3. The New Massage-Institute of Berlin University. J. ZABLUDOWSKI.

4. The Physiology of the Kidneys and Ureters. E. WARSCHAUER.
5. The Case of Plague in Bremen. KURTH and STOEVESENDT.
6. The So-called Enteritis Membranacea. H. WESTPHALEN.

2.—After a series of experiments with frog material for the purpose of ascertaining the possibilities of **glycogen formation when albumins are used as food**, Blumenthal and Wohlgenuth reach the following conclusion: (1) That feeding with casein results in very little if any increase in the total amount of glycogen found in the animal; (2) that feeding with gelatin causes no increase in the amount of glycogen; (3) that feeding with ovalbumin (an albumin containing a carbohydrate radical) results in production of glycogen. [H.H.C.]

3.—Zabludowski gives a description of the new **Institute of Massage** at the University of Berlin and the purposes for which it was established. [H.H.C.]

4.—As a result of experiments in the catheterization of the ureters, Warschauer reports the following interesting facts concerning the **physiology of the kidneys and ureters**: (1) If catheters are introduced into both ureters as far as the pelves of the kidneys, the flow of urine is continuous, dropping slowly from the ends of the catheters; (2) in such cases all the urine passes through the catheters, none escaping into the bladder; (3) if the catheters are withdrawn slightly, the flow of urine is no longer continuous (in drops), but in interrupted jets, due to the contractions of the renal pelves and ureters, the action of both sides not being synchronous; (4) while the introduction of the catheters is hardly felt, the injection of fluid into the ureters causes an immediate colicky pain, especially if the distention be great; (5) the existence of a renorenal reflex is undoubted, as shown by the operation cited under this heading; (6) in at least some cases an upward flow of urine from the bladder into the ureters takes place; (7) the former theory that a pyelitis may be diagnosed by the presence of certain epithelial elements in the urine, can no longer hold, since the urine drawn by ureteral catheterization from patients suffering from pyelitis revealed no such structures, but instead leukocytes in varying stages of disintegration; (8) unless anomalies in the shape of malposition, neoplasms, calculi, diseases of the uterine adnexa, etc., the ureteral openings are easily seen by the practised operator, and catheterization is consequently easy. [H.H.C.]

5.—Kurth reports in detail the case of **bubonic plague** which occurred in Bremen during October, 1900. Clinically the case resembled a severe cellulitis of the cervical region, the spleen was only slightly swollen, and there was an entire absence of other glandular complications. The lungs were unaffected until just before death, when a slight infiltration of the right lower lobe occurred. The diagnosis was based entirely on the antemortem bacteriologic examination. [H.H.C.]

April 22, 1901. [38 Jahrg., No. 16.]

1. The Conservative Treatment of Purulent Adnextumors (Pyosalpinx, Pyoovarium) and the Results of Vaginal Incision. DÜRRSEN.
2. The Diagnostic Value of the Freezing Point of Blood. A. V. KORÁNYI.
3. A Case of Carcinoma of the Stomach with an Unusual Course. B. LEWEY.
4. The Splashing Sound in Atony. H. ELSNER.
5. The So-called Enteritis Membranacea. H. WESTPHALEN.

1.—Will be abstracted when concluded.

2.—Von Korányi, of Budapest, as a result of his investigations on the **diagnostic value of the freezing point of blood**, states that a freezing point of 0.56° , or at the highest 0.58° , is compatible with adequate renal function, but that 0.59° denotes a functional disturbance of both kidneys as far as insufficient respiration and acetoneuria are concerned. He finds that insufficiency of renal function may be due to reflex causes (unilateral renal pain, the other kidney being intact), or to mechanical causes (large tumors in the abdominal cavity, whether connected with the kidneys or not). In conclusion he condemns the careless technic and incorrect results of Waldvogel's work along the same lines. [H.H.C.]

4.—In his article on the diagnostic value of **splashing sounds** in cases of **atony of the stomach**, Elsner asserts that these phenomena are in themselves of indifferent value, except

when they occur at least 7 hours after a test meal or in an empty stomach—provided always that the stomach be in its normal position. Under these conditions splashing sounds may be regarded as a rather poor diagnostic substitute for the evacuation of the stomach contents by means of the stomach tube. Splashing sounds are never of diagnostic value in cases of gastropnoia. [H.H.C.]

5.—In the conclusion of his article on **membranous enteritis**, Westphalen reaches the following conclusions: (1) The separation of the so-called enteritis membranacea into 2 etiologically different groups (Nothnagel)—into an enteritis as the expression of an intestinal catarrh and into a colica mucosa, an intestinal neurosis—is scarcely possible. All cases of the disease should be regarded from a common etiologic standpoint. (2) The formation of the so-called enteritic membranes is probably due to a nervous hypersecretion of mucus in the intestine. (3) If the case be one of uncomplicated secretion—neurosis, abnormally copious quantities of mucus are evacuated. (4) If the case be complicated by spastic conditions of the intestine (obstipatio spastica), the excessive quantity of mucus is compressed and evacuated as a cord-like mass. (5) Should the evacuation of these masses be accompanied by intestine pain, we may assume (with Rosenheim) the existence of a concomitant sensory neurosis of the intestine. [H.H.C.]

1. Experimental Investigations Concerning the Principles of Detoxification (Entgiftung). ERNST VON CZYHLARZ and JULIUS DONATH.
2. Concerning Clinical Observation of the "Tension-Period" (Anspannungszeit), Based upon Retardation of the Pulse, and its Significance in the Diagnosis of Mitral Insufficiency. RUDOLPH SCHMIDT.
3. Malignant Tumors of the Lung. MAXIMILIAN WEINBERGER.

1.—Von Czyhlarz and Donath, from a review of the literature, conclude that it is generally conceded that the **liver possesses the power to diminish the toxic properties of various alkaloidal and other poisons**. To determine whether this power really belongs to the liver and whether a similar power is possessed by other organs, they performed 3 series of experi-

ments—71 in number. In the first series, mixtures were made of strychnin and different organs (liver, spleen, kidney, brain, and blood), and the mixtures were injected into lower animals. It was found that the poison was thus deprived of some of its toxic property—the loss being greater the longer the organ-emulsions were permitted to act on the poison before being injected into the animals. There was no marked difference in the detoxifying power of the different organs. It was noted, however, that the richer the emulsion in organ-cells the greater was the reduction of the poisonous power of the strychnin; whole blood also was active, whereas emulsions poor in cells and the blood-serum were inactive. In a second series of experiments, the liver, immediately it was removed from the body of an animal, was deprived of its blood, and through it was passed for a certain time a solution of strychnin. The strychnin solution was then injected into other animals with the result that it was found to have lost considerable of its poisonous properties. Thus was demonstrated that detoxification is a property of the organ tissues and is brought about without the intervention of the blood. In the third series of experiments, after ligating an extremity of an animal, strychnin in toxic doses was injected into the extremity. No ill effects resulted upon the removal of the ligature at the end of 4 hours—demonstrating that during life detoxification may be brought about through contact and interaction of the tissues and the poison. From the results of the experiments it is concluded that the liver possesses the power of reducing the poisonous properties of strychnin, but that this power is not characteristic of the liver alone, being possessed also by other organs. [A.O.J.K.]

2.—Schmidt refers to Martius' division of the ventricular systole into the closed-period (verschlusszeit) and the expulsion-period (austriebszeit), and to the later substitution of the term **tension-period (auspannungszeit)** for closed-period. Although used for the same period of the cardiac cycle, correctly both terms tension-period and closed-period are not interchangeable. Martius characterized the closed-period as that period of the cardiac cycle during which all of the valves are closed. Such being the case it has been held that in mitral insufficiency there could be no closed-period. Schmidt employing the term tension-period and basing his opinion upon clinical observations and theoretic considerations, believes that in mitral insufficiency not only is the tension-period present, but that it is also prolonged. He reports a case of mitral insufficiency and stenosis, aortic insufficiency, and tricuspid insufficiency with distinct heart-beat and apex-beat. He states that but little attention has been paid to **retardation of the pulse** as contrasted with the apex-beat, and he concludes that neither the apex-beat nor the heart-beat is dependent upon the presence of a closed-period and that neither occurs at the same time as does the closed-period; that paying attention to the retardation of the pulse as contrasted with the apex, is possible even clinically to observe marked prolongation of the tension-period; that in many cases of organic mitral insufficiency, both those well compensated and those developing acutely in the course of articular rheumatism, the pulse is markedly retarded after the apex-beat; that this retardation of the pulse is to be attributed to prolongation of the tension-period, and the prolongation of the tension-period to the mitral valves remaining open during systole; that this marked retardation of the pulse is no more pathognomonic of mitral insufficiency than is any one of the classic cardinal symptoms; that, nevertheless, in the combination of signs it deserves consideration and in difficult cases it may serve as a differential diagnostic sign between uncomplicated mitral insufficiency and murmurs occurring in anemia and after infections. [A.O.J.K.]

3.—Weinberger, referring to the varieties of **malignant tumors of the lung** that may occur, reports 2 cases of **primary bronchial carcinoma**. The first case, that of a man of 42, is interesting in that the course at first resembled that of tuberculosis. The diagnosis, however, was soon made with certainty by means of tracheoscopic examination. The second case, that of a man of 52, is interesting in that the diagnosis was made by means of microscopic examination of particles of the tumor that the patient expectorated. There is reported also a third case, that of a girl of 20, who suffered from a **lymphosarcoma**

of the mediastinum that invaded the lung by continuity of structure. The cases present additional interest in that besides the usual methods of examination the Röntgen-rays were made use of. Several radiographs are shown. By means of these it was possible to compare the pictures secured during life with the conditions found after death, and from this to draw various diagnostic conclusions. [A.O.J.K.]

March, 1901. [Vol. XXII, Part 3.]

4. Enteroplasty. TRNKA.
5. Contribution to the Diagnosis and Differential Diagnosis of Extra-uterine Pregnancy. JOSEF FABRICIUS.

1.—According to Bayer the congenital nature of an inguinal hernia is demonstrated when the sac of the hernia is made up of the nonobliterated or but partially obliterated processus vaginalis (hernia testicularis, hernia funicularis); when the spermatic cord is not a single cord, but when on the contrary, its various constituents—vessels, nerves, and vas deferens—are separated and repose in a small amount of adipose tissue; when the tissue surrounding the hernial sac is the unbroken, and not perforated cremasteric muscle; when, as an indication of persistence of embryonal conditions the aponeurosis of the external oblique muscle forms an unbroken, and not perforated membrane at the external inguinal ring; when because of the conditions just mentioned the external inguinal ring really does not exist; and when the hernial contents exhibit peculiarities with regard to the hernial sac, that permit of the supposition of primary failures of localization during development (heterotopia). The report of several additional and illustrative cases and a discussion of the subject are appended. [A.O.J.K.]

2.—Under the designation inferior peritoneal adhesions, Altenecker discusses a symptom-complex, which he believes presents a characteristic clinical and anatomic picture. Of clinical interest is the symptom-complex as given recently by Gersuny: Pain in the lower abdomen on both sides usually chronic constipation and increase of the pain, at times extreme colicky pain shortly before defecation, especially if the feces be inspissated; increase of the pain by bodily movements, and during menstruation; tenderness in the region of the appendix (McBurney's point), and at a corresponding point on the left side of the abdomen—pain in the region pressed upon and not in removed areas as occurs sometimes in chronic appendicitis; pain on coitus and vaginal examination. The results of objective examination are distinct in primary genital disease; in other cases they are absent or slight. In general, the palpation of the appendix is the only objective manifestation. Altenecker gives the results of the operative treatment of 42 cases, of which 35 were diagnosed correctly before the operation. One patient died. In only 33 of the remaining cases could the result be ascertained. Among these there occurred 13 cures, 18 improvements, and 3 nonimprovements. There follows a lengthy discussion of the etiology and pathology of the condition. [A.O.J.K.]

3.—Escher, referring to the cases of resection of the esophagus already reported and found by De Quervain in 1898 to be 14, reports a case—that of a woman, who had been suffering about 2½ years with gradually increasing difficulty in swallowing. Examination revealed occlusion of the esophagus due to a cicatrix about 1 cm. thick, on a level with the fourth tracheal ring. At operation 1.5 cm. of the esophagus was removed and the 2 ends of the esophagus brought together by circular suturing. The patient made a good recovery, and some months after the operation she reported that she could swallow as well as ever. The cicatrix was thought to be syphilitic. [A.O.J.K.]

4.—Trnka reports a case of extensive destruction of the cecum and ascending colon, in which it was found necessary to supply the defect with skin-flaps. This was done with complete success. For 8 days after the operation the intestines were kept empty, the patient being nourished with subcutaneous injections of oil; the following 8 days he was given liquid diet and then ordinary hospital diet. [A.O.J.K.]

5.—Fabricius, writing of the diagnosis and differential diagnosis of extrauterine pregnancy, states that the history of the case, the genital bleeding, the discharge of decidua, the cramp-like pains that sometimes occur, the growth of an adnexal tumor and the development of a hemocele are quite characteristic of extrauterine pregnancy. The adnexal tissues of the opposite side are usually normal. A ruptured extrauterine pregnancy or tubal abortion may be diagnosed when the dorsal vaginal wall is prominent and displaced to one side by a hard or sometimes semifluctuating tumor the size of a fist or child's head behind the uterus; when the somewhat enlarged uterus is displaced laterally and upward behind the symphysis, when its posterior wall cannot be marked out on account of the tumor and when the vaginal portion is discolored; when the adnexal tissues of one side are normal, whereas those of the other cannot be limited; when we ascertain that recently menstruation has been irregular and that the periods have been missed once or twice, or have been delayed, and that bleedings with or without decidual discharge have occurred; when the abdomen is enlarged and a resistance can be felt in the region of the symphysis or to one side thereof; when rectal examination reveals the organ displaced and its lumen constricted by compression. The differential diagnosis between retrouterine hemocele and conditions that may simulate it, such as retroflected uterus 3 months gravid, transitory amenorrhea with hematometra, cyst in Douglas' culdesac, soft myomas in Douglas' culdesac, further growth of an extrauterine pregnancy and parametric and perimetric exudates is detailed. Reference is also made to the fact that a gravid tube may become displaced either before or behind the uterus and simulate a pregnant uterus. Finally, reference is made to the features of pregnancy occurring in malformed uteruses, and to the fact that there occur cases in which, in addition to an intrauterine, there is also an extrauterine pregnancy. [A.O.J.K.]

April, 1901. [Vol. XXII, Part 4.]

1. Elongation of the Tubes Associated with Ovarian and Parovarian Cysts. HARRY LEPMAN.
2. Malignant Myoma of the Uterus. ANTON MASTNY.
3. Concerning the Relations Between Toxin and Antitoxin. RICHARD KRETZ.
4. Concerning the Anatomic Findings in Death by Strangulation and by Hanging. FRITZ REUTER.

1.—Lepman, as the result of prolonged investigations, concludes that the elongation of the tubes associated with ovarian and parovarian cysts results from the tubes participating in the general increased growth of the vicinity, and that a mild mechanic irritation may engender a marked hypertrophy of the longitudinal bundles, whereas, when a marked stretching occurs, the hypertrophy is associated with atrophy. [A.O.J.K.]

2.—Mastny, after a discussion of the literature, reports a muscular tumor of the uterus that assumed large dimensions and gave rise to numerous metastases in different organs. It is included among those rare cases of myomas of the uterus, in which the muscle tissue has lost its typical structure and, through the agency of some unknown influence, has become transformed into sarcomatous tissue—that is, round and spindle-shaped cells, between which there is but a fine connective tissue reticulum. It is believed that one is justified in designating such tumors as myoma sarcomatodes (Williams) or better, myoma malignum. [A.O.J.K.]

Endowment for the Roswell P. Flower Library.—In 1897 Governor Roswell P. Flower presented to Cornell University \$5,000 to found a library for the use of the New York State Veterinary College, and now Mrs. Flower has given \$10,000 to endow this library. With the books and periodicals purchased with the original gift and those which can be added from year to year by the income of the endowment, it is expected and believed that the Flower Library will become one of the best equipped libraries in comparative medicine in the world, and be not only of great service to the live stock interests of the country, but also in solving some of the interesting and important questions relating to the diseases common to men and animals.

THE PUBLIC SERVICE

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended May 17, 1901:

SMALLPOX—UNITED STATES AND INSULAR.

		Cases	Deaths

On Japanese steamship Taichu Maru.

Changes in the U. S. Marine-Hospital Service for the 7 days ended May 16, 1901:

GODFREY, JOHN, surgeon, upon being relieved by Surgeon J. J. Kinyoun, to proceed to Wilmington, N. C., and assume command of the service, relieving Surgeon T. B. Perry—May 11, 1901.

WEADIN, EUGENE, surgeon, to proceed to Gardner, Ill., for special temporary duty—May 14, 1901. Bureau order of May 14, directing Surgeon Weadin to proceed to Gardner, Ill., revoked—May 14, 1901.

PERRY, T. B., surgeon, upon being relieved from duty at Wilmington, N. C., to proceed to Baltimore, Md., and report to medical officer in command for duty and assignment to quarters—May 11, 1901.

WOODWARD, R. M., surgeon, granted 10 days' extension of leave of absence—May 13, 1901.

YOUNG, G. B., passed assistant surgeon, granted leave of absence for 2 months and 22 days from May 30—May 9, 1901.

STIMPSON, W. G., passed assistant surgeon, to proceed to Guthrie, Oklahoma, for special temporary duty—May 14, 1901.

MYDEGGER, J. A., passed assistant surgeon, granted leave of absence for 1 day—May 15, 1901.

GREENE, J. B., passed assistant surgeon, granted leave of absence for 10 days from May 13—May 14, 1901.

FOX, CARROLL, assistant surgeon, to proceed to Sitka and Juneau, Alaska, for special temporary duty—May 10, 1901.

TURNBURY, F. J., assistant surgeon, relieved from duty at Chicago, Ill., and directed to proceed to Dutch Harbor, Alaska, and assume command of the service—May 16, 1901.

DUFFY, FRANCIS, acting assistant surgeon, granted leave of absence for 2 days from May 21—May 16, 1901.

ULRICH, C. F., acting assistant surgeon, granted leave of absence for 12 days from May 14—May 10, 1901.

MASON, M. R., hospital steward, relieved from duty at San Francisco, Cal., and directed to proceed to Dutch Harbor, Alaska, and report to Medical officer in command for duty—May 16, 1901.

Changes in the Medical Corps of the U. S. Army for the week ended May 18, 1901:

GRANDY, Major LUTHER B., surgeon, recently appointed, now at Atlanta, Ga., will upon the expiration of the leave granted him May 1, proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

WILKINSON, Captain H. BROOKMAN, assistant surgeon, recently appointed, is granted leave to include June 7.

HALLOCK, Captain HARRY M., assistant surgeon, is granted leave for 3 months, from about June 1.

BLOCK, Captain WILLIAM H., assistant surgeon, is granted leave to include May 29.

CUTLIFFE, Captain WILLIAM O., assistant surgeon, recently appointed, is relieved from further duty in Porto Rico, and will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

CUTLIFFE, Captain WILLIAM O., assistant surgeon, is granted leave for 1 month.

MENAGE, H. E., acting assistant surgeon, is granted leave for 1 month, with permission to apply for an extension of 1 month.

MASON, Captain CHARLES F., assistant surgeon, upon the completion of the duty assigned him May 7, will proceed to Fort Sam Houston, for duty to relieve Lieutenant-Colonel Charles B. Byrne, D. S. G. Lieutenant-Colonel Byrne will proceed to St. Paul, Minn., and report to the commanding general, department of Dakota, for duty as chief surgeon of that department.

CARLING, Captain JOHN, assistant surgeon, leave granted May 1, is extended 1 month.

MASON, GEORGE L., contract dental surgeon, will proceed from Cambridge, Mass., to San Francisco, Cal., for transportation to Manila, P. I., where he will report for assignment to duty.

WILKINSON, Captain H. BROOKMAN, assistant surgeon, now at Bishopville, S. C., will upon the expiration of the leave granted him May 11, proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

SILMER, First Lieutenant IRA A., assistant surgeon, is granted ordinary leave for 1 month, to take effect upon the expiration of his present sick leave.

Changes in the Medical Corps of the U. S. Navy, for the week ended May 18, 1901:

DIEHL, Surgeon O., detached from the Indiana, upon reporting of relief, and ordered to the League Island Navy Yard, immediately.

BIDDLE, Surgeon C., detached from the League Island Navy Yard and ordered to the Indiana, immediately, as relief of Surgeon O. Diehl.

WISE, Medical Director J. C., appointed member of a board for the physical examination of candidates for appointment to the Naval Academy, May 17.

GROVE, Passed Assistant Surgeon W. B., order appointing him a member of a board for the physical examination of candidates for appointment to the Naval Academy, May 17, revoked.

AMERICAN MEDICINE

1321 Walnut Street

Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may begin at any time. Volumes end with the last issues of June and of December.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medical Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

The Disunity of the New York Profession is most regrettable. Whatever may be the judgment as to the causes that led to the result, there is but one feeling as to its continuance. So great are the evils of division and sectarianism that the entire profession will not long tolerate them, whatever justification or excuse may be offered. In the face of our reiterated scorn of sectarianism as to schools, so-called, of medicine, it is clear self-stultification to encourage or permit the thing itself among ourselves. The astonishing fact that over 67% of the members of the State Association hold membership in the county societies (the basis of the rival organization) is proof that the individual physicians concerned do not themselves look upon the sectarianizing logic as a very serious affair. There sometimes comes a time in the wrangles of men and societies when principle demands the surrender of principle. The higher principle must supplant the lower. We do not say either controversialist is right or is wrong. We take no side, because we think that so long as there are "sides" so long is the higher duty of unity not triumphant. With disunity the profession cannot secure the legislation imperatively demanded. Lawmakers only await our common single-voiced request. No state can have rival representatives in Congress, and so this controversy prevents a proper representation in our medical congress, the American Medical Association. Professional disunity is professional sin.

The Need of a Reorganization of the Business Work of the American Medical Association has been alluded to in previous editorials and we last week copied the outlines of a plan to bring this about which has been reached by a committee appointed for this purpose. Even in 1887 a similar committee concluded that "The desirability of having more time and deliberation given to the purely business matters of the Association by a properly organized council or standing committee on business, has long been recognized by all the more experienced members of the Association; and various plans have been suggested from time to time without leading to any definite action." At this time there were only 3,278 members. How much greater is the desirability now! The work of the present committee has been onerous and most conscientiously done. Doubtless there will be differences of opinion as to details, but as to the wisdom of the large principles stated and suggestions made, there should be a general accord of the members.

It is evident that the fundamental needs of the professional unity and association efficiency have been present in the minds of the committee as the guiding principles and motives. Their plan, we believe, will bring about the realization of these things. Surely it is only by means of some such a reorganization as the committee have proposed can there be, as it says, "Good reason to hope that in five years the profession throughout the entire country may be welded into a compact organism, whose power to influence public sentiment will be almost unlimited, and whose requests for desirable legislation will everywhere be met with that respect which the politician always has for organized votes. With the Association in constant, personal, definite, and essential touch with each State medical society, and through them with the societies in every county, the profession of medicine can at no distant day demand and receive that respect from law-makers, from government officials, and from the general public to which it is admittedly entitled by reason of its ideals, its education, and its power for doing good to all mankind."

Vacation Schools.—Sixteen years ago, a physician, Dr. Win. N. Barringer, then Superintendent of Schools at Newark, N. J., proposed, and the citizens of Newark accepted, the plan of vacation schools. Since that time one city or community after another has followed the excellent example, until now there are probably a score or more in which it is in practical working. Nature-study, cooking, wood-carving, bent-iron work, drawing, painting, basket-weaving, cane-seating, athletics, are some of the subjects taught. The women's clubs have been most active in encouragement of this progressive movement. Physicians will certainly help to make it general, and see that proper athletics and physical culture are parts of the program. Such schools, rightly managed, are surely great preventives of disease, and helpers in establishing a high grade of healthful life. Coupled with the vacation playgrounds they constitute a powerful sanitary as well as moral influence for the betterment of the lives and bodies of the coming generations.

State Regulations Concerning Tuberculosis.—Dr. Walter Wyman requested the health officers of the States and Territories of the United States to inform him concerning the laws in force as to the registration and notification of tuberculosis. No replies from Georgia,

Kentucky, Missouri, New York, Oregon, Tennessee, Texas, District of Columbia, Alaska, Arizona, Indian Territory, New Mexico and Oklahoma were received. In the States not listed below there is no law as to registration and notification. In the following States the conditions are as follows:

Their ingenuity and pertinacity in infesting all ships and the unsanitary quarters of all cities is most remarkable. The medical commission of the Japanese Government says that to avoid the spread of bubonic plague, rats must be exterminated. But this is plainly an almost impossible task. It would, however, seem possible to

STATES.	NOTIFICATIONS.	SANITARY MEASURES.	REMARKS.
Indiana.....	Required to be reported.....	Not quarantined.....	The State board, under the health law of Indiana, is given power to pass rules and ordinances for the enforcement of the act to prevent outbreaks and the spread of contagions, infectious and other diseases.
Kansas.....	No State law bearing directly on the subject. A statute exists, granting authority to the municipalities to make the necessary regulations to prevent the spread of epidemic diseases. Notification is required at Topeka.		Under the statute named, ordinances may be passed requiring such notification.
Maine.....	Cases required to be promptly reported.	Not subject to quarantine or isolation. Disinfection is advisory when the family owns the house; compulsory when the house has been vacated by a family in which the disease has occurred.	Local boards of health are instructed and advised by the State board to furnish families in which tuberculosis is present with the circular of the board, giving instructions relative to precautions against the spread of infection.
Massachusetts.....	Physicians and householders are required to notify the local board of health of each case of disease dangerous to public health. The interpretation of the phrase is left to the discretion of each local board.		
Michigan.....	Phthisis pulmonalis is being reported.		A statute law exists relative to notification of cases of sickness from certain diseases. Phthisis pulmonalis has been declared by the State board to be a disease dangerous to the public health. A test case is before the State courts to judicially determine whether or not phthisis pulmonalis comes within the meaning of the statute.
New Jersey: Asbury Park, Montgomery, Trenton.	Ordinances requiring notification of cases of tuberculosis have been enacted.		
Washington.....	Practising physicians in cities of the first and second class are required to report each case of tuberculosis which has been attended by them, or which has come under their observation.	Each patient, or the head of the family, shall be furnished with printed rules for the prevention of the spread of communicable diseases. The local board shall see that the premises occupied by said patient are kept in a sanitary condition. Within 5 days after death or removal of said patient, the board shall see that the premises are properly disinfected.	Failure to comply with Section 1 of the act for preventing the spread of tuberculosis which requires a report of cases of said disease is subject to fine.

The Extermination of Rats, because they are the carriers of plague-infection, seems fast becoming a duty of all civilized governments. The Local Government Board of England recognizes this fact in a circular to the sanitary authorities, on the risk of importing the disease by means of ships infested with plague-infected rats and the precautions necessary to prevent such introduction. On other grounds it would be well if these justly detested animals could all be killed. These pests have been supposed to be scavengers, but the answer to the plea is that the filth upon which they live is unnecessary, and even a danger.

Simond believes the infection is due to the fleas with which rats are commonly infested; but Dr. Nuttall, who has made an extensive study of the subject, claims that his researches do not bear out Simond's theory. Professor Ashburton Thompson, in an account of the plague in New South Wales, says that he is convinced the disease reached Sidney through the rats on vessels from Noumea, at which place plague existed. His investigations lack a connecting link between rats and man, and the hypothesis that infection is conveyed by a suctorial insect infecting rats and transferable to man would furnish this link. Certain it is that rats are easily inoculable, and that they do carry the disease over the world.

kill them on ships from infected ports. An effective method of doing this has been suggested by means of sulfurous acid forced into all parts of the vessel for twenty-four hours.

Experimental Production of Cirrhosis of the Liver.—There are many problems in connection with cirrhosis of the liver that require elucidation, the two most interesting being the etiology and the ultimate pathogenesis. The solution of either one of these will greatly help us in solving the other. It is still unknown whether the first change produced by the morbid agent affects the liver-cells or the connective tissue. When a typical example of atrophic, or Laennec's, cirrhosis, is examined, the first impression is that the connective tissue bore the brunt of the attack; but there are many points which suggest that primary chronic interstitial inflammations are exceedingly rare, and that when we find inflammatory changes in the connective tissue, they are the expression of a reaction secondary to changes in the parenchyma or higher tissues. The experimental evidence in proof of this explanation of interstitial inflammations is still meagre. In connection with the liver, Charrin was one of the first to produce interstitial inflammations. He employed pyocyanus for this pur-

pose. Flexner obtained cirrhotic changes in the livers of animals after the injection of toxalbumins of bacterial, vegetable and animal origin. Weaver employed a bacillus belonging to the colon group, and Hektoen, the colon and pseudodiphtheria bacilli. Flexner's experiments seemed clearly to show that the cirrhotic changes were a secondary reaction—an attempt on the part of the liver to repair necrotic changes in its parenchyma. By employing antipyrin in small doses over a long period, Marekwald has succeeded in producing in frogs a fairly typical picture of interstitial hepatitis. He was able to prove that the inflammation was not primary, but was caused by an antecedent degeneration in the liver-cells. When he took starving frogs, the only change obtained was an extensive degeneration of the liver cells, without reaction of the connective tissue; when, however, he fed the frogs—he had accustomed twelve of them to live on meat—an inflammatory process in the connective tissue was superadded to the degeneration of the liver cells. Marekwald explains the difference in the reaction between the starving and the well-fed frogs, as being the result of the depression of the vital functions in the former, so that the liver was incapable of reacting with the production of new cells.

There is, of course, a wide abyss between the frog and the higher mammals, and it would not be proper to apply the results obtained in the former to the explanation of cirrhosis in man; but the unity of the inflammatory process in the animal world, the demonstration of which we owe to the magnificent studies of Metchnikoff, permits the belief that the results of animal experiments may, with proper limitations, be employed in the explanation of morbid processes in man.

The extermination of birds is not alone the work of fashionable vanity but of fashionable gluttony. The recent seizure in a New York cold-storage warehouse of great numbers of dead birds during the close season illustrates the easy evasion of the law by those careless of consequences. In hotels travelers often find upon the bills of fare the names of birds unknown to ornithologists and dictionary-makers. When asked what kind of birds these represent the waiters are permitted to answer only by smiles and silence, or by confessions of ignorance. In the cold-storage house in New York were found so many birds that the legal fines would have run to millions of dollars. What would they amount to for the United States? As a result of such practices everywhere those butchers and dealers who obey the law are really punished for their honor while the reckless are rewarded by great profits. We are fond of pointing out excellent spheres of work and usefulness for those who are greatly troubled by a few deaths of animals in scientific laboratories. Why should this stupid and ruinous war of extermination of birds with its great resultant suffering not arouse the energies of the S. P. C. A.?

Summer Play-Schools.—In Europe, play-schools for city children have long been organized under the guidance of competent teachers, and in American cities more recently the same excellent plan is being started.

In New York it is to be carried out with more thoroughness this summer than ever before. Last year as many as 1,000 children in the city were taught to swim, and the School Board will issue certificates of proficiency to these. The schoolhouses and yards are to be utilized for carrying on instruction in sewing, modeling, wood-carving, in kindergarten and household work. Gymnasiums are also planned. In Boston last summer 20 school yards were used by 3,800 children. What a great influence for health, good morals and a better life must be exerted by such methods of getting children out of the hot, crowded streets, with their evil associations of all kinds. It is an unselfish charity—one that prevents disease as well as cures it. The School Boards of the country have in this scheme a noble opportunity to do a great work for the betterment of their communities, not only educationally but also physiologically and sociologically.

Arsenic Poison in Beer-Drinkers.—Drs. T. N. Kelynaek and William Kirby, of Manchester, have recently published an interesting work on Arsenic Poisoning in Beer-Drinkers (London, Baillière, Tindall & Cox. 1901. Svo., pp. 125, with Bibliography), based upon the epidemic of last summer among the habitual consumers of beer in England, especially in Manchester and vicinity.

The fact that peripheral neuritis among alcoholics has been for years past a prolific cause of paralysis in Lancashire had something to do with the fact that suspicion of arsenic poisoning was not aroused until the cases of so-called "alcoholic paralysis" had become so common in June, 1900, as to constitute an epidemic. Unfamiliar symptoms, such as pigmentation of the skin, soon led to the suspicion that something was "wrong" with the beer, especially as the patients themselves held the beer to blame; but the suggestion that the poisoning was due to arsenic was not made until November, by Dr. Reynolds. It required but a few hours to confirm his suspicion and this confirmation was followed by thorough scientific investigation covering over 300 cases in Manchester alone. The majority of cases occurred among the working classes; but individuals of both sexes and all ages were afflicted. No cases occurred among drinkers of whisky or brandy, the epidemic being confined to consumers of beer and stout.

The patients complained of prickling sensations in the extremities, great weakness, thickening and desquamation of the skin, alteration of the nails in transverse ridges, eruptions, cold in the head, and especially of pigmentation of the skin. Walking was painful and difficult in most cases, there was marked mental sluggishness, loss of flesh, erythromelalgia and other manifestations of peripheral neuritis. In the majority of cases improvement began at once when the contaminated beer was stopped.

Previous to this epidemic there seems to have been no indication in medical literature that arsenic was ever considered as a possible impurity in malted beverages, and this lack of suspicion together with the frequency of alcoholic paralysis and the delicacy of the available methods for the detection of small quantities of arsenic in organic fluids undoubtedly accounts for the

extensive spread of the epidemic before the detection of its cause.

The use of glucose and invert sugars by English brewers appears to be the rule; in some instances as much as 50% of the malt was found to be substituted by sugar. The general practice of using arsenic pyrites in the manufacture of the sulfuric acid employed in the preparation of glucose, whereby the acid is contaminated with arsenious acid to the extent in some instances of 1.4% of its weight, lay at the foundation of the difficulty, the arsenized glucose carrying with it as high as 2 grains of arsenious oxid to the gallon of beer.

This English epidemic calls for a close inspection of glucoses by Board of Health chemists generally, for the hitherto unsuspected danger of arsenic contamination of malt beverages and of "soft" drinks in which glucose is used, inasmuch as it is clear that cases of chronic arsenic poisoning among the poorer classes and alcoholics may exist over very considerable periods without detection and without becoming epidemic.

The Medical Department of the Philadelphia High School for Girls was established in 1893. Prior to this time the attendance of any physician was depended upon in an emergency, so that much time was lost and the uncertainty of obtaining assistance was great. In 1893 the services of a graduate of the Woman's Medical College were secured. The duties of the head of the Medical Department constantly increased from one hour a day to the continual attendance from the opening of the school at 9 a. m. until the close of the session at 2 p. m.

At the beginning of each school year in September all vaccination certificates and scars are examined; in doubtful cases a certified re-vaccination is required. Teachers at the beginning of each morning session inquire whether any student is suffering from sore throat, headache or other ailment; all such are at once referred to the Medical Room. A daily record of students sent to the Medical Room is carefully kept. Any student with a temperature of 100° is detained in the "sick room" until the temperature becomes normal. If a rise takes place the student is sent home in a carriage. On stormy days students who have wet shoes, stockings or skirts are required to report at the Medical Room, where dry garments are provided. All wet clothing is dried in a room prepared for the purpose, and is made ready for the student at recess in the Medical Room at noon. Every part of the entire building is thoroughly cleansed daily. The bannisters and desks throughout are carefully cleansed each day with antiseptic solution. The drinking water is filtered, then sterilized, and the ice is made from sterile water. The sanitary condition of the toilet rooms is excellent. There are now individual compartments, where formerly there were congregate rooms.

The medical department is ideal in location, having a south and east exposure, with a good supply of sunlight, while its situation, back of the "library," insures all the quiet necessary. This room is supplied with all that is required for any emergency that is likely to occur. There is an ample supply of filtered water and

appliances for obtaining boiling water. The department is provided with four wicker couches with cushions covered with linen slips; the latter are frequently removed and laundered, while the cushions themselves are detached, shaken and placed in the sunlight. A part of the engine room space is used for drying clothing, etc.

That the work of the department has been greatly appreciated is evident by the letters and personal visits from parents and physicians of the students. The number of students on roll during one school year was 3,402, with a faculty of 87 teachers. During the year 2,233 students were referred to the medical room: 702 with headache, 137 with sore throat, 127 with toothache, 531 with dysmenorrhœa, 21 with epistaxis, 45 with diarrhea, 26 with earache, 139 with indigestion, 150 with nausea, 99 with hysteria, 21 with grip. *Accidents*: Dislocations (minor) 3; sprains, 18; burns (slight), 11; scalds (slight), 3; splinters, 54; contused wounds (slight), 28; lacerated wounds (slight), 34; incised wounds (slight), 4; punctured wounds (slight), 4; poisoned wounds (slight), 3; foreign bodies in eye, 49; foreign bodies in ear, 1. *Contagious Diseases*: Measles, 6; scarlet fever, 2; ringworm, 1; pediculosis capitis, 9. Seventy-four were sent to their homes.

Syndicating the specialists has been attempted in Birmingham, England, where an institution with five specialist consultants has been formed. The English profession has "resolved" against the scheme, and has already secured the resignation of one of the consultants. In the United States the same plan has been tried, and has, of course, failed. It would seem to many at first, as if it would be of advantage both to the patients and to the physician. In reality it can work nothing but injury to both. The reason lies in a fact we must ever relearn after the sorry forgetfulness of it has harmed us all. This fact is the old truth that money-getting as the primary object of the physician's life and work destroys his therapeutic ability and scientific judgment. The relation of the physician to the patient is an intensely personal one, and at the touch of the corporation's impersonality, it is withered as by a poison. The financial reward in a moderate degree must be secured, but only as secondary to the ideal of healing and preventing disease. Watch the medical man in whose mind and ideals money or personal success is slowly or rapidly supplanting the nobler professional aim, and we as surely recognize his loss of the power to cure, a paralysis of the deft touch, the shirking, averted, or overbold gaze, the coarsening of word and action, the failure of the healing art. Syndicating specialism multiplies geometrically the degrading selfishness of the individual.

Two Methods of Treatment are illustrated by two excerpts from a recent number of the same New York newspaper:

"Dr." David R. Jenkins, a negro, who was arrested at his office, No. 249 Sixth avenue, some time ago, at the instance of the County Medical Society, for practising medicine without a license, pleaded guilty in the Court of Special Sessions to-day. He did a good business with the colored population, posing as a "voodoo" doctor. When he pleaded guilty, Jenkins said:

"The only thing in God's world that I give my patients is Croton water. I put up Croton water in various kinds and

sizes of bottles and call each one by some different name. The coloring matter is the same as they use in making candy, and don't hurt any one. Croton water is just as good to cure rheumatism, diphtheria, cholera, or any other kind of disease, as anything. It don't hurt the patients, anyway."

The Christian Scientists have opened an institute in Brooklyn. The institute might be called a "Christian Science Hospital," for twenty healers are attached to it, and healing will be the chief work done. Nine fine rooms in the new Temple Bar Building have been engaged, and every sign of prosperity is displayed.

It will also be remembered that a year or two ago almost all aristocratic and educated England poured wealth into the pockets of a medical nostrum company, and the only medicine used by this company was proved to be simply water. Which is the greater criminal, the humbuggers or the humbugged? Of the former, our sympathies would be with the Voodoo doctor, and yet he is the only one who was punished. As to the dupes—they surely have their proper reward!

The Antitoxic Properties of Bile.—Among the means of protection possessed by the organism against infectious diseases and toxic agencies, laboratory investigation has recently placed the bile; but, as is true of so many other facts in medicine, empiric knowledge anticipated scientific discovery. Thus, the natives of Africa, according to Fraser, have long known the value of serpents' bile as an antidote in the treatment of snake-bites, and among the natives of Bengal it has been a custom, centuries old, to employ the liver of mad dogs as a protective agent against hydrophobia. In a letter to the *Gazette hebdomadaire de Médecin*, a French traveler writes as follows:

About three months ago a mad dog bit six or seven persons, among whom were two of my porters. I ordered bits of iron to be heated white-hot for cauterizing the wounds; but the natives said to me with a laugh, "Oh, Sahib, that is nothing; we have an excellent remedy for hydrophobia; you shall see." The mad dog approached again; one of the natives took a club and killed the animal. Another opened its body, took therefrom the palpitating liver, cut it into small bits, and gave them to the wounded man, who ate them raw. "There is no more danger," they said to me. As I remained incredulous, they brought me to a young man who bore large scars on his legs. He had been bitten five years before by a mad dog, but had eaten a raw piece of the animal's liver, and had felt no ill effects.

These events took place in March and it is now July 3. The wounds are cured and all the men continue to do well. Our natives even assert that their remedy will cure a man after he has been attacked by the disease.

Wehrmann found by experiment that bile destroys the toxic properties of ecl serum and of snake venom, but that it apparently has no protective or curative properties. The active antitoxic principle of bile was found by Phisalix to be the taurocholate, and especially the glycocholate, of sodium.

The important experiments of Fraser are well known. He found that the bile of both poisonous and non-poisonous serpents counteracts the toxic effects of snake venom. Oxgall has similar properties, but was estimated to be 70 times weaker than the bile of poisonous serpents. The bile also neutralizes diphtheria toxin; but, as Fraser's experiments show, only when it comes from the same species of animal as that injected with the toxin.

Perhaps the most interesting observations connected with the antitoxic properties of bile are those made by Koch in his study of the rinderpest in South Africa. It was found that cattle can be immunized when injected with the bile of animals that have died of rinderpest on the fifth or sixth day of the disease. The protection conferred lasts for a period of four months. Kolle and Turner have, however, improved upon Koch's method of immunization: by the injection of virulent rinderpest blood and of serum from animals that have recovered from the disease they have obtained an antitoxic serum that is much more powerful than bile. Kolle is of the opinion that the antitoxic properties of bile are not due to the presence in it of any soluble poison or antitoxin, but that with the bile are introduced microorganisms of the disease which grow at the point of inoculation, their dissemination being prevented by the action of the bile on the surrounding tissues. In other words the immunity is *active*, analogous to that conferred by vaccination against anthrax, and not passive, as is the immunity obtained by means of antitoxins against diphtheria and tetanus.

Vincenzi found that the bile of animals suffering from tetanus is able to antagonize a certain amount of tetanus toxin, while the bile from healthy animals is devoid of such property. That the bile has also the power of neutralizing certain poisonous alkaloids, was shown by Arnold. This investigator injected a series of frogs with varying doses of strychnin, and recorded the onset of convulsions, the severity, duration, and the time within which death occurred. Another series of frogs were injected with the same doses of strychnin mixed with fresh frogs' bile; a third with similar doses of strychnin mixed with oxgall; and a fourth, with bile alone. The frogs that had received the strychnin mixed with bile survived doses of strychnin which were surely fatal when given alone. The symptoms appeared later and were less severe. The fresh frogs' bile was more active than the ox-bile. None of the frogs died after the injection with bile alone. The bile was excreted rapidly in the urine. Finally, strychnin was mixed with fresh frogs' bile and allowed to stand for three hours. At the end of this period, strychnin could not be found by the ordinary chemical tests.

In connection with the subject of the antitoxic action of bile, it is interesting to note that the theory, so long maintained, that bile in the intestines exerts antiseptic properties, is not supported by recent investigations. Albu and others have shown that the reputed antiputrefactive property of bile is a myth. Mosso likewise demonstrated that bile has no power to arrest putrefaction, although in his experiments it seemed slightly to hinder the growth of bacteria. Whatever influence the bile possesses upon putrefactive processes in the intestine is indirect. It stimulates peristalsis, and thus shortens the time during which proteid substances are exposed to the action of intestinal bacteria. The writer has more than once noted in cases of catarrhal jaundice, in which the common duct was so completely obstructed that no bile whatever entered the intestines, that the stools were by no means unduly offensive.

Important researches upon the enzymes have been made by Professors H. W. Harper and J. K. Kastle. There are over fifty of these mysterious bodies known of which pepsin, ptyalin, trypsin and invertin are examples. Professor Harper thinks their wonderful power of inducing chemical changes in other substances without apparent change themselves is due to the vibrations of the ether-waves which they set up and which correspond in period with those of the fermentable substance. This theory of sympathetic vibrations coordinates the mechanism with that of the action of light, electricity, etc.

The transports from unsanitary and infected Cape Town are conveying bubonic plague to Southampton, Sydney, Port Elizabeth, and Western Australia. The English authorities have at last been compelled to undertake the segregation of the Kaffirs at the point of the bayonet. Up to April 27 there had been 319 cases with 217 deaths from plague at Cape Town. In modern life the *furcâ* of the old Latin proverb, *Naturam expellas furcâ*, etc., may often be translated *bayonet*.

Another physician's strike has taken place at Bamberg in Bavaria, where the physicians were treating 800 members of a *Krankenkasse* at the rate of seven cents per visit. A quack hypnotist turned the heads of the members of the Association by his abuse of the medical profession. The mountebank was not acceptable as a colleague, according to the demand of the majority of the members, and the physicians threw up their contract.

Recent investigations have demonstrated that the localization of sound by the ear is due not to the intensity but to the quality, or overtones, of the waves. In monaural hearing the localization is accurate in proportion to the complexity of the overtones. In binaural hearing the ear nearer the sound-producing point, or which more perfectly brings the waves to a focus, indicates the direction and distance.

The efforts of the Philadelphia Pediatric Society to secure pure milk for children by guaranteeing the purity of the milk of certain dairies inspected by its experts, are being widely commended. The society wisely appeals to the love of profit in the dealers competing for the society's guarantee rather than to laws and punishments.

Two French scientists report that of twenty-seven guineapigs kept in disinfected cages, fed upon sterilized food, and allowed only sterilized air, nineteen died. Of twenty-nine others treated the same way except that there was no sterilization of food and air, only ten died. The latter also lost less in weight. But why did the ten die?

It is plainly evident that the anti-canteen controversy is developing into a condition in which a desire to verify prejudice and prove "I-told-you-so" is the motive of both sides: rather than the good of the soldier, or of the service. We hope soon to see a dispassionate and scientific settlement of the vexed question.

EDITORIAL ECHOES

The Role of Fat in political physiology cannot be summed up in a simple formula; but for practical purposes it will be found tolerably safe to assume that thinness makes for revolution and fleshiness for repose, which, expressed in terms of politics, means Conservatism. The ideal demagogue is lean—*tourmenté par son caractère*, as Madame de Staël said Napoleon ought to have been. A man who has a full round belly, with good capon lined, is by the law of his physical being a Conservative, whose principle is *Quies non movere*, though he may delude himself and others with the fancy that he is a Radical. Those of our American friends who think that the well-being of the United States depends on the maintenance of a republican form of government will do well to take steps at once to repress the tendency to abdominal expansion among their citizens, or they may live to see the President transformed into an Emperor.—[*British Medical Journal*.]

Sanitation of Churches.—According to the *Revue Scientifique* of April 27 one of the Italian bishops, Monsignor Franceschini, has sent to the clergy of his diocese a circular enjoining them to adopt sundry sanitary precautions in their churches. Immediately after saints' days, when the congregations have been large, the paved floors are to be cleansed with sawdust soaked in a solution of corrosive sublimate (1 in 1,000). On ordinary occasions the floors are to be frequently swept, after a preliminary sprinkling with water in order to avoid raising dust. Every week or oftener the seats and confessional boxes are to be dusted with damp sponges and cloths. Every week or oftener the grilles of the confessional boxes are to be cleansed with alkaline lye and afterwards polished. The holy water fonts are to be emptied every week, or oftener if necessary, and washed either with boiling alkaline lye or with solution of corrosive sublimate (1 in 1,000).—[*The Lancet*.]

The County Society should have on its roster the name of every regular practising physician of good standing in the county, and each should consider it his duty as well as privilege to be a member of that body. It is by means of the State body acting through the immediate and local influence of the county organization that the power of the profession will be made felt, and through that agency more than any other will it be able to command the respect and consideration that society in general owes to it. The county society will have the additional influence of promoting a better acquaintance among its members and of breaking down that condition of selfishness that too commonly arises when one busies himself solely with his own affairs and takes no interest in the general welfare of his profession. It promotes a better understanding of each other, elevates professional regard, and stimulates the interest in the work of the State organization.—[*St. Louis Courier of Medicine*.]

Temperance Physiology in the Public Schools.—We are glad to note the signs of revulsion against the extreme temperance reformers, who have by the trick of their laws forced so much nambypamby stuff into the schools under the head of physiology. Bugaboo morals are the most childish and the soonest outgrown. We deplore the absolute ignorance of American teachers as well as children, concerning the fundamental laws of health, and we wish most heartily that temperance in the matter of eating, of tea- and coffee-drinking, and common sense concerning fresh air, exercise and sleep, as well as the economic value of foodstuffs, might be particularly taught in schools; but so unfair has been this temperance movement, and so great have been the exaggerations perpetrated on an unwary public, that we fear

the influence that the schools should have on all matters of public health, including the dangerous effects of intoxicating drinks and tobacco, will be greatly diminished. Already Western educators are opposing the teaching in its present form, and the Massachusetts Legislature is tightening the reins. Other States are realizing that they are not only being made ridiculous by their laws, but are seriously handicapped by sentimentality.—[*Medical News.*]

Truth Suppression.—The subject of prompt announcement is so woven into the affairs of practical municipal and maritime sanitation as to necessitate the fullest recognition as an elementary and indispensable part. It is inconsistent with every known law of God, of every principle of sound policy, and of well doing among men, that an individual or a city or a State can successfully protect itself behind the flimsy barrier of a lie, particularly in dealing with the phenomena of nature. If a case of cholera occurs in a city and be hidden under the disguise of a simple intestinal derangement, to avoid public clamor and injury to the commerce and revenues of the State, the last hope of destroying the contagion is wiped away and thousands of lives and the general ruin of industry must pay the penalty of the sordid, short-sighted, wretched policy. So of smallpox and so of yellow fever. The deadliest enemy of a State is the man guilty of intentional concealment.

Now, in all seriousness, the position taken by your humble servant over a year ago in the eradication of plague from San Francisco seems to be finally to be carried out. I sincerely trust that the efforts now about to be made will lead to the early termination of the disease in San Francisco, and in other places as well. The disease cannot, or never will be, stayed or eradicated, by any or all the methods which have been the main reliance for the past year in San Francisco. The problem is entirely medical, and must necessarily be solved by medical men. There must be a return to first principles—principles which are to be the guide for our faith and practices.—[Dr. J. J. Kinyoun, address before the Alameda County Medical Society.]

The Young Graduate.—At the beginning of their respective professional lives, the graduate of the present has had the advantage over the graduates of long ago, of an actual superior amount of knowledge, together with the advantage of the lengthened course of preparatory collegiate training. To the qualified and ambitious young graduate of the present, one year is the equivalent of two, at least, in the good old times. There were giants in those days, but what they accomplished was done slowly, and had to be done largely by their own unaided efforts in all the various departments of medical science, while now, by the development of the specialties and the increase in the number of workers in them, our younger physicians are furnished with abundant material ready to hand with which to build, much more rapidly and less laboriously, as the spirit moves them. It is not the number of years of natural or professional life which constitute the age or maturity of a physician, but the ability to do good work. By their fruits shall ye know them. It would be foolish to attempt to deny the beneficial effects of years in tempering and restraining even too exuberant scientific activity, but this is at all times sufficiently provided for by the inexorable fact that we all must and do grow old; but rather a thousand times the restless enthusiasm of youth than the self-satisfaction of premature senility. Age does not, however, protect from folly, neither does youth render its possessors immune to wisdom. But while it is our duty in no case to belittle any man's work on account of his youngness, it is equally the duty of the young to remember that they have no monopoly of knowledge, and that wisdom will in all probability not die with them.—[*The Hahnemannian Monthly.*]

AMERICAN NEWS AND NOTES

GENERAL.

The case of yellow fever in Havana, Cuba, has been discharged cured, it is officially reported, and there is no further occurrence of it.

Food Preservatives have been investigated by Professor Bigelow of the Agricultural Department at Washington, who finds that the manufacture of them has become a distinct line of business. Out of the 67 samples of the most common preservatives in use, each of which was obtained with great difficulty when it was known that it was wanted for a chemical analysis, 33 of them contained borax or boric acid; 10 sodium, potassium or calcium sulphite; 8 salicylic acid or its sodium compound; 7 benzoic acid or its sodium compound; 1 boric and salicylic acid; 1 boric acid and ammonium fluoride; 3 formaldehyd; 1 ammonium fluoride; 2 pyroligneous acid, and 1 B-naphthol. Professor Bigelow holds that those undoubtedly injurious, such as formaldehyd, salicylic acid and sulphites should be proscribed, and some stringent law enacted to control their use.

Obituary.—WILLIAM HENRY MORGAN of Nashville, Tenn., May 16, aged 83.—P. R. MOORE of Los Angeles, Cal., May 13, aged 65.—M. PAFFORD of Cecil, Ga., May 6.—MILES R. BIGGAR of Detroit, Mich., April 30.—SELTON W. STEVENS of Scranton, Pa., April 25, aged 39.—CHARLES D. SHERMAN of Boston, at Lancaster, Pa., May 18, aged 52.—ALONZO C. CASLER of St. Johnsville, N. Y., May 11.—EDWARD SULTAN of Baltimore, at St. Louis, May 15.—BENJAMIN F. STANLEY of Dublin, Ga., May 17, aged 67.—JOHN A. WELLS of Englewood, N. J., May 21, aged 45.—WILLIAM D. THOMAS of the Chair of Psychology of Richmond College, Va., May 21, aged 65.—JANE KENDRICK CULVER of Boston, May 23.—JOHN T. HAGAN of Baltimore, May 23, aged 51.—THOMAS F. RUMBOLD of St. Louis, Mo., April 23, aged 71.—W. L. WITHAM of Lebanon, O., May 24.—EUGENE D. ANDRUS of Seattle, Wash., May 18, aged 59.—R. A. GOTTSLEBEN of Mayville, Wis., May 23, aged 50.—GEORGE HEITZMANN of Marinette, Wis., May 22, aged 62.—HUGH STOCKDELL of Petersburg, Va., May 23.—H. T. PHILLIPS of Cheshire, Mass., May 24, aged 68.

Smallpox.—The Board of Health of New York urges vaccination as the only means of stamping out the disease of which there is no abatement, 26 cases having been reported in 1 day recently. Bureaus for free vaccination are kept open day and evening, but there is a failure on the part of the people to avail themselves of this privilege to any great extent. The president of the Camden, N. J., Board of Health has issued a circular forbidding the return to that city of all cabs, carriages, laundry wagons and other vehicles which go to Gloucester, as it is reported that from 12 to 60 cases of smallpox exist in that city. Hamonton, N. J., fears an epidemic from the exposure consequent upon a case of smallpox in a young Italian from Naples who had been detained in New York in quarantine for 10 days previous. In Plainfield, N. J., 3 cases are cited. A case of smallpox has been discovered in Baltimore, imported by a negro from St. Mary's County and a corps of 15 vaccine physicians accompanied by police have vaccinated the neighborhood. Notification was received by General Chaffee, the American commander, as he was about to leave Pekin, that 2 cases of smallpox existed among the Indian troops in camp at Tonku, where the Americans were to board their transports. Further cases of smallpox are reported on the United States transport Indiana.

EASTERN STATES.

Diphtheria exists at Princeton, N. J.; 4 cases are reported.

The **Newton Hospital** of Massachusetts, is the recipient of a large bequest by the will of Mary Shannon, which divides \$125,000 among several institutions.

Carney Hospital in Boston, in which the late Mr. Julius Adams was treated while suffering from typhoid fever from October 1896 to February 1897, will receive \$56,500 from his estate.

A "**Magnetic Healer**," named Paul Castor, has been convicted in Portland, Me., charged with practising medicine without being a duly licensed physician. This case is the first of its kind ever tried in the courts of the State.

An **Emergency Hospital** has been established by the women of Union Hill, New Jersey, from money realized from fairs, etc. It has 25 beds, a modern operating room, a staff of trained nurses, a resident physician and a surgeon.

The **New Hampshire State Medical Society** held its one hundred and tenth anniversary meeting May 16 and 17. The officers elected for the ensuing year are: President, Dr. D. S. Adams, of Manchester; vice-president, Dr. Irving A. Watson, of Concord; secretary, Dr. G. P. Conn, of Concord; treasurer, Dr. M. H. Felt, of Hillsboro.

Medical Inspection.—The authorities of Newton, Massachusetts, are holding under advisement the question of daily medical inspection for the schools of Newton. The Board of Health is in favor of the movement so far as contagious disease is concerned. The cost is estimated at \$2,000 for a single term.

Elmhurst Sanitarium, for the treatment of tuberculosis, was opened at Shrewsbury, Massachusetts, on April 6. It has 6 free patients recommended by the leading practitioners of Worcester County. Dr. W. H. Bliss will be in charge. The people were at first disposed to combat the institution, but they have been assured by the officials that there is no danger of contagion.

NEW YORK.

Free Treatment for Tuberculosis.—At the Tuberculosis Congress, Dr. Ellinger stated that a free annex for the treatment of tuberculosis would be opened next Thanksgiving Day at the Montefiore Home for Incurables in New York.

The New York Homeopathic Medical College and Flower Hospital, through a gift of \$25,000 by Anson R. Flower, have been enabled to purchase the building they occupy as dispensary and dormitory. They formerly paid an annual rent of \$1,800.

The Congress of Nurses which will be held at Buffalo, N. Y., will have representatives from all parts of Great Britain and its colonies who wish to confer with their American sisters as to the best method of advancing the profession of nursing and getting a proper recognition for it in society.

A Faith Christ, J. Luther Pierson, was held under \$500 bail for refusing to obtain medical aid for his adopted daughter. The child died of catarrhal pneumonia through lack of proper care. The bond has been signed and the man is out on bail. It is said that the case will be taken to the Appellate Division of the New York Courts.

The East Side Physicians' Club has been organized at 165 Henry Street, New York, by doctors who live on the east side, south of Fourteenth Street. Its object is the discussion of medicine and surgery, and the agitation of severer laws against quacks. The society, with a reported membership of 175, is to be nonpartisan and nonpolitical.

The Long Island College Hospital in Brooklyn will have its main building, which was erected 50 years ago, supplanted by a structure at a cost of more than \$175,000, of which about \$120,000 has already been contributed. Henry W. Maxwell, it is said, subscribed \$50,000. George Foster Peabody and Edward M. Shepard are also large contributors to the building fund.

Austro-Hungarian Hospital and East Side Dispensary will be the name of a new hospital to be remodeled from the building known as the East Side Dispensary of New York. The capacity is from 30 to 35 beds and \$10,000 has already been raised. The money has been contributed by the Austro-Hungarian Hospital Association, which has charge of the alteration, Hungarian miners from Pennsylvania, and others in the colony.

Stony Wold Sanatorium Building Fund Committee is the name of a committee of women who feel the urgent need that exists for the establishment of sanatoriums for working girls, young married women and children suffering from tuberculosis, as in spite of several organizations in the city and State of New York which care for tuberculous patients the number of the latter is so great that many urgent cases are suffering from lack of proper treatment, and they cannot be received in the hospitals except in the few which have special wards for the purpose. It is estimated that in New York City alone there are 30,000 cases.

Tuberculosis Hospital Site.—The fear is baseless, it is believed, that the action of the Legislature in making the selection of a site for the hospital for the treatment of incipient cases of tuberculosis subject to the approval of the Governor, the Speaker of the Assembly and the President pro tem., will delay the construction of the building. The Dannemora tract in the Adirondacks lying entirely outside the State forest preserve is the site agreed upon by all officially interested, and it is anticipated that this site will soon be approved by the Governor and the 2 other officers, and the work of construction for which the plans are already drawn will soon be commenced.

PHILADELPHIA, PENNSYLVANIA, ETC.

Henry Sheridan Keyes has been appointed surgeon-in-chief to the Emergency Hospital, now building at Los Angeles, California.

An Epidemic of Typhoid is reported at Beaver, Pa., and more than 40 cases listed; the malady is most prevalent among children. Pittsburg chemists have been asked to analyze the water and milk supplied to the town.

Mosquitos.—The people of South Orange, N. J., under the auspices of the Village Improvement Society, planning for the extermination of mosquitos and ridding the village of malaria, have had an investigation made of the ponds and lowlying places by Prof. L. O. Howard, Chief Entomologist of the Department of Agriculture, Washington, who saw no reason why there should not be a successful issue to the undertaking.

Prevention of Idiocy.—The Thomas bill before the House for the prevention of idiocy was passed in executive session, May 21, by a vote of 108 yeas and 44 nays, after a discussion of the subject from the standpoint of the physician. The bill provides that in certain cases surgical science may be called upon as a preventive agency. A circular from 5 medical authorities of Philadelphia had been sent to every member of the House and Senate advocating this treatment.

Prevention of Tuberculosis.—At the recent annual meeting of the Pennsylvania Society for the Prevention of Tuberculosis, Dr. Howard S. Anders reported having written (February) to Chairmen Hardenbergh and Bliss, of the Senate and House Appropriation Committees, respectively, urging the passage of a bill in the interests of a State hospital for the tuberculous poor; that favorable and encouraging replies were had from both gentlemen; and that his reprints on "The Necessity for State Aid in the Treatment of the Consumptive Poor" had been distributed among the members of these Committees to further the movement for such a sanitarium.

Is Diphtheria Quarantinable?—On May 20 the steamer Rhyndland, from Liverpool and Queenstown, arrived at the port of Philadelphia with 3 cases of diphtheria on board. She had been passed by both the Federal and the State Quarantine Stations, located at Reedy Island and Marcus Hook respectively, on the ground that the quarantine regulations, while considering diphtheria contagious, do not declare it quarantinable. The ship had left Liverpool on May 1, 1901. On May 9, 1901, the disease developed in 3 Italian children, natives of Turin. On the following day the sufferers were isolated. Thereafter no other case occurred, although numerous children were on board. An examination of the children's throats at the time of landing, by Dr. J. S. Bogges, confirmed this fact. The municipal health authorities, in view of the attitude of the national and State quarantine officers, refused to prevent the debarkation of the passengers, and merely transferred the sick children at once to the Municipal Hospital. Lists were, however, made of the passengers, in order that those remaining here could be kept under surveillance. Lists of the passengers destined for points in Pennsylvania were moreover supplied to the State authorities, and the health boards of the cities throughout the country for which any of the immigrants were bound were also notified.

SOUTHERN STATES.

Increase in Insanity.—It is reported that 400 persons have been pronounced insane within a year in Washington, D. C., and new cases are occurring daily.

Typhus Fever.—Health Commissioner Bosley reports 3 cases of typhus fever in Baltimore in one of the hospitals. The patients are Lithuanians who came from Sparrows Point, where they are supposed to have contracted the disease from sailors.

John Hopkins Medical School.—The present graduating class of 9 women and 47 men, composed of members from all parts of America and from Hawaii and India, is the largest in the history of the university. Much creditable work is reported to have been done.

Correction.—Dr. Guy Steele, city and county Health Officer of Cambridge, Md., corrects the official statistics published in AMERICAN MEDICINE of May 18, in which that city is credited with 5 cases of smallpox from April 1-30. He says there have been 2 cases, one of which was sent at once to quarantine at Baltimore, and 1 colored child quarantined in her home. A house to house vaccination was instituted and there have been no cases for 2 months.

WESTERN STATES.

Norval H. Pierce has been appointed specialist in ear diseases at the Illinois Charitable Eye and Ear Infirmary in Chicago.

E. E. Evans has been elected demonstrator of anatomy in the medical department of the University of Kansas.

The John A. Creighton Medical College, of Omaha, graduated a class of 28 on May 6. The doctorate address was delivered by Dr. W. O. Henry.

Dr. Matthews, professor of physiologic chemistry of the Harvard Medical School, has accepted a position on the faculty of the Medical School of the University of Chicago.

An antisputting ordinance of the Chicago City Council has become operative, but it has been agreed that no arrests shall be made at once, but policemen and conductors will warn all offenders.

FOREIGN NEWS AND NOTES

GENERAL.

Obituary.—PIETRO PANZERI, of Milan, aged 52. For nearly 30 years bringing under special treatment every infantile victim to faulty development among the poor of Milan and rearing many seemingly hopeless cases to normal strength. CHARLES HITCHMAN BRADDON, of Manchester, England, May 10, aged 63. FERDINAND A. HEIDENRICH, of Tilsit, Prussia, aged 80. S. PERRET, of Lyons, France. Professor AGRÉGE, of Lyons, France. EDUARD GOLEMIOWSKI, of Berlin. GEORGE ASP, Professor of Anatomy in the University of Helsingfors, aged 67.

Bubonic Plague.—Up to the week ending May 11, 610 cases of bubonic plague, with 275 deaths, have occurred in Cape Colony. The disease seems to be on the wane owing to the efficacy of the sanitary measures adopted. That the unhygienic condition of Capetown did not result in such dire calamity long ago must be principally owing to the violent gales from the southeast which prevail during the summer on the shores of Table Bay, and which are locally known as the "Cape Doctor." A considerable number of whites have fallen victims to the plague and the fact that a number have been discovered dead, would show that concealment is not confined to the natives. The disease is centered in Capetown and there does not seem to have been extensive spreading, although sporadic cases have occurred which may yet form epidemic centers. The Government ordered a regiment of foot and mounted armed police to march to the most unsavory parts of the city and take positions at the entrances to the thoroughfares diverging therefrom. A staff of physicians accompanied them to search for unreported cases; some distinct cases were discovered and sent together with those having contact with them to the hospital at Uitvlugt. About 6 or 7 colored people decidedly stricken managed to escape with the aid of their friends. In India, the plague is decreasing, and in Bombay a considerable section in the heart of the city is free from it for the first time in months. In China, up to March 31, there have been 76 cases with 73 deaths. In New South Wales a fatal case of plague occurred at the quarantine ground at Sidney. The patient was a seaman on a ship that had been at Cape Town for 2 months. A great many rats had died during the voyage, and he had assisted in removing the bodies. A bacteriologic examination proved that the rats were infected with plague bacilli, and that the seaman was a victim. The ship was thoroughly fumigated and many rats were killed. The period of quarantine completed, the vessel was about to be released when a storeman aboard was taken ill. His case so far has been mild and the only one reported. In Tokyo, Japan, the authorities are issuing to the lower and poorer class of citizens nearly 50,000 improved rat traps, at a cost of 9,392 yens. Including this sum, and that for other implements and drugs for the crusade against the rats in Tokyo this season, the amount to be devoted to this purpose figures in the estimate at 20,000 yens.

GREAT BRITAIN.

Sir Frederick Treves.—The King has conferred upon Mr. Treves the honor of knighthood.

Dr. R. J. M. Buchanan has been appointed to the office of Assistant Physician to the Liverpool Royal Infirmary. He succeeds T. R. Bradshaw who has recently been elected to the office of physician.

Extermination of rats. by means of the generation of sulphurous acid gas of a high strength, has been successfully tried on the Jelunga, a steamer of the British India line. The apparatus used is a small cylinder in which rolled sulphur is burned until it vaporizes and air being admitted into the chambers where this vaporizing takes place the combination of oxygen and sulphur vapors furnishes the sulphur oxid gas. The hatches of the Jelunga were closed and the gas admitted. The space to be operated on held 600,000 cubic feet. The next day when the vessel was opened dead rats were lying about and all other forms of vermin were extinct.

CONTINENTAL EUROPE.

The Hospital of Aix-les-Bains, France, is the recipient of a gift of 50,000 francs from Mr. J. Pierpont Morgan.

University of Halle.—Professor v. Bramann, director of the surgical clinic, has been elected rector of the university for the year beginning with the spring semester.

Diphtheria is reported so prevalent in France that Prime Minister Waldeck-Rousseau has issued a circular to French physicians in regard to its alarming spread and urging the prompt application of the anti-diphtheria serum.

Children's Hospital.—As a memorial of the Czar's coronation the Municipality of St. Petersburg has concluded on the erection in that city of a new hospital for children, consisting of 8 pavilions and containing 402 beds, at an estimated cost of 1,700,000 roubles.

SOCIETY REPORTS

ILLINOIS STATE MEDICAL SOCIETY.

FIFTY-FIRST ANNUAL MEETING HELD AT PEORIA, MAY 21, 22 AND 23, 1901.

[Specially reported for AMERICAN MEDICINE.]

At a preliminary meeting of the Society called by the Legislative Committee, several propositions were discussed. The question of a medical practice act and board of examiners was taken up, freely discussed, and a committee appointed to draft a bill providing for a Board of Medical Examiners in the State, the committee to consult such laws as are operating best in other States.

A resolution was adopted requiring that if a bill be introduced into the next Legislature, the true names and quantities of ingredients be plainly printed on each package of patent medicines and nostrums offered for sale, the Society being instructed to do what it can to further the passage of such bill, provided the Legislative Committee believes it can be done without jeopardizing other desirable bills.

Hypnotism Should be Confined to the Profession.—It was recommended that the Legislative Committee attempt to pass a bill forbidding in any wise exhibitions of hypnotism for the purpose of obtaining money.

Epileptic Colony.—The Legislative Committee was instructed to use all its power to secure the location of an epileptic colony in Illinois, which was provided for by a bill passed by the Legislature 2 years ago.

Sanatorium for the Tuberculous.—The question of attempting to secure legislation in favor of the establishment of a sanatorium for the tuberculous was referred to a special committee to report to the preliminary meeting next year.

Questions of Organization.—(1) Define exact status of membership: (a) Membership lost in a local society should also be lost in State society. A motion was made and carried that all members of the State society shall be members of some local society unless the Judicial Council sees fit to elect them members at large. (b) If honorable, qualified and not sectarian, college of graduation should not act as a bar to membership in the State society. After considerable discussion, Dr. E. Fletcher Ingals offered the following resolution, which was unanimously adopted:

Resolved, That school of graduation shall be no bar to membership in the Illinois State Medical Society, providing such physician is recognized by the local society as qualified and not claiming to practise any exclusive system of medicine.

STATE SOCIETY JOURNAL.

- a. Editorial work.
- b. Advertising.

After a free discussion of these topics, the following resolutions were offered and adopted:

Resolved, That as far as practicable the Journal of the Society be made the official organ of the city, local, county and district societies in the State.

Resolved, That the Journal may accept all ethical advertisements under the same restrictions that apply to advertisements in the Journal of the American Medical Association.

Resolved, That the judicial council select some member of the Society to act as editor and manager of the Journal, said editor and manager to be paid a reasonable salary out of the net profits derived from the publication, the amount of salary to be determined by the judicial council.

DIVERSION OF PUBLIC FUNDS.

A resolution on this subject was adopted as follows:

Resolved, That the Society looks with disfavor on any process by which public moneys appropriated for charitable institutions are diverted from their intended uses by assessments or otherwise.

Reorganization.—A committee of five, consisting of Drs. Graham, Pettit, McAnally, Ochsner and Roskotten, was appointed to study the plan of reorganization as submitted by the Secretary of the American Medical Association, Dr. George H. Simmons. This committee reported as follows: Your committee would respectfully recommend the following, believing that this form of notice is sufficiently comprehensive to allow of all desired changes and yet sufficiently specific to meet the requirements of the Constitutional provision relating to amendments:

Notice is hereby given in accordance with Article IX of the Constitution, that at the next annual meeting of the Society, to be held in May, 1902, such changes in the Constitution and By-Laws will be presented for consideration and adoption as will provide for reorganization on the basis of the following propositions:

1. That the work of the Society be divided into 2 parts, scientific and general business, the latter to include the nomination of officers, the control of finance, the conduct of the Journal, work relating to legislation and such other matters as may be referred by the Society, and to be conducted by delegates who shall be chosen by the constituent societies.

2. That membership in good standing in a county medical society, or, in the absence of such county society, then in a district or city society covering the county of residence, shall constitute membership in the State society.

The committee also recommended that the Society be requested to appoint a committee of 3 to formulate and adjust the proposed amendments during the coming year. The report was unanimously adopted.

This meeting was the most successful in the history of the Society, both as regards its scientific work and attendance. The number of members who registered was a little over 400, and at one of the sessions nearly 600 physicians were present.

The following officers were elected for the ensuing year: President, Dr. J. T. McAnally, Carbondale; first vice-president, Dr. M. L. Harris, Chicago; second vice-president, Dr. J. W. Hensley, Peoria; secretary, Dr. E. W. Weis, Ottawa; treasurer, Dr. Everett J. Brown, Decatur; editor and manager of the society journal, Dr. George N. Kreider, Springfield. Quincy was selected as the place for holding the next annual meeting.

AMERICAN LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL SOCIETY.

SEVENTH ANNUAL MEETING, HELD AT NEW YORK ON
MAY 23, 24, 25.

An address of welcome was delivered by Dr. D. B. Sr. JOHN ROOSA who, describing himself as a New Yorker of New Yorkers, and one who took an interest in everything connected with the metropolis, said they were in the habit of saying things to one another that might be supposed to reflect on the city, but they never said them to others, and in any case so far as the medical profession was concerned, they had reason to feel nothing but pride and self-respect because of the position it occupied and the work it had done. It aimed to keep abreast of the profession in all other parts of the world, and he thought it had been fairly successful in doing so. He then proceeded to give a short sketch of what the profession in New York had done, and referring specially to the branches that come more immediately within the scope of the society, he remarked that, contrary to the saying embodied in the old Roman maxim, it had been given to not a few planters to see the fruits of the trees they had assisted in planting. The progress made in laryngology and rhinology in recent years was as great as that made in any other department of medicine or surgery, and there again the advance had been as great as in the rest of the material world.

Presidential Address.—Dr. MYLES, in the course of his opening address, said the history of the society, though brief, had been one of brilliant success. Speaking as a specialist to specialists, he appealed for the recognition of a broader conception of the field of specialism. The tendency of such work as theirs was to narrow rather than broaden. They were apt to concern themselves too much with local conditions, and there was ground for the taunt that specialism militated against scholarship in medicine. He urged them all to strive against these tendencies, and also against everything that tended to give a mercantile character to their profession.

Presentation of Cases.—A number of cases, specimens and instruments were presented, among the cases being one in which external and internal deformity of the nose had been corrected by Dr. T. P. Berens, New York, by means of external appliances, while among the specimens were cancer germs collected by Dr. Eisen, San Francisco, and presented under somewhat melancholy circumstances by one of his colleagues, the doctor himself having fallen a victim to the disease he was investigating, the infection, which it is feared will soon terminate fatally, being directly traceable to the work in which he had been engaged.

A case of **Traumatic Dislocation of the Left Arcartilage** was described by Dr. HENRY L. WAGONER, San Francisco.

A paper on **Disease of the Upper Air Passages in Relation to Mental Development** was read by Dr. L. F. PAGE, Indianapolis, and gave rise to an interesting discussion. The author mentioned a number of diseases, including asthma and epilepsy, which had been traced to irritation of the upper air passages. The effect of these irritations was to cause an increased drain on the nervous system, and the result was sure to be exhaustion sooner or later. It was self-evident that the existence of these physical defects on the part of the children was bound to retard their mental development. He had had experience of many cases in which the performance of a single operation on the nose, throat or ear had had the effect of removing a cloud from children's minds.

Dr. PRICE BROWN (Toronto) thought they could not have too strongly impressed on their minds the fact that adenoids and other growths and affections retarded mental development. He had in his mind 2 boys who had been bright when young but afterwards became extremely dull, one becoming an absolute dullard, and all because of stoppages in their air passages. He did not hesitate to say that children in that condition ought to have the adenoids and other obstructions removed.

Dr. GEORGE L. RICHARDS (Fall River) told of a boy who refused to go to school because deafness, due to the stoppage of the upper air passages, prevented him keeping up with his

classmates. When the adenoids were removed the boy came back with an entirely changed expression. He thought the general profession ought to be educated to an appreciation of the importance of making these operations.

Dr. E. B. HOLT (Portland, Me.) thought every city should have one or more school physicians whose duty it should be to deal with abnormalities of every kind, as well as with contagious diseases. If there was to be a higher state of human beings in existence at the end of the century than there was now, it would be necessary to make fresh arrangements for looking after the health and mental as well as physical development of the young. If officials of the kind he spoke of were appointed, a young man's school record could be looked up when he proposed to get married, and the young lady's father could be guided by it in giving or refusing his sanction to the proposed union.

Dr. SARGENT F. SNOW (Syracuse) expressed concurrence with what had been said by previous speakers as to the harm caused by these obstructions to the upper air passages, and said that he had had a case of epilepsy that most surely was the result of unnatural nasal pressure.

Dr. F. C. COBB (Boston) suggested that if they agreed among themselves what operations were called for in cases of the kind, and when they should be performed, they would have no difficulty in gaining the confidence of the general practitioner.

Dr. JAMES F. McCAW (Watertown, N. Y.) said he did not believe the retardation of mental growth was due to physical causes as represented for example by the adenoids, but to the deafness resulting therefrom.

Dr. LEWIS A. COFFIN (New York) also took this view of the matter, contending that the dullness of such children was frequently apparent rather than real. As proof of this he mentioned that the same symptoms were often noticed on children who did not see well.

Dr. F. T. POWERS (Providence, R. I.) mentioned that in that city defective children were being looked after in the way that several speakers had recommended, and the results were very satisfactory.

Dr. A. B. ABRAMS (Hartford, Conn.) also made some remarks, after which the reader of the paper closed the discussion.

A case of **tuberculous and syphilitic granulomas of the nose** was described in a paper by Dr. WILLIAM LINCOLN (Cleveland, Ohio) and some observations upon the diagnosis and treatment of specific disease of the nasopharynx were offered by Dr. PATRICK S. DONNELLAN (Philadelphia) who referred to the impossibility of depending on the statements of patients in such affections, and said they should always insist on looking for syphilitic symptoms.

Dr. RICHARDS remarked that when the diagnosis was doubtful no operation should be attempted until antisyphilitic treatment had been continued for some time.

An **Operation for Prominence of the Auricle** was described by Dr. THOMAS R. POOLEY (New York) who confessed that he had undertaken the operation with some reluctance, but said the result had given satisfaction to the patient, an actress who had represented to him that her large ears had prevented her securing engagements.

Clinical Notes on Adrenalin.—A paper under this title was read by Dr. NORTON L. WILSON (Elizabeth, N. J.) giving the characteristics of the drug, the history of its discovery and its use in ophthalmologic work chiefly, and particularly as an hemostatic. He noted but little anesthesia. He dwelt particularly on the fact that it might be sterilized readily. Its results seemed unvaryingly accurate, and he thought its discovery of much importance.

Discussion.—Dr. J. A. STUCKY (Lexington, Ky.) said he would like to add his testimony in regard to the remarkable properties of this drug. About the first of December Dr. Takamine sent him some of the solution and powder, and since then he had used it extensively in nose, throat and ear work, and unlike Dr. Wilson, he found that it produced some anesthesia. The effect of using it was that they required less cocaine and got a longer action of that drug. He had, too, found adrenalin particularly valuable in middle ear operations. One thing which the reader of the paper had touched on they should always bear in mind, and that was the recurrence of hemorrhage afterward. He did not believe, however, that there was more hemorrhage than they might expect under ordinary circumstances when the drug was not used. He had used it in cases of acute and subacute laryngitis. He usually used a solution of 1 to 3,000 or 1 to 5,000, and he found that he could sterilize and re-sterilize it as much as he pleased. He generally added 5 grains of resorcin, which he thought a good thing to mix with it. In his opinion it was one of the most remarkable drugs they had to help them in their work. Another class of cases besides those he had referred to, in which it could be used with advantage, consisted of those in which patients were in a state of collapse as the result of anesthesia. In 1 case, that of a child who did not rally properly, he had given half a drachm of the 1 to 5,000 solution, and in 5 minutes the color came back to the child's face.

Dr. T. P. BERENS (New York) said he wished also to bear his testimony to the usefulness of the drug, which he had been using in a variety of cases. One advantage it possessed was that it kept well. He had opened a bottle and kept it on his office table for 6 weeks, and he found it perfectly sweet and

clean and its blanching qualities not at all deteriorated. Then he sterilized it, and found it very efficient for the purpose for which he wished to make use of it. It had been his habit to inject a few drops of the drug through a catheter, blowing it directly into the eustachian tube. He had also used it hypodermically, and in that way also he found that it worked very nicely.

Dr. M. D. LEDERMAN (New York) said he could endorse a great deal that had been said by the reader of the paper as to the value of the drug. "He thought they owed a great deal to it for enabling them to lessen the quantity of cocaine. He did not think there would be nearly so many cases of toxemia from cocaine after the use of adrenalin became more common. The result of his experience with the drug and the suprarenal extract was to convince him that it could be used as an internal remedy as well as a local application.

Dr. O. J. STEIN (Chicago) said all the remarks so far had been very commendatory; but it was well also to hear the other side, and he had to confess he had had some disappointing experiences with the drug. He had used it in a case of antrum trouble, and thought that the effect would surely be to give him a bloodless field to work upon. Yet he had quite as much hemorrhage as he would have expected to have without it. Again he had used it in a case where the maxillary sinus was affected, and there also he had as much hemorrhage as if he had not used it. In some cases it undoubtedly gave good results, but considering the extent to which the drug was lauded as a hemostatic it was remarkable that there should be such an amount of hemorrhage in cases of the kind to which he had referred.

Dr. T. R. CHAMBERS (Jersey City) said they should certainly hear the other side if there was one, but he had seen a good number of cases in which the Wilson operation on the septum was performed, and he had scarcely seen any blood—certainly not more than 5 or at most 10 drops—when adrenalin was used. In certain mastoid operations which he had performed enucleation would have been impossible without adrenalin because of the hemorrhage which would have taken place. The use of adrenalin made these operations successful.

Dr. H. HOLBROOK CURTIS (New York), while prepared to admit that Dr. Bates' discovery of the use which could be made of the suprarenal capsule ranked with the discovery of cocaine, agreed with the speaker who said they should hear both sides of the matter, and personally he had come to the conclusion that there were cases of individual idiosyncrasies in which it acted very badly. There were in short cases in which there was an absolute intolerance of adrenalin or the suprarenal extract. One man to whom it had been given sneezed continuously for 2½ hours afterwards. He had given it to several hay-fever patients, and after they had used it for several days they had the most intolerable pain and had to cease using the drug. He had used it on himself and the result was to set up violent coryza. Not thinking it was due to adrenalin he kept on using the drug until he found himself with a typical case of hay fever, which only stopped when he discontinued the use of the drug. In some cases it acted admirably, but it was necessary to take note of the unsuccessful as well as the successful case. He wished to ask others who had used the drug whether they had found that violent pains or fits of sneezing were frequent results of its employment. He knew of 1 case of hemorrhage of the nose in Bright's disease in which remarkable relief was given by the use of the drug.

Dr. E. B. DENCH (New York) said he had not used adrenalin, but in all cases in which he had used the suprarenal extract it had given entirely satisfactory results as regarded the control of the hemorrhage. In middle ear work in particular he thought it was of great value.

Dr. S. MACCUEEN SMITH (Philadelphia) added his testimony to the value of the drug, especially in cases where cocaine was used. As a preventative of cocaine poisoning it was of singular value.

Dr. W. H. JOHNSON (Paterson, N. J.) thought a very important matter was the preparation of the field on which the drug was to be used. It should be rendered perfectly clean. He did not know that there was any difference between the action of adrenalin and that of the suprarenal extract, but adrenalin possessed a great advantage in this respect that it was a clean and reliable solution and was always ready. Personally he had not come across any cases of idiosyncrasy of the kind that had been spoken of. In all the cases in which he had used the drug the results had been perfectly satisfactory. He had no doubt one of its principal uses would be as an agency for blanching the eyelids. It certainly did work of this kind most efficiently, and at the same time it permitted more rapid dilation of the eye in atrophy.

Dr. M. A. GOLDSTEIN (St. Louis, Mo.) supported what Dr. Curtis had said as to the irritating effect the drug sometimes had, and said he would like to ask the resourceful chemist to whom they were indebted for adrenalin whether it would not be possible to remedy this defect by making up the solution in oil? Possibly a combination with menthol or camphor would have the desired result. He had found the drug of great use to singers suffering from acute laryngitis. An application of the drug in such cases gave remarkable results, and enabled singers to go on with their work when otherwise it would be impossible for them to do so.

[TO BE CONCLUDED.]

CORRESPONDENCE

CONSERVATIVE TREATMENT OF BUBOES.

BY

ABRAHAM L. WOLBARST, M.D.,

of New York.

Referring to the editorial on "The Conservative Treatment of Buboës," in the first number of *AMERICAN MEDICINE*, I would like to add a few words in favor of the method advised by Krulle. For the past 2 years I have treated buboës by this method (slightly modified) almost exclusively, and the results have been most satisfactory.

About 30 cases were treated in this manner. The inflamed glands were dressed with an ointment containing iodine and belladonna, and tightly compressed by a spica bandage. Often this treatment seemed sufficient to abort suppuration; when, however, suppuration appeared to be inevitable, it was found advisable to wait until all the glands had completely broken down and formed one abscess-cavity, before the incision was made, thereby preventing the formation of deep-seated pockets and sinuses.

The incision was made under cocaine anesthesia, and in most instances was painless. An opening is made in the direction of the long axis of the swelling, not more than a half-inch in length. The secretion is not squeezed out, but is permitted to escape through the opening without pressure being exerted from without. The cavity is then carefully cleaned out with warm sterilized water or (in some instances) with peroxid of hydrogen. The silver solution is then injected by means of a small glass syringe, and the opening is covered with a pad of lint on which some soothing ointment, preferably boric acid ointment, has been smeared. A tight spica bandage is then applied, and removed on the third day, when the silver nitrate solution is again injected as before.

By this method of treatment the patient is not compelled to take to his bed; anesthesia is unnecessary; and the resulting scar is so small as to be hardly visible. Recovery is also attained in less time than by the more expensive open operations, the usual time being from 2 to 3 weeks, and in some instances even less than this period.

At first I used a 10% solution of silver nitrate, with most satisfactory results; but the pain following the injection was so great in some of the cases that the strength of the solution was reduced to 5% with equally good results, and with little, if any, pain. The pus disappeared after a few injections; the wound was then treated by dry dressings in the usual manner.

Unless every gland has broken down, recovery will be delayed by the formation of deep-seated pockets, which will not heal unless they are opened and exposed. Then they heal very rapidly.

There can be no doubt as to the superiority of this method of treatment over the radical method of opening up the entire abscess-cavity and removing all the glands. By the latter method, the open wound is often converted, by direct infection with the knife, into one large chancroidal ulcer, which is as obstinate to treatment as the original chancroid.

OBSCURE HEMORRHAGE FOLLOWING LANCING AN ABSCESS OF THE NECK.

BY

BAILEY P. KEY, M.D.,

of Tracy City, Tenn.

The patient, age 5 years, male, first had measles that ran a typical course. When the eruption disappeared from the face, rtheln followed at once with adenitis on the left side of the neck. The inflammation extended from the ear to the median line. It was indurated for 6 days, when a circumscribed cavity could be made out, involving the external carotid and jugular vein.

The attending physician punctured the abscess on a line anterior to the stonocleidomastoid, where the artery and vein emerge from beneath the muscle into the anterior triangle. To all appearances the abscess-cavity emptied through the opening without even a stain of blood and healed up at once with a scab adhering to the point of puncture. For 10 days all went well and the child was playful. The neck in the region of the puncture continued to fill out and grow larger from day to day

(so I was informed) until an alarming hemorrhage spurted out at the point of puncture one day while the child was playing in the room alone with its mother. The mother caught up the child in her arms and placed her finger over the opening in the skin until assistance arrived. The pressure of the mother's finger at the point of the puncture produced a large coagulum beneath the skin and arrested the hemorrhage temporarily. When the attending physician arrived, the little patient was faint and pulseless, and he returned to his office for instruments. When I came I enlarged the opening, cleared away the coagulum and caught up the bleeding vessel between the index fingers and the thumbs below and above the point of puncture and directed an assisting physician to pass a threaded needle through the skin and beneath the vessels out through the skin on the opposite side of the incision and tie the skin, tissues and vessels. The opening in the skin was then closed, antiseptic compress dressing applied as tight as could be at this point.

Seventy-two hours later the dressing was removed and the part inspected. There being no signs of hemorrhage, the dressings were reapplied. The patient had rallied from the loss of blood, and to all appearance was about well. However, the watch over him was kept up. At dawn the next morning and the fourth day from the first outbreak of hemorrhage I was again hurriedly called.

I found the patient pulseless, faint, and bleeding at a fearful rate. I opened the wound, secured the bleeding points with catch forceps, sponged the wound dry, and secured the vein above and below with catgut ligature. I then ligated the external carotid at 2 points, 2 inches from each other. Also ligated facial artery and vein, and tied 5 other bleeding points in the locality of the opening. I tied the vessels with strong catgut. I now put in 8 interrupted catgut sutures. In this row of sutures I included the soft tissues and fascia and the vessels previously ligated. I then closed the opening in the skin with interrupted catgut suture, sealing the part completely. Not a drop of blood was visible.

At 4 p. m. I was on watch, and gave the little patient some hot milk to drink. While inspecting the dressings I noticed fresh blood stains. I at once removed the dressings and attempted to arrest the bleeding, which seemed to come from the common carotid artery below and above the point of puncture. The patient bled to death before I could secure the vessels, and when assistance arrived, it was too late to transfuse.

What caused this hemorrhage? Was the vein wounded by the puncture and a thrombus formed? Was the coat of the artery punctured or an aneurysm formed? Or was there a sloughing of the veins in the locality? I incline to the last hypothesis.

HOSPITAL ABUSES IN SOUTH AFRICA.

BY

ALBERT S. ASHMEAD, M.D.,

of New York.

AMERICAN MEDICINE, May 11, quotes from *The Practitioner's* remarks regarding the report of the Royal Commission on hospital abuses in South Africa as follows: "The British public has got to realize that war is, as the American general said, simply h—l. But Mr. Burdett-Coutts apparently expected it to be a kind of game in which those who were hurt were to be sprayed with rosewater and fed on chocolate creams by smart ladies who found a new sensation in playing the part of ministering angels." "Qui n'entend qu'une cloche n'entend qu'un sou," as the French say, therefore please print the following opinion of the editor of the *Medical Press and Circular*, of March 27:—"The report of the Commission appointed to investigate the condition of the military hospitals in South Africa was generally regarded as a whitewashing document. If doubt remained on the point, it has been effectually swept away by Mr. Burdett-Coutts' speech in the House of Commons on March 20. It would be hard to imagine * * * a more damning indictment of a public inquiry of a matter of national interest. Mr. Burdett-Coutts has shown throughout the whole series of events in South Africa the valuable qualities of sturdy industry, perseverance, accuracy, and power of expression. He has analyzed the work of the Commission with relentless logic, and it is not too much to say that he has thoroughly riddled the Commission. One of the 2 officers of the Royal Army Medical Corps, who were appointed by the Commission to visit the hospitals to select the evidence, and prepare the way for the Commission, stated that everything that mental

knowledge and foresight could supply was at hand, etc. Yet this same officer had been informed by a chaplain of the forces that enteric and dysenteric patients had to walk 400 yards to a latrine, in May; that there were no bedpans, no disinfectants, no nurses, in June, etc. For such shortcomings, the editor of *The Practitioner* holds responsible "the military advisers of the Secretary of State for War, who, apparently out of mere caste prejudice, have systematically snubbed and starved the service regardless of possible consequences."

Do such delinquencies belong to the "plain unvarnished tale of war's inevitable horrors, which come upon us with an appalling shock"? The editor of *Medical Press and Circular* says further: "Mr. Burdett-Coutts appears to have established beyond contention that if the National House can be put in order only by a full-searching and relentless investigation of its defects, then the worst model we can adopt for that process, and the weakest and rottenest basis of reform will be the inquiry for which we are now voting this large sum of money."

Had the editor of *The Practitioner* been better informed on the subject which you quote, Mr. Burdett-Coutts might have been spared the ludicrous experience of his sneer.

PRACTICE OF MEDICINE IN NORTHWESTERN STATES.

BY

W. JAMES HOWELLS, M.D.,

of Spokane, Washington.

There seems to be a mistaken idea in the minds of many Eastern medical men regarding the practice of medicine in the Northwestern States; and as a consequence many young men come west with expectations of easy success, only to be disappointed.

The notion seems prevalent that the medical profession of the Western States is not only poorly represented in numbers, but poorly in ability, and that the people will flock to a young Eastern physician as soon as they see his sign. This is a great mistake, particularly in Washington State, as the medical profession is well represented in numbers (the cities averaging 1 medical man per 400 population), and in ability—many of the men now established being graduates of Eastern medical schools and frequently returning East for postgraduate study. They are hustlers and up-to-date men, well informed on the latest discoveries in medicine and surgery, and men who can hold their patients.

I have not written this short note with the intention of discouraging any of my brother practitioners, who may be contemplating locating in the West; but only to warn them that they must come prepared to meet men of ability, be willing to wait—and have the money to pay expenses while they wait—a year or two in the cities and large towns.

REMOVAL OF POWDER STAINS WITH HYDROGEN DIOXID.

BY

COLIN R. CLARK, M.D.,

of Youngstown, Ohio.

I wish to add a case confirming Dr. J. Neely Rhoad's method of removing powder stains with hydrogen dioxid. A few days after reading his note in your first issue a boy came into the office with severe powder burn of whole face and neck. We cleaned him up thoroughly and removed several grains of powder from each eye, but the face was black with stains and imbedded particles of powder. I sent him to City Hospital on account of the injury to the eyes, and ordered the face to be kept covered with pieces of lint saturated with glycerin, 1 part, and hydrogen dioxid 3 parts. A couple of days saw the complete removal of all the particles and stains, without any of the tedious and painful picking process we are accustomed to; and all marks promptly healed.

A CASE OF ANTRUM INFECTION AND SIGMOID SINUS THROMBOSIS WITHOUT PRESENT MIDDLE-EAR DISEASE, PRESENTING THE SYMPTOMS OF FACIAL NEURALGIA AND NONE OF THE ORDINARY SYMPTOMS OF DISEASE IN THE PETROSA; RETROPHARYNGEAL GRAVITY-ABSCESS, GENERAL SINUS THROMBOSIS WITHOUT MUCH IMPAIRMENT OF CEREBRATION, DEATH AFTER THREE MONTHS, PARTIAL AUTOPSY, PRESENTATION OF SPECIMENS*.

BY

DR. BAYARD HOLMES,

of Chicago, Ill.

Professor of Surgery in the University of Illinois, Attending Surgeon at the Baptist Hospital.

The following case is one of a series in which the diagnosis presented unusual difficulties. The propriety of reporting it to such a society as this may be questioned as the case presented few psychic symptoms. Well reported histories of carefully studied cases have always been of the greatest value to me in my attempts to get a vivid and working knowledge of the course of disease, and although this case was so unfortunately misunderstood as to come, perhaps unnecessarily, to a necropsy, I hope it may all the more attract your attention and thus lead to the illumination of some of its obscure manifestations, and a better interpretation of similar cases hereafter.

Synopsis:—Rigor and high temperature beginning without apparent cause. Neuralgia of right fifth nerve for 10 days. Typhoid or septic condition resembling sinus thrombosis for 6 weeks. Abscess appearing suddenly in the posterior right pharynx. Six weeks later discharge from the right ear, paralysis of the right leg, and death. *Necropsy*:—Antrum and general mastoid disease, sigmoid and general sinus thrombosis extending into the cortex of the left hemisphere.

Dr. W. had his birth, education and active life in the Mississippi Valley. He was a well-built man, 5 feet 9 inches tall, of perfect physical growth and development. He had been in the active practice of medicine in a country district for the greater part of his life. He was a hearty eater, but temperate in other respects. He was the father of a large family of perfectly healthy children. He had himself suffered from no disease, except malaria and gout. The evidences of gout were present in his thin and over-aged skin, in the enlargement of his joints, in Dupuytren's contraction of the flexor tendons of the palm and in an irritability or excitability of temper, which occasionally showed itself. I had been well acquainted with him for 10 years.

On May 20, 1898, he came in from some slight exercise out-of-doors after a long day's work in the office, complaining of a chilly sensation. He removed his shoes and outer garments and lay down on a lounge with a hot waterbag and a great many covers. In spite of these precautions he went into a terrible rigor, which lasted over an hour. After this he had a temperature of 101° F. and pain through the back and legs. Headache was not a noticeable symptom at the beginning. The fever continued, and at the end of 48 hours, general headache came on, and, about 4 or 5 days after the chill it had located as a distinct

neuralgia over the distribution of the *right* fifth nerve. Dr. Weller Van Hook saw him twice during this period and found the pharynx deeply injected, hyperemic and somewhat edematous. He believed the temperature due to an acute pharyngitis. No cultures were made from the throat. Local antiseptic treatment was instituted, but without much effect. His temperature remained high and the pain grew worse.

Sunday morning, May 28, he came to Chicago and I examined him. The patient was extremely hyperesthetic and dreadfully broken down and nervous, resembling a person in the early stages of delirium tremens. He described his symptoms and the history of his case with unnecessary picturesqueness and detail. At this time the pain over the right side of the face and scalp was intense. There was tenderness on pressure over the exit of the right supraorbital and right infraorbital nerves. The entrance of the inferior dental and the whole alveolus on the right side were exceedingly tender to pressure. The patient complained of tenderness on the right side, deep in the neck, behind the angle of the jaw. There was no evidence of suppurative disease or obstruction in the antrum of Highmore. There was no difference in the appearance or expression of the 2 sides of the face, except for a slight swelling over the right parotid gland, where the tincture of iodine had been repeatedly applied. Pressure upon the mastoid and hard thumps upon it elicited no pain. The hearing was perfect in both ears. The question of suppurative otitis media was carefully considered. The patient himself declared that he had never suffered from earache or any difficulty with either ear. A present primary catarrhal otitis media was excluded by the good condition of the hearing, absence of any discharge from the ear, the absence of pain or earache and the normal appearance of the drumhead. The diagnosis seemed to rest between a neuralgia with malaria and an osteomyelitis of uncertain origin at the base of the skull, possibly from one of the sinuses of the nose. Antimalarial treatment was instituted, with laxatives and diuretics to counteract the influence of morphia, which had been necessary to relieve the pain.

After some slight improvement, the patient returned to his home feeling better. The temperature continued above normal, but the pain in the face gradually subsided.

On July 10 he entered the Polyclinic Hospital with a high temperature, rapid pulse and such symptoms as led to an examination of his blood for typhoid. At this time he was carefully examined by Dr. J. B. Herrick and Dr. Weller Van Hook. There was no pain now and the symptoms were those of hyperpyrexia and excessive irritability. The pharynx continued red and received local treatment. At noon, on July 14, Dr. Van Hook discovered in the right vault of the pharynx a large fluctuating tumor, which he at once recognized as an abscess. He felt certain that this tumor was not present in the morning. I saw him in the evening of the 14th and easily opened the abscess through its thin wall between the arches of the palate and allowed about 3 ounces of pus of a light chocolate color to escape. The cavity was washed out repeatedly. On the following day the tongue cleared up and the temperature became nearly normal, his appetite returned and he decided to go home.

On July 21, he again sent for Dr. Weller Van Hook, who found a temperature of 103°, his pharynx was still red with the appearance of another abscess, but this time on the *left* side. One or two unsuccessful attempts were made to open it. The

* Presented to the Chicago Neurological Society.

patient was brought to Chicago and placed in the Baptist Hospital, July 22; his temperature at this time was 102° in the rectum, and pulse 90. His subsequent temperature and pulse are represented in the accompanying chart.

On entering the hospital, a careful examination was again made to discover the source of suppuration. The patient had

Fig. 1.—Temperature and pulse record showing the highest and lowest records each day.

lost considerable in weight and strength, but was in better mental condition than when he left the city. His hearing was good in each ear and his sight was unimpaired. He was able to sit up every day and read the newspaper.

There was somewhat more tremor of the hands than when last seen, but his grip was equal and not less than would be expected with his general debilitated condition. He took liquid nourishment freely and with relish. He complained constantly of a nasty, bloody taste in his mouth. He was almost sleepless, but not from any localized pains. His greatest pain and tenderness was over the toothless gums of his lower jaw, on the right side. There was no edema, fluctuation, nor other evidence of infection of the lower jawbone or between it and the periosteum. The whole pharynx was red, smooth, and in places edematous. In the neighborhood of these edematous places were three openings from which bloody pus could be extracted. Swallowing was slightly painful and made a liquid diet necessary. There was no adenitis over the mastoids or about the neck. The urine was normal in amount and composition.

Each of the nostrils, orbits and ears was separately and carefully examined. Disease was looked for unsuccessfully in both frontal and maxillary sinuses. The mastoids were separately examined and the eardrums inspected but no symptoms of disease discovered. The openings in the pharynx, seeming to give inadequate drainage, were greatly enlarged and found to connect from the right to the left side of the fauces. In this way a very complete irrigation was possible. He liked to have forcible irrigation in spite of our fear of damage.

The throat and the open spaces behind were irrigated many times daily with all ordinary antiseptics. The short rubber syringe and the fountain-syringe were used, the former to wash out the mouth and pharynx and the latter to irrigate the abscess-cavities. The amount of pus which came from these openings was many times larger than anyone would expect from all the possible findings, but gradually diminished.

The patient complained of little chills at intervals, and vomited without apparent reason, so far as the condition of the stomach and vomited matter was concerned, on July 26, 27, 28 and 29. His temperature gradually rose and on August 5, he complained of great and unaccountable nervousness. On that day he had the most pronounced chill since the beginning of his sickness. It was far short of a rigor. He did not read so much after this, but talked rationally and sometimes in an animated manner. On August 6 he complained for the first time of severe pain in the head. On the 9th, he vomited and was extremely nervous. On August 10, he was examined by Dr. T. Melville Hardie. His temperature was 99°, pulse 78, and he sat up in a chair for examination. "Posterior rhinoscopy was easily made. It showed nothing abnormal. Transillumination of the face showed 2 sides alike, not well lighted; this probably due to either thick cheeks or small antrums. Nothing abnormal by anterior rhinoscopy." Both ears were examined perfunctorily with everything apparently normal, and hearing good. No pain or tenderness in the region of the ear.

From August 5, the patient was so nervous and restless that it was necessary to give a small quantity of morphin daily. He was occasionally seen by Dr. J. B. Herrick, and I visited him twice a day, always looking for the source of infection. August 16, an abscess was opened between the lower jaw and the right side of the tongue. It communicated with the pharynx. August 25, he vomited and had a slight chill. Temperature 102°, pulse 100. He complained of stiff neck.

August 26, I made the following entry on the history sheet: "Opened an abscess over right lower jaw near angle. Felt thickening and edema above and behind the angle of the lower jaw on the left side (not the cause of high temperature). Patient complained of severe pain in left ear for a few minutes, at 10 o'clock this morning. This paroxysm was preceded by several hours of discomfort and crackling in the left ear. Growing tendency to nausea on slight provocation, especially during the last 2 days." Again the mastoids were examined but there was no indication of any disease. The hearing was good in both ears.

During the night of the 27th, at least 2 drams of dark pus was discharged from the right ear. This pus came through a perforated drum-head and gave some relief to pain and nervousness. He still took a large quantity of nourishment—about 2 quarts of milk a day.

On the morning of August 30, the right leg was completely paralyzed below the knee. This had been coming on for 4 days. At 7.15 a. m. there was a convulsion, frothing at mouth, stertorous breathing and imperceptible pulse. This convulsion lasted 20 minutes. Following this convulsion Dr. Arthur Edwards saw the patient and confirmed the findings. There were no other localizing symptoms. The discharge from the right ear continued. The eyes, face, and tongue were normal. There was no paralysis of the arm. The sensations over the affected right leg and elsewhere were normal.

A diagnosis was made of "localized lesion, probably abscess, in the neighborhood of motor cortical area for right leg and foot, secondary to suppuration in pharynx." An exploratory operation was undertaken on these imperfect indications.

During the 6 hours after the convulsion and before the operation the temperature was 100° and the pulse between 105 and 138. At 5 p. m., in the presence of Dr. Arthur Edwards and after the usual preparations, the left hemisphere of the brain was approached by means of 2 1-inch trephine openings connected by a third. There was evidence of a little pachymen-

Fig. 2.—The veins and sinuses of the head and ovale from Macewen.

gitis at the upper border, such as we often see in old drunkards. The dura bled. The brain pulsated. The dura was opened. No leptomenigitis. The brain was systematically explored with an aspirating needle 10 cm. long and 1 mm. in external diameter. No result. The bone was replaced and the scalp-wound closed. Skull-cap dressing. The anesthetic was given by Dr. D. H. Galloway. The pulse at the beginning of the operation was 130, but during the operation it fell to 80, and at the close was 140. When the patient was placed in bed his pulse

was 124. The patient did well after the operation and the wound healed completely. He was conscious and rational the day following the operation and inquired about members of his family and business affairs. He knew his end was near and disposed of several affairs requiring his signature.

On September 3 he died, gradually sinking away. On the following morning the necropsy was made by Dr. Arthur Edwards. The trephine wounds had healed without suppuration. The skullcap was moderately adherent over the longitudinal sinus. There were some flakes of pus on the convexity of the dura over the anterior portion of the sinus. The left hemisphere showed several punctate extravasations about the needle-wounds. The dura was only slightly adherent over the upper border of the left hemisphere with light fibrous exudate. The bloodvessels of the dura and pia were thrombosed over at least 6 cm. of the upper surface of the left hemisphere nearest the longitudinal sinus. The cut surfaces of the cortex itself had a dull, greenish-white appearance. The longitudinal sinus was filled with a suppurating thrombus. There were a number of flakes of suppurating fibrin along the lateral walls of the sinus. Both lateral and both sigmoid sinuses were full of pus and blood, the right distinctly fluid (Fig. 2). The dura over the right petrosa was adherent on the posterior surface. The jugular veins in the neck were not examined. No indications of infection were found in the lungs, in the heart, or in the abdominal organs.

The right temporal bone was removed for more careful study, and with it portions of the surrounding bones. This specimen is presented for examination, and the following points should be noticed: The external auditory meatus shows little change from the normal. The drumhead still persists, and does not seem modified by infection. The muccosa lining the tympanic cavity is entire, except on the side toward the antrum. There is little or no evidence of otitis media. The sigmoid sinus lies in a deep sigmoid groove, the posterior wall of which extends downward into the completely excavated mastoid and

meatus, and this whole series of cavities, except the middle-ear, is bounded by an eroded wall. The mastoid does not open externally. The sigmoid groove at its internal end is completely denuded of periosteum and the occipital bone is infected and eroded. The wall of the jugular bulb is thickened and in places eroded and perforated, and everywhere its lumen is nearly obliterated by thickening. Across the jugular bulb, just as the sigmoid joins it, is a band of organized material, showing that at one time a thrombus bridged it over, and was partially organized. Subsequent suppuration has never completely destroyed it. The portion of the jugular external to the skull seems to be completely obliterated by new

Fig. 4.—Showing the relation of the eighth nerve to the petrosal and sigmoid sinuses.

connective tissue which is stained very dark yellow with blood-pigment. Near the occipital condyle the jugular can again be recognized, but the jugular bulb is completely filled above with partially organized thrombus. The external surface of the occipital near the condyle is eroded and infected. The carotid is patent and easily recognized.

If we attempt, in the light of the autopsy, to analyze the symptoms in this case and refer each to its pathologic source, we must first assume an early forgotten or overlooked middle-ear disease, perhaps as early as childhood or babyhood. There can be little doubt that the antrum was the primary focus of the infection which made itself known by the chill of May 20. The pharyngitis which was subsequently observed could not have infected the sigmoid sinus without producing a middle-ear disease which certainly would have been recognized.

The facial neuralgia which was so marked a symptom during the first 10 days cannot be explained by any clinical history in the literature with which I am acquainted, nor by the pathologic findings in the neighborhood of the fifth nerve. Since all the branches of this nerve were equally and simultaneously affected, the lesion must have been somewhere posterior to the ganglion, and since the neuralgia was only of short duration without any remnant of subsequent pain or loss of function, it must have been nondestructive in its character.

The fifth nerve, as shown in the accompanying figure (Fig. 4), passes under the petrosal sinus and over the end of the petrosa. It does not pass very near the jugular end of the sigmoid sinus. If the petrosal sinus had been obliterated early in the course of the disease by the infected thrombus, the irritation of the nerve might have produced the pain. Had that been the case, the petrosal sinus would have been the center of infection which would have left traces on the bone. This was not the case.

The history immediately following the chill on May 20 is not sufficiently explicit to permit us to say whether the sigmoid sinus was or was not at once affected. Certainly

Fig. 3.—Section of the petrosa near its base and through the antrum and excavative mastoid. E, Extreme auditory meatus. S, Groove for sigmoid. M, The mastoid. The osteoporosis about the antrum is evident.

upward into the antrum (Fig. 3). The wall of the anterior surface of the petrosa over the antrum, just posterior to the tegmen tympani is almost perforated. The antrum opens into the middle-ear, and the middle-ear into the external auditory

by the last of June or the first of July, we have the picture of sigmoid sinus thrombosis and infection. On or about July 10 the sinus opened and drained into the retropharyngeal and retramaxillary spaces and this gravity-abscess was discovered and first opened on July 14. The character of the pus showed clearly that it arose from thrombosis.

There are 2 ways in which the pus might have escaped from the sinus into the retropharyngeal spaces, the more direct and likely method by way of the obliterated jugular, the less likely and less direct by way of the cavernous sinus, the meningeal veins and the pterygoid plexus. It seems highly probable from the symptoms that the jugular was obliterated in the neck during the first 10 days of the sickness. It is unlikely that the cavernous sinus and therefore the inferior petrosal sinus was obliterated before August 25, because until that time the hearing was good in both ears. This it seems could hardly have been the case if the labyrinthine veins had been obliterated.

During the latter part of July, the unobscured condition of the mind, the slight chills, the vomiting and the septic temperature all spoke plainly for sinus thrombosis.

About August 5, the drainage into the pharynx and retramaxillary spaces became obstructed, probably by granulation tissue which was found post mortem to almost completely close the posterior lacerated foramen, and the infected thrombus began to advance into the superior frontal sinus and at last on August 25, into the lateral and sigmoid sinuses of the opposite side of the head. At this time the left jugular became thrombosed and practically an abscess as indicated by the pain, tenderness and swelling in the neck. The slow coming paralysis of the right leg speaks for the thrombosis advancing from the dura into the pia and cortical center.

August 30 some sudden and very general extension of the infection took place probably entirely within the skull. This produced the convulsion and chill which began the end.

This exceptional case illustrates the great difficulty of diagnosing disease of the antrum or mastoiditis. Disease of the right petrosa was always suspected even from the very first. No one can say that the consultants in this case or even the attendants are or were ignorant of the disease or inexperienced in its diagnosis and treatment. It was always talked of as a possibility, but was quickly excluded by the lack of tenderness, the presence of hearing and an intact and unscarred ear-drum and by the absence of pain. The fact that the patient was a doctor and that he insisted upon his entire freedom all his life from any symptoms of middle-ear disease, stopped the consideration of latent disease in the mastoid antrum more effectually than a similar history would do from most patients.

We must, however, insist that sufficient importance was not given the presumptive source of infection within the skull. When there is evidence of peritonitis we do not neglect to presume it a case of appendicitis unless some other source of infection can be demonstrated. Infection of the mastoid antrum is the appendicitis of the head. In the great bulk of cases the source of infection is through the nose and nasopharynx. Had this fact been

adequately considered the right mastoid would have been opened July 14 and there would have been some chance at least of perfect recovery. It would not have been a serious procedure, and had the mastoid been found healthy the retramaxillary abscess could have been opened outward and the source of infection sought elsewhere.

From a study of this case in connection with the literature of the subject, it seems reasonable to make the following brief conclusions:

1. Mastoid antrum disease is the appendicitis of the head.
2. In every case of infection within the head where some other source of infection cannot be demonstrated, the mastoid antrum should be explored.
3. The facial neuralgia is not explainable by the pathologic findings.
4. The excellent mental condition even up to the last seems hardly consistent with the obliteration of both jugulars and the suppuration in all the great sinuses of the dura, although mental or cerebral disturbances are not prominent symptoms of sinus thrombosis.
5. The convulsion is unexplained.
6. The clinical picture is otherwise quite fully explained by the pathologic findings.
7. The case was of neglected rather than of erroneous diagnosis.

TYPHOID FEVER AND PHARYNGEAL DIPHTHERIA.

BY

MORRIS MANGES, M.D.,
of New York.

Professor of Clinical Medicine, New York Polyclinic Medical School;
Visiting Physician to Mount Sinai Hospital.

The more or less markedly stupid state of patients attacked with typhoid fever, associated with the fact that physicians as a rule pay little attention to the condition of the mouth beyond inspection of the tongue, may be the explanation why so little has recently been written about the changes in the pharynx in this disease. It is only when difficulty in swallowing, hoarseness or dyspnea develop that a search for the causes of these symptoms reveals conditions which may easily escape notice both during life and at postmortem examinations. This will also explain why there is such a wide divergence in the various works on typhoid fever as to the relative frequency of pharyngeal complications. That they are by no means uncommon becomes at once apparent after a study of the literature of typhoid fever, especially of the older writings. Indeed, it is to the older writers that we are indebted for the terms "pharyngotyphoid and laryngotyphoid fever." Huxham, Louis, Chomel, Bouillaud, Murchison and Griesinger had recognized and carefully described the initial erythematous angina and the various manifestations of diphtheria at the onset and during the course of the disease, and they had also studied and classified the different forms of ulceration which may occur in the larynx, pharynx and esophagus.

As most of these cases occurred in "prebacterial times," the correctness of the diagnosis of diphtheria

has been questioned by numerous writers; indeed, so experienced a clinician as Curschmann¹ expresses his views very positively in his classical treatise on typhoid fever:

"Diphtheritis and typhoid fever have been regarded as coexistent, especially by the older writers, and chiefly during severe epidemics. 'Undoubtedly in these cases we are dealing with diphtheritis in the older anatomic sense. So far as I know no thorough modern bacteriologic investigations have yet been made. I myself have never seen typhoid fever complicated with diphtheria according to the modern etiologic view, with the demonstration of the Klebs-Löffler bacilli."

This view is not correct. In 1893, F. H. Williams² of Boston, reported a case in which diphtheria and typhoid fever occurred simultaneously:

"L. J., a girl, 17 years old, complained of sore throat 5 days before admission, and 2 days later a membrane was seen in the throat, in which Dr. Councilman found the Klebs-Löffler bacillus. The membrane was seen for the last time on the eighth day after admission. On admission to hospital the temperature was 104°-105°, pulse 130-140, but on the following day the temperature reached 105° and the pulse 150; 1 rose spot was found on the abdomen; the number of spots increased daily for 7 days, and were unusually profuse and characteristic. Spleen enlarged, hemoglobin 90%, and the number of leucocytes normal, 7,500. The temperature remained about 104° for a week and then fell by lysis to normal. Recovery."

Dr. Councilman, in commenting on this case, stated³ that:

"While it is not at all true or even probable, that all the pseudomembranous inflammations of the pharynx in typhoid fever are due to the Klebs-Löffler bacillus, this gives at least one positive case in which the organism was found. On the same day cultures were made from a case of virulent diphtheria, from a case of pseudomembranous inflammation accompanying scarlet fever, and from this case of typhoid. In all these the identical organisms were found. Inoculations of guineapigs were made at the same time from the cultures obtained from these 3 cases. All 3 of the guineapigs died within 36 hours, and the organisms were recovered from the animals in all cases. The pseudomembranous inflammations accompanying typhoid fever are much more common than is usually supposed. In our experience the membrane is more apt to be found just at the beginning of the esophagus on the posterior pharyngeal wall than any other place. Like the scarlet fever pseudomembranes, it is very probable that they are generally produced by the streptococcus, but so far as we know, no bacteriologic examination has been made in these cases."

In 1896 Hektoen⁴, of Chicago, published 2 fatal cases of typhoid fever complicated with diphtheria, in both of which virulent Klebs-Löffler bacilli were found. In the one case (man, 29 years old) in the membranes found post mortem in the pharynx, larynx and esophagus, Streptococci and Staphylococci (citens) were also present. Tracheotomy was necessarily late in the third week of the disease on account of dyspnea and dysphagia; but the patient died soon after. The other case was also an adult man who very early in the disease had grayish-white membranes on the tonsils and soft palate. Klebs-Löffler bacilli were found. The patient died 3 days after admission in the second week of the disease. Double infection with Klebs-Löffler bacilli is also admitted by Dreschfeld⁵ and Baginsky⁶.

Osler⁷ reports the case of a man of 22, who on the sixteenth day developed a diphtheric membrane on the lower lip, 2 by 3 cm.; the throat was reddened and inflamed, but presented no membrane. Cultures from

the membrane showed diphtheria bacilli. None was found in the throat. On the same day 600 units of antitoxin was injected; the membrane cleaned off in a few days. This complication did not seem to influence the course of the disease in any way.

Catrin⁸ reports the case of a young soldier who on the nineteenth day of his typhoid fever complained of difficult swallowing. The tonsils were swollen, especially the right; on the same side small submaxillary gland. Two days later, 2 or 3 small whitish patches appeared on the right tonsil; the condition was unlike Bouveret's ulcers or diphtheria. Two days later orthopnea appeared, the throat was completely covered with false membrane and he coughed up membrane. In the latter pure cultures of Klebs-Löffler bacilli were found. Death on same day. At autopsy it was found that the membranes extended into the finest bronchioli.

My own cases, which will be detailed below, also show that Klebs-Löffler diphtheria does occur in typhoid fever and that it is by no means rare.

The bacteriologic evidence of these various cases, therefore justifies us in assuming that some of the cases reported by the older clinicians were infections with true diphtheria. It may also be added that 2 epidemics of this double infection have been reported, 1 by Oulmont⁹ and the other by Holst¹⁰. Councilman¹¹ also states that Wagner (who called special attention to this subject) pointed out that pseudomembranous throat inflammations accompanying typhoid fever were most frequent when epidemics of diphtheria prevailed at the same time.

The prognosis of these cases is gloomy, especially in children; it was fatal in the majority of cases reported. That recovery is possible even after tracheotomy had been necessary was shown in the case (that of a boy, 8 years old), reported by Gayton.¹² (No cultures made.) Recovery also followed in the case of C. E. Paget¹³ of a pregnant woman who, during the course of her typhoid fever had 2 attacks of diphtheria, one of which lasted 15 days. (No cultures made.) Osler's observation that the presence of the false membrane did not seem to influence the disease in any way coincides with my own experience in some of the cases reported below, only 1 of which was fatal. The diphtheria antitoxin was well borne in all of the cases.

CASE I.—M. J., 25 years old, female nurse; admitted to hospital June 6, 1899. History was typical of typhoid fever, of 1 week duration. On admission temperature was 105°; no Widal or Ehrlich reactions; Widal reaction was only partially obtained on forty-ninth day of the disease. Roscola did not appear till twentieth day. On the eleventh day complained of sore throat; on examination it was found red, dry and glazed with 2 small grayish patches on right tonsil. Cervical glands enlarged. Cultures from throat showed Klebs-Löffler bacilli, streptococci and staphylococci. Two doses, each of 1,500 units of antitoxin were injected on June 12. On next day leucocytes were 12,000; general condition improved. Throat clear on June 15; cultures showed only staphylococci and streptococci.

The subsequent history was that of a very severe typhoid fever, the disease being complicated with a right pyelitis, lobar pneumonia of right lower and left upper lobes, singultus and a relapse. Temperature did not reach normal till fifty-fifth day.

CASE II.—B. S., 20 years old; domestic; admitted on Novem-

ber 27, 1899, to Female Ward III, to service of Dr. Brill, with symptoms of typhoid fever of 1 week's duration; no Widal or Ehrlich reaction. The course of the disease was moderately severe. Temperature normal on thirty-seventh day (December 26). Relapse on January 6, 1900. On that day temperature rose to 102.6° and she complained of severe headache and pain in throat. Grayish membranes were found on both tonsils; cervical glands enlarged. January 7, temperature 101°-101.6°; pulse 128-140 and very weak; respiration 32 to 44. Klebs-Löffler bacilli having been reported from the throat-cultures, the patient was isolated and 2,700 units of antitoxin was injected.

January 8. General condition much better; membrane disappearing rapidly from both tonsils, but the latter are still swollen and edematous. January 9, throat almost clear and patient is much stronger. January 12, throat cultures negative, returned to ward. January 31, normal. February 4, slight temperature with enlargement of both tonsils. February 5, white patches on both tonsils; cultures showed Klebs-Löffler bacilli. Pulse, respiration and temperature normal. February 7, tonsils clean; cultures negative. Pulse, respiration and temperature normal. February 11, discharged from hospital cured.

CASE III.—L. G., 14 years old; schoolboy; admitted to Male Ward II, May 22, 1900.

The onset of this case being so peculiar, the history is given in more detail. The history of a fall, combined with the patient's general appearance, led at first to an erroneous diagnosis of cerebrospinal meningitis.

Has had otitis media, but never had meningeal symptoms. Was well up to May 15, when he fell and struck on his head. This was followed by epistaxis. He walked home, ate supper, and slept well. Next day he had epistaxis, vomiting and head ache. On May 16, 17, 18 and 19, repeated epistaxis, and vomiting. Constipated, frontal headache, but no abdominal distention. On the 20 he became noisy and delirious, and continued so up to admission. No eruption was ever noted by parents. His general condition was poor, but he was fairly nourished. The tongue was moist and coated; pupils normal. There were some enlarged glands in neck, 1 macular rose-spot in left hypochondrium. No tache cerebrale, but marked Kernig phenomenon present, and cervical rigidity. Negative results from examination of the lungs, heart, and liver; abdomen, slightly retracted and rigid; spleen, not palpable, upper border at eighth rib, anterior border in anterior axillary line. On admission the pulse was 60, respiration 18, temperature 103.8°. There was slight epistaxis and involuntary urination. The Widal test was negative, as was also lumbar puncture. May 23, the pulse was dirotic; the Ehrlich reaction was present. Ophthalmoscopic examination was negative, and there was absence of Kernig's phenomena and cervical rigidity. The next day the rose-spots were more abundant and Kernig's phenomenon present. May 25, the pulse was 100, respiration 28 and temperature 102° to 104.8°. May 26, the Widal test was made with negative results. Rose-spots were noticed at the tips of the scapula. There was a trace of albumin in the urine and the Ehrlich reaction was present. May 27, Klebs-Löffler bacilli were found in throat culture, and an ulcer appeared on the right side of the uvula and patches on the uvula and fauces. There was considerable rigidity of lower limbs; no photophobia. Temperature 102.2°. He was sent to the isolation-house, and was given 2,000 units of antitoxin. This amount was repeated the following day. His highest temperature was 101.60°. He was given nutritive enemas. The rose-spots disappeared from back and the spleen was soft and palpable. There was considerable tympanites. The Widal test was positive. May 29, the highest temperature was 103.4°, and the membrane in throat had disappeared. May 31, highest temperature 102.2°. Spleen still large. June 2, pulse, respiration and temperature normal. The patient was transferred to the ward on June 11. After having been normal 9 days the temperature began going up, and reached 100°. He was put on a fluid diet again. The throat was a little reddened. June 12, he was limited to a soft diet. The temperature was up to 105°. The plunge baths were resumed. June 14, the temperature ranged from 102° to

103°. The spleen was still large to percussion, but not palpable. He was plunged regularly when the temperature was above 103.6°. June 18, Klebs-Löffler bacilli were again found in cultures from the throat. There was no membrane, but redness of fauces. He was retransferred to the isolation-house. June 20, pulse, respiration, temperature normal. June 25, spleen still palpable. June 27, full diet. Back to ward. July 11, discharged cured.

CASE IV.—N. R., 19 years old, peddler, admitted June 6, 1900. Had had typhoid fever 8 years previously. When admitted he had a history of typhoid fever of 6 days' standing. There were rose-spots present on the back, abdomen and arms; the spleen was enlarged, the abdomen tympanitic. Temperature 103.4°; pulse 84. Blood examination: Reds 5,400,000; whites 9,050. Widal test negative. Two days after entrance the throat was complained of; it was deeply reddened, but no membrane could be seen. Cultures made and the Klebs-Löffler bacilli were found. The temperature was 100.6°-103.6°; pulse 68; respiration 24. He was sent to the isolation-house and 2,000 units of antitoxin injected. On June 14 the temperature was normal, but Klebs-Löffler bacilli were still present. The rose-spots had disappeared but the spleen was still enlarged to percussion. June 17 the throat was free from diphtheria bacilli and on June 29 he was discharged.

It is noteworthy that the Widal reaction was never positive.

CASE V.—J. P., 12 years old, schoolboy, was admitted to service of Dr. H. W. Bey September 1, 1900, complaining of headache, poor appetite and vomiting of 8 days' duration. He had diarrhea, but no blood in the discharges. His general condition was good. He was well nourished, the tongue was clean, very red, and moist. There was one maculopapular rose-spot on the left arm. The lungs, heart, and liver were negative to examination. The spleen was not palpable, but the abdomen was moderately distended. Results were otherwise negative, except that examination of the blood showed 7,400 white blood-cells. The temperature was 103° to 105°. Pulse 100, and respiration 22. Plunge baths were given. He was quite delirious. September 8, the general condition was good. The spleen was palpable, the rose-spots marked, the stools loose and greenish. Temperature was 101° to 103.2°; pulse 100, respiration 22. September 15, he was highly delirious at times. There was dullness on the left side of the scapular region; below the angle there was flatness and diminished voice and breathing; the Ehrlich reaction was still present in the urine. The temperature ranged from 105° to 105.6°. Fresh crop of rose-spots appeared. White cells, 7,000. September 22, the Widal test was positive. Redness and congestion of pharyngeal mucous membrane existed. The temperature was 104.4°. September 24, subsultus was marked. The chest was about the same, there was some cough. There was marked congestion of the pharyngeal wall, and firmly adherent membrane on base of uvula which bled on attempt to remove it. Klebs-Löffler bacilli were reported. The patient was transferred to the isolation house, and 3,000 diphtheria antitoxin units injected. Pulse 128, respiration 38, temperature 103.2°. September 25, the general condition was much worse, pulse 148, respiration 38, temperature 101.4° to 102.8°. The patient was delirious, the tongue was dry, subsultus marked, the abdomen distended and tympanitic, the spleen dull in the seventh space, anterior axillary line, and not palpable, on account of tympany. There was no tympany over the liver. The lungs gave a dull note and breathing was very poor at both bases. There was exudate around base of uvula. September 27, the general condition was slightly better, but there was alternating delirium and stupor, and sibilant and sonorous breathing posteriorly. Pulse 130, respiration 32, temperature 100° to 104°. Involuntary urination was noticed, over the buttocks and left scapula were vesicles which first contained fluid and then became hemorrhagic. September 30, the general condition became much worse. The patient was hard to arouse, there was some rigidity of the neck and spine, but no tache cerebrale. The pupils reacted to light and accommodation. Pulse 138, respiration 32, temperature 99° to 104°. He complained of pain in the abdomen. On October 2, the general condition was about the same. There

was tympany over the liver, and there seemed to be slight bulging in the hepatic region. October 6, ophisthotonus was present, but the general condition seem to be somewhat brighter. The abdomen was still tender. Pulse 148, respiration 32, temperature 101° to 102.8°. October 13, the patient was much emaciated, but the general condition was improving. There was a discharge from the left ear, and tenderness over the mastoid. October 20, the general condition was much worse, the pulse reaching 130; respiration 26, temperature 100° to 103.8°. Dulness and moist rales were noticed at the angle of the scapula, on the left side. The heart was very weak. There were petechial hemorrhages on the front of the chest and edema of the eyelids. The patient died October 21. There was no autopsy.

I wish also to call attention to certain peculiar ulcers of the pharynx which occur in typhoid fever and which were first described by Bouveret in 1876, and after him by Duguet, Féréal, Landouzy and others. These ulcers have recently been carefully studied by Andre Schaefer¹⁴. They are situated on the anterior pillars of the fauces, and as they have certain typical features may be said to be pathognomonic of typhoid fever; and since they occur especially in the early stages of the disease, they may even be of value in establishing an early diagnosis. Duguet, Lecorché, Vaissan and Schaefer have reported cases in which these ulcers were observed before the rose-spots had appeared. The size and situation are very characteristic; as a rule they are symmetrically placed on the anterior pillars of the fauces, and are oval in shape, averaging about 6 mm. to 20 mm. in length and 4 mm. to 12 mm. in width, the long axis of the ulcer being parallel to the long axis of the tonsil. They are often surrounded by a small hyperemic halo; the base of the ulcers is grayish-yellow or grayish-red in color, usually smooth, but sometimes granular; there is no false membrane, nor is there any marked glandular enlargement. As a rule they are single; sometimes there are several smaller ulcers which coalesce into 1 large one. For 2 or 3 days they may increase in size and depth, but then heal rapidly within 5 days. The average duration, according to Schaefer, is about 12 days.

In 5 cases examined bacteriologically, Schaefer was unable to find typhoid bacilli in these ulcers; only the ordinary bacteria of the mouth were obtained. Their presence is explained by the fact that these areas are part of the digestive tract which are rich in lymphoid tissue. As such, they are specially exposed to the action of the typhoid bacilli or its toxins; as the result of which necrosis of the epithelium follows, if its vitality has been lessened by dryness of the mouth, the relative immobility of the pillars of the fauces and compression; this process is hastened by the coaction of the ordinary saprophytes of the mouth.

Although I have looked for these ulcers during the past few years, yet none have come under my observation. For one case, however, I am indebted to Dr. H. W. Berg, to whose service the patient was admitted. The abstract of the history is as follows:

CASE VI.—M. F., 15 years old, admitted August 31, 1899, with history of 8 days' malaise, fever, headache, occasional vomiting, diarrhea, and abdominal pain. Three days before, he began to have sore throat and slight cough. On admission he presented a typical picture of the early stage of typhoid, with a few rose-spots on the abdomen and back. The tongue was coated, edges and tip clean. On both anterior pillars of fauces

were small symmetric ulcers (1 on each pillar) with prominent edges and covered with a whitish atypical patch. General redness of pharyngeal mucous membrane. Cultures from the throat show Klebs-Löffler bacilli. The Widal and Ehrlich reactions were negative. Temperature, 104.2°; pulse, 104; respiration, 32. Cultures from the throat on the next day were negative. On September 9 the ulcers in the pharynx persisted. The Widal and Ehrlich reaction were still negative. Course of illness in all respects typical of moderately severe typhoid fever. September 27 the temperature was normal. The ulcers in the pharynx persist and present a brilliant red surface, with well-defined edges. September 30. The patient had a relapse: this lasted till October 12. Unfortunately there is no note of the time of the disappearance of the ulcers.

It will be noted that the ulcers in this case were typical in situation and size and number; yet differed, inasmuch as there was an atypical whitish patch that Klebs-Löffler bacilli were present for 1 day, and that the ulcers lasted over 3 weeks. Clinically, therefore, they cannot be considered as typical Bouveret's ulcers, but must rather be regarded as Bouveret's ulcers with a diphtheric infection.

Very little comment need be made on these cases, since they prove conclusively the correctness of the views of Councilman, Hektoen and others, that true diphtheria may occur during the course of typhoid fever, and they also disprove Curschmann's statement to the contrary. The importance of Case 4 of this series is questionable, since there was no false membrane and the presence of the Klebs-Löffler bacilli in his throat did not affect the course of the disease in any way.

To determine the frequency of the presence of Klebs-Löffler bacilli in the ordinary course of typhoid fever, cultures were taken from the throats in 20 cases of the disease in 1899 and 1900; but in not one of them were they found.

Unfortunately the virulence of the diphtheria bacilli was tested in but 1 case, and in this, the guineapigs survived inoculation. That we were not dealing with very virulent organisms was also proved by the fact that but 1 in the series of 86 cases was fatal. However, this question of virulence was determined in the positive results of Councilman and Hektoen quoted above.

Paupers in Kansas.—In 1896, Finney county purchased the poor farm for \$16,000, and spent \$7,000 for improvements. A superintendent was found who contracted with the county commissioner to take charge of the farm, to take all paupers applying for care without expense to the county, and to pay the expenses out of the proceeds of the farm. After a few years it was discovered that he had saved \$25,000, and he was removed and a closer contract was made with his successor, who also amassed a small fortune, and in turn was removed. Then the county commissioner made a contract with the probate judge of the county to act as superintendent of the poor farm. In 2 years this official saved \$25,000, and recently he was removed and the fourth superintendent hired on a salary. Finney county's poor farm now will net the county \$10,000 a year. There is only one pauper on the farm.

PRACTICAL THOUGHTS ON PULMONARY TUBERCULOSIS.

BY

HOWARD S. ANDERS, A.M., M.D.,

of Philadelphia.

Lecturer and Clinical Instructor in Physical Diagnosis, Medico-Chirurgical College; Attending Physician to the Samaritan Hospital, Philadelphia.

At a recent meeting of the Philadelphia County Medical Society the subjects of registration, and the home treatment of pulmonary tuberculosis, were treated in respective papers. Time, and the arrangement of the program with appointed speakers, did not permit of a general discussion, in which I had hoped to participate. Some thoughts, especially on treatment, not presented by others and which it was my purpose to offer then, have seemed worthy of writing down now with the humble hope that the few seeds of suggestive value may be as productive of benefit in the practice of others as they have in that of the writer.

Home Treatment.—While by this term is understood the treatment of consumptives in a hygienic home, as distinguished from distant climates, by an increasing number of writers*, it is doubtful whether it is so understood by the majority of practitioners, for whom it means the domestic care rather than the climatic attempt at cure of these patients. At this time when the treatment of tuberculosis in sanatoriums holds such a prominent and justly increasing interest for us, the appropriateness of the phrase "home treatment" is at once apparent; particularly since there is a growing judgment in favor of segregating consumptives in favorably situated (climatically, meteorologically, topographically) municipal and state institutions in or near the cities and counties where tuberculous cases are most numerous, rather than transporting them to distant regions which for decades have been celebrated for their salubrity and life-saving natural environments. Nevertheless, until the establishment of sanatoriums sufficient for the needs of the consumptive poor,†—whether the outcome of a government sense of duty or a philanthropic seizure of opportunity—or, until that philosophic and social Utopia is reached, when we shall cease to have the poor with us always, we must continue to grapple with pulmonary tuberculosis in a considerable number of thousands of patients whose limited means preclude their obtaining treatment away from the humble city dwellings in which they barely live and can hardly move and must inevitably and inexorably have their ending!

Concerning the home treatment of such as these I purpose offering a few more or less disjointed remarks:

Fresh Air and Sunlight.—Patients that are confined to the house, owing to weakness or fever, for example, may be seated or couched near an open window, with all other windows and doors kept closed to avoid draughts. Even in winter, for certain periods during the day, patients can be wrapped well and exposed, just as is done on the piazzas of sanatoriums,

where they often sit for hours with a temperature so low as zero Fahrenheit, or as has been recorded at the Loomis Sanatorium, N. Y., in an atmosphere 15° below zero. Of course, windows facing east should usually be closed during the prevalence of raw, damp, stormy northeast winds; and likewise windows facing north, when northerly or northwesterly winds prevail with heavy blasts and much flying street dust. Mouth breathing should be prohibited as far as possible.

Rooms having southern exposure are always most desirable, and are the only ones that get all the sunshine there is to be had in winter. Whenever most convenient and the temperature is safe the patient should be instructed to lie quite nude exposed to the sun's rays for ½ hour to 2 hours at a time, so that whatever beneficent effects the sun may have upon tissue nutrition, repair or vigor, may be obtained from his actinic (probably) rays.

There is a very general prejudice against admitting night air into the sick-room; but it should be insisted upon that night air is purer than day air (barring sunlight's effects), as the dust raised by traffic, and the smoke of factories, are comparatively absent.

The problem of house ventilation in the congested, crowded and cramped districts of a great city will not be solved fully and satisfactorily, however, until better *street ventilation* is provided for by the razing of slum tenements, the opening and widening of streets, the effacement of narrow, partly closed or cul-de-sac alleys, the judicious distribution of city parks, and the planting of trees along the streets. For, as I have shown in my thesis ("Street-Width: Its Causal Relation to the Mortality of Phthisis," *University Medical Magazine*, October, 1890), there is a close and direct relation between a high mortality rate from pulmonary tuberculosis and street narrowness. "The free course of pure air through wide, unobstructed streets is as clearly necessary for the proper ventilation of cities as it is for the ventilation of habitable rooms." * * * "Streets are the ventilating flues of cities." The topographical improvement of our cities means much in forestalling a predisposition to, as well as preventing an aggravation and aiding in the amelioration of tuberculosis in the individual.

Respiratory Exercise.—This should be encouraged in practically all cases that are not advanced to the condition of constant prostration in bed. Standing erect with shoulders back, and unimpeded by outer garments, the patient should breathe in deliberately and deeply and at the same time slowly raise the arms straight out and up so that the hands meet over the head at the end of the inspiration; with held breath, the abdomen and diaphragm should be contracted firmly for a few moments, thus squeezing the air, as it were, into the ordinarily unexpanded vesicles of the lungs; expiration and lowering of the arms then follow: this may be repeated several times, until the patient begins to feel tired, or perhaps, a little dizzy. Both at night and in the morning, these exercises kept up for weeks tend to be of service in pulmonary expansion, in oxygenation, in nutrition, and in affording useful mental diversion. As to the last named, my experience has been that although the more intelligent consumptives are outwardly

*Also by the American Climatological Association, in its preliminary program for the 1901 meeting.
†The Necessity for State Aid in the Treatment of the Consumptive Poor, by the author, *Philadelphia Medical Journal*, June 16, 1900.

and expressibly cheerful and hopeful, nevertheless, evidences of profound discouragement and despondency sometimes manifest themselves, so that any measure which contributes to psychic buoyancy as well as to physical elasticity is to be recommended. I have not infrequently seen annoying cough much diminished by the practise of forcible expiratory efforts. And this leads me to say that, in a majority of the cases, no symptom of the disease seems more distressing than the harassing cough; in a minority of cases, tuberculous diarrhea, and the pain of a tuberculous laryngitis, are characteristically agonizing.

Postural Alleviation of Cough.—It is a common observation that the cough of consumptives is worse on lying down. A distinct improvement of this may be gained so that the patient may have additional relief in the avoidance of sleepless nights, by assuming the extreme flat dorsal decubitus for short periods several times during the day, and practising the deep breathing exercises. This may be combined occasionally with the naked sunning. In this manner the pulmonary circulation may be influenced and the lungs trained, so to speak, to be less irritable at night, so that cough may not be easily provoked; just as the bowels may similarly become responsive to the will from the habit of regular voluntary solicitations to action.

Medication.—This is so generally well known, and the resources are so many—too many in fact, for the little good gained and the many stomachs deranged—that I merely wish to mention 2 drugs, seldom referred to, that have proven to me of distinct value in some cases. They are aromatic oils: The oil of sandalwood and the oil of erigeron. The first, in 10 drop doses on sugar, every 3 or 4 hours, or as needed when the cough is unusually distressing, has seemed to afford much relief for this symptom, especially in the earlier stages of the disease; the latter, a much neglected drug I believe, has, under my observation, been of decided benefit in the hemoptysis of tuberculosis, administered in 5 minim capsules every 2, 3 or 4 hours. Only recently, in a case of acute pneumonic tuberculosis with moderately profuse hemorrhages from the lungs, a most gratifying response was obtained.

In the discussion on tuberculosis which led to the writing of this article, as hinted at the beginning, Dr. R. G. Curtin did not refer to these 2 oils, and yet it is to his suggestive experience of some 10 or 12 years ago that I owe my first ideas regarding their therapeutic value.

Chest Strapping.—In several cases of tuberculosis where the cough was apparently excited to a large degree by dry pleuritis, considerable relief was obtained by strapping the affected side with adhesive plaster, as for fractured ribs.

Olive Oil.—As a substitute for plain or emulsified cod liver oil, or even other animal fats, as cream and butter, I have found olive oil most desirable, palatable and digestible. It keeps well, may readily be taken with celery or lettuce salad, or soaked up with day-old whole wheat bread, and is not so apt to cause eructations, nausea and indigestion.

Registration of Tuberculosis.—Dr. Matthew Woods' opposition to this public health measure of registration

is analogous to Ingersoll's antagonism to religion. Just as the brilliant colonel delighted his modern audiences in smashing a "man of straw" caricature of the "cruel" theology of the past, so Dr. Woods imagines a panorama of the horrors of registration to be, protests, and enlists our sociologic sympathies for the despairing few; while he courageously and ironically ignores a safe step toward sanitation for the many—for the "majorities" that "are always wrong" (quoted from M. Arnold by him). If the reporting of the cases of tuberculosis in the manner proposed by its advocates, and as tested in New York City, was as "unnecessary, unscientific, ghastly, barbarous, extravagant, cruel, and misery-producing" as he so adjectively assumes it to be, then truly, let us have none of it. The time to report a case, especially if the patient is ignorant and careless, or surrounded by such as are, is when the results of the physical examination are corroborated by a cough giving rise to tuberculous sputum.

THE RECOGNITION OF TABES DORSALIS.*

BY

THEODORE DILLER, M.D.,

of Pittsburg, Pa.,

Neurologist to the Allegheny General Hospital; Visiting Physician to the Insane Department of St. Francis Hospital.

The first clear clinical description of locomotor ataxia was given by Todd in 1847, and the first description of the characteristic changes in the cord was that made in 1858 by Türk. An English physician, now living, upon returning home from a visit to Germany, told his colleagues that his attention had been called, while in Germany, to a new symptom of tabes—called Westphal's Sign—consisting of a loss of kneejerks, which he believed was of value in the diagnosis of the disease. Thus it will be seen that the recognition of the clinical picture and the pathologic changes of this most striking disease have been made within the professional lives of physicians still living. But since these first descriptions of the disease, numerous contributions to our knowledge of its pathologic anatomy and clinical manifestations have been made, so that today a complete description of it cannot be made in a short essay, but requires a volume to contain it.

While the most striking pathologic changes are still found in the posterior columns of the cord, the posterior nerve-roots, with their attached ganglia, are as constantly involved in the same degenerative process. The accumulation of evidence seems to point to the peripheral sensory neuron, with its cell in the ganglion of the posterior nerve-root and its process extending downward to the skin, muscle, joints, etc., and constituting the sensory nerve, and its process extending inward to the nerve-cells of the cord or upward in the columns of Goll and Burdach to the nuclei gracilis and cuneatus at the top of the spinal cord as the primary seat of the disease. According to this view, the degeneration of the posterior columns of the cord and of the peripheral sensory nerves is merely a secondary or Wallerian degeneration. Dr. Batten,¹ however, holds that the initial change is in the muscle-spindle; that the peripheral portions of the sen-

*Paper read before the Allegheny County (Pa.) Medical Society, December 18, 1900.

sory nerve are first to degenerate, and that the disease is primarily a disorder of the muscular sense-organ. The disease is not confined to the posterior columns of the cord, the posterior nerve-roots and the sensory peripheral nerves; it may involve any of the cranial nerves or their nuclei, especially those having a sensory function. The gray matter of the cord is sometimes involved in the degenerative process, especially Clark's vesicular column.

The symptoms of tabes are chiefly those due to the involvement of the peripheral sensory neurons, viz.: the lost kneejerks, ataxia, the various paresthesias, anesthesias, analgesias and painful sensations. Loss, diminution or perversion of pain, tactile and muscular sense are observed. Trophic changes, sometimes profound, are also seen; and occasionally, though rarely, except in the advanced stages of the disease, motor symptoms are present.

A typical case of tabes, with absent kneejerks, ataxia, Argyll Robertson pupils and lightning-pains, is very easy to recognize and is seldom mistaken for any other disease. As a rule, it is only in the early or pre-ataxic stages that tabes presents any real difficulties in diagnosis, and ataxia is seldom an early symptom of tabes. Patriek says emphatically it is never the first symptom. Certainly tabes may be established for years before the appearance of this symptom. In a few cases, indeed, it never appears. Doubtless, too much importance has been attached to staggering as a symptom of tabes, and many cases are unrecognized simply because of the absence of this symptom. While, of course, ataxia constitutes a striking and highly characteristic symptom when present, the diagnosis of tabes may and should be made in most cases in its absence with clearness and certainty.

Another stumbling-block in the diagnosis of the disease is the insistence upon the absence of kneejerks. The kneejerks are absent in about nine-tenths of all tabetic patients, and absent early, too; but in the other one-tenth of the cases they are either present or only diminished. The shape and position of the patella tendon varies so much in different persons that a number of efforts should be made to obtain it before the jerk is pronounced absent, as the first taps may fail to bring it out. The patient's attention should be diverted while his kneejerks are being tested, and he should, at the same time, be directed to grasp firmly his own or the hands of an attendant (so-called reinforcement) while the test is being made.

A third stumbling-block in the diagnosis is the insistence upon the presence of the Argyll Robertson pupil. There is, according to Limbach,¹ some pupillary change in about 70% of tabetic patients; but this change does not always consist in the loss of the light reflex of the pupil with contraction of the pupil upon convergence (the Argyll Robertson pupil), although this is the most frequent and most characteristic pupillary change. Like the kneejerk symptom, the Argyll Robertson symptom may not be complete; *i. e.*, there may be present a very slight contraction of the pupil to light stimulus. In cases like this it is helpful to test the pupils of a normal person as a control experiment, just before or after testing those of the patient. Occasionally, but rather rarely, the

light reflex is preserved while the accommodation or convergence reflex is lost—a reversal of the Argyll Robertson pupil. Myosis, mydriasis, or inequality may be observed.

The Argyll Robertson pupils, the absent kneejerks, and the ataxia, when it is only brought out by having the patient stand or walk with the eyes closed, are not symptoms for which the patient consults the physician. The three chief symptoms which do lead him to seek medical aid are: (1) lightning pains in the legs; (2) loss of functions of bladder and sexual organs; and (3) double vision or failure of vision.

The lightning pains are well so-called, since they come and go quickly. The intervals between them may be minutes, hours, or days; and they may last for a second, for some minutes, or even hours. They usually appear in the legs or around the waist, but, occasionally, when the tabetic process is high in the cord, they are present in the arms. This symptom was the first to appear in 9 of 24 of my cases whose histories I have examined. The presence of these pains commonly leads the patient to diagnose his case as one of rheumatism, and this view is unfortunately too often concurred in by physicians, notwithstanding that these pains constitute such a striking and significant symptom that they should always lead to the suspicion of tabes.

Ocular symptoms were the first to appear in 6 of my series of 24 cases: in 4 cases as transient diplopia or ptosis; in 2 cases as optic atrophy; while in 2 other cases, optic atrophy was an early, although not the first, symptom to appear. In the presence of a transient and recurrent diplopia, or ptosis, or an unexplained optic atrophy, one should always suspect tabes and seek other signs of the disease; and should he fail to find them or any other adequate explanation of the symptoms (as *e. g.*, paralytic dementia, brain-tumor, disseminated sclerosis, or cerebral syphilis), the patient should be regarded as a "suspect" and reexamined from time to time. Many observers contend that when optic atrophy appears as an early symptom, the other symptoms are late in their appearance or may never appear. My own experience leads me to believe this view correct. In one of my cases optic atrophy was the only symptom present for many months. In another case optic atrophy and absent kneejerks were the only symptoms present when I first saw the patient. Optic atrophy is present in about 10% of all cases of tabes.

Cystic weakness, or sexual impotence, or both, were the first symptoms complained of in 3 of my 24 cases. At some time in the course of the disease, 10 suffered from vesical weakness, 9 from impotence and 2 from defective control of the anal sphincter. Generally, cystic and sexual weakness were present in the same patient. Cystic weakness is usually manifested by difficulty in starting the flow of urine and in completely emptying the bladder. The abdominal muscles are called into requisition to empty the bladder. The flow of urine is often slow and intermittent.

Two patients complained of weakness in the legs as the first symptom, and in 5 other cases this symptom appeared at some time in the course of the disease. This feeling of weakness was largely or wholly due to sensory

disturbances in the legs (paresthesia or anesthesia), or disturbances of muscular sense in the legs, and was not a true motor paralysis. These perverted or lost sensations, and ataxia in the legs are frequently described by patients as "weakness."

The loss and perversion of sensation constitute a significant set of symptoms in tabes, and should be carefully inquired into. Paresthesia was recorded as present in 8 of my 24 cases. Limbach recorded its presence in 64.5% of the 400 cases whose histories he examined, and this observer found that 33.75% of the cases in his series exhibited slight analgesia of the legs. Trunkal anesthesia or girdle-sensation was present in 8 of my patients. Testicular anesthesia, impairment of muscular sense, persistence of painful impressions, and delayed sensory impressions, are sensory phenomena which are present occasionally, though less commonly. Hypotonus is also an interesting and common symptom of tabes, but how frequently it occurs I am not prepared to state.

Occasionally, though infrequently, the tabetic process attacks the upper portion of the cord, and when it does pains and other sensory disorders occur in the arms and hands. Again, also rarely (except of the nerves of the ocular apparatus), the process largely invades the brain, and in such an event any of the cranial nerves may be involved. Oppenheim¹ records a case in which the solitary bundle and the fifth nerve-root on the left side were, upon postmortem examination, found completely atrophied. He believes that the involvement of the oblongata is not rare.

Gastric crises (sudden attacks of vomiting, or gastric pains, or both together) occur in about 5% of all cases (Limbach). In 2 of my cases this symptom occurred, and in both it was the first symptom to appear. Sudden pains in the larynx, intestines or bladder, constituting crises, may also appear occasionally. When the gastric or other crisis is present as the first symptom of tabes, the physician is often misled as to the diagnosis. Paralytic symptoms due to motor involvement are rare in the early, but common in the later, stages of tabes. Trophic disorders affecting various tissues of the body are seen in tabes. Such changes in the bones render the tabetic patient, like the paralytic dement, liable to sustain fractures. The Charcot or tabetic joint, characterized by sudden enormous, painless swelling with subsequent disorganization of the joint, is another striking symptom of tabes. Perforating painless ulcer of the foot and herpes zoster are among the other trophic changes seen in the disease. When the disease-process attacks the fifth nerve-ganglion, the teeth may loosen and fall out.

Tabes may be confounded with paralytic dementia and, indeed, the tabetic symptoms indicate sometimes but the beginning of the larger process of paralytic dementia. These diseases are closely allied; and Fournier asserts that they are but one in their underlying pathologic process. But ordinarily the mental and speech disturbances of paresis will serve to distinguish it. Tabes sometimes closely simulates cerebrospinal syphilis; but the differential diagnosis cannot be entered into here.

Multiple neuritis may be mistaken for tabes, for it

exhibits 3 of the 5 chief symptoms seen in tabes, viz.: absent kneejerks, ataxia and pains in the legs. But in multiple neuritis the Argyll Robertson pupil is absent, the onset of the disease is more acute, there is tenderness upon pressure along the nerve-trunks, and more or less atrophy, with loss of power, appear early. The symptoms related to the bladder and genitals, so commonly present in tabes, are absent in multiple neuritis.

If one has in mind the larger picture of tabes and does not insist upon the presence of any single symptom, and, above all, is on the alert to recognize the disease before the advent of ataxia, failure to detect the condition will occur only occasionally. To test the kneejerks and pupils, and examine for sensory changes is easy enough. In any patient complaining of lightning-pains in the legs, or of failure to empty the bladder with ease or completely, or who complains of impotence, or who exhibits transient diplopia, ptosis or optic atrophy, tabes should, if possible, be established or excluded by examination, unless these symptoms are clearly explained upon other grounds.

In patients complaining of paresthesia or anesthesia, or who are subject to obscure attacks of gastric pains with vomiting, laryngeal or cystic pains, or who exhibit trophic changes in the skin, nails or joints, the possibility of tabes should be considered.

Upon the presence of how few symptoms may the diagnosis be made?

The following symptoms, I believe, may be said to be the cardinal ones of tabes, and are named in the order of their importance:

1. Failure of kneejerks.
2. Romberg symptoms (swaying with eyes closed).
3. Argyll Robertson pupil.
4. Lightning-pains.
5. Loss of functions of the bladder or sexual organs.

With the presence of any 3 of these symptoms, I believe the diagnosis may with certainty—and in the presence of any 2, with probability—be made, when evidence pointing to multiple neuritis, paralytic dementia or cerebrospinal syphilis is absent.

Among the important secondary symptoms or signs are:

- a. Paresthesia, anesthesia, or analgesia of the legs.
- b. Locomotor ataxia.
- c. Transient ocular palsies.
- d. Paresthesia in the ulnar distribution.
- e. Optic atrophy.

With the presence of 2 of the cardinal signs of tabes and 1 of the secondary signs, I believe the diagnosis may be made with certainty, and made as most probable, with the presence of 2 of the secondary, and only 1 of the primary symptoms, and, indeed, it may be made with certainty, in the absence of all the cardinal symptoms. Many combinations of symptoms are, of course, seen in tabes, and the evidence presented by each case should be carefully weighed. When this is done it will happen but rarely that the diagnosis cannot be made with certainty or probability.

SIMPLICITY IN THERAPEUTICS.

BY

EDWIN W. PYLE, M.D.,

of Jersey City, N. J.

Fellow of the New York Academy of Medicine; Assistant Surgeon of the New York Eye and Ear Infirmary.

Stories may live by tradition but therapeutics must be perpetuated upon facts. Individual experiences with drugs may vary, but they must admit of a reasonable verification to be of scientific value.

Taking these sentiments as the basis of a theme, we approach the subject of small doses with an explanation as to their use in therapeutics, with a degree of hesitancy, by reason of the criticisms that arise from prejudice and misunderstanding.

The small dose has not yet run the gauntlet of professional prejudice, but it has been championed by the people to such an extent, as to become a revolutionary agent in methods, and a positive contribution to therapeutics. We use this term with reference to the fractional, or the appreciative dose, with no regard for an infinitesimal standard.

The outgrowth of studying the effects of drugs upon the healthy body, has been the teaching of the elective affinity which all medicines seem to have for definite tissues.

Upon this subject the late Professor Stillé has said, "Future investigations will throw light upon this obscure department which must hereafter furnish the surest basis for a science of therapeutics."

The word "specific" is used in reference to a medicine which antagonizes disease, as quinine for malarial plasmodium; but in a physiologic sense it refers to the elective relation which certain drugs bear to certain tissues, parts, or organs. Thus podophyllin has a specific affinity for the small intestines, chiefly for the duodenum, and attacks these parts from whatever source introduced. The active principle of cantharides passes into the blood, producing acute congestion of the kidneys and urinary passages. Colchicum irritates the stomach and intestines, whether swallowed, or injected into the veins. Likewise, colocynth influences the colon; aconite the vascular system; gelsemium the cerebrospinal centers; aloes the rectum; others selecting glands, or organs according to their varied properties. Dr. H. C. Wood bases the eleventh edition of his "Therapeutics" upon physiologic study, while Cushney devotes a chapter to the special subject of affinity, with the comment that some cardiac poisons act only on the auricles, while others influence the ventricles.

Here, evidently, is a principle in therapeutics, supported by excellent authority, with very little evidence of its practical application in selecting medicines according to their specific relations. Apparently, some drugs act only through chemie union, combining with protoplasm to alter the function of cells; others increase functional activity by a law of stimulation, depending upon the *quantity administered*.

It is in the prescribing of the latter, that the small dose is particularly applicable, and may be selected with a fair degree of therapeutic precision.

We hazard the opinion that when a special part or organ becomes inflamed or disturbed in function, the physiologically selected medicine acts as a stimulant to restore balance of forces, when given in small and frequently repeated doses; but irritates, congests, or paralyzes recuperative power, thereby aggravating the malady, when given in *large* doses at *long* intervals, precisely as alcohol influences the system under like administration.

It is well known that a full dose of alcohol paralyzes the cerebrospinal centers; but if that same amount be administered in small doses at short intervals, instead of stupor, we obtain the highest degree of stimulation. Many medicines furnish the same evidence.

To illustrate: digitalis acts upon muscular fiber, causing slower relaxation, quicker contraction and is thus indicated in weak heart-action with low blood-pressure. Under such conditions 10 to 20 drops of the tincture may give excellent results; but more frequently the morbid action will not be corrected by this size dose. If, for convenience, we put the same quantity into 20 teaspoonfuls, or a half-glass of water, and give 1 or 2 teaspoonfuls every 1 or 2 hours (dose gtt. ½-2), the result will be better, and generally a slow, sustained action follows. The late Dr. Edward Mayer has written: "Small doses will steady the same heart that has been made to flutter under large ones."

Aconite influences the vascular system, and bryonia limits effusions of serous membranes. (Phillips.) In sickness characterized by fever, quick pulse, labored breathing, pleuritic pain and rusty sputa, 5 to 10 drops of these strong tinctures into 20 teaspoonfuls or a half glass of water, 1 or 2 teaspoonfuls given every hour or 2 hours (dose gtt. ¼-1), constitutes an early treatment for pleurisy and pneumonia that has given results incredible to those who have been accustomed to large doses and severe antiphlogistic measures. This fact has been verified by years of experience and is no longer in the "primary stage of laudation."

Dr. Cooper¹ writes: "In asthenic cases of pneumonia I rely on minute doses of aconite and bryonia, frequently repeated," and adds, "under this treatment we should not lose over 5% of our cases." The probable explanation is that the small dose stimulates and equalizes, without interfering with the essential *vis medicatrix nature*.

Belladonna determines blood to the capillary circulation with heat and redness; Rhus. tox. will in addition, produce a vesicular eruption. If in erysipelas either of these medicines, depending upon the character of eruption, be given as above directed, the results are fewer deaths and quicker recoveries, *ceteris paribus*, than when Tr. ferri. chl. is administered in unwelcome doses. We disclaim any estimate of the value of this medication, we only know that nature thus simply treated gives better results than when burdened by an irritating product, and in this particular instance we are supported by the testimony of Cushney, the Hôtel Dieu, (Paris), and the Royal Infirmary in Edinburgh.

Phytolacca is a specific irritant of the throat. It is physiologically indicated in follicular tonsillitis with fetor of the breath, and in small doses is a most positive

remedy. Jaborandi produces diaphoresis, yet in small doses will check the sweating of tuberculosis.

Nitroglycerin causes congestive headaches with intense throbbing; when properly selected for morbid conditions of similar character, gr. $\frac{1}{1000}$ doses will give relief.

Apomorphin acts upon the medulla, produces convulsions, rapid breathing and great prostration. A small hypodermic dose will stimulate the spinal centers, relieve hysteria, stop the convulsions in childhood, and abort the pains of vasomotor disturbances.

Ipecac and calomel, both nauseants, correctly prescribed, will stop bilious vomiting. Colocynth, universally known as a purgative, will, in small doses, relieve diarrhea characterized by griping umbilical pain. (Hughes.)

Fractional doses of podophyllin relieve a form of diarrhea characterized by dark-colored movements, cutting pains and worse in the mornings. (Ringer.) Less than 1 drop doses of cantharides relieve the distress of cystitis and hematuria. (Mayer.)

Arsenic, in minute doses, is extolled in the coryzas of childhood and in the vomiting of drunkards. (Murrell.) Potas. bichromate in gr. $\frac{1}{100}$ doses relieves hoarseness and aphonia. (Phillips.) Calomel in gr. $\frac{1}{2}$ doses every hour relieves irritable stomach (Aulde), and every 2 hours is a clinical routine treatment for certain systematic dyscrasia. (Knapp.) Strychnin arsenate, in doses of $\frac{1}{134}$ gr. every hour makes "the most permanent tonic stimulant." (Jackson.)

Malcolm Morris, of England, recommends the wine of antimony in drop doses as specific treatment for acute eezema.

These, with many similar facts, have long been known and admit of sufficient application to merit more general recognition. They must, however, be arrayed against other facts of a totally opposite character, and constitute no foundation for a belief in small doses only, or in the universality of a law of cure. There are many instances in which the fibril cannot replace the lash; when to remove conditions, to antidote poisons and to eliminate disease, vital, chemical, and well-proven drugs are essential in the fullest doses.

The physiologic action of a drug may point the way to its therapeutic use. Every prescriber should know not only the pathology of disease and the antagonizing influence of medicines, but also their elective affinity for tissues of the healthy organism.

Whenever it is possible to apply the stimulating influence of the physiologically indicated dose, prescribing becomes ideal; relief is not wrought at the expense of other organs, as is the case when syrups are given for coughs, nor is the physician's mind tormented by a senseless, unreliable symptomatology.

To prescribe, in every instance, opiate astringents for diarrheas, many of which can be relieved by diet; morphine for certain abdominal pains that readily yield to dioscorea; or massive doses of bismuth for vomiting that can best be treated by a judicious application of heat; burdens the system unnecessarily and prostitutes therapeutic measures.

The single remedy hygienically given in whatever

dose, not only simplifies prescribing, but is scientifically correct. Polypharmacy is largely the result of physicians writing their own histories and never taking their own medicines.

Dr. Hare has made a strong argument against the irrationality of this method of combining many drugs, whose action is little understood, and putting them into bodies of which we know less.

The experience of those treated by other systems makes the strongest argument. All believe that if there be no good in "infinitesimals" there is at least directly no harm.

"Yet," says Dr. Osler in his review of the nineteenth century medicine, "nobody has ever claimed that the mortality among homeopathic practitioners was greater than among those of the regular school," an observation well substantiated by statistics. But a more significant fact is observed in the psychic method of cure in which faith is the great lever. Faith, from childhood to age, is more or less a panacea for human ills, and, however reposed, should never be rudely shaken. Whether it be in prayer, or in the plainest doctor, it is the same precious commodity without which we can do nothing, and with which we, too, can work wonders.

To see a large assemblage of people, many from the highest circles of life, bright, animated, in full possession of all that is splendid in womanhood and manhood, to know that they sleep, eat, work, with all the functional activity of a God-given nature, without the stimulus of "pills" should have its lessons without necessarily endorsing popular fallacy. We are rapidly learning that to cure a patient is not so often to cast out disease by medicine as it is to return to natural methods of diet, rest, exercise, etc. Most generally the individual requires the special care rather than the disease. It is an everyday experience to meet those who are courting sickness through ignorance of natural laws, who need to be shown the way to health, rather than to be given medicine.

"Of all the ills that suffering man endures,
The largest fraction liberal nature cures."

The evolutions of medical practice, assisted by sanitary science, that brightest star of the closing century, has curtailed the once unlimited boundary of therapeutics, and has simplified its methods.

The alpha and omega of typhoid fever prescribing is no longer quinine, but diet and nursing. Innocent childhood with innocuous croup is no longer vomited with turpeth mineral, but is equally relieved by the gentleness of aconite and spongia; and in diphtheria, the long list of horrid doses has given way to antitoxin and supportative treatment. While in puerperal convulsions the unfortunate victim of her own economy is no longer held in the vise of overpowering hypodermics, but the system is rationally relieved of poisoned blood and the life-giving impetus of an intravenous transfusion takes its place.

Having been reared under influences which prompted relentless dosing for every ailment; when Watson was the authority recommending the scarifying and blistering of every pneumonic patient; when water was denied

to the burning thirst of fever till tongues were parched and nights were filled with dreams of constant drinking; having lived to see the decadence of nauseating compounds and temporizing dilutions, we thrice welcome the uprising of a new dispensation of medicine, which puts faith in natural methods and a few well-proven drugs, simply administered.

Were we to retrospect 30 years of general practice, to select one from many experiences, to leave as a parting injunction to the rising generation of physicians, it would be a request in the interest of humanity to simplify prescribing, in using the smallest dose and the least medicine possible to accomplish the therapeutic purpose.

THE RADICAL CURE OF INTERNAL AND EXTERNAL PILES BY EXCISION.

BY

JOHN A. HAWKINS, M.D.,

Pittsburgh, Pa.

Demonstrator of Rectal Diseases in the Medical Department of the Western University of Pennsylvania.

The fact that so many different operations are recommended for the radical cure of internal piles clearly proves that something is lacking in all of them to make an ideal operation. This brings up the question as to what is to be considered the ideal operation for the relief of this distressing disease? It must be the one that can be done safely, rapidly and completely, free from pain at the time of operation and afterwards and allow the patient to resume his usual avocation in the shortest possible time.

The operation for piles by the ligature does not answer this definition. It is practically safe if properly performed. It is easily and quickly done and the results are good. It is followed, as a rule, by considerable pain frequently requiring a quantity of morphin to control it, and the patient is confined to his bed for a variable time ranging from 10 days to 3 weeks.

The operation by the clamp and cautery is quite an improvement on that by the ligature in that there is no ligature to slip or slough off and the cure is more quickly accomplished, but it is not a safe operation in the hands of a surgeon who only occasionally performs it, as the danger from ulceration is as great as by the ligature operation and there is also a great danger both from insufficient or excessive cauterization of the stumps. The proper estimation of the degree of heat required is of importance and should be well understood by the operator attempting it. Again, I have known of several surgeons, whose skill as general surgeons would hardly be questioned, who have applied the cautery to the skin stump as well as the mucous stump in the mixed variety, with the usual disagreeable result—retarded convalescence with subsequent contraction. Whitehead's and the American operations are as unnecessary as the removal of both legs when one of them is crushed.

The treatment by injection will cure certain cases but

its scope of usefulness is limited; still, it should not be thrown aside. It has its dangers and they are not a few. Within the past 2 months I have seen several patients who possess fistulas directly traceable to this method. True, both were injected by quacks of the vilest order, but abscesses from the hypodermic syringe, though infrequent, are not entirely unknown to our most skilful surgeons and best trained nurses, notwithstanding careful asepsis. The injection method is not rapid, as I have met patients, from the hands of these gentlemen of great promises, who have been under treatment for more than a year and yet uncured.

During the past 9 years, which I have devoted to the study of pelvic diseases, I have tried all the operations, not once but numbers of times, in order to find the best operation for this most common disease. I have witnessed the operations of the leading men in this country and Europe and am now convinced that there is a better method of radical cure for piles. Neither the ligature nor clamp and cautery operation recommend themselves as a modern surgical operation. Why persist in using an antiquated operation in the treatment of piles only? The injection method is not to be considered as applicable to modern ideas.

My idea of the up-to-date operation is the one in which we approach the hemorrhoidal tumor in just the same manner as we would a tumor situated in any other location, using asepsis, hemostasis and suture.

With the hemostatic forceps or clamp shown in the accompanying cut, I have been enabled to operate

Hawkins' Pile and Pedicle Clamp.

quickly and with the minimum loss of blood. The patient either under the influence of a general or local anesthetic is placed in the dorsal position and the lower rectum cleansed with antiseptic soap and sterile water. If the tumors protrude the sphincter need not be divulsed, otherwise it may need some stretching. Each pile is now picked up with ordinary hemostatic forceps and its base well defined. The most posterior mass is taken up first and drawn into the jaws of the pile clamp and if an external pile is continuous with it, it also is drawn into the clamp. The jaws are now tightened and *the entire mass is cut off close to the clamp*. Now with a full curved needle armed with catgut take a stitch through the healthy mucous membrane above the end of the clamp. Fix the end of the suture with a hemostat so that the end will not be pulled through. Now pass the needle under the clamp and touching it and out at the other side of the clamp. Bring the needle over the clamp and insert it again on the same side and $\frac{2}{3}$ or $\frac{1}{2}$ of an inch below the first entrance. Bring it out opposite

and continue until the entire stump is sewn up. Now take one more stitch below the clamp and in the healthy skin and the sewing is completed. The sutures must *not* be drawn tight as they are introduced. The jaws of the clamp are now to be released and the clamp withdrawn and by gently but firmly pulling upon each end of the suture the stump is drawn up and its edges nicely approximated. A shot may be put on each end of the suture if thought necessary. There is no reason why the patient should be confined to his bed when he wishes to get up. I have performed this operation at my office and allowed the patient to return to his home immediately thereafter. There is no danger from hemorrhage; very little pain; a quick recovery and an absolute cure.

The ordinary preparatory and after treatment is used, the bowels being first moved in 36 or 48 hours and daily thereafter, each passage to be followed by a weak creolin or carbolic acid enema and evacuated at once.

The clamp I use was made for me by Charles Lentz & Sons of Philadelphia.

RIGIDITY OF THE SPINE. (SPONDYLOSE RHIZOMÉLIQUE).*

BY

MAX H. BOCHROCH, M.D.,

of Philadelphia.

Instructor in Electrotherapeutics and Chief Clinical Assistant in the Nervous Department of Jefferson Medical College Hospital; Neurologist to the Out-patient Department of St. Joseph's Hospital, Philadelphia.

H. G. C., aged 25, white, single; occupation, physician.

Family History.—Mother and father living. Patient is the youngest of 3 children. Mother had been a sufferer from "rheumatism" and headache as far back as he can remember; father, also, has had rheumatic pains for 10 years, but neither of them has ever been confined to bed with the disease. One brother is a great sufferer with headache. Maternal and paternal grandparents were not afflicted with any nervous disease.

Personal History.—Patient had the ordinary diseases of childhood, but was otherwise well up to the age of 15 years, when he had an attack of rheumatism involving the left shoulder and hip, but he was not confined to his bed. The attack lasted about a week.

He remained perfectly well for 5 years, during which time he enjoyed athletic sports, entered college, played football and tennis. At the end of this time he had another attack of severe pains in the shoulder and hip of the same side as before. In this attack he was confined to bed for about a week; the parts, however, were neither red nor swollen. Subsequently he took and completed a course of massage in the Orthopedic Hospital of this city, in 1894. He then entered upon his medical studies and during the following 4 years frequently gave massage.

In September, 1900, he had a third attack. It began with pain and stiffness in the left shoulder and a sense of numbness in the left arm. Gradually the right shoulder and hip became involved. Again there was no redness or swelling, and the salicylates proved of no avail.

It should be here stated that he has used alcohol and tobacco only in moderation. He had gonorrhoea 5 years ago. Sores are denied.

He came to Philadelphia the end of last February for change and rest, and on April 16 he came under my care at St. Joseph's Hospital.

Status Præsens.—Patient is spare, but shows signs of excellent muscular development. Says he has lost 20 pounds in the last 5 months. Rising in bed, or from a chair, gives him

* Read (and patient shown) before the Philadelphia Neurological Society.

considerable pain which is referred especially to the back and neck. All movements of the head are painful and limited in extent. He cannot touch his chest with his chin, or move the head backward. Lateral movements are decidedly interfered with and forcible rotation causes great pain.

On inspection the back presents a flat beard-like appearance, the spinal gutter being entirely obliterated.

On palpation along the vertebral column, the absence of the interspinous spaces becomes conspicuously noticeable. The lumbar and dorsal vertebrae especially give the impression of a continuous hard structure. Deep pressure causes intense pain, as does transmitted force down the spine; flexing the trunk forward, backward or laterally also produces considerable pain.

He can elevate his right arm at the shoulder normally, but the left can be raised only with difficulty and pain.

Flexing the legs on the abdomen is also painful, the pain being especially felt in the abductor muscles of both thighs. The hipjoints are mobile but painful. Fibrillary contraction of the muscles is not observable, even on mechanical irritation.

The left trapezius muscle is atrophied and he holds his head inclined toward the right. There is also atrophy of the supra and infraspinatus muscles of both sides, possibly more marked on the left than on the right side. The gastrocnemii seem flattened equally on both sides. The muscles respond normally both to a galvanic and faradic current.

The kneejerks are plus. There is no ankle clonus and the Babinski sign is not present.

Romberg's symptom is also absent. Bowels and bladder normal.

He complains of a belt-like sensation around the waist.

No anomalies of sensation can be detected.

This case evidently belongs to the affection, characterized as spinal rigidity, to which v. Bechterew, Sachs, Strümpell, Marie, Fraenkel and others have called attention. It is difficult to classify this case under the subdivision made by Sachs and Fraenkel. These authors divided the cases into the type of v. Bechterew and the type of Strümpell-Marie: The first, according to Sachs and Fraenkel, is characterized by chronic rigidity of the spine, often limited to the cervical region; other joints free. Root symptoms predominate. Anatomical findings: chronic leptomeningitis, with root and spinal cord changes; vertebral joints not affected. The second is characterized by chronic rigidity of the spine, with involvement of shoulder or hip joints. No root symptoms. Anatomical findings: ossification of ligaments, hypertrophy and ankylosis of joints.

At first sight this case would belong to the first subdivision, but, on the other hand, the undoubted involvement of the vertebral joints would refer it to the second subdivision. It is true that the patient here presented has no fixation of the shoulder and hip joints, and yet they are undoubtedly involved. It would seem to me better not to attempt a subdivision of these cases on clinical grounds, as the one before us cannot be fairly grouped with either; further, the erection of these cases into a separate clinical entity seems to me of doubtful value. The case before us can be readily explained by the theory that the affection is merely one of the forms of chronic rheumatoid arthritis. The wasting of the muscles and the exaggeration of the kneejerks do not necessitate the view that the cord is involved. Such wasting as is present can be readily understood on the ground of disuse or possibly because of root involvement. Such involvement would also explain the belt-like sensation from which the patient suffers. The

exaggeration of the kneejerks can be readily explained by the well-known fact that in rheumatism the tendon reactions are frequently exaggerated.

SOME NOTES ON A CASE OF CEREBRAL EMBOLISM.

BY

ANNA M. LITTLEFIELD, M.D.,

of New London, N. H.

The majority of cerebral emboli have their source in chronic endocarditis of the left heart. In this case there was a history of an attack of rheumatism which affected the heart some 10 or 12 years before, and left it weak afterward. For a number of days before the apoplectic seizure the patient felt a peculiar "quivering feeling" which seemed to be in the heart itself. She said it seemed "as if some little thing was fluttering inside," said it was "not at all like palpitation" for she "knew what that was."

Was not this caused by the loosened vegetation partly torn from the heart valve which soon after became separated and washed away in the blood stream? The sensation had never been noticed before this time nor was it afterward. It was not troublesome enough to cause complaint and was only described in answer to questions about the condition of the heart.

November 23, 1897. Mrs. S., an intelligent and energetic woman, 60 years old, and in ordinary health, rose and dressed as usual. On going to the kitchen, she suddenly "felt something in her head," became very dizzy and would have fallen if she had not been close to a chair. She thought she was unconscious a short time after she sat down but soon came to herself and called the family.

When first seen, half an hour later, she had not been moved from the chair. There was severe nausea, vertigo, and a "very bad feeling" in the head. The left pupil alternately dilated and contracted. After a short time it remained contracted. The left hand was numb and on the right side of the body and face there was complete thermo-anesthesia.

As soon as possible she was placed on a bed with her head raised on pillows. The nausea and vertigo were aggravated by any motion of the head, even turning it on the pillow. Her clothing had to be cut off to save disturbing her head in removing it. She could not bear to open the eyes because vision increased her discomfort. She saw everything tipping over toward her right. She said, "I don't see how you can stay on that chair when you lean over so much," to a person sitting upright at the foot of her bed. She also had the feeling that she was all the time rolling over toward the left, and was afraid that she would roll off the left side of the bed when she was really lying partly on her right side. She would hardly believe the testimony of all the bystanders that her head was looking to the right until in drinking some water, a little spilled on her face and ran down the right side. Then she said, "Why how strange; that water runs out of the right side of my mouth when I know my head is turned to the left."

There was some dysphagia. It was at first uncertain how much of this was due to the nausea. Probably there was some impairment of the muscles of the throat. For several days rectal feeding was used, as the stomach was very irritable. There was retention of urine for about 10 days.

November 26. Complained again of the head. Thought she had another attack "like the first." This time she saw everything straight, but vision caused so much nausea that she kept the eyes shut for days.

A constant feeling as if the head was falling off to the left made her draw the head so strongly to the right that the muscles of the back of the neck became very sore and painful, and

the head had to be gently turned back and confined in the right position to relieve the strain on the neck. The slightest motion produced severe nausea. For a week the head had to be kept as still as possible on the pillow.

November 28. Severe pain in "inside and back" of head. Very sensitive to noise and jar, or any one touching the bed. If even a fold of the nurse's dress rubbed against the bed, she felt it in her head. At this time the left pupil was dilated, and the patient said that when she opened that eye "the light shone in all the way to the back of the head." At one time had double vision, another time saw things upside down.

November 29. Extreme hyperacusis gave a great deal of trouble for a week, but gradually wore away. It was worse for low-pitched sounds than for high ones. She could see objects upright, but they looked very small.

December 10. A small spot in back of the head gave pain which was quite severe on the following day, and for several days gave some trouble. This spot was located about 1½ inches above the left mastoid process. Also the lobe of the left ear burned constantly. Ice applied to it gave some relief to the head.

After this time there was a continuous though very slow improvement. Dizziness kept her very quiet a long time. To be moved a little in bed would make it so bad as to produce nausea. In 1 month she began to be raised up on a bed rest; in 2 months she was moved to another bed; in 3 months sat up in a reclining chair. In 6 months sensation of heat and cold returned to the face; in 3 years it has partly returned to the rest of the body. At present time she is able to keep house; still complains of occasional slight vertigo.

The fact that the patient was conscious all the time and could accurately describe her feelings, was a help in the treatment. She could appreciate the effect of aconite in lowering pressure and relieving pain in the head. Aconite was given every 15 minutes till the pulse softened whenever discomfort in the head was accompanied by hard and wiry pulse. Belladonna was also given, and seemed to have decided effect on the hyperacusis and intracranial irritation. When pain was severe, it was controlled by ice and ethyl chlorid spray. It was thought that the free use of spray did much to limit the spread of inflammation beyond the region of the original lesion.

Constant attention was given to bowels and kidneys. Nutrition was promoted by careful feeding, bathing and massage. Absolute quiet and good nursing in a private house where everything was subordinated to the welfare of the patient, furnished favorable conditions for recovery.

Dr. Halle L. Ewing, of Hastings, Nebraska, has been elected assistant physician in the women's department of the State Hospital for the Insane.

Tuberculosis Sanitarium.—A sanitarium company, composed largely of medical men, is now being formed at Albuquerque. It will be incorporated under the laws of the Territory of New Mexico, and the stock and control of the company will ultimately be in the hands of the medical profession of the United States. The sanitarium will be conducted upon exclusive scientific lines. Nothing in the nature of "specific treatments" or "sure cures" will find a place in it. All reliance is to be placed upon climate, diet and baths, including a solarium for "sun baths," massage, mineral waters and everything of value in the science of modern hygiene will be impressed into service. A continuous life in the open air in this region has proved of the utmost value, hence this feature of the treatment will be a leading one. It is the purpose of the incorporators of this company to establish and operate a "chain" of sanitariums at various altitudes and latitudes within this territory, thus providing the proper point for each case. The company will be incorporated and capitalized at \$500,000 comprising 500,000 shares of stock at the par value of \$1 each. The incorporators especially desire that most, if not all the stock shall be held by members of the medical profession, and it is their conviction that such an enterprise can be made a complete success, both from a scientific and financial standpoint.

SPECIAL ARTICLE

REPORT OF THE GENERAL HOSPITAL FOR THE TREATMENT OF PULMONARY TUBERCULOSIS AT FORT BAYARD, N. M., FOR THE PERIOD ENDED DECEMBER 31, 1900.

BY

D. M. APPEL, M.D.,

Major and Surgeon U. S. Army, Commanding Hospital.

To the SURGEON-GENERAL, U. S. ARMY, WASHINGTON, D. C.

Sir:—I have the honor to submit the following report from October 3, 1899, on which date I arrived at Fort Bayard and established this hospital: In accordance with your instructions I first selected 3 company barracks and 7 sets of officers' quarters for the use of the hospital, in addition to the old post hospital and hospital steward's quarters, but soon found that more buildings would be required and on my recommendation an order was issued directing that Fort Bayard be discontinued as a garrisoned post, and that all the buildings pertaining thereto be transferred to the Surgeon-General.

As the abandonment of the post had been contemplated for some years, the buildings were very dilapidated and the water and sewer systems in a deplorable condition. Repairs were at once begun and although they

Officers' Hospital.

have progressed considerably, are still incomplete. The main system of sewerage has been entirely reconstructed and is now in excellent condition, and in a short time all the lavatories, bathrooms and waterclosets will be completed according to the most improved sanitary requirements. The water-supply has been increased by connection with another well and is now ample for all purposes. A new corrugated iron pump-house has been erected. In this has been installed a new and larger boiler, pump, sawmill and lathe, in addition to the old pump and boiler.

The ice plant has been repaired and renovated and now requires a new shelter, for which estimates are being prepared.

Building No. 9, formerly a double set of officers' quarters, has been repaired throughout and altered for use as an officers' hospital. It contains 6 bedrooms, a diningroom, kitchen, readingroom, sittingroom, billiardroom and 2 bathrooms. Building No. 17, formerly band quarters, is used for the mess of ambulant patients and contains a large diningroom, a pantry, kitchen, cook's room and storeroom. Building No. 16 furnishes 2 large recreation rooms, in which patients congregate after supper and during inclement weather. The old

post-hospital is being thoroughly repaired. The roof has been newly shingled; the porches, wards, office and dispensary will be newly floored; steel ceilings have been placed in all the rooms and the walls are being covered with soapstone finish. The north room on the

Old hospital, now used as infirmary.

second floor has been transformed into a very satisfactory operatingroom. The diningroom and kitchen, being too small to accommodate the patients on low diet, were refitted and are used for the preparation of special diets and for the nurses' mess. The outbuilding formerly used as a storeroom and laundry has been connected with the main building by a covered passageway and with slight alterations and necessary repairs makes an excellent diningroom and kitchen for patients on low diet. The old quarters of the hospital steward are occupied by the acting steward and 2 privates on duty in the infirmary, and 1 room has been reserved as a small ward for the hospital corps and civilian employees. The hospital steward, on duty as chief clerk, occupies the south half of Building No. 1. In Building No. 14 are the barracks for the hospital corps, with the mess for them and the civilian employees; and in the south annex, a ward for convalescents. The north half of the main building of Building No. 15 is used as a chapel; the south half and north annex are storerooms for medical supplies, and the south annex is a dormitory for ambulant patients. Building No. 13 is entirely occupied by ambulant patients, with the use of the lavatory and waterclosets in the north annex. The main building of Building No. 12 is used as a dormitory for civilian employes and both annexes as a laundry. In Building No. 10 (a large frame cottage), formerly a double set of officers' quarters, are the dormitories of ambulant patients with severe cough, there being but 2 beds in each room. Building No. 34 is used as an administration building, with an examination

Infirmary showing new covered way to dining-room.

room and laboratory in the rear. Building No. 21, the old administration building, contains the library, quartermaster's offices, postoffice and store. Building No. 8, formerly a double set of officers' quarters, is used as quarters for nurses.

The selection of Fort Bayard as a site for a sanatorium for the treatment of pulmonary tuberculosis has been amply justified by our results. Its location in the arid mountainous region of Southern New Mexico, at an altitude of 6,040 feet, affords a climate permitting comfortable outdoor life during the entire year. The mean maximum and minimum temperatures and the precipitation for the past decade are as follow :

MONTH.	MEAN MAX.	MEAN MIN.	PRECIPITATION.
January	52.77°+	23.15°	1891 19.30"
February	54.13°	25.83°+	1892 8.89"
March	60.52°+	30.92°+	1893 15.47"
April	68.43°	37.10°	1894 9.12"
May	77.33°	45.45°+	1895 15.09"
June	86.45°	52.68°	1896 18.85"
July	82.91°+	55.34°+	1897 18.00"
August	85.32°+	56.98°	1898 15.91"
September	81.97°	52.00°+	1899 10.43"
October	71.34°+	41.20°+	1900 12.66"
November	61.29°+	31.90°	
December	53.20°+	24.66°+	
General Average	69.56°	39.79°	

During the year 1900 only 52 cloudy days were noted.

From October 3, 1899, to December 31, 1900, 283 patients were admitted as follow :

Officers (including one retired)	6
Enlisted men, regular army,	196
of whom 114 remained after discharge from the service, as beneficiaries of the Soldiers' Home, and 1 after retirement.	
Discharged soldiers, as beneficiaries of the Soldiers' Home,	49
Enlisted men, volunteers,	23
Discharged volunteers, by special authority,	2
Acting Assistant-Surgeons, assigned to duty at hospital,	1
Civilian clerk, assigned to duty at hospital,	1
Civilian clerk, temporary admission authorized by Surgeon General,	1
Civilians residing at post,	1
Female nurses,	2

Total, 283

The following instructions to patients are conspicuously posted throughout the recreation rooms and dormitories :

INSTRUCTIONS TO PATIENTS.

Consumption is an infectious disease caused by a germ which is found in the spit, therefore, the spit together with everything coughed up by patients must be carefully destroyed. Should it be allowed to dry and in the form of dust float around in the air, millions of these germs would be set free and would endanger not only those who are well, but would often reinfect the sick, and thus undo the benefit derived from months of care.

Spit only in your spitcup or into the large spittoons provided for that purpose, never on the floor, in the bathtubs, sinks or closets, nor in your handkerchiefs.

Carry your own spitcup with you everywhere, spit into it carefully, to avoid having to wipe your lips, whiskers, or the edges or sides of your cup. Never swallow your spit.

The only safe method of disposing of the spit is by burning it, therefore the paper cups and spittoons must be burned when half filled and the frames washed frequently with carbolic solution. Should you by accident spit on the floor or bedclothes, or spill your cup, report it at once, to insure proper disinfection.

To be benefited by this most excellent climate, you must live outdoors as much as possible, and always when indoors keep the windows open.

Go to bed early, take moderate exercise, when not instructed to the contrary; eat your meals slowly and chew your food thoroughly.

Do not help yourself to food from any dish except your own plate with your own fork or spoon, but use those provided for that purpose. Try to refrain from coughing at meals, you can with slight effort do much to prevent it.

The use of stimulants and cigarettes is forbidden. Smoking and chewing tobacco in moderation is permitted. Whiskers and moustaches must be closely trimmed.

PATIENTS NOT BEDRIDDEN MUST OBSERVE THE FOLLOWING RULES :

1. They must occupy their quarters only from 7.30 p. m. until 8.00 a. m.
2. They must make their own beds and neatly arrange their personal belongings, none of which are to be left on the floors.
3. They must stay outdoors at least 8 hours daily.
4. They must not visit in quarters.
5. They must bathe at least once a week.

Each patient is provided with a spitcup of the pattern made by Seabury & Johnson, consisting of a tin frame with spring cover, in which is placed an impervious paper receptacle; and large covered spittoons with paper receptacles are scattered throughout the rooms and on the porches frequented by the patients. A shelf is fitted under each chair in the diningrooms, on which the spitcup is placed during meals. The spitcups and also the dejecta from patients with intestinal tuberculosis, are destroyed in crematories, two of which have now been in use for several months.

Abundant good and nutritious food is provided, and our dairy now furnishes an ample supply of milk. Patients are weighed every Friday, the weights are recorded and a report of the gains and losses affords a good index of their progress. On several occasions patients have gained over 10 pounds in one week. The following is a copy of the last weekly report :

REPORT OF GAINS AND LOSSES OF PATIENTS FOR THE WEEK ENDING DECEMBER 28, 1900.

The old post-hospital is occupied as an infirmary for bedridden cases, including not only those in which the disease is far advanced, but all febrile patients whose maximum daily temperature reaches 101° F. In a large majority of these cases, after a short period of absolute rest, the fever permanently subsides.

The treatment pursued here consists mainly of outdoor life, ample good food and rest. Regulated exercise

is permitted when advisable. The ambulant cases are daily instructed in breathing exercises. Cod-liver oil with guaiacol is extensively administered, and in the few cases in which the stomach does not tolerate it, guaiacol carbonate is prescribed in 1 gm. doses twice daily. The laryngeal lesions, as a rule, do well with a simple spray of 1% tricoresol in liquid vaselin, which apparently prevents pyogenic infection, and the tuberculous lesion improves with the general condition. Otherwise the treatment is symptomatic. Tuberculin is used only for diagnostic purposes.

On July 22 we began, with 5 patients, an experimental use of antitubercle serum made by the Biochemic Division of the Bureau of Animal Industry of the United States Department of Agriculture. It was necessarily discontinued September 3, because of the death of the horse from which the supply was derived. On October 14 a new supply was received and its use resumed, but on account of the permanent rise of temperature produced it was soon abandoned.

Since October 17 the antiphthisic serum TR. has been used in 21 cases, and in 8 it is continued. There is no doubt that this serum, as well as the one above mentioned, like the tuberculin, exerts a specific action which is frequently detrimental. In several cases it apparently caused permanent rise of temperature, which subsided when the serum was withdrawn. In one case it was followed by reappearance of tubercle bacilli in the sputum, fever and loss of weight, in a patient previously apparently convalescent. In 2 cases tubercle bacilli have disappeared from the sputum during its administration; this, however, frequently occurs under our ordinary treatment. In the cases still under treatment the results to date are apparently negative.

In the following study of our clinical histories and results, the statistics have been very carefully compiled by Acting Assistant Surgeon E. S. Bullock, Pathologist, and in Charge of Clinical Records.

Of the 283 patients admitted, 124 were discharged, 34 died and 125 remain under treatment.

To elucidate our results better the cases will be divided into 3 classes, viz.: (1) cases exhibiting permanent afebrility without tubercle bacilli in the sputum; (2) cases exhibiting permanent or approximately permanent afebrility with tubercle bacilli (pure tuberculosis or a minor degree of mixed infection); (3) cases exhibiting permanent febrility, with tubercle bacilli (mixed infection).

Certain features common to all these cases are worthy of emphasis. The first and most striking is the apparent permanency of the different types, at least as the disease is manifested in this climate and under our treatment; i.e., cases in which the maximum daily temperature does not drop below 100° F. shortly after admission usually remain permanently febrile. These are true cases of phthisis pulmonalis, and the results in this class are no better than in less favorable climates. Cases afebrile on admission or those where, following absolute rest, the temperature drops below the febrile point shortly after admission, also exhibit great permanency of type, and the same is true of the remaining class, viz.: febrile cases without tubercle bacilli. In these last 2 types favorable results may be anticipated, especially in the latter.

The next feature which merits attention is the relatively insignificant role of a tuberculous family history as an etiologic factor in pulmonary tuberculosis, when contrasted with the importance of the lessened resistance resulting from a preexisting disease. A prominent feature, and one which militates against the best results here, is the limited period that patients remain under treatment, the average being but 4.1 months, and in such a markedly chronic disease this must be considered in the interpretation of our statistics. Many were discharged at their own request, convalescent and improved, who after their discharge from the service were unwilling

to submit longer to the necessarily rigid rules and regulations of the hospital. Many also were unable to resist the pangs of nostalgia, due largely to the isolated location of the hospital and the aridity of the vicinity.

In 51% of all our cases there had been a history of pulmonary hemorrhages. When this is contrasted with the fact that they have occurred in but 15 cases here, it is

Barrack buildings, and frame cottage on the rise to the north.

evident that the prevalent opinion that residence in high altitude is contraindicated in such cases has no foundation in fact. In 78% of the cases the disease was contracted in the tropics.

Reinfections, diarrheas, nightsweats and intercurrent diseases, owing to the hygienic environment, play so unimportant a part in the course of the disease as manifested in this hospital that they are not deemed worthy of special tabulation. In 90% of our cases there was evidence of the pulmonary affection in the conformation of the chest.

In 5 cases the diagnosis of pulmonary tuberculosis was not confirmed, as follows: In 3 the physical signs gave evidence of "healed tuberculosis," and the tuberculin test was negative on admission. One patient had septic bronchitis and died of acute peritonitis of unknown origin, and the fifth had tuberculosis of the chest-walls and pleura, without involvement of the lungs. In this case the tuberculin test was also negative on admission, and death resulted from rupture of an aortic aneurysm. Of the remaining 153 patients who were discharged or died, 16 were under treatment less than 1 month and will not, therefore, be considered in this report of results, leaving 137 patients, of whom 24 or 17% died; 42 or 30% were unimproved; 33 or 23% were improved; 22 or 16% were convalescent; and 16 or 11% were clinically cured.

Patients are classed as convalescent when no tubercle bacilli are found after repeated examination, and, though active symptoms have almost disappeared, they still react to the tuberculin test. Those who, after all symptoms have disappeared, fail to react to the tuberculin test are recorded as clinically cured.

Of the 137 patients who died or were discharged, 30 or 22% exhibited *permanent afebrility*, and when admitted had *no tubercle bacilli in their sputum* (class 1). In these the following facts were elicited on admission: Family history was negative in 23 and positive in 7. In 9 the pulmonary tuberculosis was complicated by other diseases of the lungs or pleura, viz., emphysema, fibrosis, chronic bronchitis, and pleuritis with effusion. In 1 there was tuberculosis of the peritoneum in addition to the pulmonary lesion. Secondary anemia was present in 14; hyperleukocytosis in 3. In none did the blood show degeneration of red-cells or myelocytes. In all the presence of adventitious organisms in the sputum was a marked feature. These organisms, named in order of frequency of their occurrence, though several varieties are commonly found in one specimen, are: staphylococci, streptococci, Micrococcus pneumoniae crouposae, Friedlander's bacillus, Micrococcus tetragonus, Leptothrix buccalis, and Sarcinae. In 20 cases or 66% the tuberculosis was secondary to a preexisting disease: Malaria ranked first, being a factor in 10; pneumonia next, in 7;

dysentery in 2, and pleurisy in 1. In 22 patients or 73% the pulmonary disease was evidenced by the conformation of the chest, viz., retraction of tissues over apices, drooping of one shoulder, narrowing of intercostal spaces, and rigidity of ribs; only 4 of this class presented tuberculous facies when admitted. In 22 the lesion was infiltration and in the remainder infiltration plus consolidation. The diazo-reaction was absent in all. In 16 there was a history of pulmonary hemorrhage. In 22 the tuberculin test confirmed the diagnosis—in 2 cases at first negative, tubercle bacilli subsequently appeared.

In contrast to the above data which illustrate the condition on admission the following facts were noted at the time of discharge: 12 or 40% of these 30 patients were clinically cured, 13 or 43% convalescent, and 5 or 16% unimproved. In 10 there were complicating pulmonary affections—this is 1 more than on admission, 1 patient developing emphysema while under observation. Anemia was present in 4, which is 10 less than on admission. Hyperleukoeytosis was present in 2. In one patient tubercle bacilli did not appear in the sputum until 5 months after admission. Adventitious organisms were present in the sputa in 12, which includes all who had any expectoration on discharge. None had tuberculous facies at the time of discharge, but 18 presented evidence of disease in conformation of chest, which is 4 less than on admission; 12 presented the physical signs of a lesion best described by the term "healed tuberculosis"; 17 still presented the physical signs of infiltration, and 1, which is 6 less than on admission, had infiltration plus consolidation. Only 1 of this class had a hemorrhage while under observation, notwithstanding that over 50% presented a history of hemorrhage. In 9 of the 12 discharged as clinically cured, the tuberculin test was negative. The other 3 objected to the tuberculin test, but were entirely without symptoms of active disease, and it was therefore considered unnecessary to insist upon its administration. Four of this class had a relapse, in 3 tubercle bacilli were present for a short time, and they were found in but 1 at the time of discharge. The diazo reaction was still absent in all.

Conclusions in regard to afebrile patients without tubercle bacilli (Class 1).—This class presents a pure type of tuberculosis without mixed infection. Slight secondary anemia is often present but is never marked or constant. Degenerated red-corpuscles are never present, abnormal leukocytes are very rare and when found are apparently accidental and ephemeral, and the same is true of hyperleukoeytosis. Adventitious organisms in

occasionally associated with moisture over the affected area, even after the patients have passed the tuberculin test and are clinically cured, is uniformly present. A history of previous hemorrhage occurs in this class as often as in others but a hemorrhagic tendency is not ex-

Section of crematory in use at United States General Hospital, Fort Bayard, N. M. Description: Built entirely of brick with fire-brick lining. If slow cremation is desired, partially close damper A and open C. For fast cremation, partially close damper C and open A and open door B. Door D permits removal of pan for cleaning.

hibited. The prognosis in this class is very good, as evidenced by 12 clinical cures and 13 discharged convalescent before complete arrest of the disease could be reasonably expected. In this class the diazo-reaction is never observed. The average daily maximum temperature is 98.9° F., which is evidence that pure uncomplicated tuberculosis is an afebrile affection.

In the 2 cases where the tuberculin test was negative on admission, tubercle bacilli subsequently appeared, possibly as the result of reinfection in a susceptible subject. In one case this is the most probable explanation, for the tubercle bacilli did not appear until 5 months after the test; this patient was the only one of this class discharged with tubercle bacilli in the sputum. In the other it is hardly so applicable, for the tubercle bacilli were found within a week after passing the test and apparently as a result of the action of the tuberculin; however, within a few weeks the bacilli disappeared, the patient again passed the test and was finally discharged clinically cured. In this case also the tuberculin test failed to demonstrate the existence of tuberculosis. In one patient in whom there was complicating fibrosis and arteriosclerosis the tuberculin reaction had an unfavorable influence upon the subsequent course of the disease, though in this case tubercle bacilli were never found, and the patient was discharged unimproved. In still another case a negative result of the tuberculin test was followed by an evening temperature slightly above 99° F. for several weeks, though it subsequently fell to normal.

Of the second class, afebrile cases with tubercle bacilli, 59 patients were discharged. In these the general course of the disease was afebrile and when fever occasionally occurred it was always amenable to rest-treatment.

The following facts were elicited from them on admission: In 45 the family history was negative, in 1 un-

PLAN OF U.S. GENERAL HOSPITAL FORT BAYARD N.M.

the sputum are a permanent feature while expectoration continues and they, therefore, bear no relation to the presence or absence of mixed infection, as there is no mixed infection in this class.

The typical lesion is a slight infiltration of one apex with or without signs of activity, though some consolidation is occasionally encountered. Increased density,

known and positive in the remaining 13. In 4 there were complicating affections of the lungs. In 3 there was chronic laryngitis. In 10 there were other complications, including malaria, cerebral syphilis, chronic nephritis, hernia, anal fistula, dementia, otitis media and hemiplegia. There was tuberculosis of other organs in 8, as follow: testicles 2, peritoneum 1, larynx 2, inguinal glands 1, and intestinal tuberculosis 2. In 42 there was secondary anemia. In 35 there was hyperleukocytosis. In 9 there was degeneration of red-cells, and myelocytes were present in 5. Adventitious organisms were present in the sputum of 12. The pulmonary tuberculosis was preceded by some other disease in 40, or 68%. As in the previous class, malaria led, being the inciting cause in 23, malaria and dysentery together in 4, chronic diarrhea in 3, influenza in 2, catarrhal jaundice in 1, peri-neal abscess in 1, tuberculosis of cervical glands in 1, and pneumonia in 5. Tuberculous facies was present in 15. In 52 there was evidence of the pulmonary disease in the conformation of the chest. In 30 there was a history of hemorrhage. The diazo-reaction was present in 8. The lesion in 24 was infiltration alone; in 25 there was infiltration plus consolidation, and in the 9 remaining there was infiltration, consolidation and cavities.

Their condition on discharge was as follows: None of these patients died, 18 or 29% were unimproved, 28 or 48% were improved, 9 or 16% were convalescent, and 4 or 6% were clinically cured. None of this class ever became permanently febrile. In 20 there was secondary anemia, or 15 less than on admission. Hyperleukocytosis was present in 22, or 15 less than on admission. Neither degeneration of red-cells nor myelocytes were present in any. Tubercle bacilli were absent from the sputum in 10. In 4 there was no expectoration. Adventitious organisms were present in 13, and were mostly confined to those patients in whom tubercle bacilli had disappeared. Tuberculous facies was present in 13. Evidence of disease in conformation of chest persisted in 45, or 7 less than on admission. At the time of discharge the lesion in 4 was "healed infiltration," infiltration alone in 30, consolidation plus infiltration in 17, and cavities still persisted in 8. There was, therefore, a marked improvement in the character of the lesion in this class, particularly in the resolution of consolidated areas. The least change occurred in the cavity cases, and they, of course, present the most unfavorable type. In 6, hemorrhages occurred while under observation. The tuberculin test was negative in 2 at the time of discharge; the other 2 discharged clinically cured, objected to the tuberculin test, and it was not considered necessary to insist upon its administration. The diazo-reaction persisted in but 1 case, although this patient improved. There was no relapse in this class. The average maximum daily temperature was 99.5° F.

Conclusions in regard to afebrile patients with tubercle bacilli.—This class presents either a pure type of pulmonary tuberculosis or minor degrees of mixed infection. The latter is readily and accurately estimated by the degree of hyperleukocytosis which, as has been seen, was present in the majority of these cases on admission. That mixed infection in a minor degree, as in this class, is amenable to treatment is illustrated by the smaller number presenting hyperleukocytosis at the time of discharge, and by the following results: 4 clinically cured, 9 convalescent, and 28 improved, out of a total of 59. This is preeminently the type of the disease in which time is required to effect cure or arrest, and in which it is so difficult to impress the fact upon the patients, owing to the absence of pain or other distressing symptoms. The influence of other tuberculous lesions was apparently slight, even in the few cases where such complications occurred. Of 7 that presented tuberculosis of other organs, only 3 were discharged unimproved; in one case with laryngeal ulceration, and in another with genitourinary involvement, the improvement was remarkable.

Secondary anemia, a marked feature of these cases, disappeared in 50% of those who exhibited it on admission. Adventitious organisms in the sputum were confined mostly to the most favorable cases, and became a constant feature when the tubercle bacilli disappeared.

The tendency of this type is toward recovery, as evidenced by the fact that none died, and but 17 out of 59 were discharged unimproved. The diazo-reaction occurs rarely, and only in the least favorable cases.

Of the third class, cases exhibiting permanent febrility with tubercle bacilli, 48 were discharged, or died. In them the facts elicited on admission were as follows: The family history was negative in 35 and positive in the remaining 13. In 6 there were complicating diseases other than tuberculosis. In 12 there was tuberculous involvement of other organs, of the larynx in 9. Secondary anemia was present in all; hyperleukocytosis in all; degeneration of red-cells in 15; myelocytes in 6, and adventitious organisms in the sputum of 14. In 28 the tuberculosis followed some other disease. Again malaria led, being a solitary factor in 10 cases, malaria with dysentery or chronic diarrhea in 3, dysentery in 4, pleuritis in 3, pneumonia in 2, typhoid fever in 2, chronic diarrhea in 2, measles in 1, and appendicitis in 1. All of these cases presented tuberculous facies and all gave evidence of the disease in the conformation of the chest. There was a history of pulmonary hemorrhage in 20. The diazo reaction was present in 23.

Of the 48 in this class, 24 or 50% died; 20 or 42% were discharged unimproved, and 4 or 8% improved in general condition. None was cured or discharged convalescent, and 13 had tuberculosis of other organs, one more than on admission,—this patient developed intestinal tuberculosis while under observation. None ever became afebrile. All those discharged presented anemia and hyperleukocytosis, 19 had degeneration of red-cells, and in 6 there were myelocytes. In 1 tubercle bacilli were absent from the sputum, but were found in pus withdrawn from the pleural cavity. Adventitious organisms were still present in 10. In 4, all of whom died, hemorrhages occurred while the patients were under observation. The diazo-reaction was present before death or discharge, in 30. Consolidation, infiltration, and cavity or cavities, were present in 38 cases; 9 had consolidation and infiltration, and but one infiltration alone. The average maximum daily temperature in this class was 101.5° F., which is much lower than is commonly observed among similar cases in lower altitudes.

Conclusions.—The family history does not assume a more important place in this than in other types of the disease. Tuberculosis of other organs is more frequently present, particularly laryngeal tuberculosis, and though the latter is not directly a cause of death it contributes to the fatal termination. Hyperleukocytosis and more or less severe anemia are constant features. As might be foreseen, degeneration of red-cells as a manifestation of advanced secondary anemia, is present more frequently than in any other class, but its absence cannot be interpreted as indicating a favorable prognosis; this is likewise true of the presence of myelocytes in the blood and the diazo reaction in the urine. Another fact readily anticipated from the nature of the cases in this class is the constant evidence of disease in the conformation of the chest, and the tuberculous facies.

Adventitious organisms in the sputum, if they bear any relation to mixed infection, would certainly be a feature of this class, which is undoubtedly one of mixed infection, and yet they are absent in the large majority of the cases, and when present are apparently accidental and without relation to the type. With a death record of 50% and a hopeless prognosis in the remainder, the futility of climatic treatment for this class is unquestionable.

Of the 125 patients still under treatment, in 2 the

diagnosis was not confirmed, as the tuberculin test was negative on admission, and they are apparently cases of "healed tuberculosis." Twenty-three have been under treatment less than 1 month, leaving 100 cases for consideration, with results as follow: 26 unimproved, 48 improved, and 26 convalescent.

Of the first class, afebrile cases without tubercle bacilli, there are 23 patients. In these the following facts

were elicited on admission: In 20 the family history was negative, and positive in 3. Complicating pulmonary affections existed in 7, and other complicating diseases in 4. There was tuberculosis of other organs (inguinal glands) in but 1; 13 presented varying degrees of secondary anemia; there was hyperleukocytosis in 3; degeneration of red-cells, or myelocytes, were not observed in this class. Adventitious organisms were present in the sputa of 19, the other 4 having no expectoration. In 18, or 78%, the tuberculosis was preceded by another disease, malaria in 7, dysentery in 5, pleuritis in 2, pneumonia in 1, yellow fever in 1, chronic diarrhea in 1, and inflammatory rheumatism in 1. Tuberculous facies was absent in all. In 17 there was evidence of the disease in the conformation of the chest. The lesion was infiltration alone in 21; in 2 infiltration plus consolidation. In 7 there was a history of pulmonary hemorrhage. The tuberculin test was positive in 22—the one case in which it was negative on admission gave a characteristic reaction later. The diazo-reaction was absent in all.

Condition at present: 4 or 17% are unimproved, 19 or 83% are convalescent; complicating pulmonary affections persist in 6. The tuberculous inguinal glands have been removed by operation. Anemia persists in 6, 7 less than on admission; hyper-leukocytosis in 2, 1 less than on admission. Tubercle bacilli appeared in 6 and are still present in 3 of these. In 6 expectoration has ceased. In 13 adventitious organisms persist. The lesion remains unchanged in all but 2, in which consolidation heralded the appearance of tubercle bacilli in the sputum. In no case has a hemorrhage occurred since the patients have been under observation.

Of the second class, afebrile patients with tubercle bacilli, there are 63 under treatment. The following facts were elicited on admission: The family history was negative in 49 and positive in 14. In 4 there were complicating pulmonary diseases; in 21 there were other complications. In 5 there were tuberculous lesions of other organs—the intestines, tonsil, lower jaw, testicle, and larynx. Secondary anemia was present in 40, hyperleukocytosis in 39, degeneration of red-cells in 3, and myelocytes in 1. Adventitious organisms were present in 19. In 41 or 83% the tuberculosis followed some other disease—malaria in 24, dysentery in 5, chronic diarrhea in 3, pneumonia in 2, pleuritis in 2, chronic bronchitis in 1, influenza in 2, typhoid fever in 1, and syphilis in 1; 24 patients presented tuberculous facies. In 60 there was evidence of the disease in the conformation of the chest. The lesion in 31 was infiltration, in 27 there was infiltration plus consolidation, and in the remaining 5, cavities were present. Thirty-six presented a history of hemorrhage. The diazo-reaction was present in 5.

Their present condition is as follows: 13 or 20% are unimproved, 44 or 69% are improved, and 6 or 9% are convalescent. Complicating diseases of the lungs persist in 4. In 13, 8 less than on admission, other complications remain. In 4, 1 less than on admission, there are

still other tuberculous complications—the lesion of the lower jaw having completely healed. Twenty-five, 15 less than on admission, are anemic, and 31, 8 less, have hyperleukocytosis. Two have degeneration of red-cells and myelocytes. In 6 the tubercle bacilli have disappeared from the sputum. In 19 there are adventitious organisms in the sputum. Nineteen, 6 less than on admission, have tuberculous facies. Nearly all give evidence of the disease in the conformation of the chest. In 28 there is infiltration alone, in 26 infiltration plus consolidation, and in the remaining 9, cavities—practically the same as on admission. Four had pulmonary hemorrhage while under observation. Six presented the diazo-reaction—1 more than on admission. One patient relapsed after having become convalescent.

Of the third class, presenting permanent febrility and tubercle bacilli, 14 are still under treatment. The following facts were elicited on admission: The family history was negative in 12 and positive in 2. Five presented complications other than tuberculosis. There was tuberculosis of the larynx in 2, and in 1 there was tuberculous pyopneumothorax. Anemia and hyperleukocytosis were present in all, degeneration of red-cells in 2, myelocytes in 1, and adventitious organisms in but 5. In 9, or 64%, there was a history of preceding disease;—malaria in 7, pneumonia in 1, and pleuritis in 1. Tuberculous facies was present in all but 1, and evidence of the disease in the conformation of the chest in all. In 6 the lesion was consolidation and cavity, in the remainder consolidation plus infiltration. In 8 there was a history of pulmonary hemorrhage. The diazo-reaction was present in 6.

Their present condition is as follows: 9 or 64% are unimproved, 4 or 28% improved in general condition, and 1 is convalescent. Three present other complications—2 less than on admission, in which malaria and dysentery have disappeared. Three still present complicating tuberculosis; 1 became afebrile; 10 continued anemic—4 less than on admission; 11, or 3 less, have hyperleukocytosis; 1 has degeneration of red-cells, and 1 presents myelocytes. Tubercle bacilli have disappeared from the sputum in 1; adventitious organisms are present in all but 2; 12 have tuberculous facies, and the entire number have evidence of the disease in the conformation of the chest. In each one the lesion is the same as on admission. Two have had pulmonary hemorrhage while under observation, and 7 have the diazo-reaction.

In general it may be said that the prognosis of these patients is a trifle better than for those of the same type discharged, owing to a process of selection, only the most favorable remaining; but even in these there is little prospect of ultimate cure.

The case of the patient who became convalescent and in whom the tubercle bacilli disappeared, is worthy of note. Here there was pyopneumothorax of the left chest. For months the patient was bedridden, expectorating from $\frac{1}{2}$ to 1 liter of offensive pus daily. At one time his weight was reduced to 89 lbs., the evening temperature was constantly from 101° to 103° F., but his appetite, though capricious, remained. Expectoration suddenly ceased almost entirely, the patient improved and now weighs 136 lbs., and except for a badly injured left lung is practically well.

The combined results of 236 patients, who have been under treatment for 1 month or over, are as follow: 24 or 10% died, 68 or 28% are unimproved, 80 or 33% are improved, 48 or 20% are convalescent, and 16 or 6% are clinically cured.

Some interesting features were found in postmortem examinations. In one case both lungs were on the right side, the partially collapsed left lung having been crowded over by an enormous tuberculous infiltration of the chest-walls and pleura, and an aortic aneurysm. In another, which had presented typical symptoms of appendicitis, a tuberculous infiltration of the appendix was found. In

2 cases which succumbed to the pulmonary involvement, and in which on admission there was extensive laryngeal disease with absolute aphonia, the larynx was found completely cicatrized. In 3 instances when death followed a very rapid and malignant form of pulmonary tuberculosis, a peculiar amyloid degeneration of a solidified lung was observed:

To determine whether there is, as alleged, a congenitally small heart in those susceptible to pulmonary tuberculosis, we now carefully weigh that organ in all postmortem examinations. In 19 the average weight was 300 grams, which, in view of the general atrophy of all tissues characteristic of the later stages of tuberculosis, may be considered normal.

An Excellent Charity.—According to the rules of the Board of Education of Chicago, the floors of schoolrooms must be scrubbed twice a year, but the Bureau of Associated Charities has hired poor women to scrub weekly, during the muddy season, the schoolrooms in the central and stock yards' districts. The plan subserves a double good, for the schools are thus kept clean, and needy women secure work. The work will probably extend to other parts of the city.

Lefthandedness.—Chicago in connection with the public schools, maintains a department of child study, and in the seventh annual congress of the Society for Child Study held there recently, the question of righthandedness and lefthandedness was discussed, bringing out statistics from extended observations to show that 93% of the bright children were righthanded, and that a large number of the children whose speech was defective were lefthanded, about 40%. Conclusions were drawn disapproving of the interference with lefthandedness, though on the question of the advisability of teaching ambidexterity there was a division.

Consumption of Fluids.—*The American Grocer* has been collecting statistics concerning the home consumption of beverages, excepting water and sodafountain products, for the year 1900. According to this authority the amount spent was \$1,228,674,925, in the following proportions:

Alcoholic drinks	\$1,059,563,787
Coffee	125,798,530
Tea	37,312,608
Cocoa	6,000,000

Total \$1,228,674,925

Thus the percentage was, for alcoholics, 86%; Beer 50%, whisky and other spirits 30%, and wine and other alcoholic stimulants 6%. Being more costly the alcoholic drinks led; thus the \$125,798,530 for coffee represents 1,257,985,296 gallons, while the more than \$500,000,000 worth of beer measured but 1,221,500,160 gallons. The consumption of spirits per capita fell from 1.43 gallons in 1891 to 1.27 in 1900, wine from .45 to .40, and beer increased from 15.31 to 16.01. This proves that drinking is not on the increase, and the amount spent per capita is less than 4½ cents a day. It is surprising that in spite of an increasing output of good domestic wine, that wine-drinking is declining, while the consumption of beer seems to be on the increase.

The Massachusetts General Hospital had its origin in a circular letter bearing date August 20, 1810, from Drs. James Jackson and John C. Warren asking subscriptions "for a hospital for the reception of lunatics and other sick persons." January 1, 1900, the value of the hospital plant and income producing investments aggregated about \$1,500,000, of which less than \$100,000 was derived from State grants; the remainder had been given in sums varying from 25 cents from "a poor black" prior to 1844 to almost \$1,000,000 given by the Honorable Henry L. Pierce in 1898. Besides the General Hospital in Boston the hospital plant comprises the McLean Hospital and the Convalescent Home in Waverly, a town 8 miles distant. The General Hospital has 261 beds for medical and surgical house patients; an out-patient, and an accident department. During the year 1899, 5,086 house patients, 31,003 out-patients (new cases) and 3,877 patients in the accident rooms were treated. The hospital maintains a training school for nurses and affords annually facilities for the instruction of several hundred students from the Medical School of Harvard University. The history of the General Hospital records the first production of complete anesthesia in connection with a capital surgical operation, October 16, 1846, when W. T. G. Morton made a successful application of sulphuric ether for the prevention of pain to a patient undergoing a serious operation. Of its medical and surgical contributions may be mentioned the method of reducing hip dislocation and the operation of litholapaxy by Dr. Henry Jacob Bigelow, visiting surgeon from 1846 to 1886; also, an investigation of the inflammations in the region of the cecum, published June 18, 1886, by Dr. Reginald H. Fitz, visiting physician, which drew attention to the disease appendicitis, and led to its surgical treatment.

PRACTICAL THERAPEUTICS

Under the charge of
A. A. STEVENS,
Assisted by
L. F. APPLEMAN.

The Treatment of Malaria.—Patrick Manson (*Practitioner*, March, 1901) writes that quinin is the only reliable remedy. Necessary conditions for success are that it be given in such a way that it is absorbed and that the dose be adequate. Equinin is at present on trial. It appears to be equally efficient, and has the further merit of being tasteless. Its greatest drawback is its expense. For an ordinary intermittent fever the dose of quinin may be 10 grains, given when the sweating stage commences, followed by 5 grains every 6 or 8 hours for a week, and with the view of preventing relapse, 5 grains 3 times every fifth, sixth or seventh day for 2 or 3 months. For bilious remittent, the same treatment applies. It is good practice to give a dose of calomel, followed by a saline at the outset of treatment of this type of malarial fever. Quinin is said to be most effective when given about an hour before the paroxysm, that is, when the spores are free in the plasma; but to give the drug at this time in ordinary intermittent is to aggravate the headache, and in the case of bilious remittents and of pernicious malaria, it would be a grave error to await doubtful occurrence of a remission. In serious cases quinin should not be given in pill, capsule or tabloid form. It should be given in solution by the stomach or rectum, or better, hypodermically. For intramuscular injection the best salt is the hydrochlorate. Intramuscular injection is not only less painful than subcutaneous injection, but less liable to induce abscess. It may be safely asserted that any intermittent fever which resists quinin for 3 or 4 days is not malarial. Arsenic, though of value as a blood restorer after an attack, has no power over the parasite. Methylene blue, in 3 or 4 grain doses, appears to have some virtue, and may be of service when, owing to an idiosyncrasy, quinin cannot be taken. As a prophylactic remedy, the author recommends euechinin, 5 to 10 grains, once or twice a week, or even daily.

The Treatment of Apoplexy.—J. J. G. Brown (*Scottish Medical and Surgical Journal*, April, 1901) writes that no unnecessary movement of the patient should take place. He should be gently conveyed to the nearest bed and allowed to lie there in such a position and with his clothing so arranged as to allow of the free return of venous blood from the head and neck. If the diagnosis is certain, and if there are signs of a continuing hemorrhage, and if the site of the lesion is the usual one, it may be advisable to compress the carotid artery. It may even be advisable to ligature that vessel in special cases, as in one recorded by Derenn and Keen. The power of clotting of the blood may be increased by the administration of calcium chlorid, and as the conditions are urgent the remedy should be given hypodermically. The blood tension can be considerably lowered by free purgation. For this purpose croton oil or calomel may be employed, and the lower bowel may be emptied by means of an enema. The quickest way of lowering intracranial tension is by bloodletting. But before venturing to abstract blood, either by opening a vein or by the less objectionable method of applying leeches to the neck, the diagnosis of cerebral hemorrhage must be clear, for such a practice as bloodletting in the case of embolism or thrombosis would be very harmful. The cases in which venesection is likely to do good are those in which the face is darkly flushed, the pulse slow and full, and the coma profound.

Treatment of the Night Sweats of Tuberculosis.—J. Strassburger (*Therapeutische Monatshefte*, March, 1901) notes that external applications of formalin and alcohol give good results, but that the vapor of formalin when thus applied is very irritating to the eye and respiratory tract. Various devices may be adopted to confine the vapor to the body, but the method is convenient. As a substitute for formalin the author has lately used with great success tannoform. It is perfectly harmless, it does not irritate the skin, the patient can apply it him-

self, and it is just as efficacious as pure formalin. The author uses it as a dusting powder in the strength of 1 to 3, applied by means of wad of cotton. [Tannoform is a combination of tannic acid and formaldehyd. Hesse and Adler speak very favorably of its use in excessive sweating of the feet. Hesse recommends a mixture of tannoform, 1 part, and Venetian tale, 2 parts. This remedy will be found especially useful when the condition is associated with more or less maceration of the tissues.]

Treatment of Erysipelas.—Keirle (*Philadelphia Medical Journal*, VII, No. 7) has treated 30 cases of erysipelas by the following method with uniform success: The affected area is first enclosed in a ring of tincture of iodine painted from 2 to 3 inches from the edge of the reddened area. A sufficient number of coats should be applied to cause a slight desquamation of the upper layers of the skin. At the same time the whole surface enclosed in the ring is covered with an ointment of ichthyol 1 dram, vaselin 1 or 2 ounces. This is covered with a piece of gauze, a hot stupe applied and renewed every 4 hours. At the end of 12 hours the ichthyol ointment is washed off and a fresh coat applied; if the iodine has not had sufficient effect its application is repeated once or more. Internal treatment may or may not be instituted as the result is the same in either case.

Silver Nitrate in the Treatment of Inflammations of the Upper Respiratory Tract.—Gleason (*Therapeutic Gazette*, March 15, 1901) states that fetor of the breath in atrophic rhinitis may be fairly well corrected by directing the patient to cleanse the nose once or twice a day with Dobell's solution and sniff into it every 3 or 4 hours a little powdered starch containing 1 or 2 grains of silver nitrate to the ounce. Stearate of zinc may be substituted for the starch with advantage. This acts as an irritant and provokes a watery discharge which washes away and prevents the accumulation of semi-inspissated and decomposing secretions. Because of their irritating effects, solutions of silver nitrate are rarely employed inside the nose. Organic salts of silver are as a rule unirritating to the nasal mucous membrane and may be employed as astringents and antiseptics in solutions of 20 to 30 grains to the ounce. As an astringent to the nasal mucous membrane, the extract of suprarenal capsule or its newly discovered alkaloid, adrenalin, is the most powerful known. The alkaloid is active in the strength of 1 to 10,000 parts of water, and in the strength of 1 to 5,000 furnishes the best local treatment for hay fever and nasal hydrorrhea. In these conditions it may be applied every 2 hours, either as a spray or by means of pledgets of absorbent cotton saturated with the solution and placed within the nose. Silver nitrate solution 60 grains to the ounce painted on the lateral walls of the pharynx 2 or 3 times a day is one of the best methods of aborting acute pharyngitis or tonsillitis. By using this strength the irritant effects, as compared to the weaker solutions, are scarcely perceptible. The posterior wall of the pharynx should then be painted with a 20 grain solution of protargol. This treatment, if repeated twice or thrice a day, for 2 or 3 days, will abort phlegmonous tonsillitis in a large proportion of cases. In follicular tonsillitis a 60 grain to the ounce solution of silver nitrate is equally effective in aborting the attack when applied to the tonsillar crypts after the removal of the pseudomembrane.

Thioocol in Catarrhs and Tuberculosis.—Goldman (*Canadian Journal of Medicine and Surgery*, January, 1901) has used thioocol with satisfactory results in 24 cases of chronic bronchial catarrh complicated with recurrent febrile attacks, severe cough-irritation and difficult expectoration. The fever subsided in all cases within 5 days, expectoration was greatly facilitated, cough-irritation lessened and respiration became free. Convalescence was well established in from 4 to 7 weeks. The drug was used in 10% syrupy solution, of which 1 dessert-spoonful was given to adults 3 times a day after meals; children received 1 teaspoonful thrice daily, with milk or coffee diluted with water. No disagreeable after-effects were produced by the drug. In every case the condition of the patient improved, and an increase of from 4½ to 10 pounds in weight was noted within a period of scarcely 2 months. Equally satisfactory results

were obtained with thioocol in 8 cases of acute and chronic pulmonary catarrhs in various stages; special care being directed by the writer to the unmistakable antiseptic action of the preparation, evidenced by the rapid reduction of fever. Constant reduction was observed after the first few doses of the solution; and in cases in which the fever had, with other remedies, always recurred, it disappeared completely after a 6 days' treatment with thioocol, and remained absent. The general symptoms of the disease were much relieved in a short time, and later physical examination showed evidence of complete cure. The syrupy thioocol solution was also employed in 9 cases of tuberculosis, three of these were young persons 14 to 23 years old, and 6 were patients ranging from 34 to 59 years of age. Among the latter there were 2 of the most severe form, with cavity formation and repeated hemoptysis. In the milder cases the remedy afforded complete cures in from 4 to 6 months; in moderately severe cases complete cures resulted in from 6 to 11 months. In 2 very severe cases in the third stage the night-sweats were lessened; the fever was reduced, the appetite improved, and the severe and annoying cough-irritation lessened to a certain extent by the administration of thioocol, which results are all that can be expected in such cases.

The Uses of Arsenic.—Rolleston (*Treatment*, April, 1901) writes, for the curious condition known as geographical tongue; arsenic may save us further trouble in knowing what to do. As an appetizer or pick-me-up, a dose before meals of a minim of Fowler's solution, with 10 grains of bicarbonate of sodium and infusion of gentian, is a useful and popular prescription. It is also recommended in small doses in other forms of dyspepsia, and especially in irritative dyspepsia and alcoholic vomiting. Curious as it may seem, it produces a good effect if given before meals. In the annoying form of morning diarrhea, in which a large evacuation is passed with but little warning half an hour or so after breakfast, a minim of Fowler's solution frequently acts like a charm. It has also been recommended for mucous colitis, that troublesome form of disease manifesting itself by the passage of casts of the bowel formed of coagulated mucus. When arsenic given by the mouth disagrees, it may be given hypodermically, and may be more conveniently injected into the substance of the muscles than into the subcutaneous tissues. Large doses can thus be often borne without any bad effects. Rolleston cites a case in which arsenate of sodium (1 in 500 of eucain B. solution) was given hypodermically for 271 days, 105 grains of the drug having been thus administered without toxic symptoms. The solution should be injected at blood-heat. The author has tried the new preparation known as sodium cacodylate, both by the mouth and hypodermically, and has never seen any toxic symptoms from its use. On the whole, he regards sodium cacodylate as less powerful, both for good and for evil, than ordinary arsenic.

Rules for Paracentesis in Acute Pleurisy.—J. Mitchell Bruce (*Treatment in Practical Medicine*, 1900) says there are 2 great clinical guides to the performance of paracentesis. First, lapse of time, or duration of the effusion, second, urgency. First, no considerable effusion should, under any circumstances, be kept for more than 3 weeks, unless signs of ebb have commenced and are progressive. Fourteen days would probably be a wiser limit, and, indeed, cases have done well which were not permitted to pass the tenth day, although there was no urgency and fever was still present. If flint be allowed to remain indefinitely in the chest, the lung and the chest wall both become steadily more impaired in function, and the difficulty of spontaneous absorption increases with thickening of the pleura. Only harm can result from leaving it longer. Second, urgency of symptoms demands immediate operation, however long or however short the duration of the case. Urgency is recognized by (a) universal dullness of the affected side. This evidence is otherwise described as disappearance of skodiac resonance at the apex. Some authorities do not wait for complete collapse of the lung but operate when the fluid signs reach the level of the second rib in front. (b) Signs of pleurisy on the opposite side. (c) Development of rales in the opposite lung. (d) Signs of bronchitis or of pneumonia. (e) Signs and

symptoms of serious embarrassment of the heart, whether by simple dislocation or by associated endopericarditis or by previous valvular disease, or adherent pericardium, pallor, faintness, coldness of extremities, palpitation, great anxiety, and failing pulse. (f) signs and symptoms of grave involvement of other organs, subdiaphragmatic abscess, acute or chronic Bright's disease with severe symptoms, etc. (g) Urgent symptoms of intrathoracic pressure, whatever their cause, persistent dyspnea, even in bed, with cough, frothy serous expectoration, lividity and sweats. (h) Signs and symptoms of increase of effusion after previous arrest or decline.

Treatment of Seasickness.—T. Lauder Brunton ("Lectures on the Action of Medicines") says if you put the head absolutely flat down it tends to prevent seasickness to a great extent. You can also greatly lessen the tendency to seasickness by giving drugs which will quiet the medullary center; bromid of potassium is exceedingly useful for this purpose. The way in which I use it is this: I take with me in a little paper parcel about $\frac{1}{2}$ a dram or a dram of bromid of potassium. When on board I go to the steward and say, "I want a bottle of soda-water and a large tumbler;" I throw in the bromid of potassium, shake it up and drink it. You need not be at all afraid of bromid of potassium, and you can keep up its action during a long voyage across the Atlantic; and you can push it so far that the patient becomes quite drowsy without doing him any harm whatever. Another drug that seems to be very useful is chloral. There is one point to be remembered about seasickness, and that is that there is often a good deal of bile in the stomach, and if you clear the bile out the patient is eased considerably. This is done by simply giving the patient a large draught of hot water; this he vomits, and thus the bile is well cleared out; afterward you can give your remedies with some chance of success. In using the bromid of potassium you must remember that it is a salt and just like chlorid of sodium, which is a powerful emetic, bromid is an emetic in itself if taken in too concentrated a form. If it is given at all, it must be given freely diluted.

Mercuriol in Syphilis.—Ayres (*Philadelphia Medical Journal*, 1900, No. 19) after a thorough and extensive test of mercuriol in the treatment of syphilis, finds (1) that it causes less disturbance of the gastrointestinal tract than any other preparation of mercury used internally; (2) it controls the skin manifestations and the pains much better than any other preparation, while on the mucous membrane eruptions it has as good an effect as any other, and has equally as good an effect upon the chancre. The author advises $\frac{1}{2}$ to 1 grain as a beginning dose. Salivation has been produced by 2 grains, while in other cases as much as 6 grains have been taken without any disagreeable effects.

Euphthalm.—This is derivation of amygdalic acid, a radical involving mydriatic properties. Chemically, it is closely related to B-eucin. It appears as a white crystalline powder, freely soluble in water. According to Cipriani (*Wiener Med. Woch.*, No. 46, 1900), it causes mydriasis by paralyzing the terminations of the oculomotor. Dilation of the pupil commences after 20 to 30 minutes, and disappears in from 3 to 6 hours. The corneal epithelium is affected by a 10% solution, but not by weaker solutions. It does not increase intraocular tension, disturb accommodation, nor produce disagreeable after-effects. Without being toxic or irritating it may be used in all cases requiring simple mydriasis. In iritis often better results are obtained from a 2% solution of euphthalm than from repeated installations of atropin. The author concludes that euphthalm in from 2 to 5% solutions is perfectly harmless; and that it meets the need of long continued mydriasis, which is so important for ophthalmoscopic examinations and observations.

Cocainization of the Spinal Cord.—At a recent meeting of the Academie de Médecine (*Medical Press and Circular*, April 3, 1901) Tuffler stated that out of 1300 cases of medullary anesthesia, there was only 1 fatal case, and that was a person who had disease of the heart. In 80% of the cases there was malaise nausea, vomiting and fever. Almost any operation could be done under cocain analgesia, but it was not suitable to children or hysteric subjects, nor for operations on the intra-

abdominal organs, as the nausea might trouble the surgeon. Guéniol stated that the injection of $\frac{1}{4}$ of a grain of cocain produced anesthesia in obstetrical cases; that instead of impeding uterine contractions it rather favored them, and that it rarely gave rise to any troublesome accident. Porak, on the other hand, confessed that in the 10 times he had practised the method he had failed 4 times. He considered that the injections were not necessary in normal cases, and should be reserved for obstetrical operations. Laborde said that the injection of the smallest quantity of cocain into the arachnoid cavity exposed the patient to the gravest dangers; one inherent to the local action of the poison, the other to its absorption. By reason of its absorption and diffusion in the cephalo r'achidian fluid, it affects the bulb, hence the troubles of respiration and circulation so frequently observed—the syncope (sometimes fatal), the vomiting and headache. Consequently this method of inducing anesthesia should be proscribed as dangerous, and should not be regarded as a substitute for chloroform and ether.

Treatment of Uterine Hemorrhage.—Davenport (*Annals of Gynecology and Pediatrics*, April, 1901) states that uterine hemorrhage occurring in the years immediately after puberty and before marriage, is usually due to some general cause, and local examination and treatment is usually unnecessary. Between the ages of 20 and 40, endometritis is the most common cause, with fibroids next, and when hemorrhage occurs during this period an examination should always be made. After 40, uterine hemorrhage is more serious, as cancer more often starts at this time, and local examination should be insisted upon in all cases of hemorrhage. The author considers ergot the drug par excellence for arresting hemorrhage where muscular contraction is indicated, as in uterine fibroids. Hydrastis has failed in these cases, but acted well in endometritis. In mild forms of menorrhagia the fluid extract of hydrastis, given in half to teaspoonful doses 3 or 4 times a day for 2 or 3 months, has materially checked the flow. After that length of time, it may be used for 7 to 10 days preceding the menstrual period. Capsules containing 5 grains of gallic acid, given 3 to 5 times a day, seem to act more promptly in arresting hemorrhage than other agents. In cases of severe hemorrhage the vagina should be firmly packed with cotton after being thoroughly freed from clots. This should be repeated as soon as blood shows through the cotton and if followed up continuously will usually control the flow in a short time. Some obstinate cases of metrorrhagia occur in young girls shortly after puberty, due to lack of exercise, overstudy and general debility, associated with anemia. Tonics—especially iron—are indicated, together with outdoor exercise, forced feeding and regular hours. Local treatment should be avoided, if possible. In uterine hemorrhage occurring late in life, local examination should always be made and suitable operative measures employed, if indicated. Curetment will often effect a cure if endometritis is the cause of the hemorrhage. In uterine fibroids the same procedure will temporarily check the hemorrhage, thus giving the patient time to recuperate and be in better condition for a more serious operation if this be deemed necessary.

Antidiphtheric Serum in Pneumonia.—Raynaud (*La Médecine Moderne*, March 27, 1901), reports the case of a woman, aged 67 years, attacked with severe double pneumonia which began with a violent chill followed by prolonged coma and associated with very marked congestive phenomena. Two injections of 20 cc. each of antidiphtheric serum were given in the morning and evening of the day on which the diagnosis was established. The day following the injections defervescence began, and the author considered her out of danger on the second day following the injections. The injection of 40 cc. of antidiphtheric serum in 1 day produced no untoward effect.

The Removal of Hardened Cerumen.—Savage (*Medicine*, February, 1901) uses hydrogen peroxid with excellent results to aid in the softening and removal of hardened wax from the ears. The peroxid is warmed and allowed to remain in the auditory canal for 5 or 10 minutes, which is usually sufficient to soften the hardest wax so that it can be readily removed with a stream of water. If the accumulation of wax is of recent origin it will be dissolved by the peroxid.

Rhus Glabra in Enuresis.—Cassidy (*Merek's Archives*, April, 1901), reports 3 cases of enuresis cured by the administration of rhus glabra in the following manner:

℞
Fluid extract of rhus glabra 6 drams
Syrup to make 2 ounces
A teaspoonful at bedtime.

The bowels were regulated by a laxative consisting of:

℞
Ferric citrate 100 grains
Syrup of calcium lactophosphate.
Aromatic syrup of easeara of each 2 ounces
A teaspoonful after the noon meal.

This treatment was continued every day for 4 months. The author emphasizes the necessity for continued and long treatment.

Benzin in Seborrhea.—Leftwich (*British Medical Journal*, No. 2,088), recommends benzin applied once in 5 days for the removal of dry seborrhal crusts. As the benzin leaves the hair and scalp very dry the following inunction should be used every morning:

℞
Bay rum of each 1½ ounces
Tincture of cantharides 2 drams
Cologne water 4 drams.

The effect of benzin on the baldness following seborrhea is very satisfactory. To conceal the odor, the author advises the addition of 10 minims of oil of geranium to each ounce of benzin. In mild cases of seborrhea the benzin is mixed with equal parts of alcohol.

Ichthyol in Erythema Nodosum.—Brownlie (*British Medical Journal*, January 5, 1901) reports a case of erythema nodosum which he treated by local applications of the following solution:

℞
Ichthyol 2 drams
Alcohol
Ether of each 3 drams.

Relief was immediate. The burning pain diminished after the first application, and disappeared entirely in 2 days, the temperature at the same time becoming normal. Salophen in 15-grain doses was used internally. In preparing this solution the alcohol and ether should first be mixed, then the ichthyol added. If the ichthyol is put into the bottle first, and then the other ingredients added, an insoluble sediment is formed.

Neuralgia.—

℞
Tincture of aconite
Tincture of colchicum seed
Tincture of eimicifuga
Tincture of belladonna of each 1 dram
Six drops every hour until relieved.

Bleeding and Tender Gums.—

℞
Gelatin 30 grains
Sodium chlorid 8 grains
Carbolic acid 2 grains
Beta-eucain hydrochlorate 8 grains
Cocain hydrochlorate 2 grains
Distilled water 3½ ounces
Use as a mouth wash.

Effect of Atropin on the Intestines.—According to the *Therapeutic Gazette*, April 15, 1901, Ostermaier has used hypodermic injections of atropin to overcome intestinal inactivity associated with hepatic or renal colic, movable kidney, and other conditions where laxatives have failed. He found that atropin produced copious fecal evacuation in from 12 to 36 hours, and that if it failed to act in this manner a very small dose of castor oil, or some other purgative, was efficacious. It is also suggested that atropin be used hypodermically to overcome the intestinal feebleness or inactivity following severe abdominal operations.

1.—See AMERICAN MEDICINE, Vol. I, No. 8.

2.—Montizambert, in notes on a mild form of smallpox, refers to "a very ordinary form of international courtesy"—the threatening of Canada with, and in some places her invasion by, smallpox from her neighbor, the United States. He points out that in the United States during the 3 months from December 28, 1900, to March 29, 1901, there occurred, according to the official reports, 11,964 cases of smallpox with but 157 deaths, a mortality-rate of but 1.31%. Commenting upon the mildness of the disease he suggests the designation *variola ambulans*. He believes that the disease is not chickenpox, as has been suggested, and that on account of the mildness of the disease and the vaccinations that its presence induces, a large proportion of the people of Canada should be rendered immune to the smallpox, and so for some years the Dominion may be safe from any severe epidemic of the disease. [A.O.J.K.]

3.—Copeman, in a note on the probable relationship of vaccinia to the inoculated form of smallpox in man, states that for some time past it has been borne in upon his mind more and more convincingly that it was not improbable that much of the cowpox, in the prevaccination era, was derived from the inoculated variety of smallpox rather than from the ordinary variety. Determining to investigate the subject, in default of inoculated smallpox in the human subject, he made trial of the monkey. Human smallpox lymph or pulp was first inoculated directly on calves with altogether negative results in every instance. But with monkeys success was invariably obtained, and, when after one or more passages through this animal, the contents of the local inoculation vesicles were employed for insertion on the calf, an effect was produced which, after one or more removes in that animal, was indistinguishable from typical vaccinia. Moreover, from the contents of the vesicle raised in this manner on the calf, children were vaccinated, with the result that such vaccination "took" normally. Details are promised in a subsequent communication. [A.O.J.K.]

4.—Barling reports a case of dilation of the first portion of the duodenum in a young man who for 4 years had suffered from pain and sickness after taking food; later frequent vomiting occurred, sometimes of food which had been eaten 24 or 36 hours before. The patient was greatly emaciated and physical examination showed dilation of the stomach. This was verified on operation. There was no pyloric obstruction but extensive adhesions between the pylorus and the parietal peritoneum and liver existed. A gastrojejunostomy was performed by Halsted's method. Death occurred on the fifth day. Necropsy revealed a general peritonitis, resulting in a tear in the duodenum, the first portion of which was enormously dilated and the walls very thin. The anastomosis was firmly united. [J.W.M.]

5.—Moynihan reports a case of complete rupture of the intestine for which a gastrojejunostomy was performed.

The patient was a boy of 6, who sustained an abdominal injury which was followed by collapse and evidence of fluid in the peritoneal cavity. On opening the abdomen free blood was found, and a complete rupture of the intestine at the duodeno-jejunal flexure. The duodenum was closed and an anastomosis between the jejunum and the anterior wall of the stomach performed by means of Murphy's button. The patient did well for 104 days when collapse occurred suddenly and death an hour later. Necropsy showed that the Murphy's button had perforated the lower portion of the duodenum. The case is of interest in that it shows that the function of the stomach is not interfered with by the passing into it of the bile and pancreatic juice, nor does it favor the idea that it causes regurgitant vomiting. [J.W.M.]

6.—Wilson reports a case of **gastric sarcoma**. For 10 years the patient had suffered from dyspepsia, and for 8 months before operation, from almost constant pain. There was much loss of weight, and a mass was palpable under the right rectus. Operation was performed, and the mass which involved the greater curvature of the stomach and the duodenum, removed with a portion of the pancreas and 3 enlarged glands. The duodenum and stomach were united by means of Allingham's bobbin, and the parietal wound closed. Complete recovery followed. Microscopic examination showed the growth to be sarcoma. [J.W.M.]

7.—Shettle reports a **successful operation for perforated gastric ulcer**. The patient was a girl of 17, who had suffered from anemia and had some dyspeptic symptoms for some time. The typical symptoms of gastric ulcer were wanting. After eating, she was seized with a sudden and severe pain in the epigastric region, followed by general abdominal pain and vomiting. The abdomen became distended and tender; temperature, 99.4°; pulse, 110. On operation the abdomen was found to contain a turbid fluid, and the intestines were glued together with recent lymph. A perforation was found in the anterior wall of the stomach, which was closed with silk sutures. After sponging the abdomen clean, the abdominal wound was closed with gauze wick drainage. An uninterrupted and complete recovery followed. [J.W.M.]

8.—Maitland reports a case of **resection of the cecum for tuberculous disease**. The patient was a man of 44, of tubercular tendency, who for 8 years suffered from occasional attacks of pain in the appendicular region where a mass could be distinctly outlined. These attacks became more frequent, and there was obstinate constipation and marked emaciation. Operation was performed, and extensive tuberculous disease involving the ileum, cecum and a portion of the ascending colon found and removed. The lower end of the colon was closed, and the end of the small intestine united to it by a lateral anastomosis. The subsequent progress of the case was uneventful. The case is of interest in that it had been diagnosed appendicitis, and also in the absence of diarrhea and hemorrhage, which are usual in intestinal ulceration. [J.W.M.]

9.—Stevens reports an instance of **spontaneous cure of a hydatid cyst of the liver**, and refers to the various explanations offered to account for such occurrence. The chief features of the case were that there were 2 cysts in different stages of degeneration; in the smaller one there was a quantity of laminated hydatid membrane, but in the other not a trace of this remained and, indeed, nothing to indicate its nature except a few hooklets that were found only after repeated examinations; both cysts were situated in the peripheral parts of the liver and projected considerably beyond its surface; there was no evidence of pus in the contents of either cyst; the capsules of the cysts were globular and tense and there were no signs of puckering or contraction; neither contained bile; there was a general fibrous condition of the liver. With regard to the cause of spontaneous cure in hydatid cyst, he mentions the following explanation: The natural death of the parasite; the toxic action of the bile from its entrance into the cavity of the cyst; absorption of the hydatid fluid; inordinate multiplication of the internal brood; and changes in the ectocyst. The last named is believed to be the correct explanation of the phenomenon. [A.O.J.K.]

10.—See editorial.

11.—Robertson in a note on **responsibility and crime**, cites several cases from his own experience that he believes fully bear out the statement that epileptics are not infrequently really unconscious of doing apparently purposive acts of a criminal nature, though such acts may appear to be done consciously with evil intent. [A.O.J.K.]

8. Medical Notes on the Life of Edward Gibbon, the Historian. WILLIAM H. HORROCKS.

1.—Edmunds, in his first lecture on the **pathology and diseases of the thyroid gland**, states that the gland consists of closed vesicles lined with epithelial cells, which secrete colloid. In addition to the thyroid proper he describes parathyroid glands which consist exclusively of cells, are developed earlier than the thyroid and number 4 for each thyroid lobe. Experiments show that the thyroid is intimately concerned in the nutrition of the central nervous system, and in the regulation of the cerebral circulation. The symptoms which follow the complete removal of the thyroid and parathyroid glands in the dog are: convulsive seizures, high temperature, hurried respiration, and later, paralysis of the hind legs followed by death on about the fifth day. This result is but slightly improved by the administration of thyroid extract or by grafting a thyroid lobe. On removal of 1 lobe the other undergoes hypertrophy. The removal of all but 2 parathyroid glands gives rise in time in rabbits to failing health, loss of hair and a myxedematous swelling of the lower portion of the face. [J.W.M.]

2.—Jones, in an address on the **importance of the teaching of insanity to the medical student in relation to the prevention of insanity**, points out that there is in Great Britain and Ireland 1 insane person to 300 of the population, or 5 certificates of insanity to each member of the medical profession. He strongly urges the teaching of insanity to medical students, not only because of the responsibility pertaining to certifying to insanity, but also because of intimate relations the medical man bears to the family in general, and because he should be the first to determine the forebodings of insanity and by instituting appropriate treatment in the early stages, cure, if possible, the condition. He emphasizes the importance of a proper study of physiologic chemistry in an effort to solve many of the problems connected with the etiology of insanity, and he suggests that every public asylum should become a school for postgraduate study of alienation. [A.O.J.K.]

3.—Morse, in discussing **general versus local anesthesia in special cases of abdominal surgery**, expresses his belief that the 2 causes of surgical shock are the anesthetic and the injury to nerve structures, and advocates the use of local anesthesia in cases of acute peritonitis, internal hemorrhage, and intestinal obstruction. He mentions 6 cases in which the method was employed with gratifying results. [J.W.M.]

4.—Worth discusses the **cause and treatment of convergent strabismus**. Binocular vision is the blending in the brain of the 2 impressions received from the eyes; this is called the fusion faculty. In a convergent squint in addition to the deformity, there is a defective development of the fusion faculty, usually a suppression of the vision of the deviating eye, with more or less amblyopia of it and a refractive error. In 74% observed by the writer the deviation appeared before the end of the fourth year. The essential cause of squint is defective development of the fusion faculty usually associated with

other developmental defects, as hypermetropia and congenital amblyopia. A sudden fright, a blow on the head, or the straining of whooping cough, may be exciting causes in a child with an abnormal fusion faculty. The treatment consists in correcting the refractive error and astigmatism by glasses, and to exercise the deviating eye so as to prevent the loss of its fixation power. This is done by instilling atropin in the straight eye, and by the use of the "amblyoscope." Should these methods fail after the age of 9 years the deformity should be corrected by tenotomy or advancement. [J.W.M.]

5.—Bronner discusses the causes, symptoms and treatment of diseases of the maxillary antrum. The diseases mentioned are acute and chronic empyema, both of which are usually of nasal origin. The latter is very rarely of dental origin. Chronic empyema, except in syphilitic or tubercular conditions, as a rule occasions but little discomfort. The most common symptoms are neuralgia, a blocking of one nostril, with a nasal discharge and an unpleasant odor in the nose. Cysts of the antrum are rare and mostly of dental origin. When large it causes distension of the cheek, and on pressure over it a crackling noise is heard. Carcinoma is the most common antral tumor. Empyema of the antrum may arise by direct extension of disease of the nasal mucosa, or by the blowing through the ostia of infective material. The treatment of chronic empyema consists in the establishment of free drainage by opening the antrum through the middle or lower meatus, the canine fossa or the alveolar process, preferably the latter. Care must be exercised to avoid puncturing the nose or orbit. A tube should be inserted and the cavity irrigated with a hot antiseptic solution, followed by the insufflation of aristol and boric acid. Should the discharge continue more than 5 weeks the presence of a polypus or disease of the bone may be suspected. Acute empyema usually gets well without surgical interference. [J.W.M.]

6.—Bellei, discussing mental fatigue in children, mentions methods of determining such fatigue, details the results of his personal experiments, and concludes: (1) No conclusion could be drawn as to the influence of the single subjects of teaching; (2) the first hour of lessons is a useful mental exercise, because the children are able during that time to overcome the state of inattention in which they were at the time of coming to school; (3) the morning lessons do not produce great mental fatigue; (4) the midday rest is of great use to the children because it does not destroy the good effects of the mental exercise in the morning and enables them to do work of better quality than that which they produce after a long rest, as one observes at the beginning of the morning lessons; and (5) though immediately after the midday rest the children are in the best conditions of mind, an hour or so of application in the afternoon is sufficient to produce such a mental fatigue as to lead at the end of the afternoon lesson to the worst work of the day. Therefore, if the morning application does not fatigue, it consumes the mental energy of the children in such a manner that they cannot undertake light work in the afternoon without falling into great mental fatigue. [A.O.J.K.]

7.—Wylley's reports 3 cases of myxedema of varied type. The first case was that of a woman, of 60, who exhibited myxedema, suffered with delusions and hallucinations, became maniacal, and died in a few weeks. The second case was that of a woman, of 45, whose manifestations of myxedema were insidious and poorly developed, but nevertheless correctly interpreted, and improved by the administration of thyroidin. The third case was that of a woman, of 53, whose manifestations resembled those of Bright's disease, and who presented evidences of brain disease, and atheroma of the aorta. She improved under the administration of thyroidin. [A.O.J.K.]

9. Cough Due to Reflex Irritation in the Upper Air Passages. FRANK S. MILBURY.

1.—In 1,048 autopsies, 10 cases of tuberculous pericarditis were found. These are reported and with other statistics show it is not a rare lesion. There may be an acute miliary eruption with serous or bloody extravasation mixed with fibrin; or the eruption may be accompanied by synechia; or caseous masses may be found; or there may be an acute inflammation without tubercular lesions by extension; or as one of the manifestations of terminal bacteremia. Fibrous tubercular pericarditis is the commonest. Infection may be hematogenous, lymphogenous, or by extension. In the first form the lesions are generally acute. The second form is more common and occurs from a reversal of the flow in the lymphatics, due to obstruction in the glands. There may be direct extension from the pleura, and direct extension from contiguous and adherent glands has been assumed, but it is probable infection is more often via the lymphatics even when the glands are united to the sac. Healing often occurs, but possibly only after the form due to the diffusion of sclerogenous toxins. Calcification is possible, but no authentic case is reported. With massive exudation there are symptoms of pressure on the heart. Synechia are less malignant than those of rheumatism and a differential diagnosis is possible. Cardiotuberculous cirrhosis of the liver is described, also the forms of secondary myocarditis with the beginning of general miliary tuberculosis by this route. Death generally results from associated tubercular disease. [H.M.]

2.—There are 2 types of tuberculosis of the fascia, the cold abscess type from acute infection, followed by cheesy degeneration, liquefaction and a detritus-filled cavity; and another in which the onset is more chronic, resulting in connective tissue overgrowth with or without disseminated cheesy foci. The latter form is often overlooked. In the majority of cases it is secondary to other tuberculous lesions. In the first type, scraping with a sharp spoon leaves a healthy, smooth surface. The second can be relieved only by knife and scissors, and all the new fibrous tissue must be removed to prevent nonrecurrence. The operation must often be most extensive, as it regularly involves intermuscular septa, sheaths of tendons and muscles, and passes easily to the joints. In the first type there has probably been rapid and simultaneous infection of wide fascial planes; in the second, infection has arisen at one point and spread gradually. Cuts of sections are presented. [H.M.]

3.—The literature of primary sarcoma of the pancreas is reviewed and a case reported with a description of the autopsy and microscopic examination. [H.M.]

5.—The operation should not be one of choice but necessity. Its history is briefly reviewed and the author's experimental operations on dogs described. A 2-inch longitudinal incision is made through the peritoneal coat of the bowel which is then loosened and retracted. A $\frac{3}{4}$ inch incision is next made through the remaining coats. The ureters are severed from the bladder and held together by a silk suture. A suture is passed into the intestine $\frac{1}{2}$ inch below the lower angle of the inner wound, brought out through the wound, passed through the cut ends of the ureters, then back through the incision, emerging near the point where it was first inserted. The ends are now tightly tied, thus drawing the ureters into position and firmly holding them. The incision in the muscularis and mucosa is sutured transversely, and that in the peritoneum longitudinally. By this means sutures which have entered the bowel are covered by peritoneum and risk of infection obviated. From the results of the experiments which are recorded, it is concluded that the technic is satisfactory, that simultaneous bilateral implantation is extremely dangerous, that unilateral implantation is justifiable when other means fail.

notwithstanding the inflammatory reaction invariably present; that the rectum will tolerate the presence of urine. No strictures resulted but might possibly have done so after months or years. [H.M.]

6.—It consists in hypertrophies on usually both sides of the vomer which deflect the intruding, dustladen, dry, cold air against the Eustachian eminences resulting in perpetual irritation. When ear disease exists these, however small, should be removed. Afterwards, not before, take off enough of the posterior turbinal hypertrophy to relieve stenosis and prevent reproduction of vomerine growths, but not enough to expose the Eustachian eminence to direct blasts. This factor has been present in 25% of the writer's ear cases. [H.M.]

7.—Skiagraphs show the line of fracture and healing, and statistics revealing the unfavorable results of the usual treatment are given together with the mechanical reasons for the infrequency of the accident. Other treatment proving unsatisfactory the patient was anesthetized, the opening in the soft parts enlarged, holes drilled in both fragments which were united by means of a common wood screw $1\frac{1}{2}$ inches long with a ferule slipped over it to keep the head outside of the soft parts. Flexion to more than a right angle, extension almost to normal, with prospects of still further improvement are the result. [H.M.]

8.—The general practitioner should be able to diagnose and treat these joint diseases. The proximate cause is often a slight injury, causing a destructive localization of germs, and therefore the history is important in making a diagnosis. The usual symptoms are enumerated. Fixation is best obtained by molded splints of wood—plastic material, and protection by a high shoe combined with the use of crutches or a Thomas knee-splint. Gradual extension when the kneejoint is flexed can be accomplished by means of newly molded splints every 10 days, and in the case of the hip by this combined with traction by weight and pulley. The technic of applying the splints is described and constitutional treatment considered. [H.M.]

9.—Milbury believes all coughs are reflex, and quotes various authorities. The majority are caused by some abnormality of nose, throat or ear. The various reflex causes in these localities are enumerated with special consideration of those in the glossoepiglottic spaces. [H.M.]

Boston Medical and Surgical Journal.

May 23, 1901. [Vol. CXLIV, No. 21.]

1. Municipal Care of the Consumptive Poor. S. A. KNOPF.
2. Echinococcus of Liver with Perforation Into the Lungs and Bronchi. WILLIAM F. GAY.

1.—In connection with the movement for the establishment of a city sanatorium for poor consumptives in Boston, Knopf shows by statistics the much higher mortality of the disease in that class and states that in the early stages there are from 60% to 80% of chances of cure. Death is most frequent between 17 and 35, and the economic loss is pointed out. The essentials for treatment are plenty of pure air, sunshine, food and medical supervision. Tuberculosis is a costly disease, and everything that is needed is lacking in the tenements of the poor. By means of sanatoriums, not only are breadwinners saved and further spread of the disease limited, but the actual cost to the taxpayer is \$4.00 less per week per capita than for the care of the incurable consumptive in the general hospital, the length of residence averaging the same, and in the latter it requires more care to prevent harm to fellow-patients than can be given. In the sanatorium the patient is taught to be religiously clean and careful, how not to take cold, the dangers of intemperance, etc., and he goes out as an educator to the community. In German villages where these have been established, voluntary imitation of the clean habits of the institution has reduced mortality from tuberculosis to one-third. In connection with the city institution should be a dispensary and reception hospital for the selection of cases, and a seaside sanatorium for scrofulous children, and a commission for examination of candidates, medically and pecuniarily, for reporting on the sanitary condition of dwellings and distributing literature and information on the prophylaxis of the disease. [H.M.]

2.—Gay reports a case of perforation into the bronchi of an echinococcus cyst of the liver. The patient was a man of 25, whose health was poor until his fourteenth year, then fair until his twenty-third, since which time he suffered from attacks of hemoptysis. When he came under observation he presented evidence of acute pneumonia superimposed upon a preexistent pulmonary tuberculosis. The pneumonia ran the usual course. At this time an enlargement of the liver was observed, and after a short period of improvement hemoptysis recurred; the liver continued to enlarge uniformly; there was tympanitis and constipation with clay-colored and fetid stools. Temperature was 101°; pulse 120; respirations 32. These symptoms continued for several days, when he vomited a quantity of orange-colored matter, and continued to expectorate the same copiously for a few days. The temperature declined, the breathing improved, the liver decreased in size and general improvement followed. By examination of a piece of membrane found in the sputum the diagnosis of hydatid of the liver with rupture into the lungs and bronchi was made. Entire cysts of varying size were expectorated for some time. The diagnosis previous to the rupture of the cysts was obscured by the intercurrent disease to which the patient will succumb. [J.W.M.]

Medical Record.

May 25, 1901. [Vol. 59, No. 21.]

1. Orchitis and Epididymitis in Typhoid Fever. FRANCIS P. KINNICUTT.
2. The Operative Treatment of Umbilical Hernia in Adults. JOSEPH A. BLAKE.
3. The Borderland of Insanity: Where and What Is It? HENRY WALDO COE.
4. Recurrent Oculomotor Palsy: Report of a Case, with Remarks. WILLIAM M. LESZYNSKI.

1.—Kinnicutt discusses epididymitis and orchitis as sequels of typhoid fever and reports 2 cases each of which followed a mild typhoid infection. The infection reaches the point of origin by the blood, or from the urethra by way of the vas deferens. The following conclusions are deduced from a study of cases reported: (1) Epididymitis or orchitis occurring in the course or during the convalescence of typhoid fever is a rare lesion and is of typhoidal origin. (2) Only very exceptionally is it due to secondary microbial infection. (3) It develops at a late period in the disease or during convalescence. (4) The lesion, although as a rule unilateral, may be bilateral; and involves either the epididymis or testicle or both, and not infrequently the cord. (5) Effusion into the tunica vaginalis is rare. (6) Termination most often is by resolution. (7) Suppuration occurs in 25% of all cases. (8) Localized necrosis and extrusion of testicular tissue is not uncommon. (9) Exceptionally there is destruction of the entire testicular structures. (10) Atrophy of the testicle occurs, but is a rare sequence. (11) The lesion gives rise to little constitutional disturbance. (12) Death as a direct result of the lesion has not been noted. [J.W.M.]

2.—Blake in discussing the operative treatment of umbilical hernia in adults, states that this is the most common form of hernia in women over 40 years of age. They are divided into those in which separation of the recti does and does not occur, the former presenting the greatest difficulty. The symptoms to which a large hernia give rise are pain and gastric disturbance. Ulceration of the overlying skin, obstruction, and strangulation may occur as complications. When the hernia is small and an effective truss can be worn operation is not indicated. According to some operators recurrence occurs in about 30% of large and 15% of moderate sized hernias. The method of operation which the writer considers most applicable to those cases in which stretching of the linea alba and separation of the recti exists, consists in dividing the linea alba in the median line above and below the sac, excising the ring if necessary, and divesting the front of one rectus of fat it is overlapped by the other, the overlapping being greatest at the hernial site. Both edges are secured by means of mattress sutures of chromicized catgut. [J.W.M.]

3.—The most reasonable gauge of mental health is in a comparison of past and present. Insomnia is the most common prodrome of insanity. With borderland insomnia, restlessness is generally present, with either mental distress or superlative pleasure. A change of temperament is always suggestive. Anger is another symptom. It is an evidence of nerve-cell instability, and like epilepsy it tends to its own repetition. Constantly dwelling upon one theme, especially if the problem be intricate, will lead to insanity. Imperative ideas are commoner than is ordinarily believed, from the fact that the subject is generally sane and uses concealment to avoid suspicion of insanity. These are based on loss of will power due to defect in residual nervous energy in the cortical central cells. Every user of opium and cocain and of alcohol in excess is on the borderland. Masturbation leads oftener to insanity in women than in men, owing to the more depressing mental effect growing out of different ethical standards. Prolonged excessive sexual indulgences, no matter how normally accomplished, sends multitudes into the borderland. The erroneous belief, in and out of the profession, that sexual expenditure is necessary for good health, has much to do with sexual excesses. It is doubtful if one such case ever existed. The treatment must be hygienic, dietetic and reconstructive. Work must be given up or changed, complacency encouraged, and new currents of thought suggested. Under these methods the result may be full mental vigor. [H.M.]

4.—The cardinal symptoms are unilateral headache, limitation of paralysis to the same side, the involvement of the same nerve in all attacks and intervals of complete freedom. Some cases have resulted in complete recovery, others in permanent paralysis. There is great diversity of opinion as to causation. Two cases have been studied post mortem, showing tumor at the base, which probably pressed on the nerve-trunk during the increased vascularity accompanying the attacks of migraine. [H.M.]

1. The Pathology and Bacteriology of Ureterointestinal Anastomosis. F. ROBERT ZEIT.
2. Air, a Factor in Digestion. EDWIN W. MOORE.
3. The Proper Administration of the Schott Exercises. VICTOR NEESEN.
4. The Use of the Suprarenal Capsule in Diseases of the Heart. Second Paper, with a Report of Cases. SAMUEL FLOERSHEIM.
5. Relations of Vascular Disease to Heart Disease. WILLIAM H. THOMSON.

1.—Zeit, in his second paper on the pathology and bacteriology of ureterointestinal anastomosis, sums up his investigations as follows: (1) Ureteral implantation into the rectum is always followed by ascending infection. The resulting pyelonephritis is caused by *Bacillus coli communis*; (2) The primary mortality is very large, 84%, no matter which operation is done; (3) of 120 dogs operated upon, 90% died of peritonitis due to leakage of urine or general sepsis and pyelonephritis during the first 10 days; (4) dogs living a longer time died of pyelonephrosis and pyemia; (5) dogs which had fully recovered from the operation and the resulting pyelonephritis, and were, to all appearances, in perfect health and vigor again, all had granular contracted kidneys, due to induration and cicatrization of diseased areas. The rectum acts as a fair substitute for the bladder in such cases; (6) dogs which had fully recovered after unilateral implantation were living by the other kidney. The kidney of the side operated on was atrophic and granular, the result of an early pyelonephritis. The functionally active kidney was 2 to 8 times the size of the atrophic one; (7) a review of the literature on ureterointestinal anastomosis in man shows that no better results can be expected in man than in animal experiments; (8) the ureters are frequently dilated, but show very little or no disease, no matter how extensive a pyelitis or pyelonephritis is present; (9) the bladder is always infected by way of the urethra, whether it is emptied at the time of operation or not. A purulent cystitis was found in every case, caused by *Staphylococcus albus* and *Bacillus coli communis*; (10) artificial immunity to infection by the so-called colon

group of bacteria is the only hope of making ureterointestinal anastomosis a feasible operation. [H.H.C.]

2.—Moore, in his article on air as a factor in digestion, states that the oxygenation of the venous blood in the lungs, which contains the food elements gathered up by the lacteals and veins, is a most important factor in digestion and should be considered as such. These food elements are not absorbed by the body tissues until exposed to the air in the lungs, and hence the importance of the atmosphere as a digestive factor. [H.H.C.]

3.—For the proper administration of the Schott exercises Neesen gives the following rules: (1) Each movement is to be performed slowly and evenly, without jerking or trembling. (2) Each movement is to be followed by an interval of rest (sitting); (3) Arm movements should alternate with leg or body movements. (4) No part of the body is to be held so as to compress the bloodvessels or interfere with the breathing. (5) The patient should be instructed to breathe naturally and regularly. (6) The patient should be watched closely for (a) irregular breathing, (b) straining, (c) trembling, (d) flushing or pallor of face and lips, (e) dilation of nostrils, (f) yawning, and (g) drawing down of the corners of the mouth. The primary object of the exercises is, not to develop the muscles, but (a) to relieve the overburdened heart by (1) drawing the blood away from it into the extremities and muscular structures; (2) accelerating the circulation (contraction of the muscles upon the bloodvessels); and (3) soothing the nervous mechanism of the heart by acting upon the motor nerves through the slow movements of the muscles; and (b) to strengthen the heart muscle. Contraindications to the exercises are advanced atheroma, aneurysm, and acute inflammatory carditis. [H.H.C.]

4.—Floersheim, in his second paper on the use of suprarenal capsule in diseases of the heart, states that after the administration of the suprarenal powder, the following was observed: (1) A weak and irregular-acting heart became stronger and more regular; (2) a dilated heart was contracted; (3) a diffused apex beat became localized; (4) a diffused, loud, and rough mitral regurgitant murmur became localized, smoother, and lessened in intensity, while in some cases the murmur disappeared; (5) a murmur which, owing to the extreme weakness of the heart, could scarcely be heard, became more distinct, thus aiding in the diagnosis; (6) the normal cardiac sounds, when indistinct, became clearer and more easily distinguished; (7) in some cases a rapid pulse became less rapid; in other cases a slow pulse became faster; (8) patients who were very weak, with organic heart disease, were improved; (9) no effect was observed in organic heart disease when the pulse was strong and regular. [H.H.C.]

5.—In his article on the relation of vascular disease to heart disease, Thomson states that "the development of atheroma in the pulmonary artery in mitral stenosis, as well as in the portal system in cirrhosis of the liver, shows that the primary seat of the obstruction is beyond the vessels and in the area of the capillaries. This is further demonstrated by the fact that the most widely diffused and most serious sclerotic changes are to be found in the arterioles, just those vessels which have relatively the largest supply of the actively living muscular tissue whose one function is to produce movement. To find them most affected has but one meaning, and that is, that they have had the most work to do in the struggle against an obstruction beyond them. It cannot be too clearly recognized that the arteries are but conduits to the capillary area. That no appreciable processes take place in them, but that it is in the capillary area that everything goes on. It is there that all the nutritive and all the chemical changes take place which make up the processes of life. According as the interchange is natural between the extracapillary and intracapillary fluids will the physical conditions of the coming current of blood in the arteries be normal. But let chemical or vital changes occur in the capillary area that interfere with the normal interchange through the walls of the capillaries, and the arterial flow must be correspondingly affected. The arteries become very palpable to touch because overful with blood from obstruction further on, and the pulse rises in tension. Hypertrophy of the muscular coat of the arterioles follows, on account of increased work; but

hypertrophy in a muscle is always at the expense of its reserve stock of vitality. All hypertrophied muscles degenerate sooner than normal muscles, and arterioles illustrate this law very fully. We are thus brought to the remote, or ultimate, causes of this leading form of vascular disease, and they may be conveniently summed up under the term of *tissue poisons*. The coexistence of vascular disease may alter the conditions of the problems of heart disease, whether in a pathologic, a clinical, or a therapeutic sense. For while it is true that primary disorders of the heart affect the circulation in most patients after 40, we often find the converse equally true—that primary disorders of the circulation affect the heart, and that physical examination of the arteries may afford as important indications of the nature of cardiac disease as physical examination of the heart itself; and the same may be said of signs observable in the venous, lymphatic, and capillary systems." [H.H.C.]

1. Some Notes on Medical Diagnosis. WILLIAM N. BERKELEY.
2. The Mineral Waters of Mt. Clemens, Michigan, as Viewed and Compared with Those of European Watering Places. RICHARD LEUSCHNER.
3. The Treatment of Chronic Purulent Otitis Media. JAMES F. MCKERNON.
4. Tuberculosis of the Iris. WILLIAM F. MITTENDORF.

1.—Under the practical methods of diagnosis to be employed are considered the use of instrumental and chemical aids and the general mode of procedure at the bedside. The laryngeal mirror, ear speculum and ophthalmoscope should be familiarly in the hands of every general practitioner. About the stethoscope there is no dispute. The phonendoscope deserves more attention. The pleximeter sometimes gives more accurate results than the finger. The sphygmomanometer and the sphygmograph are more valuable scientifically than clinically. Every physician should be familiar with the microscope. Under bedside procedure are considered in detail history taking, general inspection, inspection of head, chest and abdomen; palpation, percussion and auscultation. Having ascertained the facts, the diagnosis is to be made according to the "Law of Parsimony." Causes are not to be multiplied beyond necessity, yet the rule must not be too rigidly interpreted. [H.M.]

2.—The careful physical examination and strict regimen of patients at the various famous springs of Europe, is described in a general way and contrasted with the lack of it at many American resorts. The mineral ingredients of the various wells of Mt. Clemens are given and the high percentage noted, special attention being called to the contained sulphur, iodine and bromine. The subject of absorption through the skin by means of baths is discussed. That such absorption takes place, especially with highly concentrated mineral waters, is confirmed at the latter resort by the fact that a salty taste in the mouth and traces of bromine and iodine in the urine invariably follow bathing with massage. [H.M.]

3.—McKernon says in treating a case of chronic purulent otitis media we should have 3 objects in view, the cure of the otorrhea, the improvement of the hearing, and the relief of the distressing subjective symptoms. Cleanliness is a prime object in treating the discharge. This is accomplished by first mopping the canal with sterilized cotton and then applying some antiseptic solution. But if the discharge be profuse syringing must be resorted to, and in doing this care should be used to see that the canal is made straight by drawing the auricle upward, backward and a little outward. But little force should be used in irrigating, and this procedure should be practised only sufficiently often to keep the canal clean, as more than this irritates the diseased tissue. If irrigation produces disagreeable symptoms, as vertigo, nausea, pain, etc., it must be discontinued and the cleansing accomplished by means of mopping with cotton. Every case should be examined early for abnormal condition of the upper respiratory tract. In case there is a large amount of granulation tissue in the diseased ear it must be removed. The best agents for this are silver nitrate, chromic acid and the curet. If, after the above outlined treat-

ment has been carried out for some 2 weeks, there is still a discharge and tendency to the formation of granulation tissue then the strong probability is that there is dead bone present. If in any case drainage is insufficient a free incision should be made for that purpose. To improve the hearing after the discharge is under control divide the adhesions. This will give relief in a very large majority of cases. Inflation and vaporizing the middle ear will tend to prevent adhesions. To relieve the distressing after-symptoms, such as tinnitus, give potassium iodid, beginning with 5 grain doses, and ascending until relief is secured. [A.B.C.]

4.—Tuberculosis of the iris is sometimes primary, but usually secondary. There are solitary and multiple forms, and the latter may be either acute or chronic. But one eye is generally affected. When following tubercular disease of the general system it takes an acute form, characterized by one or more grayish nodules becoming later larger and reddish-brown, with broken down matter in the anterior chamber. This may cause ulceration of the cornea, or the whole eyeball and orbit may be involved, or after perforation of the cornea, shrinking may occur. A less violent form may be associated with the early stages of pulmonary tuberculosis. There may be multiple deposits, yellowish, and rarely coalescing. Synechia may form, but some absorption takes place after the use of atropin and general treatment. A more serious form is a single deposit at the bottom of the anterior chamber, involving the ciliary body with adhesions to the lense and injury to the cornea. Even this may yield to treatment. Creosote and cod-liver oil or Koch's tuberculin are indicated, also atropin, hot compresses, leeches in acute or rapidly progressing cases, and morphin for great pain. Iridectomy may be done if the deposit is confined to a small area. If there is debris in the anterior chamber, and the disease does not respond to medical treatment, it is safer to enucleate. [H.M.]

4. Two Cases of Lobar Pneumonia Following Ether Anesthesia, with Unusual Course. W. S. SCHLEY.

1.—See AMERICAN MEDICINE, Vol. I, No. 8, page 335.

2.—See AMERICAN MEDICINE, Vol. 1, No. 7, page 292.

3.—Pearce, in his paper on trauma as an exciting cause of paralysis agitans, gives his clinical experience with the disease and cites several especially marked cases, the majority of which he believes are the direct result of concussion. As a treatment, he considers nerve stretching to be the most rational procedure. [H.H.C.]

4.—Schley cites 2 cases of of lobar pneumonia following ether anesthesia, developing respectively on the first and third days after operation. In each case only the right lower lobe was involved. Sixteen hours after the initial rise of temperature 1 patient was given 25 grains and the other 20 grains of calomel, whereupon the temperature immediately began to fall and resolution commenced within 2 days. They were the only cases of pneumonia following anesthesia occurring in his experience of several thousand cases covering a period of about 24 years. [H.H.C.]

1. The Pathology and Theory of Migraine. M. SHILE.
2. Three Cases of Cataract After a Flash of Lightning. JOSEF PREINDLSBERGER.
3. Primitive Organs of Vision. THEO. BEER.

1.—As the result of a personal observation, Shile has come to the conclusion that the aura and other focal symptoms

of migraine and the pain are crossed; and that the pain cannot be considered a localizing symptom. The symptoms, exclusive of the pain, are due to a nutritional disturbance of certain cell territories of the cortex, and are probably connected with a special predisposition on the part of the affected cells. The subjective symptoms are referable to the sense of sight. When the disturbances are in parts of the brain that produce no localizing symptoms, such as the prefrontal lobes, the only symptom is pain. The hemieric cell disturbances may be located in several parts of the cerebral cortex at the same time. The exciting cause of the migraine is probably a toxic substance; and Sihle refers to the observations of Ratchford on the presence of paraxanthin in the urine in migraine. The pain in migraine, the author believes, is due to the irritation of the pia overlying the affected parts of the cortex; hence, it is on the side opposite to that of the other symptoms. As the hemieric foci may be located in various parts of the brain, they may also manifest themselves in those areas in which vasomotor centers are situated, and give rise to the vasomotor spasm or paralysis that at times precedes migraine. There is some relation between **epilepsy and migraine**; but in epilepsy aura and spasm are on the same side, while in migraine aura and pain are crossed. The uric acid diathesis, tuberculosis, anemia, and other chronic nutritional disturbances, are the foundation upon which the hemieric tendency develops. [D.R.]

2.—Preindlsberger reports 3 cases of **cataract** in patients of 11, 13 and 21 years respectively, due to the effects of lighting. [H.H.C.]

1. Etiologic-bacteriologic Diagnosis. EDMUND NEUSSER.
2. The Question of a Special Excitant of Disease in the So-called Botryomycosis of Man. R. V. BARACZ.
3. Intestinal Hemorrhage Following Reposition of Incarcerated Hernia. JOS. PREINDLSBERGER.

1.—An interesting address, in which Neusser, whose mastery of bacteriologic data, so far as they illumine clinical medicine, is phenomenal, shows the important **debt that clinical medicine owes to bacteriology**, and how necessary a knowledge of the latter is in making correct diagnoses of obscure conditions. As an illustration the following case may be quoted: A woman of 50 entered the hospital with obstructive jaundice. Three days later there was a chill, with a sudden rise of temperature, an increase of the fibrin in the blood, marked polynuclear leukocytosis, and a diminution of the chlorids in the urine. Physical examination showed the absence of pneumonia; but 2 days afterward a diastolic murmur developed at the aortic cartilage. Subsequently symptoms of meningitis manifested themselves and the patient died in coma. As the blood picture corresponded to that of pneumonia, the author concluded that the pneumococcus was responsible for the objective findings at the aortic cartilage and the meningeal symptoms, and made a diagnosis of cholelithiasis, cholangitis, pneumococcal endocarditis and meningitis. The autopsy and the bacteriologic examination completely corroborated this diagnosis. Another case is cited, in which, however, an erroneous diagnosis was made through overlooking one minute point. The patient presented, together with pulmonary and pleural symptoms, and splenic tumor, choroidal nodules surrounded by a pigmented arcola. A diagnosis of military tuberculosis was made, but the autopsy showed a **miliary actinomycosis**, originating in the vermiform appendix. Pigmentation does not occur in choroidal tubercles; its existence in the case should, the author thinks, have made him suspicious of the diagnosis. [D.R.]

2.—Poncet and Der claim to have found in certain small, pediculated tumors of the fingers and hands, a peculiar bacterium resembling the staphylococcus, which they consider as identical with the **botryomyces** or **botryococcus**, found by Bollinger in the so-called castration fungus of horses. In a tumor of this kind observed by Baracz, no botryococcus was found; instead, streptococci and staphylococci were present. The histologic picture was that of a myxomatous fibroid. [D.R.]

3.—Preindlsberger reports 2 cases of **intestinal hemorrhage** following reposition of incarcerated hernia, and discusses the possible causal factors involved. [H.H.C.]

April 11, 1901. [14 Jahrg., No. 15.]

1. The Toxic Action of Alcohol in Certain Nervous and Mental Diseases. WAGNER V. JAUREGG.
2. Alcohol and Mental Aberration. JOSEF A. HIRSCHL.
3. The Local Application of Carbonic Acid in Menstrual Disturbance. GUSTAV LOIMANN.

1.—**Acute alcoholic intoxication** is by no means clearly understood. It is not known whether the state of drunkenness is due to the direct action of alcohol on the brain, or to an indirect action upon the bloodvessels or upon the blood. Regarding **delirium tremens**, von Jauregg is of the opinion that it is not due to the alcohol, but to a poison developed in the body under the influence of alcohol—an **alcohologenic poison**. To this poison, alcohol is, in reality, an antidote; hence, delirium tremens, according to the author, develops chiefly after the sudden withdrawal of alcohol, and is, therefore, an abstinence symptom. On this basis the author employs alcohol in the treatment of grave cases of delirium tremens. There is some analogy between delirium tremens and infectious diseases; thus there is a leukocytosis as well as a disturbance in the relation of the leukocytic elements; likewise, a transient albuminuria and alimentary glycosuria. Alcoholic multiple neuritis and the psychosis accompanying it (Korsakow's psychosis) are likewise due to the hypothetic poison. Gastrointestinal intoxication is a factor in the production of the multiple neuritis. The hepatic changes resulting from alcoholic abuse may also be due to the action of poisons which are produced by the alcohol in the gastrointestinal tract, and which then pass through the liver. [D.R.]

2.—Hirschl gives some statistics of the frequency of **alcoholism** in patients admitted to Krafft-Ebing's psychiatric clinic. Thirty percent of the men, and 4.4% of the women were alcoholics. Among **epileptics** and **paralytic demented**, 18.9% had used alcohol. Of 3,579 alcoholic patients, 28.1% became insane. [D.R.]

3.—The **therapeutic value of carbonic acid** was known only in comparatively recent times—the latter half of the eighteenth century. Its existence in many mineral springs led to its use at one time for a long catalogue of diseases in many of which it failed and fell into disuse. But Loimann considers it very effective for many **menstrual anomalies**. Baths are frequently recommended, but he thinks its local application as a douche is much more effectual and he has devised an instrument by which the pressure of the gas stream can be known from the sound produced and regulated by a valve in the tube. A vaginal gas douche causes a reddening of the portio and an increase of the secretions so that after its use the menses often occur earlier and are more copious. Hence its therapeutic value in cases of oligomenorrhea or amenorrhea in cases not due to anatomic changes but to nervous or metabolic disturbances, also in cases of failing or spare menses from obesity. But the carbonic acid douche should never be used when there is a possibility of pregnancy as it tends to loosen the placenta and produce abortion. [W.K.]

1. Renal Calculi, Especially Their Gastrointestinal Phenomena. M. STERNBERG.
2. Otitic Encephalic Abscess Cured by Operation. OTTO PIFFL.

1.—Sternberg, of Vienna, reports several cases of **nephrolithiasis** which presented prominent gastrointestinal symptoms. He summarizes his observations as follows: Besides the ordinary symptoms of renal colic, there were present gastric and intestinal disturbances which consisted principally of painful constipation and meteorism. These attacks were best treated with opium. Such attacks were accompanied by increased arterial tension. There are cases of renal colic in which the gastrointestinal symptoms assume such a prominent role that the clinical picture changes sufficiently to warrant the term "gastrointestinal form of renal colic." Of diagnostic importance in such cases are the facts that, first, the involved ureter may give rise to pain on pressure in the region of Mac Burney's point (simulating appendicitis), and second, changes in the urine are often entirely lacking for a considerable length of time. An important diagnostic aid consists in the fact that

the raising of the lower portion of the trunk (Trendelenburg's position) results in an easing of the pain. [H.H.C.]

1. Pernicious Anemia. TH. RUMPF.
2. New Experimental Investigations Into the Curative Action of Anthrax Serums. A. SCHLAVO.
3. Why Does Cerebral Syphilis Appear Almost Incurable? O. ZIEMSEN.
4. Resection of the Lower Turbinate Bone. J. FEIN.
5. Nervous Tachypnea. RECKZEH.

1.—After careful chemical analysis of the blood and important organs in a number of cases of pernicious anemia, Rumpf arrives at the following facts: (1) The abnormally great quantity of water contained in the blood; (2) the small quantity of solid substances; (3) the large quantity of chlorin; (4) the poverty of the blood and tissues with respect to potassium, iron and (5) fat. Acting upon these data, Rumpf recommends a "potassium therapy," basing his advice on the theory that the high percentage of NaCl present in the blood and tissues is in itself injurious and has a detrimental effect on the formation and preservation of the blood, while the lack of potassium in organic combination also presents an obstacle to hematogenesis. Again, free exhibition of potassium in some form results in its combination with the excessive quantity of chlorin (in the NaCl) present, thus not only freeing the body from superfluous NaCl, but also feeding the "potassium-hungry" tissues with the very element which they need. [H.H.C.]

3.—In discussing the apparent difficulty encountered in curing syphilitic lesions of the central nervous system, Ziemssen, of Wiesbaden, states that the real reasons are: (1) The fear which many physicians seem to have that the routine mercurial treatment itself may give rise to neuritic affections; (2) The relative misproportion between the often mild initial symptoms of the disease and the grave cerebral complications following; (3) the difficulties in the way of early diagnosis; (4) the course of the cure itself. A general opinion seems to prevail that lesions of the central nervous system not responding to a 3 to 4 weeks' specific treatment must be due to some other cause than syphilis. As to therapy, Ziemssen insists that thorough, energetic and long-continued mixed treatment carried to the furthest extent compatible with safety is the only condition under which good and permanent results may be looked for. This procedure applies to all conditions, no matter how apparently insignificant, and should be continued long after every vestige of constitutional symptoms has disappeared. [H.H.C.]

Deutsche medicinische Wochenschrift.

April 11, 1901. [27. Jahrg. No. 15.]

1. Diffuse Peritonitis with Appendicitis. E. SONNENBURG.
2. Rare Extraperitoneal Stratified Cystic Abdominal Tumors. C. HELBING.
3. Two Cases of Urogenital Colibacillosis. W. KARO.
4. Asepsis in Cervical Operations. O. V. BÜNGNER.
5. The Casuistics of Total Extirpation of the Stomach (esophagoenterostomy). A. V. BARDELEBEN.

1.—The difficulties attending a correct diagnosis of the different varieties of peritonitis following appendicitis are discussed by Sonnenburg, who reaches the conclusion that, (1) differential recognition of the various forms of diffuse peritonitis due to bacterial action is almost impossible; (2) the bacterial forms are scarcely to be differentiated from the so-called "chemical" forms; (3) the indications for operative treatment in cases of beginning peritonitis are not clearly defined from those in cases of appendicitis during the attack; (4) often the diagnosis is made but very little easier by an explorative abdominal incision. Sonnenburg does not believe in irrigation of the abdominal cavity except in extreme cases, but prefers an extensive tamponade of the peritoneal cavity from a lateral incision. In support of this method of treatment he inserts a table of statistics showing the mortality percentage in cases operated upon by him. [H.H.C.]

2.—Helbing reports 3 rare cases of extraperitoneal cystic tumors of doubtful classification and obscure origin. [H.H.C.]

3.—After reference to the nonspecific infections of the genitourinary tract with particular mention of the forms of orchitis and epididymitis reported by various authors as due to the presence of staphylococci, Bacillus pyocyaneus, Talamon-Fränkel's pneumococcus, Friedländer's diplobacilli, Diplococcus lanceolatus of Fränkel-Weichselbaum, etc., Karo reports 2 cases of orchitis and epididymitis in which Bacillus coli was the exciting cause. In both cases a history of recent enteritis was elicited. In the first case unilateral castration and internal treatment with urotropin resulted in complete cure, while in the second, puncture of the abscess cavity and internal treatment with urotropin were sufficient. In both cases repeated bacterial examination revealed almost pure cultures of Bacillus coli. [H.H.C.]

4.—Von Büngner describes what he calls a "chin stirrup," intended to prevent sepsis in operations upon the cervical region. The apparatus consists of a loop of wire upon which is stretched a piece of sterile gauze, and the 2 limbs of which are so bent that they fit around the ears of the patient, thus forming a small upright screen completely separating the scene of etherization from the region of operation. [H.H.C.]

5.—Von Bardeleben reports a successful total extirpation of the stomach with subsequent esophagojejunostomy in the case of a woman of 52, suffering from carcinoma of the stomach. [H.H.C.]

2. The Technique and Adaptability of Subcutaneous Injection of Quinin. BLÜMCHEN.
3. The Identification of Human Blood. UHLENHUTH.
4. Funck's "Sporidium Vaccinale." W. PODWYSZOZKI and A. MAKOWSKI.
5. Imperfect Sugar Oxidation in Organisms. P. MAYER.

2.—Blümchen, after experimenting with subcutaneous injections of quinin in malarial cases, finds that 0.5 gram of chinin hydrochlorate dissolved in 1 cc. of hot water and injected under aseptic precautions beneath freely movable skin causes no pain and seldom produces infiltration of the neighboring tissue—or if it does, such infiltration never results in necrosis. His method presents the following advantages: (1) The simple aqueous solution in hot water is aseptic; (2) the process is painless; (3) the solution is easily prepared under all circumstances; (4) the results are certain; (5) the cost is trifling; (6) in using

great quantities of the drug, this method affords a rapid mode of assimilation. [H.H.C.]

3.—In continuing his experiments on human blood, Uhlenhuth finds that in spite of exposing several specimens of blood to the effects of decomposition for several months, none had lost their power of reacting to his test. [H.H.C.]

4.—Podwyssozki and Manowski, in the attempt to corroborate the investigations of Funck on the existence of a "Sporidium vaccinale" in the contents of vaccine pustules, reach the conclusion that at least one of the alleged protozoan organisms described is in reality nothing but an epithelial cell undergoing fatty degeneration. [H.H.C.]

May 2, 1901. [27 Jahrg., No. 18.]

1. Serum: Diagnosis of Tuberculosis. E. ROMBERG.
2. The Bacillus Pathogenic for Rats Found by Danysz. J. KISTER and P. KÖTTGEN.
3. A Recovered Case of Otogenous Meningitis. BERTELSMANN.
4. The Aims of Functional Diagnosis, with Remarks on Blood as an Organ and the Regulatory Function of the Kidneys. ROSENBACH.
5. Changes in the Malaria Parasite During Treatment with Methylene-blue. A. IWANOFF.

1.—In the first part of an article on the serum diagnosis of tuberculosis, Romberg, after giving the results obtained by various investigators with the Arloing-Courmont method, gives it as his opinion that the importance of a trustworthy serum reaction for tuberculosis cannot be overestimated, but that the prospects looking to the general introduction of the Arloing-Courmont method are small, since the difficulties in the way of procuring proper culture-material and hence a uniform test-object are too great. [H.H.C.]

2.—Kister and Köttgen give the results of their experiments on the virulence of the bacilli found by Danysz to be pathogenic in the case of rats and mice. They find that after having made the passage of the animal's body for the tenth time, cultures of the bacilli were no longer infectious. [H.H.C.]

Centralblatt für Gynäkologie.

April 6, 1901. [No. 14.]

1. Four Cesarean Sections in Transverse Fundal Incision. L. HEIDENHAIM.
2. The Therapy of Retroflexion. A. SCHUCKING.

1.—Heidenhaim adds 2 more to the 2 Cesarean sections previously reported. He is of the opinion that to-day the conservative Cesarean section is less dangerous to the patient than many forcible deliveries per vias naturales which involve severe lacerations and other extensive injuries, too often causing sepsis and death. In 3 cases the uterine contraction was marked and the bleeding was immediately checked, and in the fourth, it soon yielded to compression and tampons. He uses fine silk sutures for the uterus, with the best results. [w.k.]

2.—Schucking refers to the importance of preserving the mobility of the uterus, and, for this reason, disapproves of both ventral fixation and shortening the round ligaments as interfering with this mobility, and describes a method of his own which he thinks is very much to be preferred, although he admits that time has not yet been sufficient to show its effect upon pregnancy. [w.k.]

April 13, 1901. [No. 15.]

1. Upon the Remedial Results in Cancer of the Uterus. I. PFANNENSTIEL.
2. Upon Removal of the Placenta by External Manuever. W. ZANGEMEISTER.

1.—Pffannenstiel gives an extended review of 3 methods of operating for uterine cancer—high amputation of the cervix, vaginal total extirpation of the uterus and abdominal. He points out the indications for each and gives statistics showing percentage of cure and of mortality under varying conditions and changes of technic. In conclusion, he expresses the opinion that it is not to the further advance in operative technic that we are to look for the cure of cancer, in the future, but to the earlier diagnosis of the disease. Physicians must be taught to

give earlier and greater consideration to the initial symptoms of cancer. This will increase the cases relieved by operation, as Winter has shown that in the course of years in great cities like Berlin, the operability of cancer has increased from 28% to 46%. It is also important to know that uterine cancer is not a disease of the aged. Most cases are found between the ages of 40 and 50 years, and in not a few, especially of the portio, before the age of 30. He also affirms that in the choice of operation one must consider not only the condition of the parametrium, but also the kind of cancer. While the soft and recent forms give a more favorable prognosis, they must be operated upon only when entirely local; but the older and harder forms, on the other hand, permit operation when much more extended. [w.k.]

2.—Because of the great danger attending the manual loosening of adherent placenta, Zangemeister thinks all available external measures should first be used, and thus the percentage of cases in which the introduction of the hand is required, becomes very small. Expression is difficult from without only when the placenta lies in the body of the uterus either free or adherent. In the former, it can usually, under narcosis, be delivered by expression; but in the latter, if expression fails, then he recommends massage of the uterus. In the intervals of labor pains the uterus should be pressed inward on both sides alternately, and forward and backward with the fingers so that surface depressions are present. This kneading will more and more loosen the adherent placenta from its fixed place, until after 1 or 2 repetitions at intervals it can be delivered by expression. Inversion is prevented by this procedure, as the pressure is never from above but sideways, forward, and backward. [w.k.]

April 20, 1901. [No. 16.]

1. Criticism Upon Atmokausis and Zestokausis. LUDWIG PINCUS.

1.—Pincus refers to the rapid extension of atmokausis and zestokausis into most European and American countries, but asserts that the procedure belongs exclusively to the gynecologist and surgeon, not being adapted to general practice since it requires exact diagnosis and considerable apparatus. No gynecologist is justified in resorting to extirpation of the uterus for elimaetic hemorrhage unless he has tried atmokausis curretage having failed. In time he thinks it will be as valuable to the gynecologist as curretage. The curet, without after-treatment, is scarcely a means of healing, whereas atmokausis is, especially if it is used after the mucosa has been carefully cleansed. He recommends it in cases of abortion only, when the hemorrhage continuing after the uterus has been emptied, is due to endometritis. It is of service in septic puerperal endometritis and myomatous hemorrhages. In chronic gonorrhoea of the endometrium atmokausis is approved and zestokausis for the cervix. In such cases if pain accompanies atmokausis, the stream of hot vapor should be immediately interrupted, as this is an indication that the adnexa are involved. Zestokausis in general is inferior in efficiency to atmokausis, though valuable in some forms of dysmenorrhoea [w.k.]

April 27, 1901. [No. 17.]

1. Sterile Permanent Yeast and Its Value in Gynecology. WALTER ALBERT.
2. The Influence of Steam Upon the Uterine Mucous Membrane. M. KOLENSKO.

1.—In 1899 Landau first described the treatment of leucorrhoea with yeast, spraying the vagina with a 1/2 ccm. of a solution of yeast in beerwort. R. Albert, of Berlin, devised a process of making a dry powder from beerwort without destroying the peculiar characteristics of the yeast cells, which powder is known as sterile permanent yeast. This substance has sufficient bactericidal force to weaken or destroy the virulence of the bacteria, causing little or no inflammation of the mucosa as compared with other disinfectants. Albert describes the technic of the procedure in the use of this yeast, 4 g. (about 1 ccm.) being mixed with 20 ccm. of 20% solution of sugar. It is introduced by the proper apparatus into the vagina and allowed to remain 12 to 14 hours, the patient retaining a recu

bent position. After its removal there should be a vaginal irrigation with warm water, and in the 2 following days with salt water; the procedure being repeated on the third day. The results are thus stated: (1) The diminution of the virulence of the vaginal bacteria; (2) changes in the vaginal secretions; (3) rapid healing of any erosions of the portio. Walter thinks that thus a healthy vagina is secured which is a *sine qua non* in the treatment of genital catarrh; also that this sterile yeast may prove to be of great service in preparing for vaginal operations, as the use of it some hours or the evening previous to the operation is a much better preparation than irrigation with severe disinfectants immediately before the operation. [w.k.]

2.—Kolensko describes with illustrations the effects of *atmokansis* upon the mucous membrane of the uterus and thus states the result; first day, the destruction of the mucosa to a known limit; third day, limiting of the necrosed parts; sixth day, sloughing off of the same, and finally after the ninth day the regeneration of the mucosa, with restoration of its normal functions. He thinks that the undoubted healing influence of vaporization upon the uterine mucosa will lead to its beneficial application in puerperal sickness when the infection has not become general. [w.k.]

Sundry French.

1. Treatment of Arteriosclerosis by Subcutaneous Injections of Inorganic Serum. C. TRUNECEK (La Semaine Médicale, April 24, 1901).
2. On the Vasomotor Role of Iodids. GUMPRECHT (La Semaine Médicale, April 24, 1901).
3. On a Lipoptyc Gastric Ferment. VOLHARD (La Semaine Médicale, April 24, 1901).
4. Eosinophilia as a Sign of Appendicitis. LAIGNEL-LAVASTINE (La Semaine Médicale, April 24, 1901).
5. The Camphorates of Pyramidon in the Treatment of Pulmonary Tuberculosis. BERTHERAND (La Semaine Médicale, May 1, 1901).
6. Iron in Human Milk and its Importance for the Nursing Infant. FRIEDJUNG (La Semaine Médicale, May 1, 1901).

1.—Trunecek, of Prague, points out the coincidence of the fact that phosphate of lime, which is insoluble in distilled water though soluble in alkaline solutions, and which is kept in solution in the body so long as the blood-serum is rich in sodium chlorid, with the observation that cases of arteriosclerosis usually occur at an age when sodium chlorid exists in the blood in diminished quantities. He therefore recommends the subcutaneous injection of a solution of alkaline salts, in the relative proportions in which they normally exist in the blood-serum. The formula of this "inorganic serum" is as follows:

Sodium sulfate	0 gr. 44 centigr.
Sodium chlorid	4 gr. 92 centigr.
Sodium phosphate	0 gr. 15 centigr.
Sodium carbonate	0 gr. 21 centigr.
Potassium sulfate	0 gr. 40 centigr.
Distilled water	q. s. to 100 gr.

The author concludes that in increasing the measure of alkaline salts in the blood and in augmenting the alkalinity of the fluid, a solution of the phosphate of lime which incrusts the arterial walls is effected, organic combustion is rendered more active, intercellular exchanges are raised to a normal rate, and as a consequence the functions of the various organs, especially of the heart and bloodvessels, are regulated. [c.s.d.]

2.—Gumprecht, of Weimar, draws the conclusion from recent researches that iodids have no action on arterial tension. [c.s.d.]

3.—Volhard, of Giessen, announces the extraction by means of glycerin of a ferment which actively transforms emulsified fats from the mucous of the stomach. [c.s.d.]

4.—Laignel-Lavastine points out the fact that there is an augmentation in the proportion of the polynuclear eosinophiles of the blood in cases of acute appendicitis. [c.s.d.]

5.—Bertherand has experimented with soluble camphorates of pyramidon in cases of pulmonary tuberculosis and finds preferable to antipyrin or pyramidon; the dose is 1 gram daily. [c.s.d.]

6.—Friedjung concludes from his investigations on the importance of iron in mother's milk that it holds a direct relation to the casein present, and that when the iron falls below a normal average of 5.09 mg. to the liter, the nursing infant presents chronic disturbances of nutrition. [c.s.d.]

THE PUBLIC SERVICE

Health Reports.—The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended May 24, 1901:

Changes in the U. S. Marine-Hospital Service for the 7 days ended May 23, 1901:

PECKHAM, C. T., surgeon. Granted leave of absence for 30 days from April 19, on account of sickness—May 16, 1901. Granted 30 days' extension of leave of absence, on account of sickness from May 20—May 21, 1901.

GLENNAN, A. H., surgeon. To rejoin station at Havana—May 21, 1901.

WERTENBAKER, C. P., passed assistant surgeon. To proceed to Meridian, Miss., for special temporary duty—May 18, 1901.

GREENE, J. B., passed assistant surgeon. Granted 5 days' extension of leave of absence—May 19, 1901.

DECKER, C. E., assistant surgeon. Granted leave of absence for 10 days from May 11, on account of sickness—May 20, 1901.

CLARK, TALIAFERRO, assistant surgeon. Granted leave of absence for 30 days from May 22—May 23, 1901.

CORPUS, G. M., assistant surgeon. To proceed to South Atlantic Quarantine—May 16, 1901. Granted leave of absence for 1 month—May 16, 1901.

RODMAN, J. C., acting assistant surgeon. Granted leave of absence for 4 days—May 18, 1901.

SLAUGHTER, A. W., acting assistant surgeon. Granted leave of absence for 4 days from June 4—May 22, 1901.

Board Convened.

Board convened to meet at Washington, D. C. May 29, 1901, for the purpose of making physical examination of applicants for eadship in the Revenue Cutter Service. Detail for the Board: Surgeon L. L. Williams, chairman; Assistant Surgeon B. S. Warren, recorder.

Changes in the Medical Corps of the U. S. Army for the week ended May 25, 1901:

WASHBURN, Major FREDERIC A. Jr., surgeon, is granted leave for one month, from about May 13.

HADRA, Major FREDERICK, surgeon, having reported from leave, will proceed to the Presidio for temporary duty.

CALKINS, GEORGE H., acting assistant surgeon, will proceed to his home, Tonawanda, N. Y., for annulment of contract.

WILLIAMS, First Lieutenant ALLIE W., assistant surgeon, is relieved from duty at Fort Columbus, and will proceed to Fort Logan, for duty.

JERAULD, FREDERICK N. C., contract surgeon, will proceed from Buffalo, N. Y., via Seattle, Wash., to Fort St. Michael, Alaska, and report to the commanding general, department of Alaska, for assignment to duty.

PEED, Captain GEORGE P., assistant surgeon, leave granted is extended one month.

WATTS, G. GRAHAM, contract surgeon, is granted leave for 10 days.

WINTER, Captain FRANCIS A., assistant surgeon, having reported by telegraph his arrival at San Francisco, Cal., will proceed to Fort Sheridan, for duty.

BACHE, Colonel DALLAS, leave on surgeon's certificate granted A. S. G., February 19, is extended three months on surgeon's certificate.

WASHBURN, Major FREDERIC A. Jr., surgeon, recently appointed now at New Bedford, Mass., upon the expiration of the leave granted him May 7, will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.

The following changes in the stations and duties of officers are ordered: First Lieutenant RICHARD P. STRONG, assistant surgeon, is relieved from further duty in the division of the Philippines and will proceed to Hot Springs, Ark., and report at the Army and Navy General Hospital for duty, to relieve Captain JOSEPH J. CURRY, assistant surgeon, Captain CURRY upon being thus relieved will proceed to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty as a member of the board of officers appointed by par. 22, S. O. 13, January 16, 1900, this office, for the purpose of studying tropical diseases as they occur in the Philippine Islands.

BARNEY, CHARLES N., contract surgeon, is relieved from duty at Fort Monroe, and will proceed to Key West Barracks, and relieve Contract Surgeon Robert C. Eve, who will proceed to Fort Monroe for duty.

GRANDY, Major LUTHER B., surgeon, leave granted May 1, is extended 15 days.

BRECHEMIN, Major LOUIS, surgeon, is relieved from further duty as a member of the board of officers appointed by par. 6, S. O. 102, May 2, 1901, this office, and will proceed to Fort Bayard for temporary duty in charge of the U. S. General Hospital at that place during the illness of Major Daniel M. Appel, surgeon. Upon completion of the temporary duty herein ordered Major Brechemin will comply with the requirements of so much of par. 18, S. O. 49, February 28, 1901, this office, as relates to him.

AGRAMONTE, ARISTIDES, contract surgeon, is relieved from further duty as a member of the board of medical officers appointed May 24, 1900, for the purpose of pursuing scientific investigations with reference to the infectious diseases prevalent in the Island of Cuba, and will report to the commanding general, department of Cuba, for assignment to duty.

WHINNERY, JEAN C., contract dental surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report for transportation to the Philippine Islands, where he will report for assignment to duty.

The following changes in the stations and duties of officers are ordered: Colonel William H. Forwood, assistant surgeon general, upon being relieved from duty as chief surgeon, department of California, will repair to Washington, D. C., and report to the surgeon general of the Army for duty in his office; Colonel Dallas Bache, assistant surgeon general, is relieved from further duty in the office of the surgeon general of the Army.

METZGER, Major JOHN A., surgeon, leave granted April 29, is extended 1 month.

BRECHEMIN, Major LOUIS, surgeon, orders of May 21, which direct to proceed to Fort Bayard, for temporary duty in charge of the U. S. General Hospital at that place, are revoked.

SWIFT, Captain EUGENE L., assistant surgeon, will report to Lieutenant Colonel Calvin De Witt, D. S. G., president of the examining board at the Army Medical Museum Building, District of Columbia, for examination for promotion.

Orders of February 16, which relate to Captain Charles M. Gandy, assistant surgeon, are so amended as to direct him upon his relief from duty at Fort Slocum, to proceed on the transport Ingalls, via the Suez Canal to Manila, P. I., and on arrival to report to the commanding general, division of the Philippines, for assignment to duty.

FELDER, LAWRENCE A., contract surgeon, leave for 7 days granted May 16, is extended 7 days.

Changes in the Medical Corps of the U. S. Navy, for week ended May 25, 1901:

KENNEDY, R. M., passed assistant surgeon, ordered home from the Bennington via public conveyance.

STONE, M. V., assistant surgeon, detached from the Buffalo, May 31, and ordered home and to wait orders.

DELANCY, C. H., assistant surgeon, detached from the Bancroft, when put out of commission, and ordered to the Buffalo, as relief of Assistant Surgeon M. V. Stone.

FURLONG, F. M., assistant surgeon, ordered home from the Brutus, via public conveyance.

KERR, D. B., assistant surgeon, ordered home from the Marietta, via public conveyance.

GROW, E. J., assistant surgeon, ordered home from the Isla de Luzon, via public conveyance.

GRUNWELL, A. G., assistant surgeon, ordered home from the Brooklyn, via public conveyance.

BEEBE, D. G., assistant surgeon, ordered home from the Marietta and from duty with marines at Port Isabella, P. I., via public conveyance.

LANGHORNE, C. D., assistant surgeon, ordered home from the Princeton and from duty with marines at the Cavite Naval Station, via public conveyance.

STEPP, J., assistant surgeon, detached from the Castine and ordered to the Isla de Luzon.

GROW, E. J., assistant surgeon, detached from the Isla de Luzon and ordered to the Castine.

THOMPSON, E., assistant surgeon, detached from the Solace and ordered to the Petrel.

PLUMMER, R. W., assistant surgeon, detached from the Petrel and from the Cavite Naval Station and ordered to the Nashville.

FURLONG, F. M., assistant surgeon, order detaching from the Brutus and ordering him forwarded to Guam, I. I.

AMERICAN MEDICINE

1321 Walnut Street

Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free: foreign postage, \$2.50. Subscriptions may begin at any time. Volumes end with the last issues of June and of December.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is on dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amount under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address a correspondence to 1321 Walnut Street, Philadelphia.

PUBLISHED WEEKLY AT 1321 WALNUT STREET, PHILADELPHIA, BY THE AMERICAN-MEDICINE PUBLISHING COMPANY

VOL. I, No. 10.

JUNE 8, 1901

\$4.00 PER ANNUM.

The Presidential Address of Dr. Charles A. L. Reed, printed in the foregoing number of AMERICAN MEDICINE, should be carefully read by every American physician. From beginning to end, regardless of unimportant details about which one may differ, it is charged with the spirit of true professionalism, and inspired by the religion of scientific medicine. There is one thing urged by Dr. Reed which we earnestly hope may be accepted by the Association, and become its settled policy. We allude to grants and commissions by the Association to encourage scientific investigation and promote professional progress. Nothing should henceforth be allowed to interfere with or crowd out this most beneficent work, nor can there be a better policy, viewed solely as a method of increasing the power and membership of the Association. In the eyes of the intelligent and educated public such work really gives us our *raison d'être*, beyond a mere trades-union, and the allegiance and cooperation of the best part of the lay world are precisely what we as a profession need to hold the nation back from the abyss of quackery and commercialism run mad. And it is by such investigation-work in the common interest that we can secure the attention of legislatures and the passage of laws in the interests of both community and profession, which is the most important of all our duties. As to the other recommendations of Dr. Reed we are in general in hearty accord. Professional unity!—that is the motto under which we must henceforth make war upon disease, and upon the slaves of disease—ignorance, humbug and greed.

A Useful Disposition of Wealth.—John D. Rockefeller has by a large gift established the Rockefeller Institute for Medical Research, to furnish facilities for original investigation, particularly in such problems in medicine and hygiene as have a practical bearing upon the prevention and treatment of disease. He has placed \$200,000 at the disposal of the Board to begin the work. This is not for an endowment, but may be used in a series of years for current expenses. The home of the Institute will be in New York, although medical men from other cities will share in its management. The Board of Directors is at present constituted as follows: William H. Welch, M.D., Baltimore, president; T. Mitchell Prudden, M.D., New York, vice-president; L. Emmett Holt, M.D., New York, secretary; C. A. Herter, M.D., New York, treasurer; Theobald Smith, M.D., Boston; Simon Flexner, M.D., Philadelphia;

H. M. Biggs, M.D., New York. It is not intended to build at once; but with the funds placed at the disposal of the Board, work will be begun under its direction immediately in the leading pathologic laboratories in the country, notably Johns Hopkins, Harvard, McGill, the University of Michigan, the University of Pennsylvania, the University of Chicago, and the several laboratories connected with medical schools and the Board of Health of New York. When the permanent home of the institution has been built, it is planned so that those doing research work in connection with it shall receive pay sufficient to command their entire time, releasing them from any necessity either to practise or teach. The Board will at first devote its energies to shaping the lines of the work along which the Institute may wisely develop, both in contributions to knowledge and in the application of existing knowledge to humane ends. When this is done it is felt that such local habitation as the future of the Institute shall require can be more wisely planned.

The potential value of an institution of this kind, founded under such auspices in medical science, and in the interests of humanity, can hardly be overestimated. If plans are conceived with intelligence and carried out with executive ability, the work must inevitably produce beneficent results. The only possible weak point would be in the complexities naturally attendant upon the initial carrying out of the work at so many different places. The sooner centralization is attained and a recognized head chosen for the scientific direction of the work, the more immediately successful it will be. Under such unified labor alone can the best results be expected, and all effort should be directed toward its establishment.

The Function of the Laboratory in Surgical Practice is admirably epitomized in the masterly address of Dr. Wyeth, printed in our present issue. One is struck by the noteworthy fact that but a few decades ago the surgeon was almost utterly oblivious of the conditions set forth, conditions which have wholly revolutionized surgery and in a hundred ways have linked it with general medicine and science. Surgery then seemed to be almost wholly an art; now that art is subordinated to and almost entirely dependent upon preliminary studies in the laboratory of which the older surgeons had almost no knowledge. The lesson stands out clear that in no department or specialization of our work may there be any closing of the mind to new ideas and revolutionizing

methods. Expertness in operative technic, however marvelous, the greatest or longest experience, the most complete knowledge of anatomy—all such will not avail unless there is also to guide and govern all art and knowledge the illuminating help of clinical microscopy, of bacteriology, and of chemistry. Hereafter there can be no rushing into the glory and profit of surgical fame except through the painstaking and profound science of the laboratory. Henceforth the art of surgery, as Dr. Wyeth says, is inseparable from the science of surgery.

Progress in Hygiene and Sanitary Science.—Medicine is such a progressive and forward-looking science that the young practitioner is very likely to know little of the history of the long struggle that has preceded our present attainment. This warrants and makes interesting the occasional glances backward or the summarizations of advance by the orators and presidents of our larger medical societies, and the one who is so absorbed in practical medicine that he fails to hear or read these addresses misses a great deal of edification, and that broad overlook which gives the mind poise and balance, even in the much-prized practical way. Moreover, in reference to Dr. Kober's capital address printed in the present issue of AMERICAN MEDICINE by the courtesy of the Editor of the *Journal of the American Medical Association*, one has emphasized the great truth that all our work, however practical, must more or less resolve itself at last into the prevention rather than the cure of disease. In this most excellent summary we see the beginnings of sanitary progress in olden and medieval times sweeping on to the modern victories over disease with which we are familiar, and looking onward to a yet greater lessening of the death-rate, and of the burden of suffering and expense which illness causes. To have extended the average length of human life in a few hundred years from 20 to 40 years is the noblest work of science and civilization.

The Action of the Mucus of the Respiratory Tract Upon the Organism.—Charrin and Moussu (*La Semaine Medicale*, January 23, 1901) have recently made some interesting studies on this subject. On injecting into the veins of a rabbit .05 to 10 cgr. per kilogram of the weight of the animal, a fresh mucus obtained from the respiratory tract of other animals and diluted with 30 or 40 times its weight of normal saline solution, death followed at the end of a few minutes. Immediate necropsy showed the presence of newly-formed clots in the right ventricle, and the coagulation of the blood was very rapid. Moreover, when a few drops of mucus were added to the freshly drawn blood of a horse, coagulation followed within 3 minutes, while under normal circumstances from 18 to 22 minutes are required for coagulation of horse's blood outside the body. They believe that they have discovered a new direct coagulant of remarkable power. The large quantities of mucus and its diffusion throughout the entire body permit us to conceive the possibility of its action in the etiology of thrombosis and phlebitis, and in the arrest of hemorrhage.

We are not aware that any studies have been pre-

viously made with regard to the action of the mucus of the respiratory tract on the coagulation of the blood. No mention is made by Charrin and Moussu of the possible influence of bacteria or bacterial products which may be contained in the mucus of the coagulation of the blood. Their report is very incomplete, and the subject seems to be an interesting one, deserving of further study.

Urine Examination During Gestation is very important and must be thorough in order to appreciate impending disaster. Marx in reviewing the toxemias of pregnancy has urged the importance of urea estimation in the investigation. The old time-honored examination for sugar and albumin is not sufficient; for in many desperate and malignant cases of toxemia during pregnancy, there is found neither albumin nor tubercasts, while the urea is always found markedly diminished in the so-called toxemias or urinemias of pregnancy. Upon this progressive diminution of urea-secretion, with or without albuminuria, will depend the indications for induction of premature labor.

A College Course as a Preparation for Medical Study.—The manifold recent advances in medical science, with the necessity for longer courses of medical study and increased demands on the student of medicine, have led many young men to seriously consider whether they would not better begin the study of medicine without a full college course. Besides the time and expense, many have urged that the college courses as now arranged are of comparatively little value to the medical student; that Latin, Greek and the higher mathematics are likely to be of little help to a man who expects later to engage in purely scientific study and work. For a number of years many of our leading colleges and universities have offered courses or electives such as may be considered the best preparation for future medical study. And of late a number of these colleges and universities have arranged so that by doing a little extra work each year the regular four years' course of study may be completed in three years, as is frequently done at Harvard, or that the last year of a four years' course for the academic degree shall count for the medical degree as well. The latter arrangement can be made at Pennsylvania, Columbia, Chicago, Michigan and a number of other colleges and universities. The recent action of Yale and Princeton, two of the most conservative of our larger universities, shows how great has been the demand for scientific studies in place of classic studies. At Princeton, President Patton has suggested offering courses in physiology and human anatomy so that students may begin their medical studies in the senior year, and he has suggested offering suitable electives for the junior and sophomore years. At Yale, Latin and Greek are still required through the freshman year, but not afterwards. Cornell admits students to its B. A. degree without Latin; Harvard requires no Latin at the University; Columbia requires Latin only in the freshman year. At Michigan, Minnesota and Leland Stanford students taking almost purely scientific courses receive the A. B.

Many will deplore this tendency to do away with the courses which were supposed to be the liberal training of

every cultured gentleman, but progressive men see that these courses are needed and demanded in the present state of scientific progress in medicine, and that for mental discipline more depends upon the thoroughness of the course of study than upon the studies taken. By shortening the college course and making it more practical many young men who would otherwise feel that they could not afford the time and expense of a liberal education will now be encouraged to take the college degree, and will bring to the medical profession the benefit of a better mental training and of a broader general culture.

Remuneration and Employment of Patients in Public Institutions is the subject of two instructive papers by Dr. A. C. Rogers and Dr. J. T. Searcy in the *Bulletin of Iowa State Institutions* of January, 1901. Dr. Rogers gathers the results of inquiries of seventy-two hospitals for the insane; sixty-seven did not pay; thirty-five disapproved; five approved, and twenty-seven expressed no opinion. Dr. Rogers gives no definite opinion concerning the matter. Dr. Searcy does not approve of paying patients for work but he is most plainly in favor of industrialism, and for the sound, general reason that regular employment is healthful, beneficial and profitable to the man who works. Laziness is a crime only equaled by that of forcing it upon people. We quote a few illuminating sentences from Dr. Searcy's admirable paper:

"While the rest-cure is good for a few of the insane, the employment-cure is good for the large majority."

"The employment feature in insane hospital management is a growing one, and a modern one—it is an up-to-date measure. Attention is being drawn to it as an excellent remedial agent more and more. Employment is the best generally beneficial agent yet invented for insanity—a general rule which is best 'proven by its exceptions.'

"An idle brain is the devil's work shop' is never better illustrated than in an insane hospital. A few days of idle confinement, because of bad weather or other causes, create disorder and dissatisfaction that can be seen all through the institution. Whether their work is profitable or not, to keep the patients occupied leads to their much more easy control and management. The satisfaction obtained by employment is evidenced in both the patients and the attendants. There is much less need of seclusion and of sedatives in an industrious hospital. The pleasure and the quietude are both enhanced by it."

"The wheel-barrow squad' that used to be considered the most worthless class of patients now proves very valuable with us; we do all our grading and road making with them."

"On both sides of the institution, most of the work that relates to the care and keeping of the wards, bed-rooms, dining rooms, yards, etc., should be done by the patients on their respective wings. On the women's side all or the greater part of the clothing should be made; sewing, knitting, darning, quilting, embroidery, and even drawing, painting and music should go on through all the wards. Some may, if able, be allowed literary work. To have something for the patient to do should be the rule of the institution; and from the supervisors down this should be part of the duties of all. If any single patient shows an aptitude for any particular kind of work she ought to be encouraged to do it."

"In hundreds of ways inside industries can be devised. Because she was pleased at it, one woman was engaged for months 'making a dictionary.' Some of her definitions were very unique. Another wrote 'novels.' All, however, should be encouraged to do some of the profitable and necessary industries."

Suitable Nourishment for the Poor in Combating Alcoholism and Disease.—In discussing the best means of preventing alcoholism at the recent Anti-Alcohol Congress at Vienna, Dr. Burtseher, of Bern, laid great stress on the importance of an abundant, inexpensive food-supply for the poorer classes. He stated that the consumption of liquors is most prevalent and the effect worst among the most poorly nourished peoples of Europe. The excessive use of alcohol is not so frequently the cause of poorly developed and nourished bodies, as is imperfect nourishment the cause of an abnormal craving for liquors. The effects of alcohol are also decidedly worse among the badly nourished. Drunkenness, delirium tremens and mental diseases are uncommon among the well-nourished peoples of Germany as compared with the condition among the badly nourished Poles and Irish. Temperance societies, tracts, cures and institutions for the treatment of drunkenness will all prove of little avail as long as the poor are unable to obtain food to nourish themselves sufficiently well to prevent abnormal craving for stimulants. The shortsighted policy of the Agrarian party in striving to prevent the importation of less expensive meats from America and other countries was emphatically condemned.

Proper nourishment is certainly as important in preventing disease as in preventing alcoholism. This is specially true as regards the prevention of tuberculosis. In our own country no difficulty exists as to the possibility of procuring an abundance of nourishing food for so great are our resources of food supply that even our poorest classes eat at least twice as much meat as the most fortunate people of the same standing in most foreign countries. There is no lack of badly-nourished people among us, however, and they are not found among the poor alone. With us the fault lies more in the preparation than in the quality and abundance of food. Sloppy soups, greasy, indigestible fried meats, fried eggs, fried fish, fried potatoes, in fact every food possible fried and greasy; soggy hot bread and cakes, and unwholesome pastry lacking in food value are the common foods of not only the poor but many of the better classes. Cooking is now taught in many of our public schools and institutions as well as in private classes. Let us hope that this will promote much-needed reform and by teaching how digestible and appetizing food may be prepared, help to improve the physical condition of the people and thus lessen the frequency of disease.

The Dreary Monotony of Hotel and Restaurant Cooking.—There is no country in which the menus of hotels, dining cars, and restaurants, contain so many items, and yet there is none in which there is such a monotonous and tiresome sameness. From Maine to California, from Florida to Wisconsin, the same choice of foods is offered, all cooked and served in the same way. But a few years ago one found some variety the "spice of life" and of cookery, in the old-fashioned dishes of New England, the baked beans and brown bread, the hulled corn, the baked Indian pudding, etc., but now these things are not to be had anywhere, or if the names greet one, the things themselves are disap-

pointing travesties of the olden toothsome delights. It is the same with the indigenous dishes of all other parts of the country. The refrigerator car makes possible the dull uniformity of the menu, and fashion stupidly demands that the palatable things of one part of the country shall be perhaps ignored where they are fresh, and transported 1,000 or 2,000 miles where they are out of season and stale. It has been said that whether one smoke good or bad tobacco, or indeed whether one's cigar be lit or not, is a matter of indifference to the smoker sitting in darkness. To the blind man it must be "all one" wherever he dines. Is it useless to appeal to chefs, cooks and caterers for the native dishes of the country, cooked as the natives cook them? Individualism is as good for health in the culinary as in the sociologic art.

The American Medical Association has great possibilities of progress through the adoption of the report of the Committee upon Organization. The changes recommended as necessary and advisable in the Constitution and By-laws have been given in a former issue of this journal. Through the broad position taken, the revised Constitution affords every opportunity for development, lifting the Association above hampering local influences, and giving opportunity for that increase in numerical strength so desirable in the representative organization of the American profession. The work of the Committee has been excellent, the seconding of their efforts by President Reed, the representative medical press, and other men of influence, has given the movement great impetus, and the action of the Association in seizing the opportunity launches the modernized Constitution on the flood tide. The meeting is reported as well attended, harmonious and enthusiastic, and the election of Dr. John Allan Wyeth, of New York, as the next president, was received with great satisfaction as the logical unfolding of the progressive ideas advanced and adopted. The next step is following out of the recommendations of the Committee by the various State and territorial medical societies in the interests of complete organization of the profession. This will come more slowly, but it is inevitable.

City or Country Practice.—Many of the thousands of young doctors of medicine who have recently graduated or will soon graduate from our numerous medical colleges have already decided where they will settle and what the character of their work will be. For the others who have as yet no definite plans the decision must be influenced by many individual considerations, but a glance over the comparative advantages and disadvantages of country and city practice may be of some help. The prizes of honor, influence and wealth which come to the leaders of the profession in large cities are very alluring, but unfortunately not one in a hundred can hope to win them. Without money and family or political influence the prospects of rising rapidly or of even making a living in the better class of practice in our large cities is not very encouraging. In a large city the young doctor is one of 500 others among many men of other professions and the individual counts for little.

It is true that many men soon get large practices and even accumulate considerable wealth in practice among the poorer classes. Some of these men are well-read, thoroughly competent practitioners who do an immense deal in sanitary and benevolent work along with their busy practice, and such men always have the respect and support of the best members of the profession. But a busy practice among the lower classes does not leave time for study, hospital or laboratory work, which often tempt men to stay in the city. For the man with health, good ability, enough to live upon comfortably for several years and a desire to learn and to progress, there can be little question that the city offers far the greatest inducements. In our country the great hospitals, laboratories and libraries are all in cities. Without these advantages and without the stimulus of association with the progressive men who are grouped about our large teaching centers, few advance far beyond the limits of what they have learned in the medical school. Besides the advantages for professional development, life in a large city offers many opportunities for general culture which cannot be left out of account.

The prospects of reaching a prominent position in the medical profession or of accumulating a fortune are not great for the man who chooses country practice. Many young graduates have visions of starting in the country and earning enough to set up in the city, but few ever do this. The long, hard rides in country practice, the frequent night calls, the great responsibility, the small fees, must all be considered. But there are many compensations: a good practice and fair income are almost certain from the start; a physician of character and ability soon becomes a respected and influential member of the community, and the out-of-door life of the country is conducive to health, and to a person with a love for nature, in many ways pleasanter than city life. While few of those who start in small towns later go to large cities and become famous, there are numerous brilliant exceptions, among whom may be mentioned Sims and Gross, and several of the world's most famous physicians and surgeons, have been country doctors all their lives; McDowell, the father of ovariectomy, and Jenner, who discovered vaccination, are examples.

In both city and country, competent, conscientious practitioners of medicine are needed. True success is not necessarily associated with fame or wealth, and a fair degree of success is almost certain to come to those who work faithfully to deserve it.

Carelessness in the Interdiction of Staple Foods.—Of all the advice which the physician has to give his patient, in many cases, the most valuable is his advice as to diet. Instances not infrequently occur, however, of specialists, who in their endeavor to "reconstitute" their patients, as the elder Jackson of Dansville fame was wont to put it, broadly condemn in a most unwarranted way some one or more of the most healthful of foods.

Sweeping generalizations as to the harmfulness of widely used foods and beverages, such as wheat flour, milk, and coffee, are too often made by physicians and as a result there have arisen numberless attempts to

replace these great staples with substitutes more or less inferior to the article condemned, and in many cases actually harmful through active ingredients, or from the omission of valuable constituents found in the natural product.

The time is nigh when the fad for substitutes and modifications of natural foods will pass, and the effort of the physician will be largely confined to the securing of purity and conformity to standard. The harmfulness of the great universal food stuffs lies rather in the methods of use than in constitution.

Notwithstanding the astounding increase in the consumption of wheat among the nations of the earth, and in face of the fact that the dominant races are wheat eaters, we constantly find persons of more than ordinary intelligence in most things who have been needlessly frightened into the disuse of this prince of foods. To account for the taboo placed upon wheat, the most specious and contradictory reasons are given.

In a recent case a specialist of prominence, in one of our great medical centers, forbade his patient the use of wheaten bread on the ground "that wheat contains such a large amount of silica that it hardens the arterial walls." There are many cases in which the use of wheat or other starchy foods might be wisely forbidden and for valid reasons intelligible to anyone conversant with the rudiments of the physiology and chemistry of digestion; but, if reasons must be given the patient for such interdiction, what excuse can there be for an attempt to satisfy his inquiring mind with this sort of twaddle. In the case noted, the sand was surely in the possession of the learned exponent of well-living rather than in the wheat flour. Silicic acid, the soluble colloid form of silica, though present in minute proportions in wheat, is not likely to be absorbed to the extent of warranting any fear of silicious arterial sclerosis. Adverse opinions regarding common articles of food soon become widespread and serve as the basis for foisting upon the confiding public all sorts of "green-gourd substitutes" for those foods which most nearly represent the staff of life. There is room for the dietist, but he should handle the taboo with discretion and with reference to the individual case, and beware how he imposes upon the public misleading notions as to the general injurious nature of common food stuffs.

EDITORIAL ECHOES

Confectionery Ornamented with Glass Splinters according to the *Lancet* is a danger to which we, or at least, the French people, are liable. The *Lancet* has analyzed samples of "sweets" and has demonstrated that the sparkling ornaments sprinkled over the surface were really glass splinters.

The Support of Hospitals.—Viewed from the standpoint of science, the hospitals that are training the best physicians and nurses that the city can supply, are doing something more than caring for the individual sick man. They are combating the disease of a nation; and the few thousands given as charity are the best investment for the city's present and future health that can be made. In these days of luxuriously appointed steam yachts, enormous country houses and elaborate

entertainments, it would be niggardly to deny to science and philanthropy any detail of perfection in the matter of plumbing, lighting, heating apparatus, service and food, that the wealthy insist on having for their own comfort.—[*Medical News.*]

Arsenic in the Dyes of Stockings, Etc.—There would appear to be now, in the light of recent inquiry, a recrudescence of the employment of arsenic in the dyes used, at any rate in stockings. This fact only shows what a sharp watch must be perpetually kept up in order to check an objectionable practice. There can be little doubt that in the cases cited the arsenic in the stockings was introduced through the dye. It would seem that the employment of arsenic and its compounds, or of substances contaminated with arsenic, will inevitably have to be placed under special regulations, for apparently the presence of arsenic is unavoidable in a very great number of materials. The Royal Commission on arsenic should include in their inquiry the question of the danger arising not only from arsenic food products but from arsenic clothing also, and should decide upon the limitations of the amounts of arsenic in any case.—[*The Lancet.*]

Alcoholic Gastritis and Caffeinism.—The symptoms of digestive and nervous disturbance incidental to chronic coffee-poisoning are liable to cause errors in diagnosis, from the fact that the results of alcoholic excess produce effects which singularly resemble the signs of dyspepsia arising from the ingestion of coffee in toxic amounts. In some cases the distaste for solid food is great. Palpitation is not often noted, but a diminution of the pulse is a matter of ordinary observation. There is insomnia, and the patient gradually becomes extremely emaciated. In well-marked instances painful cramps of the thighs are complained of. The abstention from coffee is followed by immediate amelioration of the more distressing symptoms of the disorder, and in this rapidity of recovery the affection differs in a marked respect from the results noticed in alcoholic gastritis following the disuse of alcohol. The trembling of the limbs and the twitching of the lips noticed in both conditions are generally described as being the first symptoms to show improvement when the case is one due to poisoning from coffee. In the opinion of some of the Continental observers chronic coffee-poisoning may be induced not only from the poor quality of the article consumed, but also from improper methods of preparing the beverage.—[*The Medical Press.*]

The Clinical Picture not always Sufficient for Diagnosis.—One conclusion that may be drawn is that, strictly speaking, the recognition of the clinical picture of an infectious disease is not always sufficient for its diagnosis. The clinical picture owes its existence to the infecting agent. The clinical examinations as ordinarily done cannot possibly reveal with certainty the cause of the clinical and anatomic disturbances, and it must be accepted that bacteriologic examination is essential for the scientific diagnosis of an infectious disease. In order to emphasize this aspect of diagnosis Petruschky urges the introduction of an etiologic nomenclature. An exact nomenclature would spur to renewed study and to bacteriologic examination in order to establish exact etiologic diagnosis. Streptosis, staphylosis, spirillois, plasmoidiosis, bacillois are some of the terms he suggests, which may be modified in various ways to meet the special indications. It is a well-known fact that our nomenclature cannot be changed through the spasmodic efforts of any one reformer, be the reasons ever so just. And yet we believe that all thoughtful physicians are in hearty sympathy with all effort that tends to make diagnosis more definite, and out of this feeling there may in time spring a more precise terminology than the present.—[*Journal American Medical Association.*]

AMERICAN NEWS AND NOTES

GENERAL.

The American Gastroenterological Association will hold its next annual meeting in Washington, D. C., May 1, 1902.

Mosquitos.—A campaign against mosquitos by means of kerosene sprinkled on the ponds and marshes is being waged by the Hartford, Conn., Board of Health and like measures are urged in Minnesota and Texas.

The consumption of coffee in the United States is stated to exceed that of any other country in the world. During the 9 months ended March last the importations of coffee amounted to 617,344,000 pounds, valued at \$45,218,000, an increase of nearly \$5,000,000 compared with the same months in the preceding year.

Ratio of Doctors.—The census shows that there is 1 registered physician to every 655 people in the United States, while in Germany, in 1898, there was but 1 doctor to each 2,114 of population. Some States, however, have proportionately more practitioners than others. In California, for instance, the ratio is as 1 to 416, while in North Carolina it is as 1 to 1,189. This disparity is particularly pointed sometimes in States similarly situated—Michigan's ratio is as 1 to 570, Wisconsin's proportion but 1 to 936, and Minnesota has but 1 doctor to each 1,004 people.

American Hospital in Turkey.—A Board of Trustees, to have its chief office in New York City, was incorporated on May 14, for the purpose of establishing and maintaining a hospital in Talas, Cesarea, Asia Minor. This has been done to perpetuate the work of William S. Dodd, M.D., who began in 1886 with a small dispensary over a stable; this has widened its dimensions to a stone hospital building of 3 stories with capacity for 70 beds. Since Dr. Dodd began he has performed more than 2,000 operations and has had 61,000 patients. The consequent expenses up to this date have been defrayed by his personal friends.

Yellow Fever Vaccine.—Dr. Angel Bellinzaghi, whose experiments with yellow fever serum obtained last year the official recognition of the Mexican Government, announces that he has found an active vaccine, which he believes will insure absolute and permanent immunity from the disease. Immunity by means of his serum was only temporary. A quantity of the serum and the vaccine is being prepared for use in Cuba, where he proposes to demonstrate their value. He delicately suggests that some medical institution, or even the United States Government, might supply the means for these tests, and he is careful to invite reporters to watch them.

Obituary.—ALLEN M. SUMNER, of Boston, May 25, aged 57.—GEORGE S. OSBORNE, of Salem, May 25.—G. B. QUIGLEY, of Rocky Hill Station, Ky., May 29.—HERBERT J. HOUGH, of Midland, Canada, May 16, aged 27.—GEORGE B. NOYES, of Waupaca, Wis., May 25, aged 54.—JAMES R. BAYLEY, of Newport, Oregon, May 24, aged 82.—A. RACHAEL, of Alexandria, La., May 26, aged 60.—J. R. BOYD, of Waukesha, Wis., May 17, aged 45.—MEYER SCHWAB, of Savannah, Ga., and Saratoga, N. Y., May 26.—LUTHER DANIEL ESTABROOK, of Denver, Col., May 15, aged 68.—P. HERBERT LAROSE, of Indian Orchard, Mass., May 28, aged 31.—DWIGHT MERENESS, of Milwaukee, May 29, aged 41.—CHARLES W. CLOSE, of Chicago, at Los Angeles, Cal., May 29, aged 29.—JOHN PAYNE, of Birmingham, Ala., May 30.—JOHN L. FEENEY, of Stapleton, Staten Island, May 31, aged 56.—WILLIAM WOODS, of Boston, June 1, aged 60.—D. C. THOMAS, of Adrian, Mich., May 30, aged 66.—J. J. ELSBERG, of Slatington, Pa., June 3.—HENRY G. MOYLAN, of Philadelphia, June 3, aged 25.—Surgeon ST. JOHN, of Company A, Twentieth Regiment, United States Infantry, in Manila.—EDMUND BEALE, of Philadelphia, June 1, aged 81.

EASTERN STATES.

A New Industry is reported from Concord, N. H., 50 barrels of birch sap having been shipped lately from a neighboring town to a Boston patent medicine firm.

Vaccination Compulsory.—Under the provisions of the recently-enacted law, vaccination is now compulsory in all public, private and parochial schools throughout the State of New Hampshire.

The Country Sanatorium for Consumptives, a Jewish but nonsectarian institution which is to be conducted in connection with the Montefiore Home, in New York City, was opened formally at Bedford, May 23. This sanatorium, consisting of a group of 5 frame buildings on a high hill, is the result of experimental work which has been carried on at Bedford for several years and the directors expect not only to save many lives, but also to train the uneducated consumptive taken from unsanitary environment to hygienic ways, so that he may become a beneficent factor in teaching sanitary measures and in preventing infection in his family and vicinage when returned to it.

NEW YORK.

Dr. James A. J. O'Brien, of New York, has been appointed by the Municipal Assembly physician to the county jail of that city.

Dr. Pearce Bailey, of New York, has been appointed by Governor Odell, a manager of the Craig Colony for Epileptics, to fill the vacancy created by the resignation of Dr. Peterson, who was made president of the State Commission in Lunacy.

Christian Science Treatment.—An effort will be made to fix the responsibility of the death of Mrs. Charles Ockerman, of Binghamton, N. Y., upon 2 Christian Scientists who persuaded her that she was not ill. Investigation showed that she suffered from pneumonia.

Kneippism.—A resident of Matteawan, New York, and a disciple of the Kneipp cure, was captured by a man, who supposed him to be a lunatic escaped from the State Insane Hospital. The man was able to prove his identity, but was advised to put on shoes and stockings. There is a standing offer of \$25.00 for each capture of runaway inmates of the Hospital and, consequently, the residents in the vicinity are ever on the watch for queer-looking people.

Plague Nurses.—Katherine Carpenter and Celia Harkness, of Buffalo, N. Y., are on their way to Cape Town, South Africa, to become plague nurses, where they will be attached to the British Army Nursing Service Reserve, and where there is a demand for nurses. The salary is at the rate of £4 4s (about \$22) a week, with quarters and rations. The matron of the hospital and 3 nurses died from the plague soon after their arrival in Cape Town.

Illegal Practice.—A. de Sarak, a scientist from the Orient, general delegate of the Scientific Academy of "Sauveteur" of Paris, was charged with practising medicine without a license, in the West Side police court of New York, recently, on the complaint of agents of the Country Medical Society. He admitted that he was not registered as a physician, but claimed that he was not practising medicine, merely palmistry, double vision, magnetism, etc. He was held in \$300 bail for trial.

Laundry Law.—A new section has been added to the labor law relating to public laundries, which holds that any place where public laundry work is done is a factory within meaning of the law, and shall be subject to inspection by the factory inspector, the same as any factory. No public laundry work shall be done in any sleeping or living room; the laundries must be clean, free from vermin, and all impurities of an infectious or contagious nature. This does not apply to washerwomen doing custom laundry work at home for regular family trade.

The Board of Health of New York is in somewhat of a dilemma, relative to the case of the Colonial Brewing Company and other manufacturers who are violating the Penal Code and burning soft coal in their furnaces, thus making themselves a nuisance to the public in their vicinity; the health authorities claim that they have done all in their power to secure indictments and convictions in cases of this kind, but that political influence invariably defeats their aims and that the offending parties are generally discharged by the magistrates.

Statistics of Tuberculosis.—The Department of Health of the State of New York has requested the local health officers throughout the State to make an enumeration of the number of persons suffering with tuberculosis in their respective localities. The present purpose is not to obtain a personal registry of cases nor to institute sanitary inspection or isolation of such, but to acquire an accurate record of the number of cases, the locality of the disease, its distribution and surroundings. The accumulated data will be of worth, it is thought, in the discussion of the question of State care of tuberculous patients.

The New York Hospital has divided its anatomic and pathologic collections among the following: The College of Physicians and Surgeons, the Postgraduate Medical College, Bellevue Hospital Medical College, Cornell University Medical College, and the New York University. The authorities thought that since no lectures were given at the hospital and because the museums were maintained only for visitors, they would serve better use in educational institutions. For similar reasons, the Academy of Medicine, 3 years ago, was the recipient of the library of the hospital.

Cost of Crime.—Mr. Eugene Smith, of New York, recently stated before the National Prison Association that nearly all the disbursements of a community in times of peace are due to the suppression of crime. All the machinery of justice is necessary to protect the good from the evil. This cost, Mr. Smith actually finds to be between \$3 and \$5 per year for every honest man in the community; the nation expends a total of \$200,000,000 on this account. The expense to the family, due to the criminal, is about \$25. This tremendous cost is increasing, and the cost per capita is more than we pay for our children's education.

PHILADELPHIA, PENNSYLVANIA, ETC.

Allentown Hospital is the recipient of \$35,000 for the purpose of erecting an additional wing to the hospital for the treatment of surgical cases. The donor's name is not mentioned.

Patent Medicine.—The bill before the House prohibiting the sale of patent or proprietary medicines unless the formula is registered with the Secretary of the State Pharmaceutical Examining Board, was indefinitely postponed.

Breeding of the Jersey Mosquito will be prevented by the Town Improvement Association of Summit, N. J. The swamp lands and surface of waters throughout the village will be covered with oil. The aid of the Standard Oil trust has been solicited.

The Allegheny General Hospital will soon instal 4 new resident physicians: J. Wale Elphinstone, C. B. McAvoy, A. W. Sherrill, and Louis W. Smith. Dr. Elphinstone is a graduate of Western University, and the others are from the University of Pennsylvania.

Typhoid Fever.—Dr. J. Howard Taylor, Chief Medical Inspector of the Bureau of Health, has had instruction to thoroughly investigate the increase of typhoid fever in West Philadelphia. Of 102 new cases reported last week, 40% were located in the Twenty-fourth and Thirty-fourth Wards.

The United States Marine-Hospital Service Office, adjoining the Custom House at Philadelphia, will be remodeled and a new building will be erected with a dispensary, examination rooms and waiting rooms for the use of American seamen. Dr. H. W. Austin, who devised the plans for the new building, will still be in charge.

Oleomargarine.—Bills restricting the sale of oleomargarine have become operative in Pennsylvania. Licensed dealers only, according to the proposed law, are permitted to sell the article. The oleomargarine must be sold uncolored, on its own merits and not made to imitate butter. Severe penalties will be enforced in the event of the violation of the law.

The Children's Hospital of Germantown will now be known as the General Homeopathic Hospital of Germantown. The institution will soon remove to more commodious and better adapted quarters at 47 West Penn street. Owing to change of residence, the president of the hospital, John D. Pessano, has handed in his resignation.

Location of Hospitals.—An attorney representing property owners has drawn attention to a decision of the Supreme Court sustaining the act of April 20, 1899, prohibiting the establishment or maintenance of additional hospitals, pesthouses and burial grounds in built-up parts of cities. There are several institutions in Philadelphia that are affected, because established since the passage of the act.

Joseph P. Remington, of Philadelphia, has been elected chairman of the Committee of Revision of the Pharmacopoeia of the United States (1900-1910). Professor Remington has served as first vice-chairman since 1880, and has now succeeded to the chairmanship owing to the death of Dr. Charles Rice, of New York, on May 13. This office, the most important in pharmaceutical work, was held for 40 years (1840 to 1880) by Dr. George B. Wood, of Philadelphia.

Was it Swearing?—From Elizabeth comes the story that the ambulance surgeon was compelled to postpone sending the patient to the hospital by a superior, who demanded that they should wait for the priest and the last sacrament. Irritated by the delay the ambulance surgeon then told the driver to "drive like hell." For this he was charged with profanity. Governor Voorhees was moderator in the dispute, and announced his decision, with a twinkle in his eye, as follows: "I think, under all the circumstances, I would have done the same thing."

SOUTHERN STATES.

St. Louis Insurance Men are planning to discriminate against Christian Scientists. There is at present no way to legally prohibit them.

Dr. A. G. Maylie, of New Orleans, has received an unsolicited appointment as inspecting surgeon in the United States Pension Bureau.

Prof. Ira Remsen, head of the department of chemistry in the Johns Hopkins University, was elected president of the university June 3, at the regular monthly meeting of the board of trustees.

Leper Hospital.—The project on the part of the Leper Board of New Orleans of establishing a Leper Home at the Plantation House on the Elkhorn Plantation, Jefferson Parish, La., was met by indignant protests from the inhabitants of the Jefferson and St. Charles Parishes and resulted in the destruction by fire of all the buildings on the plantation during the night of May 22.

The Ophthalmological and Otological Society of Washington City at the thirty-seventh session elected the following officers for the ensuing year: President, S. O. Richey; vice-president, W. H. Wilmer; secretary and treasurer, Anton Coo.

A Swindler, supposed to be R. G. Stearns, is being sought by Washington detectives. He represented himself to physicians and dentists as an agent selling medical magazines at reduced rates. Investigation has shown that no such man was connected with the firms he mentioned.

Filtration.—The committee appointed by the U. S. Senate to investigate methods of filtration for the supply of Washington, D. C., found that slow sand filtration was preferable for clear water, while rapid filtration, with the use of a coagulant, was better for turbid water. Either method removed the bacteria.

A Christian Science College was refused a charter by the Secretary of State of North Carolina on the grounds that the institution had not demonstrated in its petition that it would conform to the legislative policy of the State, in relation to the treatment of disease, nor the requirements and practices of the State Board of Health.

Police Marshal Hamilton, of Baltimore, is endeavoring to make arrangements with the hospital authorities, whereby the latter will report suspicious cases to the police. One of the principal reasons for this is that under the present condition of affairs a criminal may pose as a patient and thus hiding his identity, escape detection.

The Recreation Building, near Tousand, Maryland, for the use of the patients of the Sheppard and Enoch Pratt Hospital will cost, when completed, about \$15,000. It will be located about 1,500 feet from the main building and will be built on the style of a country clubhouse. It will be 1 story in height, comprising 2 departments, 1 for the women patients and 1 for the men.

Florida Quarantine Stations.—A special meeting of the State Board of Health of Florida was held at Tallahassee recently to consider a proposal submitted from the United States Treasury Department, through the Marine Hospital Service, to turn over the maritime quarantine service to the State and lease all quarantine stations to the Government, as authorized through a joint resolution passed by the Legislature. The Board accepted the agreement.

Pure Milk Supply.—The Modified and Sanitary Milk Company, of Baltimore, organized by Baltimore physicians for the purpose of furnishing that city with a milk guaranteed absolutely pure and uncontaminated, has announced the opening of its laboratory and the dispensing of the milk from it. Not only the greatest possible care is exercised over the milk in respect to its quality and the manner of handling it, but careful oversight is extended to the herds, dairies and farms supplying it.

WESTERN STATES.

J. C. Carbus has been reelected superintendent of the Illinois Eastern Hospital.

Colorado State Medical Society.—A meeting will be held in Denver, June 18-20, 1901.

A Test Case.—Indiana's new medical law will be tested by George P. Parks, who was fined \$25.00 for practising magnetic healing without holding a medical license.

The Cincinnati Hospital has received from the estate of Dr. Max Thorner a valuable addition to its library in the reference books belonging to this specialist of nose, ear and throat diseases.

A Hospital for the Tuberculous will be constructed on the infirmary grounds of Cleveland, Ohio, the city hospital being no longer large enough to accommodate those suffering from the disease.

Milwaukee a Healthy City.—Registrar Coon, of the health department has made deductions from the government statistics showing that Milwaukee is the healthiest city of its class in the world with the single exception of Buffalo.

Louisville Hospital College of Medicine.—It is reported that Dr. Dudley S. Reynolds, a member and one of the founders of this institution, has been dismissed by the faculty because he persisted in denouncing cigaret smoking and smokers before his classes.

Insurance Verdict.—Judge McMasters, of Indianapolis, recently decided that the bite of an insect, when it disqualifies a man from his labors, should be classed as an accident, and, therefore, allowed Mr. Carson, the plaintiff in a suit against an insurance company, \$30.20 damages.

Deaths Due to Christian Science.—Reports from Chicago detail 3 deaths due to faith cure and lack of proper medical treatment. Mrs. Bessie Vance died after lingering 3 weeks, while Christian Scientists endeavored in vain to save her life and that of her newborn infant. Mrs. Christensen, who was burned in a fire, died after 12 days of unrelieved pain.

Smallpox Regulation.—The school and health authorities of Cleveland, Ohio, have decided that no child shall be vaccinated without 1 day's warning. The children must then submit to vaccination or be debarred from school. If a smallpox victim is discovered in the school room, however, the doors shall be locked and vaccination of the pupils and disinfection must be made at once.

Two Dowie Healers, O. Inouye and T. Kitano, of Japan, who have been studying at Zion, are to be sent back to their native country as missionaries. The Japanese Consul, Toshiro Fujita, of Chicago, has warned them that arrest and imprisonment will be the result of any attempt to introduce their methods of healing into Japan, as they are forbidden by law. The Japanese laws prescribe vaccination every 3 years, and any evasion meets a vigorous punishment.

The Cigaret Crusade is being pushed vigorously by the authorities of Chicago. The law requiring a special license to sell cigarettes will be strictly enforced, and all dealers will be reported to the police officials who fail to meet its requirements. An ordinance has been introduced into the Council prohibiting the sale of cigarettes, cigaret paper, or cigaret tobacco within 600 feet of a school house, and also forbidding the giving away of such articles by persons unlicensed to sell them.

Leper in Chicago.—A follower of Alexander Dowie, named Stewart, is reported to be suffering from leprosy in an advanced stage. The city health department has detailed a physician to look after the sufferer, who is thought to have contracted the disease in Australia. It is said there is no law under which he can be removed from the community, but he has been warned to keep away from others. Efforts to give him the benefit of medical treatment are met with the assertion that Dowie's prayers will effect a cure.

Chicago Sewage.—Through a commission of experts who have been conducting experiments to determine to what extent Chicago sewage, conducted through the drainage canal, pollutes the waters of the Illinois River, the State Board of Health has submitted a report which is reported to disprove the contentions of St. Louis as to the effect of the canal on the water of the Mississippi. It is claimed that the experiments show that the condition of the water of the Illinois River at Grafton is the same as though no Chicago sewage went through the canal.

Sanitation of Chicago Schools will be investigated by the Chicago branch of the Association of Collegiate Alumnae. Questions relative to the cleanliness and sanitary measures adopted by the schools, the general health among the children, and a study of the diseases prevalent in the different school districts will be forwarded to the principals of the schools throughout the city. The answers to these questions will be published as statistics. The final object of the association is the enactment of a new sanitary law, and the report will be the precursor of a bill to the State Legislature on the subject.

CANADA.

Dr. George Stirling Ryerson, of Toronto, has been made a Knight of Grace of the Order of St. John of Jerusalem, for his services in South Africa.

Dr. Patterson, of Winnipeg, under direction of the Dominion Government, is visiting the northern Indian reserves in the territories to investigate the reported smallpox outbreak.

Lady Minto's Cottage Hospital plan for the Canadian Northwest territories has been furthered by a gift of \$1,000 from E. B. Osler, conservative Member of Parliament for Toronto west.

The Canadian Nurses' Association has been incorporated with the object of furthering the best interests of the profession, financially and professionally. A universal standard of training nurses will be established and maintained.

Public Health Legislation.—A bill before the Legislative Assembly of the Province of Quebec, provides that the Secretary of the Provincial Board of Health shall receive a salary not exceeding \$2,400 a year, and that the Board may appoint analysts, a statistician, and other necessary officers. It also provides for the exclusion of unvaccinated children from schools.

Ontario Physicians recently requested the government to test the validity of a \$2 annual tax imposed by the medical council. Several hundred physicians in Ontario were recently reported in arrears and some who refused to pay were suspended from practice under the Act. Objection is taken to the tax on the ground that it maintains a costly building in Toronto of which the outside physicians get no benefit.

FOREIGN NEWS AND NOTES

GENERAL.

Typhoid Fever in South Africa.—Mr. Broderick, Secretary of State for War, reports typhoid fever among the troops in South Africa as follows: January, 2,121 cases, 356 deaths; February, 2,119 cases, 391 deaths; March, 2,018 cases, 313 deaths.

Deaths from Plague.—It is reported that during the week ended May 25 there occurred in Hong Kong 187 deaths from bubonic plague. It is reported that although the plague has already invaded several hundred villages in the Punjab the regulations against its spread have been so irritating to the natives that the Government has been obliged to suspend them.

Tuberculosis in Japan.—Statistics show that 32% of all deaths in Japan are due to tuberculosis. Its prevalence and the frequency of rheumatism are attributed largely to the fact that the Japanese always live in one-story houses built upon the ground with inadequate ventilating and heating arrangements, making their homes cold, dark and damp.

Plague.—Lord Stanley, in reply to a question, reports that the plague among the troops in South Africa up to May 3, amount to 14 cases among European soldiers, 20 native drivers and 7 other employees. In Australia cases continue to occur at Perth and Brisbane. In New South Wales and Victoria the extermination of rats is prosecuted vigorously and precautions are observed against introduction by sea.

Obituary.—FREDERICK WILLIAM BAYES of Walsingham, Eng., aged 76. D. C. DAVIDSON of the Indian Medical Service, May 2, aged 50. SODEINDE ALFRED LEIGH-SODIPE at Lagos, West Africa, April 15. S. LAMANSKI of St. Petersburg, aged 60. DR. V. ITERSON, professor of clinical surgery, in Leyden. DR. DECROIX, the founder of the French Antitobacco Society, aged 80. CHARLES NATTRASS of Sunderland, Eng., May 2.

Labrador Hospitals for the fisherfolk number 3; 1 at Battle Harbor, 1 at Indian Harbor and the third is in course of erection at St. Anthony, on the North French Shore. In addition to these there is the hospital ship *Strathcona*, of which the medical officer is captain, which is equipped with 6 beds and all necessary appliances, including x-ray apparatus. This ship constantly cruises up and down the coast and last year handled 1,020 cases.

Need of Medical Research.—A strong plea is urged by the *Lancet's* correspondent from India for the establishment of well-equipped research laboratories in Calcutta and Bombay, where the field for original work in bacteriology and experimental pathology is vast and in view of the fact that no advance has been made in the knowledge or treatment of plague, cholera, relapsing fever and other anomalous fevers, of which so much is written, within the last 4 years.

Income of Berlin Physicians.—The Medical Chamber of Berlin and the province of Brandenburg has issued an interesting report on the subject of the income of the medical profession residing in that district. The chamber is authorized to fix an annual sum to be paid by every medical man for the expenses of the chamber and the support of distressed members of the profession. It has been decided that a uniform rate of 10 marks (10s) should be paid and an additional sum by those earning more than 5,000 marks (£250). The chamber has been informed by the income-tax officials that of 1,946 Berlin medical men under the jurisdiction of the chamber 529 earned from 900 to 3,000 marks (from £45 to £150), 273 from 3,000 to 5,000 marks (from £150 to £250), and 785 more than 5,000 marks, the largest income amounting to 295,000 marks (£14,750). It appeared that 107 medical men had no taxable income at all and the income of 252 could not as yet be ascertained. In the other towns of the province the proportions were similar to those found in Berlin, so that 4% of all the medical men had no taxable income, 26% had an income from 900 to 3,000 marks, 17% from 3,000 to 5,000 marks, and 40% more than 5,000 marks. In 13% no reliable information could be obtained.—[*Lancet*.]

GREAT BRITAIN.

A Monument to Huxley is proposed at Ealing, his birth-place, but the form is not decided upon.

Plague Victim.—A man has been found at Willesden, a suburb of London, apparently suffering from an extremely mild form of bubonic plague.

Alfred Harmsworth, of the *London Daily Mail*, has given \$50,000 to the Royal Hospital for the establishment of a plant for the treatment of lupus by light.

Sir William MacCormac, president of the Royal College of Surgeons of England, has been elected a Foreign Associate Fellow of the College of Physicians of Philadelphia.

Bequests.—The late Mr. T. E. Exley bequeathed by will £1,000 to the Bristol Royal Infirmary, £1,000 to the Bristol General Hospital and £500 to the Trowbridge Cottage Hospital. Miss Mary Cannington of Bristol bequeathed recently £10,000 in Consols to the Bristol Royal Infirmary, £5,000 to the Bristol General Hospital and £500 each to the Bristol Dispensary and the Bristol Eye Hospital.

Extermination of Mosquitos.—A Glasgow citizen whose name is withheld has placed at Major Ross' disposal a sum of money sufficient to make a year's thorough trial of the relation of mosquitos to malaria in some malarious district of West Africa and a corps of workers with necessary equipment will proceed shortly to Sierra Leone to exterminate the mosquitos in some selected town or district the choice of which will depend mainly upon the cooperation offered by local authorities.

Maple scale or cottony cushion is reported to have gained a foothold in Washington, Idaho and Oregon to the detriment of maple, apple and cherry trees. This pest, supposed to be brought there by the Australian Steamship Line, originated in the acacia forests of Australia, spreading to South Africa, in 1873, and later to New Zealand. It was brought into California in 1868 on trees and shrubs from Australia, and increased so rapidly that one potted plant is said to have spread the scale through the San Gabriel Valley, and soon the orchards of the State were infested. Albert Köbele was sent to Australia to investigate what means there existed there to keep its ravages in check and prevent the utter extermination of the forests, and he sent back colonies of a scale-destroying beetle and a fly which punctures the scale to deposit its eggs, which as grubs devour it. These were distributed and by 1889 the work of extermination was practically complete.

Street Cleaning in Glasgow.—This Scotch town with a population of 750,000 has learned not only to keep its 315 miles of streets clean, but to realize a large profit from the refuse. The Glasgow Cleaning Department controls several farms with an aggregate area of 800 acres, employs 1,300 men, and owns 900 railway cars, 300 horses and a vast array of carts. It has besides its own railways on its own estates, its own quarries and workshops. The city refuse is divided into 4 distinct classes, domestic garbage, refuse from business houses, excrement from public works and dwellings, stable manure and refuse from abattoirs. These last 2 articles mixed together form a compound which commands a ready sale and brings a good income to the city. There are special establishments in various parts of the city known as dispatch works for the separation of inferior material from that having value, where ashes and sweepings are screened and scientifically mixed with a fixed quantity of excremental matter for use as a fertilizer and this is eagerly bought up. The iron, tin and paper are sold separately. The useless matter is consumed in furnaces and the civic government of Glasgow is considering a scheme by which the heat resulting from the burning garbage may be utilized as its volume is sufficient to generate 890 horsepower of steam an hour, or power enough to light 600 street lamps of 2,000 candle-power each. The cost of the operations for the year ended May, 1899, was \$365,000 and the revenue was \$750,000.

CONTINENTAL EUROPE.

Hippocrates' Grave is reported to have been discovered at Larissa, in Thessaly, during some recent excavations.

A Hospital for Carcinomatous Patients and research will be founded by Professor Levschin, of Moscow. He has succeeded in raising \$175,000 for that purpose.

Military Medical Academy.—It is reported that the Russian Ministry for War contemplates the reorganization of the Military Medical Academy, where the students are subjected to military discipline and are required to serve 3 years as military surgeons after graduation.

Baby-farming in Norway.—A report from Christiania states that 3 women killed 27 children, by starvation or suffocation, in a baby farm since last summer. It is thought that some of the mothers, who belong to all classes of society, were not ignorant of the fate awaiting their offspring.

An Institute for the study and cure of tuberculosis and other infectious diseases has been founded by Professor E. Maragliano of Italy. It is modeled after the Pasteur Institute. Physicians are given opportunities for special study in the line of serum culture, etc., and contagious diseases are treated gratuitously.

Smallpox.—For the week ended May 5, 1901, the official report of cases of smallpox in Naples was 95, with 24 deaths. The disease prevails through Italy, with marked prevalence in Naples, Salerno, Avellino, and other towns. A careful lookout is kept for cases among emigrants about to embark for the United States.

Suicides in Germany.—Last year about 4,000 of the 8,000 suicides were victims of drink, and more than 2,000 were unbalanced mentally. The proportion of men to women was as 3 to

1. As if to verify the statement that women seldom shoot themselves over $\frac{2}{3}$ of the female suicides in Germany either poisoned or drowned themselves.

Memorial to Professor Ollier.—W. W. Keen, Treasurer of the committee to solicit subscriptions for a monument to the late Professor Ollier, in Lyons, wishes to inform the profession that he has received \$649 from 103 subscribers, and has forwarded the same, less \$4.60 for postage, printing, etc., to Dr. G. Mondan, of Lyons, France.

Dr. Laborde reported to the Academy of Medicine of Paris a novel and painless method (the discovery of a dentist of Paris) of extracting teeth. Tubes from a phonograph, playing gay music, are connected with the patient's ears just before the anesthetic is administered. The music shuts out all extraneous sound and the distorted visions usually incident to the beginning of anesthesia are avoided. Then, too, the after effect of nervous depression is lessened.

German School Gardens.—Many French, Swedish and German cities, but particularly Leipsic and Plauen, in Saxony, have a plot of land not far removed from the schools, where gardening is taught to the children on 1 or 2 afternoons in the week. They learn not only how to sow the different kinds of vegetable seeds, how to transplant trees, how to tell when melons are ripe, how to care for strawberry beds in all seasons, but also learn the botanic names and relationship of the plants, and the name and appearance of all the common weeds and the poisonous plants, which are plotted by themselves and labeled. A little pond holds aquatic flora.

German Sick Clubs.—Through the intervention of the municipal authorities the strike of the medical officers of the Leipsic Sick Club has closed and an agreement has been made: That the committee of the Medical Officers' Union shall be formed exclusively of members engaged in club practice; that a permanent court of arbitration shall be created, composed of members of the Leipsic Medical Chamber and members of the committee of the club, over which the chief medical officer of the city presides, and empowered to adjust any dispute that may arise between the club and its medical officers; and that the club shall maintain the free choice system and shall not issue orders direct to the medical officers without reference to their committee. This agreement has been accepted by both parties and pleasant relationships have been established again.

Red Light Treatment for Measles.—A cable from Berlin says: The treatment of diseases by the use of colored light, however much it might be ridiculed, is obtaining a footing here. The latest novelty is the cure of measles with a red light. Dr. Chatinier publishes in a popular medical magazine the results of a number of experiments, all having been favorable. Patients with measles are kept in rooms lighted with subdued red light, much like that in a photographer's dark room. Dr. Chatinier uses red silk paper pasted on his window panes. The patient receives no medicine. Dr. Chatinier explains that the prevailing red light enables the inflamed skin to rest. All other colors, especially strong shades of violet, excite the skin. He was first attracted to the discovery by noticing that the peasant women in his district always wrapped children with measles in red cloth.

Sanitariums for Tuberculosis.—M. Lemoine, at a meeting of the Academy of Medicine in Paris, deplored the haste shown by France to follow the lead of Germany in constructing huge establishments without first considering if the system of sanitariums was the best for treating tuberculosis, which causes the death of 150,000 persons yearly in France. From a study of the results obtained in various institutions of this kind, he is led to a preference for the plan proposed by Brunon, of Rouen, to transform into sanitariums the wards of communal infirmaries, or even peasants' cottages in suitable locations, and advocates admitting tuberculous patients into the existing establishments in all country places, after making necessary structural alterations and placing them under the control of the local medical men, and also enlarging the scope of the Poor-law medical officers with a view to the prevention of the disease.

Sanitation in the Austro-Hungarian Navy.—Hospital admissions 25 years ago, from the fleet, ashore and afloat, were equal to 641 per 1,000. Sanitary measures have reduced this ratio to 467 per 1,000, per annum. At Pola, the "home of the fever" (its former name) the admissions due to malarial affections have fallen from 800 per 1,000 to 30 per 1,000. Quinin, prophylaxis and sanitation have brought about this improvement. Trachoma, scurvy and smallpox, which formerly swelled the sick list of the navy to an inordinate degree, have almost entirely disappeared. Typhoid fever still is epidemic some time in the year and there is still about 0.3% of tuberculosis, but these too are gradually lessening with the improved sanitation. In the last 20 years venereal diseases have diminished from 104 to 90 per 1,000. More diseases of this character occur in the navy of the empire than in the army. This same fact has been noted in the armies and navies of Germany, England and Italy. The Pola hospital authorities have discovered that typhoid bacilli live 20 days in oysters; and they have also found that fermented grape juice is death to this germ, inoculated wine having been found sterile after 24 hours.

SOCIETY REPORTS

AMERICAN GYNECOLOGICAL SOCIETY.*

26TH ANNUAL MEETING HELD IN CHICAGO, ILLINOIS, MAY 30
AND 31, AND JUNE 1, 1901.

FIRST SESSION.

Dr. CHAUNCEY D. PALMER (Cincinnati) read paper on **Intraligamentous Cysts, their diagnosis and treatment.** He spoke first of the classification of ovarian tumors in our textbooks as being very unsatisfactory. What we need is a classification, at once clear to our understanding, and helpful by way of diagnosis and treatment. He spoke then of oophoritic, paroophoritic and parovarian cysts. The oophoritic cysts are the *hydrops folliculorum* and the unilocular and multilocular cysts. The oophoritic have a Graafian follicular origin, are not papillomatous, except very rarely. The paroophoritic cysts start from the hilum of the ovary and are papillomatous. All kinds of cysts, whether oophoritic, paroophoritic or parovarian, may grow into the folds of the broad ligament and become intraligamentous. The paroophoritic cyst is most apt to take on this special course of movement in its progressive development. He then referred to the symptoms and the signs before removal which would enable us to differentiate intraligamentous cysts. All ovarian cysts of whatever kind should be removed by surgical procedures, the sooner the better. But the removal of intraligamentous cysts demands more time, a most correct knowledge of the parts and surroundings, and superior skill. He then dwelt upon the advisability, if not necessity, of availing ourselves of the extraordinary opportunities, when the abdominal cavity is opened, to see and to feel, and to map out, *what is, where it is,* and determine *what methods* are best to adopt in the removal of these pelvic growths. Intraligamentous cysts are, as a rule, easily peeled out of the broad ligaments. Enucleation, first suggested by Dr. MINER, of Buffalo, can be done, but it ought only to be attempted when the attachments are superficial. The attempt commenced in the old way on some intraligamentous cysts may have to be resigned as an incomplete operation, or as an inoperative case. Many such patients have died on the table. He referred to the dangers of wounding the uterine arteries; and then he earnestly advocated the advisability of completely excising the uterus, as well as appendages thereof, when the cysts are bilateral, and when they are deeply imbedded within the surrounding textures. This new method of procedure, while seemingly the more radical way, is the only rational method of a skillful surgical extirpation of the diseased structures. He lauded highly the irrigation of the peritoneal cavity with gallons of hot salt water after section, and the measures he had utilized of a continuous peritoneal irrigation of hot sterilized water, used for hours or days, in many cases of post-operative septic peritonitis.

In discussion A. LAPHORN SMITH (Canada) reported 2 cases, 1 operated upon by the old method, with death of patient; the second, in which the broad ligament cyst was complicated by a uterine fibroid. That organ was removed and the hemorrhage was easily controlled. The large raw surface left was covered by peritoneum by using a running suture of catgut.

WATHEN (Louisville) thinks the essayist magnified the dangers of these operations. Thorough knowledge of the pathology of these growths makes the treatment easier. They rarely extend to the base of the broad ligament or split the mesorectum. He cited 2 cases successfully operated on when uterine extirpation was practised.

SUTTON (Pittsburg) thinks that the safe removal of these growths has been much facilitated by the employment of the Trendelenberg position.

KELLY (Baltimore) urged that the cyst be shelled out of the broad ligament, and the tube and ovary be allowed to remain if their retention was important or necessary. Sometimes it is difficult to differentiate between pseudo and true intraligamentary cysts, as these inflammations may cause adhesions, smooth in appearance, leading to mistake in diagnosis. The true cysts are rarely papillomatous, and usually monocystic. If disease is also present on opposite side, cut across from it and shell out the growth and control bleeding. Bisection of the uterus will do much to facilitate the operation. Sew the peritoneum over the raw surfaces, and if necessary drain through the vagina with iodoform gauze.

JOHNSTON (Cincinnati) spoke of the difficulty of diagnosis, and of the desirability of saving the opposite ovary when possible. He has never found it necessary to remove the uterus.

BALDY (Philadelphia) considers that the false cysts are generally small, and the true intraligamentary cyst rarely requires the ligation of either ovarian or uterine arteries, but having very slight blood supply, may be easily enucleated. He has little sympathy with the practice of using vaginal drainage, and thinks it useless and unnecessary.

HENROTIN (Chicago) entered a protest against such extensive irrigation of the peritoneal cavity; thinks that it is not

required and is, therefore, objectionable. He spoke of the liability of the ureter to pass over the summit of these intraligamentous growths in a tortuous manner, and the possibility of its being injured. E. C. DUDLEY (Chicago) agreed with him.

The paper by W. GILL WYLLIE, M.D. (New York) on **Chinical Observations on Uterine Fibroid Tumors and their Treatment** was read by title.

Dr. WM. H. WATHEN (Louisville) read a paper on **Improved Technic in the Surgical Treatment of Uterine Myomata**, describing the various procedures he employs, the methods advocated, and indications for each.

Dr. PHILANDER H. HARRIS read a paper on **Painful Menstruation as a Factor in Determining the Character of Operations on the Uterine Appendages.** He divided all cases of dysmenorrhea into 2 classes. 1. Primitive dysmenorrhea, including all cases in which the pain dated from the commencement of the menstrual function. 2. Acquired or secondary dysmenorrhea which comes on during the course of menstrual life—menstruation having previously been painless. Primitive dysmenorrhea may be increased or altered in character by the acquirement of an additional cause for painful menstruation. Tubal suppuration, either alone or with ovarian abscess, causes painful menstruation which disappears after excision of the tubes. And after this excision of the tubes, even if ovarian tissues be left, the patients are usually cured of all their symptoms. He does not remove either one, or both ovaries for the single purpose of curing dysmenorrhea, and in excising suppurating tubes, believes the apparently healthy ovaries should be spared in all cases of acquired dysmenorrhea, for by so doing, we retain the item of menstruation which contributes so much to the moral and physical well being of women, and also render menstruation painless. The least mutilating operation should be employed, leaving the patient, if possible, with the valuable quality of possible fertility.

Discussion.—MANN (Buffalo) believes that term "dysmenorrhea" should be applied to painful menstruation alone and when due to uterine disease or contraction and that the pain produced by disease of the tubes or ovaries should not be thus classified.

EDEBOHLS thinks that dysmenorrhea may be purely ovarian—the pain be present at regular intervals even when the uterus and tubes are absent. It may be due to a variety of causes and the time of its occurrence often indicates the point of disease. It is unwise to leave a vestige of the ovary in operating for symptoms due to ovarian disease.

A. P. DUDLEY believes that the foundation of the pain may be found in the nerve supply and that pelvic congestion is a prime factor—any obstruction to the pelvic circulation producing it.

LAPHORN SMITH thinks that when the pain is so severe as to incapacitate a woman for active work that removal of the appendages is justifiable. The question is how bad the case must be before the radical procedure is employed. He gives his patients the benefit of 1 year's treatment and if they are unrelieved, he then operates.

KELLY considers the treatment of these cases is very unsatisfactory. A radical operation for the relief of dysmenorrhea should never be performed unless some structural or macroscopic disease is present. Fight the battle without operation. He has secured surprising results in some cases by the use of parotid or ovarian extracts. Dilatation or division of cervix is sometimes beneficial. Use the milder sedatives and avoid morphia. Treat the case palliatively and never radically.

WATHEN mentioned the great variety of causes producing the pain and deprecates any operation when disease is absent. Curettage often gives satisfactory results.

BALDY believes that in the class of patients in whom the pain is confined to the menstrual period only palliative measures may be employed, but in that class who suffer during the greater part of the month and are thus made complete physical wrecks from the pain and excessive bleeding that complete extirpation of the uterus, tubes and ovaries, is indicated and justifiable. He would not leave any ovarian tissue if relief from pain was the object of the operation.

GORDON (Maine) advocates the complete extirpation of the uterus and its appendages, when the menstrual pain is great and lasts almost the entire month.

HENROTIN thinks that the patient should be consulted and her wishes acceded to, up to a certain point. She has the right to earn her own living, and if operation is necessary for this it should be performed. Often an incision is necessary to reveal unsuspected adhesions, which may be the cause of the trouble.

SUTTON (Pittsburg) spoke of postmarital cases of dysmenorrhea, and of gonorrhoea a factor in their causation. He has found it necessary to remove the uterus as well as the adnexa in order to give complete relief.

ENGLEMAN has successfully employed dilatation and the galvanic current for the relief of the pain and hemorrhage.

Dr. E. GEHRUNG (St. Louis) read a paper on **Status of Menstruation.** He believes menstruation is not, as has been supposed, a special function of the generative organs of woman, but only the perverted counterpart of the estruation of the lower animals. This transformation into a monthly "hemorrhage" (menorrhagia) has generally been brought about by the necessities and results of the social, moral and conjugal life of mankind, as well as through the transmission by inheritance of certain debilities of the generative apparatus, and more espe-

*Specially reported for AMERICAN MEDICINE by Dr. Wilmer Krusen.

cially by the erect position and its natural consequences, assumed by the human species. This fact being admitted, the profusion and prolongation of the sanguinous loss is a proof that it is now a physiologico-pathologic condition, predisposing to anemia and all its direful consequences, preeminently to the nervous system. In the great majority of cases the quantity of blood lost during so-called normal menstruation is an unnecessary and therefore pathologic waste of the very essence of life. It stands to reason that in all cases of depressed vitality, this loss should be reduced as much as possible. The best means for controlling the waste is the vaginal (not uterine) tampon, applied "secundum artem." When curcottage is not indicated or applicable, and where it has failed in gaining the desired result, the tampon is the means indicated. Chronic and acute inflammation of the pelvic organs are contraindications. Unless the restriction of the waste is put in execution, tonics are useless, because they simply increase the pressure and consequently the waste, while after the repression or simultaneously with it, they seem to work wonders. The superstitions surrounding menstruation, as well as the misunderstanding of its true character by the medical profession as well as the public, have caused a world of trouble and suffering by the neglect of the necessary advice and treatment.

AFTERNOON SESSION.

Dr. GEORGE I. ENGELMANN (Boston) read a paper on **The Age of First Menstruation in the United States**. Over 10,000 observations as to the time of first menstruation of American-born women, many with reference to points never before investigated, here or elsewhere, give me ample material for an authoritative solution of the questions involved. These observations, from my own practice and that of helpful friends, are many, and the identity of results obtained in far distant points, Montreal and New Orleans, Cincinnati, St. Louis and Boston, vouches for their correctness; furthermore, they are corroborated by all previous records, a total of 6,000 in such points as these may cover. The mean age of first menstruation in this country is 13.9, or 14 years, the same in the United States and in Canada. Climatic differences in no wise influence pubertal development within the bounds of the North American continent; the American-born, be they of American (14.1), German (14.5), Irish (14.5) or French (13.6) parentage of the same class, attain puberty at the same age in Montreal, St. Louis or Boston; the Negro does not vary (14.05) whether in New Orleans or St. Louis. The greatest variation caused by the extremes of all influences is 1 year, from 13.5 in the girl of highest refinement and education to 14.5, which is the period for the American-born of the laboring classes of German and Irish parentage; in other countries the difference between the extremes of social classes is from 2 to 3 years. Refinement, education, city life, nerve stimulation, determine precocious puberty; ignorance, poverty and manual labor retard; social status in itself means very little; heredity and race have a slight determining influence. The American-born are more precocious than the women of other countries in the same zone; 14 is the age of puberty in the United States and Canada, 15.5 in the temperate zone of Europe. The native American is more precocious than the American born of foreign parents, but the latter closely approximates the American of American parentage, even in the first generation. Racial characteristics fade rapidly away; the age of puberty in Germany is 15.5 to 16, in Ireland 15.3, and for the girl born in America of German or Irish parentage, 14.5, in St. Louis as it is in Montreal; the Canadian French are the only exception, between 14 and 15 in their native land, these alone of all races are more precocious than the American of the same class when born in this country; 13.7 is the mean age. Climate here has absolutely no influence; race, mentality, surroundings, education and nerve stimulation stand out prominently in this country as the factors which determine precocity.

Dr. BALDY (Philadelphia) read a paper on **Cancer of the Body of the Uterus**. He expressed incredulity as to the accuracy of German statistics and emphasized the wide practical difference between cancer of the cervix and cancer of the fundus. Operations of all kinds have proven a dismal failure as far as securing a cure in cancer of the cervix, and the proportion of permanent cures is probably as low as or below 5%. Of 24 cases of cancer of the fundus which have applied to him for treatment, 3 refused operation, 21 were operated upon; 2 died from operation, 1 from recurrence, a total of 6 not cured, or 75% of cures. The enormous difference in results of treatment in same disease located in different parts of the same organ was particularly noticeable, even when allowance is made for all possible mistakes and for the total unreliability of statistics.

Dr. CYRUS A. KIRKLEY (Toledo) discussed the **Status of Hysterectomy for Uterine Cancer**. The paper was a plea for conservatism in the surgical treatment of uterine cancer, and contrasted its pathology and treatment of half a century ago with that of the present. While we have revised nomenclature as to the varieties of uterine cancer, actual knowledge of the disease has not materially advanced. Old truths may have been made a little clearer as to its pathology, but its etiology is still unknown, and notwithstanding the advantages of asepsis, and perfect operative technic, its treatment is still unsatisfactory. Due credit was given the advocates of vaginal hysterectomy for their skill, and for whatever pathologic progress may have been made within the last few years. Its peculiar fascination made it too general, and proper indications for it were too

often disregarded, and as often misunderstood. Instances were given pointing out this truth. With these discordant views as to the propriety of so serious an operation, the primary mortality of which is at least 10%, we might well hesitate in its adoption. The operation should be done at that early stage when microscopic examination is necessary for a correct diagnosis. Most cases have passed the limits of radical operation when they apply to the surgeon. The paper took the view that adenocarcinoma of the body of the uterus in its early stage, while yet localized, is the only form of cancer clearly indicating vaginal hysterectomy. Hysterectomy gave the best results in this variety of cancer. Dr. Cullen's and other tables were quoted showing average primary and remote results, but little was found in them to recommend vaginal hysterectomy as a general rule of practice. He then discussed the Rumpf-Reis-Clark operation, in which Dr. Pryor had reported in a total of 95 cases by different operators, a primary mortality of 11.2%. When the disease has extended so far as to require it, little could be expected from any radical operation, because in most cases it was impossible to know whether all the diseased glands and infiltrated tissue had been removed. From the paper's view-point the only indication for abdominal hysterectomy for cancer is when the disease is strictly confined to the cervix and body, or to the body alone. Electrocauterization as practised by Dr. Byrne was given the preference over all the other methods of operating. It had not received the recognition it deserves. Dr. Byrne's skill in its application, could only be acquired as in other operations. Freedom from danger, and longer period of exemption were its strongest recommendations. An old table published by Dr. Byrne in 1889 was referred to, so that in comparison vaginal hysterectomy might have the advantage. In a total of 367 cases there was not a single death from the operation. The position held by our fathers 50 years ago, that hysterectomy for cancer has its narrow limitations, that it should be done early, if at all, and that only temporary relief can be hoped for is just as true today.

A paper on **Prolapse and Procidencia of the Uterus** was read by Dr. HENRY T. BYFORD (Chicago). He holds that the essential features of prolapse are the want of supporting power of the pelvic connective tissue. To suture the uterus to the abdominal walls is to support the pelvic connective tissue by means of the uterus and is wrong and inefficient. The best and most rational method is to draw up and attach the periuterine tissue and thus keep the uterus up by means of its natural supports. In addition to the ordinary operations for lacerations and relaxation at the vaginal outlet, the following method is proposed: (1) Shorten the round ligaments intraperitoneally, making one large loop of each ligament, and then stitch the loop to the parietal peritoneum a little above, and internal to, the internal inguinal ring, which is plainly marked by the entrance of the ligament. The uterus is now held in a nearly normal position and the relationship of the other ligaments, as well as the effect of our work upon them and upon the position of the uterus, can be gauged at every step. (2) Suture the infundibulo-pelvic edges of the broad ligaments forward to the parietal peritoneum, external to the internal inguinal rings, as high as they can be drawn without much resistance. Then suture any available relaxed part of the broad ligament forward over or beside the round ligament loops. (3) Put a suture through the base of each round ligament at its junction with the uterus, and suture it to the peritoneum over and beside the bladder. (4) Examine the sacrouterine ligaments. If the peritoneum corresponding to their location is not drawn up and made somewhat taut by the new position of the uterus, or if the cervix sags far forward toward the vaginal entrance, take a short fold or tuck in it and suture it to the broad ligament beside the cervix, and perhaps slightly to the edge of the cervix, getting as broad a peritoneal apposition as possible. (5) Search for the remains of the urachus at the lower end of the abdominal incision. Start a slit in the peritoneum an inch above the lower angle, and half an inch on either side, and extend them downward and outward to the bladder wall. Make a transverse incision on either side, uniting the upper end of the slits to the abdominal incision. Separate the peritoneum between these slits, including as much connective tissue as possible, from the underlying fascia, and there will be formed a partly divided flap of connective tissue and peritoneum with the urachus near its center. Fold or twist this loosely into a sort of cord and attach it to the rectus fascia at the edge of the incision, and high enough up to draw the bladder and anterior peritoneal wall well up. This suspends the bladder somewhat after the manner described by Dawson (*British Medical Journal*, July, 1898). The external sutures should catch hold of the newly formed vesicle cord, or artificial urachus, and the lower one may even engage a few fibres of the vesicle wall.

GEORGE M. EDEHOHL, of New York, read a paper on **Panhysterokolpectomy, a new Prolapsus Operation**: The very multiplicity of operations heretofore proposed for the cure of complete prolapsus of the uterus and vagina is proof, if such were needed, that no operator of larger or longer experience is entirely and absolutely satisfied with the results of all his prolapsus operations. There is room, in the treatment of complete prolapsus of the uterus and vagina, for an operation which, properly and successfully performed, will guarantee a certain and permanent cure of the prolapse. Such an operation is panhysterokolpectomy, the essentials of which consist in complete removal of the uterus and vagina, followed by operative

obliteration or columnization of the bed of the genital tract. The tubes and ovaries are not disturbed, if healthy; if diseased, they are removed with the uterus and vagina. Obliteration and columnization of the bed of the removed uterus and vagina is effected by means of from 7 to 9 buried pursing sutures of chromicized catgut placed about 2 to 2½ centimeters apart and running parallel to each other. Each suture gathers the raw surface from the periphery in circular fashion and draws or purses them together in the median line. It is buried by being pushed upward toward the abdomen while the next suture is being tied beneath it. The effect of the completed operation is to build a solid pelvic floor 10 to 15 centimeters in depth, and to establish broad apposition of the base of the bladder and the anterior surface of the rectum, conditions similar to those obtaining in the male pelvis. The patient is kept in bed for a week after operation. Recurrence of prolapse is impossible after a correctly and successfully performed panhysterocolpectomy. The operation is indicated in the severest cases of total prolapse, and more especially where other operative procedures have been tried and failed. The interference with further marital relations must be explained and accepted by the patient prior to operation. In the case of a married woman the husband must also be consulted. Four cases have thus far been operated upon by the author of the operation, all with perfectly satisfactory results.

HUNTER ROBB (Cleveland) read a paper on **Pus in Abdominal Operations**. He emphasized the value of perfect technic in abdominal surgery—operators frequently err in carrying out an operation when the patient is too weak for radical work. In pelvic abscesses, operations should be deferred if possible until the acute stage passes. The streptococcus pyogenes is the microorganism most to be feared. Drainage through the abdominal incision is rarely necessary and if drainage is required he selects the vaginal route. In operating, the healthy peritoneum should be protected with large gauze sponges and large quantities of normal salt solution be used to irrigate and to dilute any poisonous material—a quantity being left in peritoneal cavity. He presented a careful statistic study of 72 cases of suppurative disease of the appendage that had been operated upon, with 2 deaths. In about 33% of these cases a gonorrhoeal history was clearly established. Many of them were accidents of labor or abortion.

The first paper read was on the **Removal of the Female Urinary Bladder for Malignant Disease**, MATTHEW D. MANN (Buffalo). This will be published in a future number of AMERICAN MEDICINE.

MANN says that the operation for removal of the bladder has not received enough attention in this country, there being very few cases on record. Cancer of the bladder is rare, but is the commonest form of growth found in the bladder. The diagnosis can be made by the symptoms, the use of the cystoscope, palpation, and the examination of the urine. Treatment may be removal through the urethra, the vaginal septum, or by suprapubic cystotomy. The operations are the removal of the growth and its base, resection of part of the bladder, or cystotomy. Indications for total removal are multiple growths, return after removal, extensive involvement of the base, and extension of cancer of the cervix uteri into the bladder. The ureters need no attention at the time of operation, as by the removal of a portion of the anterior vaginal wall, they will discharge into the vagina. If possible the ureteric openings into the bladder should be left intact. This will rarely be possible. He does not believe in ureterointestinal anastomosis. The vagina can be used as a receptacle for the urine, as was done by Pawlik. If this be done, there will be little danger of infection traveling to the kidneys, as the newly-made bladder can be kept clean. The operation is done in the Trendelenberg position. The peritoneum over the bladder being cut, the bladder is enucleated by the fingers, and the base, with the anterior vaginal wall still attached, is removed. The uterus is then removed, and the peritoneum closed over the floor of the pelvis. Mann reports 2 cases, both of which recovered from the operation, and has collected from the literature 14 cases more. He concludes that in certain malignant disease of the bladder, total extirpation is a justifiable operation, offering no serious difficulties to an experienced abdominal surgeon, and giving the patient a chance for a comfortable continued existence.

The President, Dr. VAN DE WARKER, then delivered his annual address and commented upon the splendid achievements of gynecologists as specialists, their duty to the profession and the laity, and the relation of the gynecologist to the general surgeon and to other specialists. His subject was **The Future of Gynecology as a Surgical Specialty**. The general scope of Dr. Van de Warker's address was given in an anecdote of a noted ovariologist, who was invited by the president to contribute a paper to the Section on Obstetrics and Gynecology of the American Medical Association, at the session at which he presided as chairman. The ovariologist declined on the ground that he was not a gynecologist, that ovariectomy and hysterectomy, and other abdominal operations were general surgical procedures, and were more in the line of the general surgeon than the gynecologist, and wound up his letter of refusal by predicting that the time was not far distant when these operations would be by the general consent of the public in the hands of the all round surgeon. The speaker asks the question if that time has not arrived? The public consults the general surgeon

as frequently as the special surgeon. A large proportion of the major pelvic operations are now made by men who are not specially recognized as gynecologists. Surgery in general has made as marked advances in all directions as that which was at one time by common consent relegated to the specialist. The lay public has become more familiar with serious abdominal operations made by the general surgeon than those made by the gynecologist. The great frequency of operations for appendicitis, on the gallbladder, for intestinal injuries, and for other intraabdominal conditions has educated the public to place as much reliance upon the surgeon at large in a field of surgery, which at one time was regarded as the exclusive domain of the specialist. The same woman who would apply to the general surgeon for the removal of her ovaries would seek by chance the specialist for the performance of a genitoplasty operation. In her choice of a surgeon she is guided more by her senses than by her knowledge of her physiology.

This evolution, for so the speaker regarded it, since it involves the diffusion of skill and knowledge among the many which was at one time the property of a few, has already had a marked effect upon gynecology as a surgical specialty, an influence which will have still wider effects in the future. This result is already to be detected in gynecologic literature. The old operation, ovariectomy, is but rarely seen in the title of a paper and is relegated from the current journal to the pages of the textbooks. The same may be said of the removal of the tubes and ovaries, the removal of pus sacs, Battie's and Tait's operations. Great international reputations were made in these fields which is no longer possible. By making these operations common property to be practised by all surgeons and all made on general surgical principles they have to that extent ceased to be special operations confined to a few men.

The influence of the gynecologic surgeon will, however, always be felt. To him as a man of last resort will always be left the question of methods and expediency. Total hysterectomy for cancer is yet on trial. It is already abandoned by able men while others are hopeful of good results. Will the final verdict upon this question be given by the general or special surgeon? The latter is trained in dialectics; he will bring to bear on the ultimate solution of such a problem qualities which the former cannot possess, because he cannot have universal knowledge and be the possessor of unlimited technic. All the great abdominal operations which are so eagerly exploited by the surgeon at large passed through this ordeal at the hand of the gynecologist and were turned out finished procedures both in expediency and method into other hands.

The day is nearly passed when great gynecologic reputations can be made by the exploitation of a few operations. That belonged to the formative period of the art. A continent can never be discovered more than once, nor a new star give honor to more than one by its discovery in this alert age. But there is enough yet left for gynecology to explore and add to the sum of its literature. The subject of pelvic dynamics is still left to research. We know little of the subject of genital ptosis in women; our treatment of uterine displacements is rank empiricism. The physiology of the pelvic organs must at last be given its true value by the gynecologist rather than by the physiologist in his laboratory, as it must be studied functionally rather than structurally. Questions of sociology, the insane, the criminal, social and industrial feminism, appeal to the gynecologist with greater force than to other physicians. The question of coeducation, into which educators have rushed without heed of consequences, must ultimately come before him for discussion. Many other fields of investigation yet unexplored, or only imperfectly known, yet remain invitingly open.

Gynecology will always have its future, possibly brighter, more generally fraught with usefulness, from the fact that its best minds are no longer concentrated upon matters purely mechanical, and which appeal to a comparatively few unfortunates, but because it will embrace in a broader scope all humanity. These are a few of the problems which the gynecology of the future must meet and in which men trained as we are ought to feel a profound interest. We not only study the diseases peculiar to women, but we must also study social conditions that may tend to disease. There is no other department making such imperious demands upon its advocates as the gynecology of the present, and we may be sure that it will not diminish in the future. There is nothing that contributes to the mental equipment of a man that the gynecologist can do without. The ascendancy of gynecology as a surgical department will in no manner diminish because it shares its surgical triumphs with all who have the skill and knowledge to follow its lead; on the contrary, it will have a greater moral power when its advocates can find a field, broad and in close touch with humanity all about, beyond the limits of the operating room. Would not the gynecologists of France be doing a better service to their country and to science if they were to find the cause and conceive the remedy for the decadence of the birth rate rather than bend their energies in finding a new way to perform an operation? If surgery has its limits there are no limits to higher gynecology. Either the word is badly constructed or its meaning only half understood among those who attempt to limit it to surgical lines.

A second paper on **Extirpation of the Urinary Bladder** was read by Dr. J. WESLEY BOVEE, of Washington, D. C., and will be published later in AMERICAN MEDICINE.

AFTERNOON SESSION.

Dr. EUGENE BOISE, of Grand Rapids, read an interesting paper on **Shock from a Clinical Standpoint**. The generally accepted idea that the pathology of shock is essentially a paresis of the vasomotor nerves, does not seem to be borne out by the clinical manifestations, when analyzed according to undisputed physiologic facts. The basis of the theory of paresis is the thought that the extremely low arterial tension of shock is inconsistent with vasomotor stimulation, which, by causing arterial contraction, should give high tension. On the contrary, the symptoms of shock can, in reality, only be explained by the theory of extreme stimulation of the entire sympathetic system. Laboratory experiments have demonstrated that extreme stimulation of the cervical sympathetic will cause cardiac and arterial spasm with consequent low arterial tension by reason of incomplete diastolic relaxation of the heart. Post-mortem records show that in fatal cases of shock the heart is found contracted and empty, even ruptured, showing a condition of extreme stimulation of the vasomotor system, rather than paresis. In shock, then, there is arterial and cardiac spasm, with consequent low tension. This causes the peculiar pallor and the condition of mental and physical lethargy. The perspiration of shock is caused by stimulation of the secretory nerves of the sweat glands, branches of the sympathetic system. Experiments have shown that the secretion of perspiration is independent of vascular conditions. The other clinical manifestations of shock can readily be explained by this theory of hyperirritation of the entire sympathetic system, and only by this. Moreover, those remedies which are of benefit in shock are such as act as sedatives to the vasomotor nerves. Amylnitrite and nitroglycerin are noted arterial relaxants, and yet they are very beneficial in shock. So also with strychnia. The opinion of operators of large experience is that to be of benefit it must be given in very large doses. And yet all therapeutists agree that in such doses strychnia paralyzes the vasomotor center and the intracardiac ganglions, and therefore is absolutely contraindicated if the vasomotor nerves are already parietic. So also with normal saline infusion. To derive the greatest benefit it should be used intravenously and at a temperature of 118° or 120°. Thus when diluted by the mass of blood in the vena cava the temperature is so reduced as to be sedative to the irritated cardiac and arterial nerves and muscles, and their spasmodic condition is relieved. Therefore, shock is essentially a hyperirritation of the entire sympathetic system of nerves.

Dr. FERNAND HENROTIN (Chicago) read a paper on **Resections and Excisions**, which provoked an animated discussion and will be published later in AMERICAN MEDICINE.

THIRD DAY.

Symposium on Cesarean Section.—

Circumstances Which Render the Elective Section Justifiable in the Interest of the Child Alone: Dr. REYNOLDS. (1) The cesarean section performed late in labor, or on the presence of infection of the uterus or other complicating constitutional conditions, has been shown by the experience of almost every operator who has tried it, to have so high a mortality as to be totally unjustifiable when performed in the interest of the child alone; (2) when a cesarean section is performed on healthy women, early in labor, and under otherwise favorable circumstances, for merely mechanical indications, it has, in skilled hands, no mortality other than the fractional percentage incidental to all considerable operations per se; (3) the inconveniences and high morbidity rate of symphysiotomy render it considerably inferior to the section as an operation of choice but it is an operation which as compared to craniotomy, or prolonged and forcible high forceps work without it, involves almost no increased risk to life. He therefore believes it to be the operation of choice in the somewhat limited number of neglected cases (*i. e.*, those for which the cesarean is ruled out), in which the pelvic contraction is within the range where the extraction of a living child without symphysiotomy is difficult or impossible, but after symphysiotomy is safe or easy; (4) the induction of premature labor for contracted pelvis results in so high a fetal mortality, as to be unwarranted when placed in opposition with the performance of the cesarean section at the beginning of labor and in favorable cases.

The Technic of Cesarean Section: MATTHEW D. MANN (Buffalo, N. Y.) first discusses the relative merits of the Sanger and Porro operations. He concludes that there is no rivalry, but that each has its proper place. The classic operation should be done in all elective cases, when the woman is in good health, the operation done in time, and all the conditions favorable. The Porro operation should be done when the uterus is septic; when gonorrhoeal infection is known to exist; when the uterus refuses to contract; when there are large fibroids or ovarian tumors, which cannot be removed without injuring the uterus. Small fibroids usually disappear after pregnancy. Other indications for the porro are: disease of both ovaries; when the uterus is torn or ruptured in labor; in cancer of the cervix; when the patient is greatly reduced and bearing the operation badly; in osteomalacia and bad atresia of the vagina. The uterus should not be removed simply to sterilize the woman, as this can be done, if thought best, by removal of the tubes. In this way the woman's sexuality is not destroyed. The question of sterilizing the woman is a hard one to decide, as ethical questions are involved. She may be sterilized to prevent the possibility of future offspring and in the interests of

society, as well as to prevent possible future cesarean sections; but this only at her own request. **Technic of Celiohysterotomy.** Median incision in abdomen and uterus. The removal of child and placenta. Uterus sutured with catgut. The Fritsch incision seems to be better if the placenta is in front. Uterine tourniquet to be tightened when needed. Hypodermic of ergot and hot applications to the uterus, and letting-up on the ether, to induce contractions. Careful toilet of the peritoneum. **Technic of Celiohysterectomy.** Same as before. Then the vessels tied on each side of the uterus, and the uterus removed, all but the cervix. The peritoneum closed over the stump. **Vaginal Cesarean Section.** This is done for cancer of the cervix, and for rupture of the uterus. Few cases are on record. **Reports.** Six cases have been done in Buffalo, by four operators, with the loss of one child. One mother died six weeks later of carbolic-acid poisoning.

Dr. CHARLES JEWETT (New York) read a paper on **The Place of Symphysiotomy as Contrasted with Section**, and presented the following conclusions: Symphysectomy is still a useful operation within a very limited range of pelvic contraction. It is suited to conditions in which only very little additional pelvic space is required for delivery. It is a valuable recourse, therefore, in cases in which forceps unexpectedly prove inadequate. Axis-traction forceps, with the aid of posture, should always be tried before resort to symphysiotomy. Its results would be much improved by restricting it to pelvis with a conjugate of not less than 7.5 cm., 3 inches. Under equally favorable conditions its total mortality should be no greater than that of cesarean section. When the pelvic space permits it should replace cesarean section in the presence of exhaustion. It may be elected primarily as an alternative of cesarean section, when the operator can be assured that the degree of obstruction is well within its safe limit. Here the choice of operation is largely a matter of individual preference. Within its proper field symphysiotomy is better than cesarean section for an operator of little experience in abdominal surgery.

After the discussion on cesarean section Dr. HENRY D. FRY, (Washington, D. C.) read a paper on **The Relative Merits of Bipolar Version with slow Extraction and Accouchement force in the Treatment of Placenta Previa**: The advantage of bipolar version is the ability to successfully perform it with very little dilation and with consequently less loss of blood. In placenta previa a fatal result is usually due to hemorrhage or sepsis. The hemorrhage is unavoidable and incident to the dilation of the os, consequently the method requiring the least degree of dilation necessary to perform version will naturally be expected to give the least hemorrhage. After dilation be obtained in sufficient degree to insert several fingers further continuance of the process by manual means is likely to endanger the integrity of the soft parts. The artificial dilation sufficient to perform bipolar version is comparatively safe, while that necessary for the insertion of the hand and internal version is dangerous. The rapid delivery of the infant in accouchement forcé adds additional risk of rupture. Fry summarizes the histories of 14 patients—50% of whom were primipara. Bipolar version and slow extraction were employed 9 times; membranes ruptured and delivery left to nature, 1; tampon and natural delivery, 1; forceps extraction, 4 times including 1 application to the after coming head following bipolar version. All of the mothers recovered, and 5 of the infants were born alive.

Indications as Furnished by Pelvic Contractions, by J. W. WILLIAMS, Baltimore.—In 2,123 cases delivered in the Obstetric Department of the Johns Hopkins Hospital, 278 (13.1%) had contracted pelvis. The pelvis were measured both externally and internally, and designated as contracted when the conjugata vera was 10 cm. or less in generally contracted, and 9.5 cm. or less in flat pelvis. Nine hundred and forty-one of the patients were white and 1,182 black. Contracted pelvis occurred in 6.91% of the former and 18.1% of the latter. That is, in every fourteenth white and every sixth black woman, 199 of the 278 cases ended spontaneously (71.57%). The number of spontaneous labors decreased with the increase in the pelvic contraction, as shown by the following table:

Conjugata vera 10-9 cm.,	77.28% spontaneous,
Conjugata vera 8.9-8 cm.,	61.54% spontaneous,
Conjugata vera 7.9-7 cm.,	53.2% spontaneous,
Conjugata vera 6.9-5.5 cm.,	0% spontaneous.

The cases requiring operation were delivered by high forceps, version, symphysiotomy, cesarean section, craniotomy upon the dead child, or embryotomy, according to circumstances, giving a gross fetal mortality of 12.96%, and a gross maternal mortality of 2.88%, which, by deducting the cases in which the death of the child or the mother was not due to us, gave a corrected mortality of 4.32% and 0.72% respectively.

In view of the markedly improved results following cesarean section, the indications for its use should be widened. Thus we find that Zweifel, Olshausen, Reynolds, Bar, Charles, and Cragin have performed 162 operations with 5 deaths, a mortality of 3%. We, therefore, believe that in uninfected cases the upper limit for the absolute indication for cesarean section should be advanced from 5.5 to 7 cm., and the relative indication from 7 or 7.5 to 8.5 for flat, and 9 cm. for generally contracted pelvis. With the absolute indication, the operation should be done either at the end of pregnancy or the onset

of labor; but when the relative indication is present, the woman should be allowed to go into the second stage of labor and have bearing down pains for one hour, when, if the head does not show signs of moulding or descending, cesarean section should be performed, instead of forceps upon the movable head or version. So that at present cesarean section for the relative indication should compete with high forceps or version, instead of with craniotomy upon the living child, as in the past. On the other hand, if the patient be infected, or her surroundings such that an aseptic operation cannot be performed, high forceps or version should be attempted, followed by craniotomy in case one fails to deliver the child by their means, and cesarean section reserved for those cases in which an absolute indication is present on the part of the pelvis.

A paper by Dr. ANDREW F. CURRIER, (New York) on **Injuries of the Head in the Newborn** was read by title.

Scratch-marks on the Waxtipped Bougies in diagnosis of Urethral and Renal Calculi: HOWARD A. KELLY (Baltimore) exhibited 9 drawings made by Mr. Becker, showing scratch-markings made on waxtipped bougies by calculi in the kidney and ureter; also, pictures of the calculi and the bougies used were shown. A mixture of melted dental wax and olive oil, equal parts, was used to tip the renal catheters. This substance produces a smooth and highly-polished surface, which, on coming in contact with a stone, is scratched or gouged in longitudinal strias. The mucous membrane of the urinary tract cannot possibly affect the waxed surface. In the method there are 3 sources of error: (1) Rubbing on the side of the speculum during introduction of catheter produces a flat facet which in no way resembles a scratch-mark; (2) a to and fro movement in the effort to introduce tip into the urethral orifice may gouge the wax at the end of the speculum. This is avoided by keeping the end of the catheter free in the lumen of the speculum, skillfully carrying it into the ureter at the first effort; (3) another source of error is drawing out the catheter and pulling it through the vulva hairs; this is avoided by separating the labia and careful withdrawal. The evidences of stone in the urinary tract furnished by a catheter are as follows: (1) A sense of obstruction when the stone is struck by the tip of the instrument; (2) a free flow of urine, often turbid and purulent as soon as the catheter has passed the obstruction; (3) the injection of a weak solution of hydrochloric acid (15 cc. of a one-half percent solution) withdrawn in 10 minutes, shown in one case, calcium and magnesium phosphates coming down subsequently in excess of the urine of the opposite kidney; (4) on withdrawing the catheter, it may be held by the stone as if in the bite of a stricture; (5) the stone may yield a grating sensation as catheter is withdrawn; (6) a bit of stone may be brought in the eye of the catheter, or washed out by the injection of fluid into the kidney; (7) bits of debris of the stone, little black specks, may be brought down by the urine, subsequent to the withdrawal of the catheter.

The last paper was by Dr. J. DUNCAN EMMET (New York) on **Myomectomy during Pregnancy, with Delivery at Full Term**, which will be published in AMERICAN MEDICINE.

The following officers were elected for the ensuing year: President, Dr. S. C. Gordon, of Portland, Maine; vice-presidents, Dr. George M. Edebohlis, of New York, Dr. Edward Reynolds, of Boston, Mass.; secretary, Dr. J. Riddle Goffe, of New York; treasurer, Dr. J. Montgomery Baldy, of Philadelphia. Atlantic City, N. J., was chosen as the place for the next meeting.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

TENTH ANNUAL MEETING, HELD IN ST. PAUL, MINN., MAY 30.

[Specially reported for AMERICAN MEDICINE.]

The tenth annual meeting of the Association was opened in the Hall of Representatives, State Capital, at 10.30 a. m. There was a fair attendance for the first day.

Brigadier-General A. J. STONE presided. The meeting was called to order by Brigadier-General JOHN F. FULTON. Prayer was offered by Archbishop IRELAND, followed by an eloquent and hearty address of welcome by Governor SAMUEL R. VAN SANT, also an able address by Judge E. A. JAGGARD. The secretary reported a decrease in membership of 60 during the year, partly from deaths. The SANDER prize was not awarded as no paper had been presented. A telegram of cordial and fraternal greeting was received from the Association of Medical Officers of Army and Navy of the C. S. A., now in session at Memphis, Tenn. By action of the executive committee, Dr. CHARLES FENGER, of Chicago, was elected an honorary member.

President's Address.—General STONE welcomed the association, complimenting them for the self-sacrifice that some of their members had made for country and their fellow men. To this body, and especially to members of the Army, Navy and Marine-hospital service, must the country look in the event of introduction of oriental epidemic diseases. The Army surgeon must be well grounded in sanitation. It is his duty to choose proper locations for camps and their proper relation to pure water supply, and equally his duty to protect them from contamination; only the gravest reasons should stand in the way of

his authority. Location of sinks and their control should be left entirely to him. He called attention to the shortsighted policy of limiting the amount of supplies by redtape procedure, thereby hindering the efficacy of preventive medicine. He referred to the scientific work done by surgeons in regular service in regard to yellow fever and malarial infection by mosquito inoculation, and made allusion to the plague that had found foothold at San Francisco, together with the remedy pointed out by SURGEON-GENERAL WYMAN in his report. The physician in civil life should follow the example of the Army surgeon and become a sanitary propagandist in his own State or municipality. He suggested closer affiliation between the Army surgeon and the civil practitioner. The surgeon of the Navy is an intermediary between the two. The experience of the United States surgeon in the handling of masses better qualifies him for service for the community. He favored establishing a journal, and believed it would have sufficient clientele to maintain it.

A plea for Immediate Celiotomy in Penetrating Gunshot-wounds of the Abdomen in War. This paper by Captain CHAS. E. B. FLAGG, Asst. U. S. A., was read by Major JOHN VAN R. HOFF, Captain Flagg being absent. The author was sanguine that others would soon adopt his views; expectancy is the present military method in these cases; immediate abdominal section is the rational method of diagnosing any repair of visceral lesions. The claim that spontaneous closure and recovery follow more often when produced by the small caliber bullet, is not upheld by statistics. The mortality from penetrating gunshot-wounds in the Spanish-American War was 65%, that of the Civil War 89.29%. All the combined numbers of cases numbering 5,490 with 3,649 deaths, occurring in the last 6 wars, commencing with the Crimean War to the Japanese-China War, gives a mortality of 61%, or 4% less than that of the Spanish-American War. For the year ending June 30, 1900, (Surgeon-General's Report) 116 cases occurred, 81 deaths; mortality 70%, which is 17.2% less than the Civil War, and 9% more than the mortality of the 6 wars mentioned. Spontaneous recovery from perforating intestinal wounds can only take place through adhesions to adjacent viscera. As 30% to 35% of cases recovered, it is possible that in many no penetration of the intestine occurred. These cases should not die if immediate celiotomy be made, and it should save many of the 65% to 70% fatal cases, if done by a competent operator. The Surgeon-General's report gives history of 10 cases operated on, with 9 deaths, of which Captain Flagg operated upon 3 with 2 deaths. One died on the table from ether-poisoning, the other, a Filipino, from tearing out of sutures by lumbricoid worms. The third escaped perforation of the intestine and lived. Cases should receive similar treatment as in civil practice. Unsuitable conditions is the only argument against operations during battle. There are only 2 necessities, the surgeon who knows how, and shelter and appliance for asepsis. With an anesthetist (spinal cocaine) suggested in his absence) and 1 trained assistant, one can improve the necessities of an operating room and do aseptic work.

Discussion was limited on this paper, the unanimous opinion being opposed to immediate operation on the firing line. Dr. FITZGERALD had had 12 months' active experience in the Philippines. Early operation on the field meant not only danger from sepsis, but of secondary shock added to primary shock. Noninterference constituted best treatment, with small abdominal incision and drainage give best results. Complete operations usually resulted fatally.

Captain A. E. BRADLEY, U. S. A., read a paper on **Suprapubic Operation for Varicocele and Other Conditions Occurring within the Scrotum Requiring Surgical Interference**. He reports favorable results in all cases operated on, with shorter convalescence than by other methods. He considers it of special value on account of easier and surer asepsis and quicker recovery. The usual technic as regards the preparation of location of operation, operator, instruments, etc., is followed. An incision is made from the spine of pubes, 2 to 2½ inches in length, upward as for inguinal hernia. Exposure of the external ring, lifting of cord and separation of veins, ligation and excision of same, pulling up freely the veins from below, closure of wound by subcuticular suture follow.

Discussion was antagonistic. The old operation through the scrotum was preferred; the question of sepsis was simply a matter of thoroughness. The real argument against the operation was that of tendency of weakening the abdominal wall and possibly resulting hernia. Varicocele is considered by any surgeon a sufficient disability to bar acceptance of recruits. It is always a source of complaint for the soldier, a very common trouble of men, and often used for malingering. Varicocele is not thought a sufficiently important disease to warrant discharge of the soldier by the Government, but sentence him to the hospital for radical cure.

SECOND DAY.

Secondary Hemorrhage, by CHRISTIAN FENGER (Chicago, Ill.).

Some Problems for Solution by Medical Officers of the Army Serving in the Tropics, by Major JOHN VAN R. HOFF, Medical Department, U. S. A.

These papers were read by title.

Three Noteworthy Cases of Brain Injury.—GEORGE TULLY VAUGHAN said: Injuries of the brain have attracted

the attention of surgeons and physicians from the days of Hippocrates and are still burning questions of our day. The dangers in severe injuries are shock, hemorrhage, causing compression, or anemia, and infection. Shock symptoms are immediate; those of hemorrhage immediate or a few hours later, occasionally a week later; of infection 2 days to a week, or maybe months or years after an injury, possibly as a result of secondary injury, arousing infection that has remained dormant. When shock and hemorrhage coexist, it is difficult to diagnose the symptoms due to shock and those due to hemorrhage. The remote effects are abscess, tumor, epilepsy, insanity and chronic headache. Brain surgery has been established on a firm basis during the last quarter of a century by the brilliant work of neurologists and surgeons. This dangerous region can now be invaded by competent operators with almost the same impunity as the abdominal cavity. The large amount of brain-tissue which can be destroyed without producing death and the toleration of the brain to the presence of foreign bodies is remarkable. According to my experience the greatest mortality is in injuries caused by falls from a height, striking on the head, such as being thrown from a horse or bicycle or falling from a building, scaffold or rapidly moving car. Extensive fractures of both base and vertex are the results with hemorrhage in the brain substance. Gunshot wounds of the brain are almost equally fatal. Injuries from blows upon the head give the smallest mortality. Limited fracture of the skull and limited lesion of the brain are the results. Operative interference is indicated when there are symptoms of compression from hemorrhage, depressed bone, or a foreign body. In gunshot wounds, if the ball can be located by the Röntgen ray in a reachable locality, it should be removed to avoid abscess or tumor or other dangerous sequel.

Observations in China and the Tropics on the Army Ration And the Post Exchange or Canteen read by Major LOUIS LIVINGSTON SEAMAN dealt with personal experience and will no doubt be the entering wedge for the restoration of the canteen. He gives a very graphic description of U. S. Military Hospital, No. 1, at Camp Reilly, Pekin, China, situated in one of the compounds of the Temple of Agriculture. In this magnificent building the medical staff were quartered. This building with 2 others adjacent, served for dispensary, hospital, with plenty space for medical, surgical and venereal wards, operative rooms and nurses' quarters, equipped with trained female nurses, hospital corps, extra diet kitchen, etc. The health of the men was remarkably good. The week ending February 9, 1901, showed a sick list of 80 out of a force of 1559 or .051%. Of these there was only 1 case of typhoid fever, 4 of malaria, 41 venereal, the rest respiratory and of digestive organs. The winter climate is cold, dry, and clear, with frequent dust storms which is productive of respiratory diseases, especially of recent arrivals from the tropics. Typhoid fever among the American troops was rare because of pure water-supply while the Germans, using ordinary water, had several hundred cases of typhoid. The Americans had 6 water distilling plants, only 1 being necessary for sufficient supply for themselves, and 2 tons were given daily to the Japanese army. The physical condition of the men was perfect, their digestion more than competent for the army ration which was proper for the climate of Pekin, but which had directly opposite effect in the tropics. He called attention to the dietetic value of sugar as a producer of energy. His experience goes to show the necessity of the adapting of the army-ration to climatic conditions—heat-producing foods for cold climates; foods rich in carbohydrates in hot climates. In spite of recent experience, Congress refuses to change the United States Army ration. He protests vigorously against the abolition of the army post exchange or canteen. The effect has been to deteriorate the soldier, physically, mentally and morally. The liquors which he now drinks to excess are all rank poisons, especially those of tropic production, and the results, insubordination, drunkenness, debauchery, or desertion. For comparison, there were 70 to 90 trials before the Summary Court of the Twelfth United States Infantry, Philippine Islands, during February and March, 1901, four-fifths for intoxication from native wines. A post exchange was established at the end of March, after which only 20 cases to 8 cases were before the court in any month thereafter, of which only 2 were for wine intoxication. Venereal disease, always present in military hospitals, has doubled since the abolishment of the canteen. He criticized the W. C. T. U. for "their misguided enthusiasm that was responsible for the repeal of an institution that was the soldier's friend, often saving him from disgrace and disease worse than death." There is no single cause so prolific in invaliding men here as this. By action of the members the following resolution, presented by Dr. Seaman, is to be sent to each member of Congress and United States Senator:

WHEREAS, The Association of Military Surgeons of the United States, now in session in St. Paul, recognizes that the abolition of the army post exchange or canteen has resulted, and must inevitably result, in an increase of intemperance, insubordination, discontent, desertion and disease in the army; therefore

Be it resolved, That this body deplores the action of Congress in abolishing the said Post Exchange, and in the interest of sanitation, morality and discipline recommends its reestablishment at the earliest possible date.

Discussion.—The discussion following the reading of Major SEAMAN'S paper was very enthusiastic, unanimously approv-

ing the ground taken by the author. The main idea is to restore the canteen. The question is, how? While criticizing the W. C. T. U., they hope by showing the error to get their active support in undoing their work. Also each member of the Association is to consider himself a committee of one to personally influence the representatives of Congress and United States Senate of his State for the reestablishment of the canteen.

Report of Committee on Journal.—The Committee on Journal, after considering the various propositions, submitted reports that it believes the publication of the journal inexpedient at the present time, further that many of the points suggested as reasons for the publication of the journal can be covered by the election of the permanent secretary, who shall be authorized to issue in pamphlet form within 30 days after the meeting of the Association minutes of the meeting, list of officers and committees for the ensuing year, and brief notes of interest regarding the meeting, and that circulars of information be issued by the secretary according to his judgment such as may be advisable.

Discussion on the subject of uniformity of organization and equipment of medical department of National Guards. No definite plans proposed.

A paper by General GRIFFIN (St. Louis, Mo.) followed, with no particular title, which was a potpourri of practical and surgical points. He advised more careful examination of surgical cases prior to operation, especially examination of urine. Lithiasis was the bane of American race due to their manner of living. The Englishman eats regular meals, takes plenty of time, masticates food slowly. The American swallows today, chews tomorrow. Lithiasis is largely the result of faulty eating and resulting indigestion. He cautions against the use of intravenous saline solution when the heart is feeble by shock or sepsis, contraindicated unless there has been large loss of blood, even then is questionable, as he lost 2 cases from its use. **Treatment of Gonorrhoea.**—We know as little of its treatment and of its sequels as we ever did. It is the bête noir of the profession. His experience with tendon suture has been perfectly satisfactory; suturing of muscles gives bad results. **Rubber Gloves.**—They have come to stay. A necessity for aseptic surgery, especially in serous cavities; time will remedy its interference with tactile sense. He advises the use of needles of assorted sizes, already armed with aseptic catgut sutures, that come in sealed bottles ready for use. He believes that closure of wounds without suture is practicable, but still sub judice.

Discussion.—Gen. HARVEY REED (Wyoming) criticized the use of ready-to-use suture material. To insure aseptic sutures, one must give it his personal attention.

He was opposed to the use of rubber gloves; they were clumsy, interfered with the tactile sense; thorough surgical cleanliness was sufficient. Simplicity in method and in instruments for operation should be the rule.

Dr. H. O. MARCY (Boston) spoke of the perfect technic of Keith's work, also of Tait's, who, while he was a false leader by his opposition to bacteriology, should be honored for teaching us through cleanliness. He uses rubber gloves because he feels safer by their use, but admits their interference with tactile sense. He finds it difficult to find proper gloves, they are either too thick or too thin. He thinks they are of great importance to be worn by his assistants, it makes their hands safe. Gloves also protect the operator from infection wounds. Has good results from tendon suturing, also muscle suturing, if the part is kept at rest. His results have been perfect in closing abdominal incisions, has had no hernia following in his last 1500 abdominal sections. His results due to little irritation of the tissues, layer suturing in their natural relations, subcuticular suture with collodion dressing.

THIRD DAY.

The Pennsylvania Brigade Hospital Tent was exhibited by Lieutenant H. A. ARNOLD; this tent was devised by Colonel W. F. RICHARDSON, Superintendent of State Arsenal, and is described by him as follows:

Length of tent.....	32 feet.
Width of tent.....	18 feet.
Divided into 2 apartments.....	16 x 18 feet.
Apartment fastened on wall by snap hooks and rings.	
Height of wall.....	5 feet, 2 inches.
Two ridges.....	each 16 feet long.
Three uprights.....	each 12 feet, 9 inches.
Nine side poles on either side.....	each 5 feet, 9 inches.
Fly on top.	

One end of this tent is equipped as a hospital, 6 complete cots, with mosquito bars, also writing table, wash stand, commode, slop bucket, pitcher and bowl, strips of carpet in front of each cot. Small table between the cots, 2 rocking chairs, 2 folding camp chairs and floored. Ventilator on each end of the tent, controlled by rope. Entire wall can be taken off from either side when required. Tent protected from storms by guy lines. When complete, is the most substantial ever used for such purpose. Such a tent is especially needed for tropic service, as it affords shelter without oppression. The special feature of this tent is its detachable wall, ordinary hospital tent must be reefed up along one entire side, and even then the wall interferes somewhat with ventilation. In this way free ventilation may be secured for some cots while others are sheltered. Temporary privacy may be obtained by raising the wall opposite one or

more cots. Sagging of the sides of the tents is prevented by detachable side poles, which also gives stability to the tent, so that it will stand very severe wind storms. In the event of soiling, the detachable walls may be more readily cleaned than those of the ordinary hospital tents.

The following officers were elected: President, Major John Van R. Hoff; first vice-president, General R. A. Blood; second vice-president, General Walter Wyman; treasurer, Lieutenant-Colonel H. A. Arnold; secretary, Major Jas. E. Pilcher.

An invitation to meet next year in Boston was received through General Blood, but on discussion, it was decided to refer to the later decision of the executive committee as to time and place.

THE AMERICAN PEDIATRIC SOCIETY.

ANNUAL MEETING HELD AT NIAGARA FALLS, N. Y., MAY 27, 28 AND 29.

[Specially reported for AMERICAN MEDICINE.]

A number of interesting discussions took place on the feeding of sick and well children, with special reference, as might be assumed, to the question of using cereals and various forms of modified cow's milk. Incidentally, a difference of opinion on some points was disclosed between the representatives of New York and those of Boston, though the divisions were not always so purely on geographic lines as one of the speakers made it appear. Nor was there any tendency on this account to minimize the importance of the work which the doctors of the metropolitan city are doing in the way of saving infant life in the crowded tenements. The champion of the Harvard school may be admitted to have had the best of the argument so far as theory and the niceties of scientific procedure were concerned, but even he did not seek to question the importance of the clinical results that were reported.

One of the most noteworthy papers was that contributed by Dr. CHARLES GILMORE KERLEY (New York), who gave the conclusions drawn from a study of 555 cases of summer diarrhea. Out of the total number only 10 died. In other words, the death-rate was a little over 2%, and this, the author of the paper said, showed the enormous extent to which mortality from this cause is preventable. After explaining that the cases were all taken from the homes of the poor, the doctor proceeded to say that at the Babies' Hospital they had but one rule of treatment. Irrespective altogether of the duration of the complaint, or of whether the child was being fed on the breast or not, they always cut off the milk at once. Not only did they advise this, but they said positively that the milk must be discontinued for a few days, or they would not treat the case. No milk was allowed until the stools were normal. The period necessary to bring about this improvement might be only 24 hours, or at most a few days, but it varied to such an extent that one child had to be kept off milk for 5 months. Cereal water—barley by preference, failing that rice-water—was substituted; and occasionally a little beef-juice might be added, care being taken to alternate the diet and watch its effects. Brandy and whisky should never be given; in fact he looked on the popular brandy and egg mixture as the most atrocious substitute for milk ever suggested. When it was found that the child could digest milk, its use should be resumed gradually. As to drugs, after trying a great number, he had come to the conclusion that there were only 4 that were of use and could be employed with safety. They were calomel, castor oil, bismuth and opium. He added in connection with treatment that he thought that irrigation of the colon was very much overdone. The importance of educating mothers in regard to matters of this kind, he thought, could not be exaggerated. He found poor and ignorant women ready to act on the instructions given them, and the result was that many cases that were now being brought to the hospital were already on the way to recovery when first seen by the doctor, simply because their mothers had known to stop the milk and give them a dose of castor oil, and put them on barley-water. His experience led him to say that he would as soon trust a hundred children to such treatment by their mothers in the tenement districts as he would to nurses in the best conducted hospital.

In the course of the discussion which followed, one speaker expressed surprise that the use of albumen water was not recommended, while another said he would like to add another cathartic, namely magnesia, to the list of drugs that could be used with advantage, and a third spoke with some apparent approval of an old-fashioned country practitioner of homely speech who advised giving castor oil and gum water and leaving the child alone until it was able to assimilate something else. One of the same speakers remarked in regard to castor oil that if it were only given a long name ending in "in," it would come to be looked upon as almost a cureall, at least in cases affecting the stomach and bowels. Questions on the other hand were asked as to why barley water was to be recommended for sick children if it was not approved of for children in normal health, and also as to why the use of stimulants should be so sweepingly condemned. The utility of dispensaries and hospital service in regard to cases of the kind under question was likewise debated, and the pros and cons in reference to rectal irrigations set forth in detail.

Then Dr. T. M. ROTCH, of Harvard, took the floor, and took exception to almost everything that had been advanced by the reader of the paper and his New York colleagues. At the outset, he requested a statement of the reasons there were for objecting to the use of brandy. Dr. Kerley replied that one reason was that it caused vomiting, and another was that nephritis frequently accompanied these complaints. Dr. Rotch said it was not his experience that it caused vomiting when given in small doses, and even in cases when the kidneys were affected, and they were not usually affected at the beginning of the complaint when the use of brandy was indicated, a stimulant might be resorted to. He protested, however, against the term "summer diarrhea" altogether, and said they could never get to a proper understanding of the matter unless they knew exactly what they meant. Furthermore, he thought they had proceeded to work in the wrong way by seeking to draw deductions from work among the poor. This was altogether a nonscientific method of procedure. What they ought to do was to try and ascertain what was the best treatment, irrespective of the circumstances of the patients, and then apply it as far as possible. This was what they did in Boston, where, thanks to a fund that existed for the purpose, they were able to treat the children of the poor exactly as they did the children of the rich, the physicians being free to deal with each case individually, and in the case of the poor to make such requisitions on the dispensaries as would provide whatever treatment was considered most desirable. Coming to the question of barley water, the speaker asked how much nourishment there was in it, and remarked that if it was given in large quantities the baby would not keep it down. Why, indeed, should they give anything at all for the first 24 hours or so? In the vast majority of cases the systems of their patients were not crying for food, but were crying to be left alone. And if they were prostrated he did not see why alcohol should not be administered.

After a vain attempt to reach some understanding as to the classification of complaints of the kind referred to, the general opinion being that it was impossible to decide clinically in every instance whether they were organic or not, Dr. Kerley replied on the debate. Barley water, he explained, might have to be given for a long time, and the case he had mentioned was one in point, but the practice at the New York Babies' Hospital was to try giving the children milk in small quantities from time to time to see whether they could stand it. He had ceased giving albumen water because he found that it was usually followed by an increase of the diarrhea. As to the question of classification, he believed the doctor was yet unborn who could look at a child with summer diarrhea, and say whether there was a lesion or not.

Papers by Dr. CHARLES W. TOWNSEND (Boston), and Dr. HENRY D. CHAPIN (New York), one on the feeding of an incubator baby, and the other on the place of cereals in infant feeding, were discussed together. The infant described by Dr. Townsend was one of premature birth, and was brought up satisfactorily on modified cow's milk, the increase in its weight being remarkably rapid. Dr. Chapin dealt elaborately with the question whether the judicious use of cereals in connection with cow's milk might not be justified and even recommended. The principal objection to it was that it was not scientific, and was not following nature. To show that this objection was unfounded he analyzed the milk of different classes of animals—the cat and the dog, the ewe, the goat, the buffalo and the cow, the mare, the mule and the ass, etc.—with the view of showing that they all differed in accordance with the differences in their digestive apparatus, and that they all, including cow's milk, were suited to a different digestive process than that possessed by human beings. He thought it had been practically demonstrated that the judicious use of cereals with cow's milk made it digestible, and therefore should be approved of. Replying to the objection that his statements would be taken advantage of to advertise proprietary cereals, and so increase their consumption, he said that the very opposite result would take place, because doctors would get into the way of making their own scientific prescriptions as to how and to what extent cereals should be used, and particularly in what proportion they should be given in connection with cow's milk.

At one point in the discussion, Dr. J. P. CROZER GRIFFITH (Philadelphia), sought to throw oil on the troubled waters by suggesting that it was a case in which nobody was all right or all wrong. On account of the difficulty of getting something exactly like woman's milk, they could not have an exactly scientific principle. All of them got good results in different ways, although they had all to deviate from their theories in certain cases. Dr. ROTCH, however, would hear of no compromise, contending that there must be one way that was better than all others, and that it was the duty of physicians, and particularly specialists, to find out what way that was. The controversy was expected to be renewed by Dr. JACOB, of New York, who was down on the program to read a paper on Milk Sugar, but to the regret of the members generally, a message was received from that eminent authority on pediatrics that he found at the last moment that it would be impossible for him to be present.

Another singularly interesting paper besides those mentioned was one by Dr. W. S. CHRISTOPHER (Chicago), dealing with physical measurements in puberty, their significance, variation, and applications. It was a continuation of a report

which the author made at the last annual meeting of the society, and embodied the results of work being done at his instance under the auspices of the Chicago Board of Education. A substantial appropriation, it was explained, had been made for the purpose, and the services of very competent examiners and statisticians having been secured, it is hoped that data will be collected which will be of great use in various ways to scientific investigators. Nor are these confined, it may be added, to the points handled in Dr. Christopher's paper. The mental as well as the physical developments of children are being inquired into and the results carefully tabulated, special attention being, of course, paid to those having physical or mental defects. The present paper gave the results obtained from the examination of 6,250 children, 7 measurements being made on each child, and tables being prepared to show their average height, weight, strength, etc., at different ages. Girls were separated from boys, and comparison drawn between them to show the respects in which they progressed more or less on parallel lines, or differed from each other in their rate of progress. Among the general conclusions arrived at by the author was that in both sexes there was a period of quiescence before puberty, followed by a period of exaltation. Puberty also was a period of great individualization—a period when the weak were apt to fail, and when the strong developed rapidly. It was the period of greatest morbidity, the period when latent abnormalities might be expected to develop, as a consequence of the unbalanced condition of the child physically and mentally.

The discussion of the paper largely took the form of praise of the author and his collaborators for their painstaking labor, and a hope was expressed that these labors would be continued, to which Dr. Christopher replied that there was every probability that they would as the Board of Education was keenly interested in the matter and thoroughly appreciated the work that was being done.

The attention of the society was directed by Dr. SAMUEL S. ADAMS (Washington) to the great fluctuations in temperature that take place in children in the terminal stage of tuberculosis without any apparent evidence of septic affection, and the general treatment of tuberculosis was discussed in a paper by Dr. B. K. RACHFORD (Cincinnati). A contribution from Dr. C. P. PUTNAM (Boston) on extensive pneumococcus infection was read by title, as were likewise papers by Dr. WILLIAM OSLER (Baltimore) on (1) congenital absence of the abdominal muscles, with distended and hypertrophied urinary bladder in a child of 6 years, and (2) the visceral lesions of the erythema group of skin diseases in young children. The subject of Cretinism was dealt with in papers by Drs. FREDERICK A. PACKARD and ALFRED HAND, JR. (Philadelphia) and Drs. HENRY KOPLIK and I. LICHTENSTEIN (New York) the former discussing the pathologic anatomy of cretinism and the latter making a contribution to its symptomatology.

Dr. WILLIAM P. NORTHRUP (New York) enlarged on the advantages of glass sun rooms on city roofs or winter playhouses. Dr. ROWLAND G. FREEMAN, of the same city, gave an account of an epidemic of malaria in children, and Dr. JOHN LOVETT MORSE (Boston) gave an analysis of 32 cases of congenital heart disease. Reports of cases on maternal impressions were contributed by Dr. RACHFORD (Cincinnati) on measles complicated by appendicitis, by Dr. HAROLD WILLIAMS (Boston) on amaurotic family idiocy, etc., by Dr. A. C. COTTON (Chicago) on pernicious anemia in infancy, by Drs. T. M. ROTCH and MAYNARD LADD (Boston) on general arteriosclerosis in a boy of 10, by Dr. ALLEN BAINES (Toronto) on hemorrhagic nephritis complicating influenza in a 13 months old baby, by Dr. D. J. MILTON MILLER (Philadelphia) on scalled cyclical albuminuria, by Dr. FRANK SPOONER CHURCHILL (Chicago) on pulmonary gangrene in a baby, by Dr. WALTER LESTER CARR (New York) on arsenical poisoning in an infant of 6 months, by Dr. JOHN LOVETT MORSE (Boston) on multiple arthritis in a child 2 years old suffering from gonorrhoeal vaginitis, by Dr. GEORGE N. ACKER (Washington) on (1) infantile scurvy and marasmus, and (2) gangrene of the lung, history, operation and recovery, by Dr. F. HUNER (New York) on (1) appendicitis in a child of 3 months, and (2) long-continued laryngeal stenosis of uncertain nature, by Dr. J. P. CROZER GRIFFITH (Philadelphia). The etiology of rectal polypi in children was the subject of a paper by Dr. F. HUNER and the treatment of the nasopharynx in scarlatina of a paper by Dr. A. SEIBERT, both of New York. A note on the little finger of the Mongolian imbecile and of normal children was contributed by Dr. J. PARK WEST (Bellair, Ohio) and the use of the term "exanthem" was discussed in a communication from Dr. F. FORCHHEIMER (Cincinnati).

The use of suprarenal extract in the treatment of hemorrhage in the new-born was reported by Dr. L. EMMETT HOLT (New York). The case in which he had given it was that of a child which was seized with vomiting of blood on the day following its birth. It was a strong, healthy baby, weighing about 9 pounds, and it was of interest to note that the family had lost a child, but a less healthy one, under similar circumstances, 2 years previously. In the present case, suprarenal extract was administered in grain doses every hour, commencing in the afternoon. About 12 grains were given in all, and in the morning the hemorrhage stopped. It never returned, and the child had gone on improving ever since—a period of 2 months. A colleague had since used the drug with the effect of stopping a

gastrointestinal hemorrhage, but the child in this instance had a cerebral hemorrhage as well, from which it died.

Dr. MORSE said he had tried the use of suprarenal extract in a powder, but apparently with no result. Dr. ROTCH observed that the case reported by Dr. HOLT was an extremely interesting one, and if suprarenal extract proved valuable in this connection it would be a useful addition to their agencies for the treatment of the newborn. The vitality of the child might no doubt have had something to do with its recovery, but it was certainly worth while making further experiments with the drug. In the course of further discussion it was mentioned that Dr. BATES, who had made a special study of the effect of the suprarenal extract, laid stress on the importance of giving it in solution. Dr. HOLT admitted that the child might have had a better chance of recovery than some other children on account of its being strong and healthy; but it was the prompt effect of the drug that surprised him.

A short discussion took place in regard to another case reported by Dr. HOLT, a case of diphtheria of the conjunctiva, which yielded very promptly to antitoxin. Dr. CHAPIN said antitoxin was always given in such cases at the Willard Parker Hospital, but he was inclined to place more reliance on the local treatment that was given simultaneously. Dr. ROTCH said he had experience of cases in which antitoxin had acted in a most remarkable way after local treatment had failed. Dr. KERLEY mentioned a peculiar case, in which 2 boys, sons of a nose and throat specialist, suffered from rhinitis, which their father failed to cure. He (the speaker) was consulted and found germs of diphtheria in both the noses and throats of the boys. Antitoxin was given, and they were cured. Dr. CHAPIN explained that he did not wish to be understood as objecting to the use of antitoxin. They always gave it, and he believed it should always be given in such cases. At the same time he attached importance to the local treatment.

The program having been exhausted, a business meeting was held, when the following office-bearers were elected for the ensuing year: President, Dr. W. S. Christopher, Chicago; vice-presidents, Drs. Charles W. Townsend, Boston, and John Dorning, New York; secretary, Dr. Samuel S. Adams, Washington (relected); treasurer, Dr. J. Park West, Bellair, Ohio (relected); recorder and editor, Dr. Walter Lester Carr, New York (relected). Dr. Rotch, Boston, was elected a member of the Council.

AMERICAN LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL SOCIETY.

SEVENTH ANNUAL MEETING, HELD AT NEW YORK ON MAY 23, 24, 25.

[Concluded from page 532.]

Dr. L. L. MIAL (New York) said he had had experience of 2 cases in which the suprarenal extract produced violent sneezing, which continued for 10 or 12 hours. He had obtained excellent results from the suprarenal mixed with chlorotone.

Dr. M. R. WARD (Pittsburg, Pa.) said that, like some of the preceding speakers, he had had some unsatisfactory results from the use of the suprarenal extract, but he had not attributed them to the drug. He thought they might have been due to defective method of application. He did not think that any one who had had experience with adrenalin or the suprarenal extract would question their power to control hemorrhage. In plastic work on the septum he had difficulty in the way of sloughing. Whether this was due to any fault on his part or not, he was unable to say.

The President (Dr. B. C. MYLES, New York), said that 2 or 3 years ago he had been in the habit of using the suprarenal extract in the powder form, but he had rather lost faith in it. In fact he had lost some patients through it. He generally used it with resorcin. One patient on whom he had used it called him up on the telephone 2 or 3 days afterwards and asked him what on earth that was he had put in his nose, adding that he had sneezed for hours after going home. Another patient, who was interested in large commercial undertakings, wanted to have his nostrils clear as he expected to have a good deal of talking to do. He was given some of the extract, and the result was that his wife had to sit up with him all night and he was unable to attend to 7 important committee meetings which he had down for the following day. These and similar experiences had caused him to lose some of his faith in the drug.

Dr. PRICE BROWN (Toronto) said he had not used the extract for more than a year. Before that he had used it for some little time, but he always found that it produced an irritating effect. He had not used adrenalin, but would do so after what he had heard about it.

Dr. TAKAMINE was then introduced and invited to address the meeting. He remarked that he felt mighty honored at being given an opportunity to speak on the subject, and was well pleased with the way in which the drug had been discussed. Of course he was only a chemist and could add nothing to what had been said from a medical point of view. What he had done was simply to isolate the active principle from the suprarenal gland. This was the first time that such a thing had been done. In other words, it was the first time they had got the active principle of this gland in the pure form of chemical crystals,

and this was only a beginning of the wonderful work that he believed was being opened up in the domain of organotherapy. He had no doubt that the other ductless glands would be similarly utilized in course of time. In fact, he believed that in the near future they would have the active principles of all the other glands isolated as they now had the active principle of the suprarenal capsule. It depended on the members of the medical profession to decide how and when the drug should be used, and in what strength. Everything depended on the way in which it was used. If it was misused, it would, of course, produce bad results. He did not say this was why the gentlemen who had reported unfavorable results had got them, but from a chemical point of view he was at a loss to understand why it should have had the irritating effect it had been described as having in certain cases. One writer, who was now a strong believer in adrenalin, admitted that he got bad results at first, when he used it with formalin. Adrenalin in that case got the blame which was due to something else, and it was possible it might do so in other cases also. Then they were aware that there were some cases in which distilled water would produce a stinging effect similar to that which had been spoken of. All these were matters for the medical profession to consider and account for. All that he as a chemist claimed to have done was to have given them the active principles of the suprarenal gland in a form in which they could gauge its strength, and this they never could do with the gland itself.

Replying to questions subsequently put to him, Dr. Takamine said he was still prosecuting his investigations with the view of making the drug still more stable.

Dr. WILSON, replying on the debate, said he had seen cases where the suprarenal extract produced the irritating effects which had been described, but he had not found them follow the use of adrenalin. Another advantage possessed by adrenalin was that it could be boiled and boiled again to render it thoroughly sterile. This could not be done with the suprarenal capsule. He had never found any of the sloughing which had been spoken of, and in this connection he suggested that possibly one mistake which was sometimes made was that of using too strong a solution. A solution of 1:10,000, or at most 1:5,000, was quite strong enough for ordinary cases.

Dr. T. H. HALSTED (Syracuse, N. Y.) reported a case of acute sphenoidal abscess, amaurosis and operation, with recovery of sight, and Dr. Thomas R. Pooley, New York, a case of frontal and ethmoidal disease with abscess of the orbit, the latter contending that in such cases as he described operative interference was necessary to produce permanent results.

Dr. GEORGE L. RICHARDS (Fall River, Mass.) read a paper on empyema of the frontal sinns, in which he offered some suggestions as to treatment. In the course of discussion, Dr. C. W. RICHARDSON, Washington, said there should be no hesitation in resorting to operative interference in cases where there was an abscess of the mastoid. The discharge might be slight, and yet there might be a large diseased area. The President thought that free drainage was far better than anything else in the treatment of the conditions described. All cases, however, had to be considered individually. As a general rule, a trial of conservative methods did no harm.

Observations upon the treatment of stricture of the lacrimal duct by electrolysis were contributed by Dr. L. L. MIAL (New York). He contended that strictures could be modified by this means more readily than by any other, and that there was less danger of entering false passages and tearing the mucous membrane.

Dr. T. R. CHAMBERS (Jersey City) said that he used to have great difficulty in entering the lachrymal duct, but now he employed a combination of adrenalin and cocaine, and by its means he was enabled to enter the duct with ease.

Dr. NORTON L. WILSON (Elizabeth) thought electrolysis did good by relieving the stricture.

Dr. EDWARD B. HOLT (Portland, Me.) believed that in a great many cases much could be accomplished by electrolysis.

Replying on the discussion, Dr. MIAL said he had used cocaine and adrenalin in the lachrymal duct. They relieved the pain and enabled the operator to pass the probe with more comfort to the patient, but they did not affect the stricture.

Dr. H. A. ALDERTON (Brooklyn) contributed a few remarks on a generally unrecognized ear disease. It resembled otitis media, but varied so much in the character of its symptoms that it might exist for years without being detected. The treatment he recommended was incision and evacuation of the tympanum and thorough cleansing of the naso-pharyngeal cavities.

Dr. J. F. McCAW (Watertown, N. Y.) gave a brief report of a case of tuberculous otitis media, mastoiditis and meningitis in an otherwise apparently healthy adult. The patient died, and an examination showed the existence of tubercular bacilli and streptococci in the ear, while there were no signs of tuberculosis in the lungs, liver or spleen. It was difficult to say whether it was a primary or secondary tuberculosis. The primary lesion, no doubt, might have been overlooked, but he thought it was primary.

Dr. M. D. LEDERMAN (New York) described a Schwartz-Staacke operation for chronic suppurative otitis media, reformation of the tympanic membrane and secondary myringotomy, resulting in improved hearing.

Diseases of the Facial Tonsil and Peritonsillar

Tissue.—There was a symposium of papers on this subject, the anatomy and physiology of the parts being described by Dr. NORVAL H. PIERCE (Chicago); acute suppuration being dealt with by Dr. MAX GOLDSTEIN (St. Louis); recurrent peritonsillar suppuration, by Dr. HENRY J. HARTZ (Detroit); acute lacunar inflammation, by Dr. M. R. WARD (Pittsburg); mycosis, by Dr. ARTHUR G. ROOT (Albany); tuberculosis and syphilis, by Dr. CORNELIUS C. COAKLEY (New York); and glandular complications, by Dr. T. R. CHAMBERS (Jersey City). Other 2 papers were read by title, and will be published in the transactions of the society. They were by Dr. JOHN O. ROE (Rochester, N. Y.), and Dr. F. E. HOPKINS (Springfield, Mass.), and dealt respectively with chronic hypertrophy and malignant growths. The discussion which followed was taken part in by Dr. JONATHAN WRIGHT (Brooklyn); Dr. F. C. COHN (Boston); Dr. L. A. COFFIN (New York), and others.

The results of A Year's Experience in the Treatment of Stricture of the Eustachian Tube by Means of the Electro-bougie were given in a paper by Dr. THOMAS H. HARRIS (New York). The conclusions at which he arrived were that the electro-bougie had a place in aural surgery, though less important than had been supposed; that it should be used after and not before other methods of treatment; that it was most liable to fail in cases where there were complications; that its results were not always permanent, and that its use was not without danger.

Dr. GEORGE L. RICHARDS (Fall River), described the sensations caused by a bougie passed into his own ear, and said that the ear had felt better since the operation.

Dr. WENDELL C. PHILLIPS (New York) in whose clinic the experiments detailed in the paper had been conducted, said his views coincided generally with those reported. He believed that in the electro-bougie they had a useful instrument, but he did not think that it was a cure-all, and it certainly had to be used with caution.

Dr. NORTON L. WILSON (Elizabeth) said he had found it easy to make an entry with the electro-bougie in cases in which he had been unable to do so with an ordinary bougie.

Dr. WILLIAM P. BRANDEGEE (New York) said that at the Eye and Ear Infirmary the results obtained with the electro-bougie had been more satisfactory than those obtained from any other method.

Dr. C. DUNBAR ROY (Atlanta, Ga.) said the electro-bougie when used in selected cases was superior to anything else he had tried. In the course of further discussion, the use of the electro-bougie in urethral work was referred to, and Dr. A. B. DUEL (New York), who had been credited with its introduction into aural surgery, made some remarks in which he disclaimed having ever regarded it as a cure-all, but said that he still maintained that an opening could be made by its means more readily and successfully than by any other method. Dr. E. B. DENCH (New York) remarked that if the electro-bougie had never done anything more than to have provoked that discussion, it must be acknowledged to have done a great deal, because it had directed attention to what could be effected by means of bougies. He thought the use of the instrument was perfectly safe if used subject to the conditions of aseptic surgery. Replying on the discussion, Dr. HARRIS expressed the opinion that even with ordinary caution there was danger of suppuration from the use of the instrument, though he admitted that the danger was not great in thoroughly competent hands. As to the value of the method, he regretted that he had not obtained as good results as Dr. Duel and others.

Dr. JOHN F. WOODWARD (Norfolk, Va.) read a paper in which he advocated Simple Operations on the Turbinates in place of Cauterization. He remarked that complete removal of the turbinate was seldom necessary.

Dr. DUNBAR ROY (Atlanta, Ga.) submitted a contribution regarding Chronic Nasopharyngeal Bursitis.

Among the other papers read were the following: Tympanic Vertigo due to Obstruction of the Eustachian Tube, Dr. WILLIAM P. BRANDEGEE (New York); Toxic Rhinitis, Dr. CHARLES P. GRAYSON (Philadelphia); Immunization in Hay Fever, report of 2 years' experience, Dr. H. HOLBROOK CURTIS (New York); Lichenic Pharyngitis, Dr. J. A. STUCKY (Lexington, Ky.); Management of Acute Otitis Media, Dr. F. L. JACK (Boston); Early Treatment of Mastoiditis, Dr. C. W. RICHARDSON (Washington); the Mechanical Treatment of Nasal Synechia, with demonstration of an appliance, Dr. F. H. KOYLE (Hornellsville, N. Y.); Diseases of Stenson's Duct, and the treatment, Dr. C. E. MUNGER (Waterbury, Conn.); Observations on the Treatment of Catarrhal Deafness, Dr. SARJENT F. SNOW (Syracuse, N. Y.); report of an interesting case of Aneurysm of the Internal Carotid Artery, Dr. WALTER B. JOHNSON (Paterson, N. J.); Subarachnoid Injections of Cocain for Operations on the Head, Dr. REDMOND W. PAYNE (San Francisco); Papillomatous Growths of the Soft Palate, Dr. WILLIAM DUDLEY (Brooklyn), and Variations in the Technic of Septum Operations, Dr. STEPHEN H. LUTZ (Brooklyn).

New Office-bearers.—The election of office-bearers for the ensuing year resulted as follows: President, Dr. Charles W. Richardson, Washington; Vice-presidents, Dr. H. Holbrook Curtis, New York; Dr. H. W. Loeb, St. Louis; Dr. Charles F. McGahan, Aiken, S. C.; Dr. Ernest W. Fleming, Los Angeles, Cal.; Secretary, Dr. Wendell C. Phillips, New York; Treasurer, Dr. Ewing W. Day, Pittsburg, Pa.

SPECIAL ARTICLES

THE PRESIDENT'S ADDRESS.*

BY

CHARLES A. L. REED, A.M., M.D.,

of Cincinnati, Ohio.

In approaching the discharge of my duties as presiding officer of the fifty-second session of the American Medical Association, I beg to express my appreciation of the generous suffrages by which I have been called to a position of such conspicuous honor. This appreciation becomes all the more pronounced when I reflect upon the magnitude and achievements of this great national body and upon the luster of the distinguished men who have presided over its deliberations. This thought brings me to the first duty of the occasion, and that is, officially to bring to your attention the fact that since our last reunion 3 of my most illustrious predecessors have been called from their worldly activities to the realm of rewards. Alfred Stillé, Lewis A. Sayre and Hunter McGuire, each a former president of the Association, died within a single week. Their lives were known of men, their records are ornaments of our annals, and their achievements are their eulogies. They labored zealously and with beneficent results, not alone in the scientific field, but in behalf of an organized national profession; and to guard jealously the splendid legacy which they, among others, have left us, must be one object of our labors upon this auspicious occasion. The hope is indulged that steps may be taken to procure suitable portraits of these and of other deceased presidents of the Association, to be placed in some safe gallery until such time as the Association may be able to transfer them to its own Temple of Fame. I recommend that suitable formal action be taken on this occasion relative to the life, distinguished services, and the death of these lamented *confères*.

FOREIGN RELATIONS OF THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association accredited delegates during the last year to several foreign medical conventions, notably the International Medical Congress at Paris, the Dominion Medical Association of Canada, the Mexican National Association and the Pan-American Medical Congress at Havana. To each of these organizations the American Medical Association sustains relations of peculiar intimacy. As one of the great scientific nations of the earth, the United States is naturally an integral part of the International Medical Congress. This Association, by a resolution presented by your present executive officer, took the initiative in 1891, in organizing the Pan-American Medical Congress. The first reunion of that Congress was held in Washington in 1893, under the presidency of the late lamented Dr. William Pepper. The second was held in the City of Mexico in 1896 under the presidency of Dr. Carmona y Valle, while the third has been held during the last few months in the City of Havana under the distinguished presidency of Dr. Juan Santos Fernandez. This movement has for its object the establishment of closer relations between the medical profession of the different countries of the Western Hemisphere. It has already borne excellent fruit in the increased patronage of our medical schools from the far south, in the improved status of American medical practitioners in Latin America, in a better understanding of quarantine questions in the different countries, and in the development of a concert in the investigation of the medicinal flora of the Western Hemisphere. Our

relations with the medical profession of Canada must be of increasing intimacy, and I indulge the hope that while maintaining the national limitations of our Association for delegate and legislative purposes, its membership, with the privilege of participating in all scientific matters, may be freely opened to our brethren who live beyond our immediate borders.

FISCAL AFFAIRS AND THE JOURNAL.

It has passed into unwritten law, born of the gradually developing features of our organization, that your President shall restrict his annual address to a discussion of the affairs of the Association and to the great object to which, by the terms of its Constitution, it stands consecrated—"the common interests of the medical profession in every part of the United States." In compliance with this rule, and realizing that I am leaving scientific questions to be presented by orators appointed for the purpose, I have pleasure in calling your attention to the satisfactory condition of the affairs of the Association, as indicated by the consolidated report of the Treasurer and of the Board of Trustees. From it you will observe that under the judicious management of your Board of Trustees you had a cash balance at the end of the last fiscal year of \$31,004.67, being an excess of \$3,696.66 over the preceding year. Your plant has been increased in value to the amount of nearly \$10,000.00, and the net profits of *The Journal* amounted to nearly \$14,000.00. You will be gratified to realize that, in addition, you have safely invested as part of a fund with which to buy a home for *The Journal* and for the Association, the respectable sum of \$25,000.00. If, however, you have occasion to feel satisfied with the normal condition of your finances, you must contemplate with pride the rapid increase of your journal, in quality, size, circulation and influence. The average weekly circulation grew, during the last fiscal year from 13,672 to 17,446, and I have added pleasure in informing you that, since the period covered by the report, the weekly circulation has grown to 22,000 copies. For the accomplishment of these splendid results, I feel that you will join me in hearty acknowledgment, not only of the sagacious management by the Board of Trustees, but the tireless industry and the discreet direction of our accomplished editor, Dr. George H. Simmons.

I feel that it is important, however, to call your attention to the fact that it would have been impossible for your Board of Trustees to have accomplished these results if, through its action, the Association had not become incorporated. Leases were to be executed, purchases were to be made, contracts were to be entered into, money was to be loaned and bonds were to be exacted, to do all of which it was necessary that the Association should become a legally organized corporation. This was effected, *ad interim*, by the action of your Board of Trustees, which procured articles of incorporation under the laws of Illinois, bearing date of April 14, 1897. I am not aware that this fact, attested by the document which I have laid before the Executive Committee, has ever been confirmed by the vote of the Association. I recommend, therefore, that such action be taken at the present session.

If, however, the condition of the Association, and particularly of *The Journal*, is, on the whole, occasion for much satisfaction, certain facts revealed by the report are food for thought. Thus, *The Journal* has an aggregate circulation 2½ times greater than the aggregate membership of the Association. It would seem, therefore, that while the profession at large prizes *The Journal*, it places relatively less than half as much value upon membership in the Association. This fact becomes strikingly significant when it is remembered that membership can be acquired by those who are eligible at no additional expense and with but trifling inconvenience. Does *The Journal* fulfill all the wants of the profession arising in connection with the Association? Are there no addi-

*Delivered at the fifty-second annual meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901. Published synchronously by courtesy of Dr. George H. Simmons, editor *Journal American Medical Association*.

tional advantages to be derived from membership? Is there a lack of *esprit de corps*—a lack of the sense of unity in the profession? Is the existing basis of our national organization distasteful to the majority of the practitioners? Do our subscribers embrace a considerable number of practitioners who, under existing rules, can not become members, and whose influence, therefore, cannot be secured in behalf of the Association? These are questions that I am at liberty to ask, and that you are at liberty to answer.

Another thought suggested by the report relates to the disposition of the accumulating surplus. Shall the present policy for creating a fund for the purchase of property be carried out? Shall a larger proportion of the money be expended in still further exploiting *The Journal*? Shall the members receive a direct advantage from the earnings of the property which they have created, by reducing the annual dues, or shall a certain proportion of our surplus be expended in conducting original scientific investigations on subjects of universal interest to the profession? I cannot resist the temptation in this connection to venture replies to these questions far enough to say that, in my opinion, a reserve should be held in hand large enough to meet any possible contingencies that might occur by fire or other disaster in connection with *The Journal*; that the present generous policy in promoting the welfare of *The Journal* should be continued; that the dues of the Association should not be decreased; and that the question of establishing and defraying the expenses of certain commissions for special scientific investigators should be taken under serious consideration. The question of tuberculosis is not yet a closed chapter. The causation of cancer is yet a sealed mystery. The problems of tenement house reform are not yet solved. The prevention of various endemic diseases has not yet been made practicable. The systematic investigation of the American medicinal flora, begun under the auspices of this Association more than 40 years ago, remains an uncompleted task. These are a few among the many objects of a specific character which demand and should receive the fostering care of the Association.

I feel, however, that at the present moment, and under existing features of our organization, it would be almost impossible to determine, judiciously, either of these very important questions, and I now bring them before the Association only for the purpose of directing attention to them, with the hope that they may be taken up subsequently and under more auspicious circumstances.

SCIENTIFIC WORK OF THE ASSOCIATION.

The Association began its career with general meetings devoted chiefly to questions of medical education and professional conduct, and to lengthy reports from various standing committees. In 1860 it divided itself into a few sections, each with a certain autonomy, and each devoted to a particular part of our great scientific work. This change was followed by the establishment of the Judicial Council, by which means controversial questions, many of them of a personal character, were eliminated from the general meetings. The subsequent creation of the Executive Committee still further relieved the general meetings of annoying details. Thus relieved, both the general meetings and the sections have grown in scientific importance, emphasizing the persistence of our devotion to what must ever be recognized as the essential, fundamental object of our organization—the cultivation of the medical sciences. It must be acknowledged, however, that great as has been the progress in this particular, too much of the time of our general sessions is yet devoted to the consideration of matters which might, with propriety, be relegated for final action to a smaller body. It would redound largely to the interest of our annual session if the general membership could be entertained and instructed at our general meetings by

exercises of a more purely scientific character, of such broad nature that they should not be restricted to any of the sections. A reform in this particular will be a long step in the direction of progress. The sections, in consequence of the faithful labors of their officers, offer strikingly attractive programs for the present session. In several of the lists will be found the names of invited guests who, through fortuitous circumstances, are not members of the Association, but who are, nevertheless, active workers in the scientific field, and whose participation in our labors will enrich the value of our proceedings and enhance the felicities of the occasion. I bespeak for them your cordial welcome. While the officers of sections and your President have exercised the prerogative of inviting guests, who come as guests, and not as members of any class, as specified by the Constitution, such invitations have been extended solely with the object of advancing the interests of the Association. I look upon this privilege, which has been exercised by all of my predecessors and by previous officers of sections, as one of extreme importance, and one which should be continued under any plan of reorganization which may be adopted. It is my conviction, however, that the privilege should be hedged about by certain limitations, one of the most important of which should be that an invitation should not be extended a second time to any person residing within the United States whose professional qualifications may entitle him to membership. With reference to the invitation of persons identified with the allied sciences, the matter should be left absolutely to the discretion of the President of the Association and with the officers of sections.

CONGRESSIONAL AND STATE LEGISLATIVE AFFAIRS.

The American Medical Association, during the first 50 years of its existence, exerted relatively little influence upon legislation, either state or national. Since the Standing Committee on National Legislation and the National Legislative Council of delegates from the State societies have been established and have become cooperative, there is some evidence that the voice of the profession is heeded at Washington. The experience of the splendid committee of the association, acting in concert with the National Legislative Council during the last year, has, however, shown the serious necessity for more thorough organization in protecting the interests of the profession, and the interests of society as represented through the profession. The inefficiency of our present organization for influence upon Congress was shown in the inability of your committee, notwithstanding its strong *personnel* and the influences at its command, to prevent the degradation of the army medical service. This was accomplished by the passage of a bill under the championship of Senator Hawley, by the terms of which the medical corps of the army is subjected to unfair and humiliating discrimination. This law grades the medical department for rank, promotion, and, in consequence, for pay, below every other department and special corps of the army, and, with the exception of second lieutenants, it is graded below the line. In accordance with its provisions, a medical officer, to obtain a colonelcy, must pass through three times as many files as an officer of either the Quartermaster's, the Subsistence or the Pay departments; more than twice as many as an officer of Engineers or of Ordnance, and nearly twice as many as an officer of the Signal Corps. The effect of this discrimination is not only to lower the rank and pay of medical officers, but must result in lessening the efficiency of the corps by repelling men of spirit and worth.

In every war known to history the deaths from preventable diseases have exceeded those due to battle. At no time has hygienic science been so resourceful as at present in preventing disease. A law which fails to give to armies, either in peace or in war, the fullest protection by the application of the latest scientific develop-

ments at the hands of specially trained medical men is unjust to the soldier, to society, and to the medical profession. In view of these facts, the army reorganization law of the last Congress was inexplicable and inexcusable. It, however, forces itself upon your consideration from another standpoint. Physicians are citizens of the Republic. As such they are intellectually, socially, politically and officially the equals of any other element of the body politic. There is no station to which they may not attain; there is no distinction of which they may not be the recipients. Their rights are of manhood origin and their prerogatives are inherent. They are, in very fact, peers of the realm, and the peers of any peers of any realm. When the status of any number of physicians in their representative relationship to society is lowered, the status of the medical profession in general is menaced in corresponding degree. When the Congress, by the enactment of a law, degrades, relatively, the status of an important body of medical men, engaged in the public service, it strikes at the status of every physician in the country. It becomes, therefore, the duty of every member of the medical profession, jealous of his rights, his prerogatives, and the fair name he may leave his children, to resent as personal between himself and every member of the Congress who voted for this law, the action which cast a stigma upon our profession.

It has been the conviction of many enlightened members of the medical profession that the means employed by the general government for the protection and promotion of the public health are capable of improvement. These duties have devolved upon the Marine-Hospital Service, which was originally designed to give succor to unfortunate people, without other domicile, who were employed upon our rivers, lakes and the high seas. With the growth of sanitary science this service, being the only established agency available by the government for this purpose, has been largely diverted from its original object. As a result, under the present wise administration of its Surgeon-General, its representatives are abroad investigating the sanitary condition of foreign cities, its agents are at our ports beating back threatened epidemics, while valuable investigations are being conducted in its laboratories. In the exercise of its quarantine functions, however, it comes in conflict with the police power that is guaranteed by the Constitution to the different states. The friction thus engendered has been especially marked in the seaboard states. While this is true, the Marine-Hospital Service, in scope and design, does not fulfill in highest degree the objects of a central coordinating agency for the protection of the public health. It was thought to create a Department of Public Health, with its executive officer in the Cabinet, but this idea yielded to that of a bureau in charge of a large Advisory Council, composed of representatives from the various states. Resolutions have been adopted and memorials have been sent to the Congress, committees have been appointed, money has been appropriated by this Association; bills have been introduced and hearings have been had in committee, with the result that the conditions to-day are precisely the same that they were 10 years ago, when the agitation was inaugurated in the session of this Association held at Washington.

Secretary Wilson, of the Department of Agriculture, in his report for 1899, recommended that the Congress appropriate money to defray the expense of a systematic investigation of the medicinal flora of the United States, and of experiments upon the neutralization of medicinal plants indigenous to other countries. This recommendation was based upon the fact that the United States is the only great country which either has not conducted or is not conducting such experiments, and upon the fact that the proposed measure, touching the avenues of industry, manufacture, commerce and the public health, was one of national concern. This measure, however,

with its manifest importance, was denied even courteous consideration, while its friends were denied a hearing by the committees of the Congress.

The cause of failure on the part of this Association to procure legislation by the Congress—and with the exception of preventing the passage of the Antivivisection bill last year and securing the enactment of the Quarantine bill this year, our recent efforts must be recognized as failures—I say the causes of our failure are properly subjects for careful consideration. I have examined the records of the Association from the date of its organization, and have been profoundly impressed with the fact that memorials, resolutions, or even more definite propositions addressed to the Congress have, for the most part, represented the views, or rather the impressions, of the individual members proposing them. They have generally been presented in the general meeting, and have been endorsed without the deliberation essential for wise action; but a deliberation which is simply impossible in the limited time available in our general meetings. In certain instances memorials to the Congress have been presented at one session of the Association, have been reported to committees and reported back for action, either at a later meeting of the same session or at the succeeding annual session of the Association. But it becomes evident that this course lessens the evil but a trifle, for the reason that the committees to which such matters were referred have been constituted either under the leadership of the member proposing the measure or of members of a standing committee who had no interest in or understanding of the proposed measure. Such memorials, resolutions or propositions, when acted upon affirmatively by the general meeting of the Association, have, possibly, been mailed to some member of Congress or of a legislature, but were not followed by effective work in the rank and file of the profession or among their patrons. When such bills have been presented to the Congress, and have received a certain amount of support from representatives of this Association, they have, as a rule, attained only that degree of importance that has made them valuable to their ostensible champions, as something to trade in the game and barter of legislation for something which would please a larger number of constituents and command a larger number of votes. In view of the fact that, after all, the argument of votes is the only one which appeals effectively to the average Congressman, it behooves this Association, in its efforts to conserve the interests of the profession and of society, to put itself in position to influence the largest number of votes. Every physician, therefore, should, in a perfectly respectable sense, become an active working politician. This subject, however, is of such breadth and of such depth that it may be well for us to pause at this juncture long enough to consider, from the standpoint of fundamental facts, the relationship of physicians to each other, and of the medical profession in the aggregate as an integral factor in society.

THE PROFESSION, THE ASSOCIATION AND THE COMMONWEALTH.

In approaching a study, however brief, of the relation of the medical profession to the State, or, as I prefer to call it, the commonwealth, I feel that I am inviting your attention to an eminently practical theme; one which may enable us to understand the influences by which we have arrived at our present estate, and the means by which we may advance to even greater achievements. As we approach this theme—this eminently practical theme—we discover that the status of the medical profession, like that of every other element of that complex whole which we call society, is a perfectly natural one. Whatever it may be, it has been attained in the process of evolution, and has been, and is determined, by laws as immutable as those which govern the commingling of atoms or the sidereal strides of the

planets. It is not the result of conventions or of resolutions or of statutory enactments; but these are to be interpreted as *indicia*, for the time being, of the position of the profession in the body politic. They are, indeed, consequences rather than causes, and as such they are subjects for careful inquiry. It is by a study of them that we are enabled in part to determine those laws, those natural laws, our harmony with which is essential, not alone for the present usefulness and continued progress of the profession, but for the ability of the medical profession to conserve the welfare and promote the happiness of society at large.

But I have said that the position of the medical profession is a natural one. The truth of this declaration is apparent when we go back to the beginnings of society—when we examine the evidences presented by primitive peoples. We are familiar with the classic example so frequently utilized as a starting point in the discussion of sociologic phenomena—the example of the 2 aborigines, one of whom makes better arrows, and the other better mats than his companion, when, presently, one confines himself to arrows, the other to mats, each trading his own for the other's product. Here is an example of the beginning of what the scientists call "specialization of function in the social organism." It is an interesting process, which, based upon varying necessities and diverse aptitudes, results in multiplication of handicraft until somebody is hurt. This is a new necessity, and it is met by a new aptitude, and the possessor of that aptitude—the medicine man, our honored progenitor—steps upon the scene. His companions, appreciating his services, reward him with their arrows and mats; and he, finding the life to his liking, restricts himself to his new-found vocation—and the medical profession is established! As the necessity for his services, whether of charm or incantation, becomes more apparent, the esteem of his fellows becomes more pronounced. As events progress, he is accorded certain rights, given certain prerogatives and hedged about by certain limitations, all calculated to increase his efficiency in promoting the common welfare—and thus is the practice of medicine regulated. He is spared from the battle that he may serve his companions, and he stays away from the chase that he may delve into the great mysteries—and thus is medical education inaugurated. He is the exponent, not only of his professional knowledge, but of at least the average intelligence of his people. He is, in short, an integral part of the primitive social fabric. As such, he shares the manners, the customs, the aims, the ambitions of his companions; and he, with them, is controlled by the forces which determine the common state and the common destiny. His status is, therefore, determined by the very laws which control the growth and development of society itself. So true is this that, from the dawn of history until the present day, and in every stage of sociologic development, the civilization of a people may be infallibly determined by the intelligence, the efficiency and the influence of its medical profession.

THE MEDICAL PROFESSION AND SOCIETY 50 YEARS AGO.

It would not be to our present purpose to follow the evolution of society as exemplified in any of the civilized peoples, or, as the scientists say, "distinct ethnic entities of the world," in which the present complexity has been attained by an orderly succession of events. And it would be equally unnecessary to show, what everybody knows, that the medical profession, the heritor, in common with others, of antecedent influences, has been propelled by the same forces and by equally orderly events to precisely the same standard of civilization. The lesson before us is that of the relation of the medical profession to a society which, but a few decades ago, was the most diverse in origin and the most heterogeneous in constitution known to modern history; but a society

which at the dawn of the twentieth century is one of the largest, richest and most intelligent of the world, a society well amalgamated, and which by common consent of even adverse critics is moving in harmony with the most advanced influences of civilization. I fancy I should suddenly find myself unpopular with the audience if I were to intimate that you, who comprise it—that you, the representatives of the medical profession—have failed to contribute your full quota to the great progress which that society in general has achieved, or that you do not reflect in intelligence and morality the highest type of civilized man. I hasten to allay your apprehension, for I have no such intention. On the contrary, I ask you to indulge with me in a retrospect of American society during the last half dozen decades that we may the better understand the important part that you, and the profession that you represent, have played in the attainment of present results.

As I have already stated, the middle of the nineteenth century found diverse conditions of society in the United States. The older cities of the seaboard were the centers of an advanced civilization. The remoter counties of the same State, however, were then, in the absence of railroads, the telegraph and modern mail facilities, more remote from the centers of American influence than is St. Paul today from St. Petersburg. The great tide of emigration that had already poured and was yet pouring over the mountains and spreading in lonely habitations or widely separated communities over the vast valley of the Mississippi from the Lakes to the Gulf was busily engaged with the serious problem of existence. The forest was to be felled and the prairie was to be subjugated, habitations were to be built and crops were to be raised. In the midst of these exactions, institutions of higher learning were established, and to an extent patronized, and some strong men were produced. But it must be recognized as true that society in general had but little time and less money to devote either to schooling or to the amenities of life. The medical profession, under these circumstances, was precisely like the community of which it was a part. There were but few medical colleges, and they, for the most part, were but meagerly equipped. Many doctors became such while going from one town to another. Ignorant inventors of alleged systems of cure hawked their wares in the high-ways and the byways. Dogmatism that was destructive to intelligence was rampant, while schism was fostered by the baneful commercialism that too generally pervaded the heterogeneous mass of 40,000 people that comprised the medical profession. In 8 of the 26 then existing States no laws affecting medical practice had ever been enacted; in 11, laws previously enacted had been repealed; in 3 only were there any restrictive laws, and these proved inefficient; while the facts could not be ascertained relative to the remaining 4 States.

THE ERA OF ATTEMPTED VOLUNTARY REGULATION OF MEDICAL PRACTICE.

To remedy these evils, and actuated by the love of science, the promptings of self-interest, and by devotion to the interests of humanity, representatives of the various State medical societies met in convention over half a century ago and organized the American Medical Association, with the avowed object of having its members represent and take cognizance of "the common interest of the medical profession in every part of the United States." It sought to cultivate medical knowledge among its members, to elevate the standard of medical education, to promote the honor and influence and interests of the medical profession, and to enlighten the public concerning the relation between the medical profession and society. Emulation and concert of action in the profession and friendly intercourse among those engaged in it were additional aims of the founders of this great body of representative American medical practitioners. A constitution, by-laws, and certain rules of conduct were

adopted. The constitution provided for a delegate body, delegates being accredited from recognized medical societies, medical schools, and eleemosynary institutions. The rules of conduct prescribed in detail the department of a physician, the department of the patient, interdicted the licensure of sectarian physicians, and proscribed from consultation those whose practice was based upon an exclusive dogma. The influence of the new Association was extended chiefly through the avenues of the various State societies, many of which adopted the rules of conduct that had been prescribed by the newly-formed national body as the basis of affiliation. Several of the State societies, notably those of Massachusetts, Rhode Island and Mississippi, finding either that the prescribed rules of conduct were not suitable to their respective local conditions, or feeling that they were sufficiently in touch with the ordinary forces of civilization to require no such formulas, never adopted the rules of conduct prescribed by the national body. The medical association of Alabama adopted the rules with rather a *naive* proviso that somebody be appointed to call attention to such of the special teachings of these rules "as may seem to require elucidation in view of special circumstances and conditions." Other State societies adopted more or less modifying resolutions, but the general spirit of ostracism and aloofness was maintained during the succeeding 3 decades. The result of this movement was immediately salutary; it developed an *esprit de corps* in the great body of the profession; it gave an authoritative definition to medical education, and it created a strong and influential national body within the profession. At the same time, however, it became apparent that the organization did not possess the necessary inherent strength to accomplish its avowed object to regulate the practice of medicine. As time passed schismatic medicine grew apace, its colleges multiplied, its practitioners appeared all over the country, exemplifying that law that always makes the blood of the martyrs the seed of the church. Quackery of the most flagrant character was found everywhere, and society was unprotected from its ravages, while the inability of a voluntary unchartered organization to enact and to execute plenary laws was reduced to a demonstration. The medical profession, as an organized body, discovered that its relation to the commonwealth was, as the result of its own proscriptive policy, scarcely more intimate or more influential than at the beginning of the thirty years' hopeless experiment.

THE ERA OF EFFECTIVE LEGISLATIVE CONTROL OF MEDICAL PRACTICE.

The era of effective legislative control of medical practice came as the natural reaction from the demonstrated failure to accomplish the same result through voluntary organization; but it came as the result of the sentiment which had been propagated largely through the influence of this Association. The representatives of progressive medicine, turning from the National Association, invoked the aid of their respective State societies in taking up the question with their respective legislatures. The profession in each State, however, recognizing its own local conditions, proceeded in its own way to attend to its own business. The very earliest attempts to secure State legislation revealed the fact that the so-called irregular practitioners, under the stimulus of ostracism and the fostering care of public sympathy thereby induced, had become so numerous and so influential that in a majority of States nothing could be done without their cooperation. It was no longer a theory, but a condition with which the real performers were confronted—and they met it. California, in 1876, through its regular medical society, took the initiative. After conferences with the representatives of the sectarian societies, and after securing their cooperation, a law was procured creating a licensing board composed of representatives of both the regular and sectarian schools of practice. Illinois, confronted by precisely the same

condition, took precisely the same course. Alabama, always progressive, but the happy possessor of other conditions, was able to place the regulation of medical practice for the time being under the control of its incomparable State Medical Association. Colorado created a mixed board. New York, confronted by conditions even more complicated than those in other States, took up the same task. The profession of that State, acting through its organized body, containing among its members many of the most honored and illustrious names in American medicine, found it doubly necessary to enter into treaty with the denominational physicians. It realized, however, that the rules of conduct to which it had always conformed contained, among other provisions, one which made it unlawful to ". . . examine or sign diplomas or certificates of proficiency for, or otherwise be especially concerned with the graduation of, persons whom they have good reasons to believe intend to support and practise any exclusive and irregular system of medicine."

As the thing expressly interdicted by this rule was the very thing which it was proposed to do, and which had been done in other States, and which it was very necessary to do in New York, the medical society of that State amended the rules of conduct so that it or its members might, at discretion, enter into professional relations with any or all persons whom the law of the State at that time recognized to be practitioners of medicine. When this action was brought to the attention of this national body it resulted, not as might have been expected, in the amendment or the abrogation of the rule which had grown obsolete in the march of events, but in its tacit reaffirmation and in the opprobrious excommunication, for the time being, of the entire profession of the great Empire State. This action, viewed impartially after the lapse of nearly 20 years, becomes the more extraordinary when it is observed that similar action was never taken with regard to Massachusetts or Rhode Island or Mississippi, the societies of neither of which had ever adopted the prescribed rules of conduct; nor with regard to California or Illinois or Colorado, each of which had, by overt act, if not by open declaration, so far as this rule is concerned, taken an equally nonconformist position. It is not surprising that, with such an example before the State societies, the experiment in consistency has not been repeated. But the movement of effective regulative legislation, once inaugurated, happily spread with great rapidity. Mixed boards of licensure are now to be found in the majority of the States of the Union, and in the majority of such boards are to be found members of the American Medical Association engaged in issuing licenses to practitioners of exclusive dogmas, and sitting in consultation with sectarian physicians, not over a dose of medicine, but over the vastly more vital question of the qualifications of those who are to care for the sick of our Republic.

THE MEDICAL PROFESSION AND SOCIETY AT THE BEGINNING OF THE TWENTIETH CENTURY.

The results of the 25 years of statutory regulation of medical practice are in striking contrast with the results of the quarter of a century of attempted regulations by methods of proscription. At the conclusion of that humiliating experiment, as at the beginning of it, there was not a single effective medical practice law on the statute books of a single State of the Union. Today there are 48 State or Territorial licensing boards, the most of them being composed of representatives of both the regular and the sectarian schools of practice. The laws of the different States are of varying efficiency, the one procured by the Medical Society of the State of New York, at the price of yet-maintained excommunication from this body, standing today as the model of excellence for the entire country. Under the influence of these laws, instigated by members of the American Medical Association, and which, after all, are but expressions of

the sentiments of the medical profession confirmed by society at large, many substantial reforms have been accomplished. The medical schools which, in this country, have labored bravely and efficiently under adverse conditions, have been stimulated to increased efficiency. One of the first changes accomplished was the practical standardization of requirements to enter practice; and one of the first features of this standardization was to secure for the student "the aids actually furnished by anatomy, physiology, pathology and organic chemistry"—the 4 cardinal studies which, strange-sounding as it seems, it was necessary solemnly and specifically to insist upon a half century ago. It follows, therefore, that with broadened and increasingly uniform curriculums, it can not be said that schools even of sectarian antecedents entirely "reject the accumulated experience of the profession," nor can it be said that, in a sectarian sense, they any longer possess an excuse for existence. Their graduates, or such of them as do not base practice on an exclusive dogma, are, in many instances, met in formal consultation by even conservative regular physicians, and, in more than one instance, are made members of medical societies that are in affiliation with the American Medical Association.

The Illinois State Medical Society, which has always been among the foremost in reform movements within the profession, at its recent annual session, unanimously

"Resolved, That the school of graduation shall be no bar to membership in the Illinois State Medical Society, providing such physician is recognized by the local societies as qualified and not claiming to practise any exclusive system of medicine."

The Ohio State Medical Society, by precedent, if not by formal action, established the same rule.

We thus see that the proscriptive rule which, during the more than 25 years of its dominance, propagated the very evils it was intended to correct, is rapidly expiring by limitation in the face of new conditions that have been induced, in spite of it, by beneficent and catholic legislation. In the State of New York alone the annual registration of sectarian physicians has diminished nearly 90%, under the operation of its present laws. In the State of Ohio many physicians who are graduates of sectarian schools are making application to have their classification on the register changed to "regular," while equal reactionary movements are observable in other States. Thus we observe the passing of Homeopathy and Eclecticism just as did the calm scientists of Rome witness the passing of the "Humoralism," the "Methodism," the "Eclecticism," and the "Pneumatic School" of that period; and just as passed the "Chemicalism," the "Iatro-Physical School," the "Iatro-Chemical School," and the "Brunonianism," and the dozen other "isms" of later epochs, each leaving its little modicum of truth as the memento of its existence. And let us felicitate ourselves that, with the passing of the particular sectarianism of the last century, there is also the passing of its concomitant evils, such as existed in even greater degree in the time of Galen, who "found the medical profession of his time split up into a number of sects, medical science confounded under a multitude of dogmatic systems," and, as if relating the effect of the cause, the historian continues, "the social status and the moral integrity of the physician degraded." The further results of this new order of things, however, are observable, not alone in the modified curriculums of the medical schools, but in the changed organic relations of the institutions themselves. Under the pressure of legal requirements the weight falls with almost fatal force upon the small, private and poorly equipped institutions. These institutions, in the interest of self-preservation, and to protect a respectable alumni, are forced either to expand their enterprises or to seek relations with universities which are deeply founded in the community; or else actually to go out of existence. The majority of the schools seek connection with the uni-

versities, by which step alone they become logical objects for endowment, and it is to be hoped that this movement will continue until in this great country medical education shall be as firmly established as it is today in any of the transatlantic nations.

Another of the new conditions which has developed within the last quarter of a century, as the result of an increasing professional unity, is the efficient sanitary regulations, national, State, and municipal, that now afford protection to the people from diseases that were formerly devastating in their effects. It is not necessary in this audience to mention smallpox, cholera, typhoid fever, diphtheria, anthrax, leprosy, and the bubonic plague, each of which has been brought under relatively effective control, but I do feel that it is necessary to emphasize the fact that there are many unsolved problems relating to the prevention of disease that stand as a challenge to the industry, the ingenuity and the courage of the profession. While these various changes have taken place, others of almost equal importance are observable in the relations of physicians to society. While the community, instigated by the medical profession, has given to that profession a legal status, definite and increasingly influential, and has given it certain prerogatives and certain exemptions, it has, likewise, hedged it about with certain limitations and imposed upon it certain liabilities. There are numerous laws, both common and statutory—*lex non scripta* and *lex scripta*—that admonish the physician that his conduct carries with it a liability not defined by self-imposed rules, and the numerous courts of our land proclaim that there are tribunals "other than his own conscience to adjudge penalties for carelessness or neglect" on the part of the physician. So numerous, so unjust, and so disastrous are actions before such tribunals that they have caused the development of a new, legitimate and beneficent enterprise, in the development of a company to insure physicians against malpractice. It may be true that in certain states and localities these laws are unjust, and that there is a grave error in their administration by judges created under our wretched elective system; but if so, the facts only emphasize anew the necessity for more complete organization of the profession and for the more active exertion of its influence upon elections.

THE REORGANIZATION OF THE ASSOCIATION.

This brings us again to a realization of the fact that the results that can be achieved only by the unification of our national profession cannot be attained under the present organization of our Association. The disproportionately rapid growth of *The Journal* as compared with that of the Association can have no other significance. The weakness of the Committee on Legislation at Washington was a question neither of personnel or of industry, but arose purely from the fact that there was no efficient organization in the rank and file of the profession by which speedy and effective influence could be brought to bear upon members and senators. Equal difficulty has been encountered in several States where organization has been similarly defective. The demand for more effective organization of the Association has come from all over the country and resulted in the adoption of a motion at Atlantic City authorizing the appointment of a committee of three to report a plan of reorganization at this session. Another motion was adopted authorizing the creation of a supplementary committee of one from each State and territory, entitled a Committee on Organization, which has been filled by appointing for the most part the retiring presidents of state societies for the current year. The Committee on Reorganization, consisting of Dr. J. N. McCormack, of Kentucky; Dr. George H. Simmons, of Illinois, and Dr. P. Maxwell Foshay, of Ohio, has given to the important question entrusted to it a most careful and painstaking consideration. It has laid before you the results of its

deliberation. In doing so it has emphasized the principle that this Association has its origin in the organized profession of the respective states. It emphasizes the fact that the delegate body should be so small that it can remain in prolonged session and give to various subjects under consideration that deliberate attention which has not been possible under the existing scheme of organization during the last 40 years. It recognizes the paramount importance of the scientific feature of our work by relieving the general meetings and the sections alike of the troublesome details that now consume the limited and valuable time of the sessions. It remedies the glaring and serious defects in the present constitution. It prepares the Association, by perfecting the organization, to meet important and pressing questions. These considerations, together with the fact that the existing constitutional provision relative to delay of action on pending amendments has been met by the appointment, a year ago, of a committee for the avowed and published purpose of reorganization, and by the action of the committee in laying the results of its work before every member of the Association—I say these considerations, and these facts, prompt me to advise the adoption of the proposed constitution and by-laws in their entirety at the present annual session of the Association.

The Committee on Reorganization, under the restrictions of the resolution creating it, has, very properly, left undisturbed the existing rules of conduct. These, if construed to have a fundamental importance, and if vigorously enforced as they now stand, would disintegrate the Association in a single day. This reason, and others already given, confirm me in the conviction that such rules should be either amended or abrogated, or, if reaffirmed, it should be by general resolution endorsing their underlying principles but disclaiming the present applicability of their details. There are, however, various views entertained upon this subject, and that the matter may be approached in a spirit of tolerance, may be discussed coolly and impartially, that a consensus may be reached and that harmony may be attained, I recommend that the general questions of the revision of the rules of conduct be referred to a special committee on ethics, consisting of 3 members, with instructions to report to the legislative body at the next annual session of the Association.

THE NEW SCHOOL OF MEDICINE.

The changes which I have advocated are essential for the attainment of the purposes of the Association and for the fulfillment of the high destiny of our national profession. They are demanded by the changes that have taken place during the last 50 years. The legislative functions have passed from voluntary organizations to the Congress and the legislatures, where they belong; but it still devolves upon the profession in the organized capacity, to stimulate, to restrain, or otherwise to control the law-making power. The responsibility of the profession is increased, rather than diminished. Science has come to have a clearer meaning. He who now proclaims a dogma cries alone in the night, while the world sleeps. They who demand a creed may read its varying terms only in the progressive revelation of natural laws. Practice has changed. The depletions, the gross medications, the absurd attenuations, the ridiculous antimicrobialism have given way to a refined pharmacy and to a more rational therapy. Sacrificial surgery has yielded to the spirit of conservatism. Prevention is given precedence over cure. Education implies research and discovery, and all may delve. I proclaim, events proclaim, the existence of a new school of medicine. It is as distinct from the schools of 50 years ago as is the Christian dispensation from its pagan antecedents. It is the product of convergent influences, of diverse antecedent origin. It acknowledges no distinctive title, it heralds no shibboleth. It is a school of human tolerance, of personal independence, of scientific honesty. It

is the slave of neither prejudice, nor preconception, and abandons the accepted truth of yesterday, if it only be the demonstrated error of to-day. It places no premium upon personal prerogative, and extends no recognition to individual authority. It makes no proclamation of completeness, no pretension to sufficiency. It recognizes that truth is undergoing progressive revelation, not ending to-day, but continuing through the ages. It yields its plaudits to achievement, and recognizes that he is the greatest among men who reveals the most of truth unto men. It greets as a friend him who thinks, though he think error, for, thinking, he may think truth and thereby add to the common fund. It heeds all things, and examines all things, judges all things.

To you, the exponents of this new school, of this new generation, of this new century; to you, representatives of the Democracy of Science; to you, citizens of the Republic of Letters, I extend greetings; and here, in our parliament assembled; here, where our will is supreme, I this day invoke upon our deliberations the spirit of liberty, the spirit of courage, the spirit of progress, the spirit of truth.

THE VALUE OF CLINICAL MICROSCOPY, BACTERIOLOGY AND CHEMISTRY IN SURGICAL PRACTICE.*

BY

JOHN A. WYETH, M.D.,

of New York City.

For many years, almost without exception, my predecessors in the address on surgery have devoted their labors to the exposition of some general or special subject in the domain of operative surgery, and while I would in no measure detract from the value of a thorough technical knowledge, we should not in our attention to the *art*, fall short of a proper appreciation of the *science* of surgery.

The experienced surgeon soon learns that it requires more than asepsis and the rapid and skilful performance of an operation to achieve the fullest measure of success; that although a thorough practical knowledge of regional anatomy is essential in the highest degree to the conscientious fulfillment of the professional obligation, it is equally important that there be called into requisition the invaluable aid which laboratory research alone can give in determining an accurate diagnosis; in indicating the most rational measures of treatment not only in the preparation of a patient for an operation, and in the selection of the safest anesthetic, but for the postoperative management of the case, and in removing as far as possible all doubts as to the prognosis.

Chemical analysis of the normal and abnormal secretions and excretions of the body, *clinical microscopy* and *bacteriology* should form a part of the educational requirement of every surgeon. I do not insist that the busy practitioner should attempt to master all the intricate processes of the laboratory, for this is only possible to one who devotes years of patient labor to the fascinating department of science, but he should possess that practical knowledge of the chemistry of the body in health and disease, and of clinical microscopy and bacteriology, which any diligent student, under a competent teacher, and in a properly equipped laboratory, should be able to acquire in a 3 months' course of study.

The instances are exceptional in practice where this knowledge can not be applied with great benefit to the patient, and with satisfaction to the surgeon. It is naturally of greatest value in the cases where no emerg-

* Oration on surgery before the fifty-second annual meeting of the American Medical Association, at St. Paul, Minn., June 17, 1901. Published synchronously by courtesy of Dr. George H. Simmons, editor *Journal American Medical Association*.

ency for immediate operation exists, but its advantages are not wanting in these rarer cases, since it comes to his aid in the postoperative period.

Laboratory research, especially in the department of bacteriology, has placed not only the medical profession, but the entire human family under lasting obligations for the great benefits which have already been derived from its discoveries, and it may be safely said that it has done more than all else in accomplishing the revolution in surgical thought and practice which has taken place within the last 2 decades. One of the most notable illustrations of this great advance is the triumph which has been achieved over that once fatal disease, diphtheria.

The discovery by Klebs in 1883, and the isolation and cultivation in 1884 by Löffler of the bacillus of diphtheria had its logical sequence in Behring's invaluable discovery (subsequently elaborated by Roux) that the blood of animals, especially that of the horse, rendered immune to diphtheria by inoculation, first with attenuated, and then with more virulent organisms, contained a substance capable of neutralizing the effects of the bacilli or their toxin when simultaneously or subsequently inoculated in nonprotected animals.

This antitoxin serum in its dose of 10 cc. of either the 600, 1,000, or 1,500 immunizing units is potent not only to arrest the destructive processes which formerly characterized this disease, but to prevent the infection of those who have been exposed to the contagion. How great is the importance of the knowledge that these bacilli are not only always present in the throat of a patient suffering from diphtheria, but that they are frequently found on the nasopharyngeal surfaces and tonsils of persons free from systemic infection, and as shown by Biggs, Parke and Beebe, of New York, they may remain as long as 5 weeks after the membrane has been discharged from infected subjects, all of which points to the necessity for the isolation of the infected individual, and the careful disinfection of the throats of those who have been about diphtheria cases. (McFarland).

The statistics of Professor Welch, of Johns Hopkins University, show that the ratio of mortality as a result of these discoveries has been reduced more than 55%, and that in 115 cases, in which, by reason of an early diagnosis, the treatment of serum antitoxin was begun within the first 3 days of the disease, the mortality was only 8.5%. In 546 cases in which the remedy was begun after the third day of the disease, the mortality was 27.8%, the ratio of mortality increasing with fatal precision as treatment was delayed.

To the surgeon, one of the most gratifying results of this great triumph of the laboratory is the fact that he is now rarely called upon to perform the operation of tracheotomy, which was formerly distressingly frequent, nor to witness the sufferings associated with intubation of the larynx. A professional friend in the department of diseases of children informed me recently that whereas a few years ago he had from 10 to 20 intubations of the larynx on account of diphtheria in every month, he now, since the serum therapy was practised, averaged only 1 or 2.

I believe that what is true of this disease is true of all infectious processes, and that as our knowledge expands, a safe immunizing serum will be discovered for each special toxemia. Even now it would seem that this proposition is proved in other infections in which, like diphtheria, the pathogenic organisms are localized at the seat of infection, their toxic products alone entering the tissues through the circulation.

Of this type is the spirillum or "comma" bacillus discovered by Koch in 1884 in the intestinal contents of patients suffering from Asiatic cholera. These germs are not found in the deeper organs, the morbid changes in the tissues being due to their toxin. Immunizing injections of cholera cultures have already been experi-

mentally and successfully employed, and promise rich results.

In this same group, bacteriologists claim a place for *Diplococcus micrococcus lanceolatus* of Fraenkel, the *pneumococcus*. Sternberg and Pasteur isolated this germ in 1880, and in 1884 Fraenkel demonstrated it as the prevailing organism found in the sputum of croupous pneumonia. Very late investigations give encouragement to the hope that serumtherapy will soon be applied in the early arrest of the invasion of this most painful and fatal malady. Though pneumonia is strictly a medical disease, its early recognition as a surgical complication, or in view of an anticipated operation, is of very great importance. In a recent case which came under my observation at our laboratory, a specimen of sputum was sent in for bacteriologic study. It was not blood-stained or "brick dust," but yellowish-white in color like the ordinary sputum of bronchitis, and was supposed to be "grip" or tuberculosis. The bacillus of tuberculosis was not present, but numerous micrococci lanceolati were discovered, and the laboratory diagnosis was made and confirmed within 24 hours by the well-recognized symptoms of consolidation with the "brick-dust" expectoration of this disease which supervened.

Tetanus toxemia, or "lock-jaw," the organism producing which was discovered by Nicolaier in 1894, and which for years has baffled the most strenuous efforts of the bacteriologist and clinician seems at last to be classified with the controllable infections. Professor Osler, in the last edition of his "Practice of Medicine," says the immunizing serum of Tizzoni has been successfully and encouragingly employed in doses of 2.25 grams for the first dose, and 0.6 grams for subsequent doses. Of 113 cases treated by this method 63% recovered.

It was not until the discovery of the bacillus of typhoid by Eberth in 1880 and the pure cultures of this germ secured by Gaffky in 1884, that there was made possible in the vast majority of cases of typhoid fever a positive diagnosis.

The demonstration of Widal that when 10 drops of a 24-hour bouillon culture of *Bacillus typhi* was added and thoroughly mixed with 1 or 2 drops of serum from the blood of a typhoid patient, the bacilli lose their motility and become agglutinated in masses, was one of the most brilliant advances in clinical bacteriology, and of great value in surgical diagnosis.

In many of the lesions of the abdominal viscera, and especially in those located in that battle-ground of surgery, the right iliac fossa, where the physical signs and the febrile movement may suggest either beginning typhoid, intestinal toxemia, or a pyogenic sepsis, an early diagnosis may be determined in no other way than by the aid of the laboratory.

The practitioner who has not called into requisition the invaluable aid which bacteriology affords in the differentiation of those too often obscure intraperitoneal lesions, cannot appreciate the satisfaction which this practical application affords. How often the safety of a patient hangs upon even a few hours time, and alas, how often this precious time is wasted in the uncertainties of diagnosis, when a resort to the demonstration of science, available to all, would have plainly indicated the proper method of procedure. We know too well the fallacy of relying upon the ordinary subjective symptoms, and even some of the objective symptoms afford us no accurate clue to the pathologic process which may exist. The pulse and the temperature of commencing typhoid may well be mistaken for the pulse and temperature of an appendicitis. The pain and muscular resistance over the right iliac and the right abdominal region are in many instances practically alike. The nausea, the vomiting, and the general sense of uneasiness point neither directly to the one or to the other disease, but in a crucial test by Widal's reaction, with the blood-count pointing to the presence or absence

of a leukocytosis, the question is quickly settled. I have seen all the symptoms of appendicitis present in cases in which the blood-count contradicted a pyogenic sepsis, and in which Widal's reaction told the story of typhoid. On the contrary, I have dealt with cases which ordinarily would have been most perplexing, in which all the symptoms of typhoid prevailed at a period when it was too early to recognize this disease by Widal's test, and a leukocytosis of from 15,000 to 21,000 proved at the earliest possible moment that the case was one for immediate operation.*

The discovery by Bollinger in 1877 made the diagnosis of that comparatively rare affection, actinomycosis, clear. In examining the yellow granules and accompanying pus discharged from an infected area he recognized the ray fungus or actinomyces. More recent researches have shown this fungus to be composed of bacilli in various stages of development, some being spores and some more perfectly developed organisms.

In another fortunately rare disease, malignant pustule, caused by the lodgment in an abrasion of the bacillus anthracis, we are indebted to the laboratory for our knowledge of its etiology. Bacillus anthracis discovered by Devaine in 1863 is not usually found in the blood except in the most malignant cases and in the last stages of fatal infection, but can be demonstrated in the pustule of inoculation with the microscope or by cultures.

Roux and Chamberland, according to McFarland, have found that filtered cultures will produce immunity when properly introduced into animals, and we reasonably hope from these experiments that the serum treatment will before long be made applicable to infected human beings.

Another rare organism is the bacillus of malignant edema, which was discovered by Pasteur in 1875 and called by him *Vibrio septique*. There are only 2 cases of this disease so far reported in man, and they were subjects of abnormally low resistance infected by the hypodermatic administration of a product of musk.

Bacillus pestis or bubonic plague organism was discovered in 1894 simultaneously by Yersin and Kitasato, in blood drawn from the finger tips of infected individuals, and in the broken-down lymph glands, and is described by Kitasato as greatly resembling the micro-organism of chicken cholera.

Bacteriologic research has robbed the puerperal state of much of the anxiety and dread which formerly attended this ordeal, not only in preventing sepsis, but in recognizing the infections already established in time to prevent a general peritonitis or septicemia. The puerperal uterus, or this organ when the seat of non-puerperal endometritis, offers an ideal field for bacterial proliferation and invasion, since septic organisms enter-

ing the cavity may rapidly penetrate the endometrium and enter the lymph channels whence they pass into the venous sinuses and lymphatics of the pelvis.

Professor W. R. Pryor, in a paper read before the New York State Medical Association in 1900, says, "puerperal sepsis if not rapidly fatal almost always produces lesions which seriously damage the pelvic organs or the viscera," and that "time is in this serious condition an important element." He recommends the early employment of the Döderlein tube, which, after sterilization, is passed into the uterus, being protected from contact until the fundus is reached. From the serum and debris thus obtained cultures are made, and the character of the operation—either curettage or hysterectomy—determined by the result of bacteriologic investigation.

Not only does the laboratory come to our assistance in the diagnosis of certain obscure surgical lesions of the stomach, but it is still more valuable as an aid in arriving at the exact condition of the digestive functions of this organ, any derangement of which it is at times exceedingly important to correct in order to bring a patient into suitable condition to stand an operation. Thus it is important to determine in certain instances whether or not free hydrochloric acid exists in this organ, and while the total quantity poured into the stomach in the digestive process cannot be accurately measured, clinical chemistry can closely estimate the total quantity found at a given moment during digestion. The acid-combining power of the proteids is known, and by certain tests it is feasible to estimate sufficiently close for a satisfactory diagnosis, the quantity of hydrochloric acid secreted. The small quantity of hydrochloric acid which combines with ingested inorganic elements is lost to gastric digestion, serving as it does its function in this process in the intestines.

It is clear, as stated by Van Valzah and Nisbet, that the hydrochloric acid which combines with the proteids, and that which remains free, together roughly represent the activity of acid secretions. It is logical then to conclude that the quantity of hydrochloric acid loosely combined with albumin, together with the quantity remaining free in the contents withdrawn at the end of a particular time after eating a particular meal is a practical and clinical measure of the secretory activity of the peptic glands, and of the digestive work of the stomach. All of this is made sufficiently exact for practical purposes by the laboratory method of analysis after the simple test-breakfast of Ewald and Boas, or the more elaborate test-meal as recommended by Germain-Sée.†

†The simplest method is that known as the test-breakfast of Ewald and Boas in which on an empty stomach, usually in the early morning, a breakfast roll which contains about 5 gm. of proteids, 30 gm. of carbohydrates, 1/2 gm. of fat, 1/4 of a gm. of ash, and weighs 70 gm., and 350 cc. of water (about a glass and a half) are taken. The bread should be thoroughly chewed and insalivated before being swallowed with the water. Usually in 1 hour's time a tube is introduced and the contents of the stomach withdrawn, usually by expression, or by siphonage, and then filtered. An estimate of the acidity of the filtered contents is made by using a deci normal solution of potash or soda. The number of cc. of this solution which will neutralize 100 cc. of the filtered contents of the stomach expresses in figures the acidity of the fluid withdrawn. At the end of an hour, under approximately normal conditions of digestion, the total acidity should be 50 to 60, the hydrochloric acid albumin 30 to 40, the free hydrochloric acid 10 to 20. Any departure from this rule shows the abnormal absence or excess of this important agent.

The test-meal of Germain-Sée is at times preferable, since it contains a larger quantity of proteids than the test-breakfast of Ewald and Boas just given, but the method of procedure is practically the same. The presence of hydrochloric acid can be recognized by Gunzborg's reagent, which is composed of:

Phloroglucin 2 grains.
Vanillin..... 1 grain,
Alcohol (absolute).....30 grains.

By spreading 3 or 4 drops of this reagent in a porcelain crucible, adding upon this the same quantity of the filtered contents, and slowly warming the crucible, after several seconds, a red color appears, and at times the red crystals of free hydrochloric acid are seen. Or the simpler method of employing a filtered paper which has been soaked in a 0.5% alcoholic solution of diamethylamidiazobenzol and dried. This, in the presence of a trace of free hydrochloric acid turns distinctly red.

*Two of the cases occurring in my own work within the last few months may emphasize the great value of this technic.

A man of 30 was seized with quite severe pains which were confined to the region of the cecum and appendix. Upon palpation there was well-marked resistance in the muscles immediately over these organs which was not observed in any other part of the abdominal wall. He had vomited on one or two occasions and the temperature ranged from 101° to 103° F. on the second day of this attack. The questions which were presented to the consultants were whether this temperature could be accounted for by intestinal toxemia, by appendicitis, or incipient typhoid. Although it was too early in the history of a typhoid case to encourage a belief that Widal's reaction would be present, this was made and with negative results. On the following day, the symptoms still pointing toward typhoid fever, a careful blood-count was made, and the leukocytes did not count over 7,000. Assured from this that no dangerous pyogenic process was present, the idea of operation, even exploratory, was abandoned until the examination might be repeated on the succeeding day. A second careful blood-count showed no leukocytosis, and on the fourth day, although Widal's reaction was still absent, the case was declared to be typhoid, and the subsequent history proved the diagnosis to be correct, since a few days later the reaction of typhoid was present, and the patient went through the regular stages of this fever.

In a second case, a male patient, 45 years of age, there was a typical typhoid tongue, temperature ranging from 100° to 103.5° F., tenderness and muscular resistance in the right iliac fossa and loose discharges from the bowels not unlike those frequently met with in typhoid. Widal's reaction was tried with negative results on 3 successive days. The blood-count on the fifth day showed the leukocytes numbering 21,000, justifying a diagnosis which excluded typhoid and confirmed the suspicion of pyogenic sepsis.

The presence of lactic acid in the stomach contents as shown by Kelling's test* has a distinct diagnostic value, since it takes place in comparatively rare conditions, and since these conditions are seldom fulfilled except when carcinoma is present.

Lactic acid is dependent upon the presence of a special bacillus which thrives in the stomach under abnormal conditions, and is capable of converting glucose and lactose into lactic and carbonic acid. Boas goes so far as to insist that the persistent presence of lactic acid in noteworthy quantity during the digestion of a saucer of oatmeal, chemically free from lactic acid, is a specific sign of carcinoma of the stomach.

While the stomach may under varying conditions contain hosts of various bacteria in addition to the one just considered, there are only 3 others that are of importance as pathogenic organisms. First, *Sarcine ventriculi* (in their usual cube arrangement) which when found indicate insufficiency of the stomach muscle due to nonmalignant obstruction. They are not found in carcinoma, since they perish in the presence of lactic acid, which, as we have just shown, is so common in malignant disease of this organ.

Another microorganism is the *yeast plant* also found when motor insufficiency exists. It may be present when the stomach contents are alkaline, neutral or acid.

Bacillus geniculatus is present under the same conditions which produce the lactic acid organism and is considered also to be suggestive of carcinoma.

When the presence of blood is suspected in the stomach and is not clearly defined by the microscope, chemistry comes to our aid in its recognition by the glacial acetic acid and ether test.†

A study of the discharges from the rectum is as yet of little value to the surgeon. Beyond the recognition of blood or pus, or cast-off cell elements in certain malignant neoplasms, there is but a single organism which is of real diagnostic value, namely, the ameba of dysentery, described by Lamb in 1859, which is a motile mass of protoplasm about 20 micromillimeters in diameter containing a single nucleus, and 1 or several vacuoles.

In the differentiation between the pathogenic organisms of specific and non-specific urethritis, microscopy and bacteriology are our only infallible guides. They teach us to eliminate the various bacteria found in the external genital and urinary passages, not bearing directly upon the etiology of urethritis, and to recognize distinctly the 2 forms of diplococcus, the gonococcus of Neisser, and the pseudodiplococcus, which while not morphologically different from the specific disease-producing organism, can be readily distinguished by special modes of staining as well as by cultures. In the daily routine of practice the exact nature of every suspicious urethral discharge should be subjected to careful scrutiny. The patient is entitled to the satisfaction of a negative result, which is easily demonstrated by staining the smear with methylene blue which clearly defines both organisms. If no cocci are revealed all anxiety is put at rest, but if there are present both varieties of these organisms, occupying as they do, the protoplasm of the pus corpuscles, a further research and the differentiation of the true form from the false diplococcus is imperative. The pseudococcus retains the violet color of the anilin-gentian water violet stain, while with careful laboratory technique the addition of the Bismarck brown brings out the gonococcus, the protoplasm of a single pus corpuscle showing at times both the blue stain

of the pseudococcus and the diplococcus of Neisser which retains the brown color.‡

Bearing in mind the fact that the gonococcus of Neisser may remain dormant in these passages for months, and, as maintained by some observers, for years, incapable of a further inoculation of the seemingly immunized patient, but capable of exciting the most acute and injurious inflammation in an innocent victim, it becomes a matter of the greatest importance to subject to most careful study the external genitourinary passages where an infection has once existed. It has been demonstrated that an artificial urethritis as that which nitrate of silver produces will develop the dormant gonococci and cause their presence in the discharge.

Keys and Chetwood, in their excellent volume on venereal diseases, place well-deserved emphasis upon the value of the Gram test for recognizing these organisms. They properly insist that the diplococci should be of the recognized size and have within the protoplasm of the pus corpuscle their proper shape and arrangement and remain negative to Gram's staining. Even when cultures are made to demonstrate the specific organisms beyond all doubt, resort should still be had to the Gram staining as a final means of identification.

In cases of pyelitis, many of the difficulties which formerly stood in the way of differential diagnosis between renal calculi, simple pyogenic pyelitis or the presence of tubercular disease in this organ, are now overcome by the careful methods of the laboratory.

The presence of the bacilli of tuberculosis in one or both kidneys, even when they are exceedingly infrequent in the discharge, can be demonstrated in urine drawn by urethral catheterization, or by the more simple process of bladder sequestration, when the suspected organisms are with other detritus thrown down by the centrifuge. The carbol-fuchsin stain decolorized with 5% sulphuric acid, brings out in brilliant red the outlines of the bacilli of tuberculosis, while the addition of 95% alcohol decolorizes the smegma bacillus, and thus eliminates this possible source of error to any but the more expert laboratory workers.§

In the effort to arrive at the general condition of a patient, the chemie, microscopic and bacteriologic study of the urine is only second in importance to that of the blood, and when we consider the additional and exact information which can thus be obtained concerning any pathologic process at any point in the urinary tract, the value of this analysis is very materially increased. A careful study of the urine is always indicated before determining what anesthetic it is safest to employ in the operation to be undertaken. When there is no important lesion of the heart, either in its valvular mechanism or in the blood supply and nutrition of its muscular walls, few surgeons, I hold, would employ ether in a

†Dr. Jeffreys, the director of the laboratory in the New York Polyclinic, employs the following differential stain:

Use Gram's stain followed by a contrast stain such as Bismarck brown. To prepare this stain proceed as follows:

Prepare aniline water by emulsifying 8 drops of aniline oil in about 10 ccm. of water, filter through a wet filter; to this aniline water add about $\frac{1}{4}$ its bulk of a saturated alcoholic solution of gentian violet. Stain smear with this "aniline water gentian violet" 1 or 2 minutes. Wash in warm water and then immerse in Gram's solution for 1 minute. The formula for this solution is as follows:

Iodin	1 gram.
Potassium iodid	2 grams.
Water	300 cc.

Thoroughly wash in 95% alcohol until no more blue appears to wash out; then wash in water. Counterstain for 1 minute with a saturated solution of Bismarck brown in 3% aqueous solution of carbolic acid. Wash, dry, and mount in balsam. After this treatment, pseudogonococci should be stained violet, and gonococci should be brown.

§The following process is used at the Polyclinic Laboratory in determining the presence of Bacillus tuberculosis in the urine and feces. The sediment is thrown down in the centrifuge, the smear dried slowly over the Bunsen burner and stained with carbol-fuchsin, which is then warmed over the Bunsen burner for 3 or 4 minutes without being dried. Then wash with water and decolorize with 5% sulfuric acid, and again wash with water. After this add 95% alcohol, which decolorizes the smegma bacillus and again wash in water, counterstain with methylene blue and dry. With the 1-12 oil immersion, the clusters of tubercle bacilli are readily seen.

*Kelling's test consists of 5 cc. of the filtrate diluted to 50 cc. with distilled water, to which 1 or 2 drops of official 5% solution of the perchlorid of iron is added. The yellowish-green tinge indicates the presence of lactic acid.

†To 10 cc. of the filtered contents add 3 cc. of glacial acetic acid, and extract the coloring matter of the blood by shaking with 5 cc. of ether. This turns the ether extract brown. When this discoloration does not take place there is no blood. To carry the demonstration further, to the brownish decanted ether extract, 10 drops of fresh tincture of guaiac with a few drops of peroxid of hydrogen are added. After vigorously shaking, the mixture becomes clear blue if blood is present.

protracted operation in which there was any suggestion of an acute nephritis, or in certain chronic forms of Bright's disease.

It is commendable practice to study through several days the quantity of urine passed, keeping accurate measurement, as well as making a qualitative analysis of that which is passed under conditions as near as possible similar to those to which the patient had been subjected before coming under observation, and then under conditions of rest, with proper alimentation and the free opening of the alimentary canal with calomel and Carlsbad salts (which agents in my experience most readily do away with fermentation and the production of gases in the bowels) to note the changes which occur in excretion.

The presence of oxyluria is in my opinion a contra-indication to a serious surgical operation, for the reason that it is pathognomonic of a disturbed nutrition due to insufficiency of the digestive fluids, and to fermentative processes in the intestinal tract.

An excess of *uric acid*, evident in the rosettes or rhombic or quadrate crystals (one-sixth objective), found in the urine *which has not been passed* more than three or four hours, has also a pathologic significance scarcely less than that of oxyluria. It indicates a condition of defective nutrition which is part of the gouty or rheumatic diathesis, predisposes to chronic nephritis and is one of the symptoms of various acute inflammatory processes, of leukemia, cirrhosis of the liver, gastrointestinal catarrh, and is often present in diabetes mellitus.

The chemistry and microscopy of the urine further informs us when ammoniacal decomposition of the urine is taking place within the bladder, suggesting insufficiency of this organ due to obstruction of the urethra or to atony of the bladder muscle. The large rhombic masses or stellate and cross-shaped rosettes of the triple phosphates only exist in these abnormal conditions of the bladder, and with the brownish colored thorn-like crystals or urate of ammonia are important aids to diagnosis.

The presence of epithelia from the various portions of the urinary or genitourinary tract, of spermatozoa and various bacteria chiefly pyogenic in character, are further and well-recognized evidences of the value of the microscope in surgical diagnosis. In rarer instances, the hooklets of echinococcus, the embryos of filaria and the ova of Bilharzia hæmatobium are thus discovered in the urine. I have been able once to demonstrate the presence of the eggs of the last-named parasite in the bloody urine of a missionary in Africa where he had by long residence acquired the disease.

From the laboratory we are taught the well-known tests for albumin and sugar by which all sources of error may be eliminated in determining not only their presence but the quantitative analyses as well. The pathologic conditions in which these substances are excreted are at times exceedingly grave, and it is of vital importance that their presence be discovered so that timely and judicious treatment may be instituted, or operation avoided which under such unfortunate conditions would be invariably fatal.*

In glycosuria the surgeon must know whether he is dealing with what Pavey designates as alimentary diabetes, in which the sugar eliminated by the urine is derived solely from the food as result of defective carbo-

hydrate assimilation; or whether that almost hopeless condition of composite diabetes in which abnormal disintegration is taking place, is present.

No less important is the estimate of the amount of urea which is being eliminated in a given quantity of urine. Employing the simple apparatus of Doremus with the sodium hypobromite solution† within a few minutes by the evolution of nitrogen gas in the presence of this, the amount of urea which is being carried off by the kidneys is readily demonstrable.

Nonparasitic chyluria (that form not due to the presence of filaria) is a rare affection, but it does exist, the fluid coagulating almost like jelly. In these conditions the microscope shows little that is pathologic excepting some minute granules and oil droplets similar to those in milk. (Osler.)

The presence of blood in the urine, even in the most minute quantities, can in almost all cases be recognized by the microscope, and in those exceptional instances of hemoglobinuria in which the corpuscles have disappeared, the blood-crystals of Teichmann may be recognized by the addition of a drop of strong acetic acid to a few drops of urine placed upon a watch glass. For this condition of blood pigment in the urine in which the blood-cells are absent, Osler suggests the name methemoglobin. He further states that when granular pigment or darkly-pigmented urates or fragments of blood-disks do not point clearly to the presence of blood, the 2 absorption bands of oxyhemoglobin, and more commonly, the 3 absorption bands of methemoglobin, of which the one in the red near G is characteristic, may be determined by the spectroscope. In general, however, the red and white blood corpuscles and filaments of clot are clearly recognizable with the one-sixth objective. Even without the microscope the presence of a very minute quantity of blood distributed through the urine can be recognized by Heller's test of adding a few cc. of urine to a drop or two of strong solution of caustic soda, and boiling the mixture. If blood is present a bottle-green color is produced and the phosphates fall to the bottom of the test-tube in fine flakes, tinged brownish-red by the coloring matter of the blood. (Hare.)

When blood is found in the urine as a complication of papilloma of the bladder, particles of the broken-down tumor are very frequently found in the urine, and under the microscope the epithelial elements of this neoplasm are easily recognized and point clearly to the source of the hemorrhage. In hemorrhage from the kidney substance blood casts tell unmistakably of its source.

Chemistry demonstrates in the urine the presence of indican or indoxyl sulfate of potassium, a product resulting from the decomposition of albuminous products in the intestinal tract under the influence of bacteria. It is always suggestive of persistent constipation, is found in obstruction of the intestinal canal, carcinoma of the liver or stomach, in peritonitis, and is one of the symptoms of pernicious anemia. Urine containing this substance if treated with 2 or 3 times its volume of hydrochloric acid turns a violet color.

A careful analysis of the various casts found in the urine under different conditions is of inestimable value. Blood-casts indicating not only hemorrhage from the kidney, but acute inflammatory conditions, and casts composed of pus corpuscles and studded with micrococci suggesting pyelonephritis, are most valuable results in laboratory research. It also tells us of the existence of granular casts which indicate a chronic or subacute inflammatory process in the substance of the kidney.

*To determine the presence of albumin, the nitric acid and heat test is classic and reliable. The simplest quantitative analysis as recommended by Hare is to fill the tube for the centrifuge to the 10 cc. mark with urine, to which is added 2.5 cc. of potassium ferrocyanid solution (one part to ten) 1.5 cc. of acetic acid is also added. After mixing the fluids well the centrifuge is rotated until the albumin is precipitated. Every 1 cc. mark on the tube represents 1% by bulk of albumin; that is, if the albumin extends up to the 3.5 cc. mark, the albumin amounts to 3.5%.

Fehling's test in the demonstration of sugar and the quantitative analysis by means of yeast fermentation is another important laboratory process, without recourse to which the surgeon in a certain group of cases can not satisfactorily work.

†Solution A. bromin and sodium bromite each 125 grams, water 1000 cc. Solution B. sodium hydrate 400 grams, water 1000 cc. Take of A and B each 1 part, water 3 parts. They are only to be mixed when needed for use. After the tube has been filled with the solution the pipette is filled with urine to the 1 cc. and the point carefully introduced beyond the bend. The urine in the pipette is then expelled by compression of the bulb, care being taken not to force any air into the tube.

which is accentuated when fatty casts are found, and that hyaline casts have a grave significance, as they are most frequently associated with chronic interstitial nephritis, and that the waxy variety is very common in chronic suppurative processes, usually in the bones and joints.

Today, one of the most attractive subjects of laboratory research is the blood, and although hematology is practically in its infancy, many valuable discoveries have already been made, and in the proper study of a patient, a knowledge of the blood is as essential as that of the urine. It may throw no light upon many cases, but the reward will be tenfold in that particular instance where the diagnosis is made definite and clear. It is necessary to know the normal blood thoroughly by constant practice in order to recognize the abnormal changes which may be present in a given case, and I can think of no more useful way of spending the time not taken up by practice than by going over these important features of laboratory technic.

A knowledge of hematology enables the surgeon to detect any form of anemia and to determine whether it is a type of blood impoverishment which can be corrected, or whether it is of the graver or more pernicious forms which would either preclude an operation, or if this were absolutely necessary, would enable him to announce to those entitled to information, the gravity of the outlook. In ordinary practice it is not always essential to differentiate between a pernicious anemia or a leukemia, or whether this latter condition is present in the lymphatic or splenic-myelogenous form, for the reason that all of these graver varieties call a halt to operative measures when these can be avoided. But the anemia which comes from malnutrition or malaria, or chlorosis, can be positively diagnosed by a study of the blood.

The richness of the hemoglobin may in a fair measure be determined by the comparative color test of the blood in proper solution, as observed through von Fleischl's hemometer. When a low percentage of hemoglobin is present, it is an indication to avoid any operative shock until the impoverished condition of the blood can be corrected by proper nourishment, by rest, or by medication, when this is positively indicated. This also suggests the aid of the microscope in a further investigation as to the condition of the corpuscular elements of the blood. It is advised by Mikulicz never to operate when the register of the hemometer shows less than 35, and it would probably be safer to place the standard 10 or 15 points higher. Even in the simple forms of anemia, the degenerative changes in the blood elements, especially in the red cells, are easily recognized, and are full of valuable suggestions.

When the red cells are near the normal count (about 6,000,000 to the cc.) they may still show certain characteristic deformities of individual cells (poikilocytosis) as well as variations in size in the presence of microcytes and macrocytes which appear in the field, and which are not seen in the normal blood. If the red cells are paler in color than normal, if they undergo crenation or breaking at the edges, and do not form rouleaux, it is evident that anemia is present.* The danger signals are still further in evidence when nucleated red cells (normoblasts) appear, and when there is added to these either the giant red cells (megaloblasts) or abnormally small microblasts, the condition is still more serious, since these corpuscles never exist in the normal blood.†

Hematology further enables us to differentiate with reasonable precision between chlorosis and pernicious anemia. In the former, though pale in color, the blood coagulates rapidly, while in the latter coagulation takes

place slowly, and the red corpuscles do not tend to the formation of rouleaux. The red cells in chlorosis (which are smaller and paler than normal and are frequently deformed) vary from 4,000,000 to 2,000,000, rarely falling as low as 1,000,000, while in pernicious anemia, in which the average diameter of the red cells is increased, the count rarely rises above 1,000,000, and often below this. Cabot gives 1,000,000 as the average number per cubic millimeter. The white cells are also diminished, varying from 4,200 to as low as 500, with lymphocytosis as a prominent feature. Megaloblasts are found in both conditions, but while plentiful in pernicious anemia, are rarely noticed in the milder disease, chlorosis. The more megaloblasts in pernicious anemia, the more hopeless the case.

The surgeon would be extremely unfortunate to fail in the recognition of these often obscure lesions, and if possible to correct them before subjecting his patient to the severe ordeal of an operation. In the early recognition of septic processes—chiefly pyogenic—surgery can no longer disregard the value of the blood count, especially the estimation of the leukocytes.

The relative number of leukocytes in a given quantity of blood, or their proportion to the red corpuscles can be readily determined by the use of the Thoma-Zeiss apparatus, which, as is well known, consists of 2 pipettes, 1 for the red and 1 for the white, with a well-outlined and peculiarly constructed slide or counting apparatus, and is employed with the ordinary $\frac{1}{4}$ laboratory objective. The differentiation by the use of the Daland hematocrit is not considered sufficiently exact to be satisfactory in the hands of the majority of hematologists. It is essential in making these differentiations to bear in mind the normal conditions that at the sea level the average number of red cells per cubic millimeter is 5,000,000 in men, and 4,500,000 in women, and 6,000,000 in the young and more vigorous adults, while the white cells average about 7,500 per cubic millimeter for each sex.

Certain conditions, not considered normal, influence the number of leukocytes since in the latter months of pregnancy they are moderately increased, and after parturition, and during the early weeks of lactation, a leukocytosis may be present, without pathologic significance. After hemorrhage the leukocyte count is increased, and in diphtheria, erysipelas, trichiniasis, all extensive forms of endometritis, and all acute pyogenic processes, leukocytosis exists except in those cases where the vitality of the individual has been overwhelmed by the severity of the septic process, under which condition the leukocytes no longer respond to the demand for the protection of the tissues, and are not present in the superficial blood in even normal proportions. It is probable that the application of this knowledge is more profitable at present in a study of the various lesions of the abdominal and thoracic organs. We know that in a certain proportion of cases of infection, temperature does not always indicate the increasing gravity of the lesion, while the degree of sepsis can be in great measure determined by the leukocyte count. In impaction of feces, extrauterine pregnancy, floating kidney, gallstone colic, renal colic, ovarian neuralgia, intussusception, volvulus, internal hernia, twisted pedicle, etc., there is no leukocytosis unless complicated with an acute septic process. In abscess of the liver the leukocyte count ranges from 12,000 to 48,000, while there is a well-marked increase in all the septic pyogenic processes of the lungs and the pleura.

In osteomyelitis the leukocyte count ranges as a rule from 15,000 to 25,000, and at times higher. Since in the early stages of this disease it is at times difficult by subjective symptoms to differentiate between rheumatism or gout, the leukocyte count is invaluable in demonstrating at once the pyogenic process.

In that very rare disease, trichiniasis, the leukocytes register sometimes as high as 30,000, but the special

*The average red corpuscle (normal) is 7 micro-millimeters in diameter.

†A normoblast is a nucleated red cell not over 10 mm. in diameter, with a nucleus not more than one-half the diameter of the same.

feature is the presence of a large number of eosinophile cells, sometimes as high as 50%, and in rare cases 67% of the total number of leukocytes being this form of corpuscle. A very considerable number of cases have been reported within the last year in which the diagnosis had been determined by the presence of eosinophiles.

Not only can the presence of *Plasmodium malarie* be recognized in the red blood cells, but hematology is already able to determine between the different varieties of the malarial parasite. It has been shown that the tertian organism takes 48 hours to develop and undergo sporulation; the quartan 72, while the estivoautumnal passes through irregular phases, varying from 48 hours to several days.

We are enabled to demonstrate also the presence of the spirochete of relapsing fever discovered by Obermeier in 1873. Although the corkserew or spiral threads are rarely seen unless the blood is examined in the height of the fever paroxysm, diplococcus-shaped bodies believed to be the spores of this organism are found in the periods of remission.

The time allotted has permitted hardly more than a suggestion of the methods of laboratory research, applicable in the daily routine of surgical practice. To me the moral of the lesson is that the *science* and *art* of surgery are inseparable.

THE PROGRESS AND TENDENCY OF HYGIENE AND SANITARY SCIENCE IN THE NINETEENTH CENTURY.*

BY

GEORGE M. KOBER, M.D.,

Professor of Hygiene, Georgetown University, Washington, D. C.

Hygiene is a department of medicine whose object is the preservation and promotion of health and deals, therefore, with all the factors, likely to influence our physical welfare. It is not an independent science, but rather the application of the teachings of physiology, chemistry, physics, meteorology, pathology, sociology, epidemiology and bacteriology to the maintenance of the health and life of individuals and communities. The subject is very properly divided into personal and public hygiene. In the former the doctrines are applied to individuals; in the latter to communities and States.

This branch of medicine has received such an impetus within the last few decades that many persons regard it of modern origin; such, however, is not the case, for on turning to early history we almost invariably find that the health of the population has been made a subject of legislation. Hygiene was practised by the Egyptians, the old Indians and Hebrews, and a study of the habits of the primitive peoples shows that a desire to prevent disease is innate to all men.

The Greeks and Romans paid special attention to the physical culture of their youth. They also paid much attention to the water-supply, and Athens was provided with sewers at an early period of her history.

The teachings of Hippocrates, 400 B. C., doubtless bore many fruits, and whether it is true or not, as stated by Galen, that he ordered, during a pestilence at Athens, aromatic fumigation and large fires in the streets, we have at least his writings on air, water, soil, habitations and occupations, and his views of local and seasonal influences on sporadic and epidemic diseases. In Homer's "Odyssey," reference is made to Ulysses purifying his house with burning sulphur, and Aristotle, in his "Politica," shows his sanitary acumen when he says: "The greatest influence upon health is exerted

by those things which we most freely and frequently require for our existence, and this is especially true of water and air."

The Romans, amidst their military operations, found time to construct the "Cloaca maxima" about 2,400 years ago, which not only served for the removal of refuse, but also helped to drain many of the marshes, and constitutes the principal sewer of modern Rome. Aqueducts were made to cover miles upon miles of the surrounding plains, and their splendid ruins, many of which have been restored and are now used for their original purpose, attest the munificence and abundance with which the first of sanitary requisites was supplied to the Eternal City. It is stated that between 400 B. C., and 180 A. D., about 800 public baths were established, among them the "Thermae Caracallae," which alone would accommodate 3,000 bathers at one time.

During the reign of the Caesars, attempts were made to drain the Pontine Marshes. Sanitary officials and physicians to the poor were appointed, and homes for poor girls and orphans were established. In the meantime the true spirit of Christianity asserted itself, and we read of the establishment of hospitals as early as the fourth century. These were speedily followed by infant and orphan asylums and homes for the poor and incurables. During the Middle Ages sanitation received a decided check; ignorant and brutal prejudices appear to have been the ruling spirits and for many reasons it was the most unsanitary era in history.

PESTS AND UNSANITARY CONDITIONS OF THE MIDDLE AGES.

About this time most of the towns in Europe were built in a compact form, surrounded with walls; the streets were narrow and often winding for defensive purposes, shutting out light and air from the houses. The accumulation of filth was simply frightful. Stables and houses were close neighbors, human filth was thrown on the streets or manure heap. The dead were buried within the churchyards. Sewers and aqueducts having been permitted to fall into disuse, the inhabitants were compelled to resort to wells with polluted subsoil water. All the conditions were favorable for the spread of infectious diseases and in the fourteenth century alone the Oriental or bubonic plague, according to Hecker, carried off one-quarter of the population of Europe, or over 25,000,000 victims.

Although this disease had been described as early as the third century, B.C., a lamentable state of ignorance is shown, when we remember that the majority of people regarded the plague as the dispensation of God's providence, an evidence of divine wrath, which they hoped to allay by all sorts of self-inflicted punishments, and the Passion Plays of Oberammergau and elsewhere originated about this time. Others accused the Jews of being the cause, and hundreds were burned at the stake until Pope Urban IV placed them under his special protection. The Faculty of Paris attributed the epidemic to the conjunction of planets on a certain day in 1345, and the Faculty of Leipzig, with equal gravity, asserted that it was connected with earthquakes, unseen waves of air, inundations, etc. Venice, alone of all Europe, took a sensible view of the matter, and for the first time in history, in 1348, appointed 3 guardians of public health, and the rules adopted later to isolate infected houses and districts for 40 days has given rise to the term quarantine—from *quaranta giorni*.

The repeated invasion of the Oriental pest appears to have everywhere compelled some sanitary efforts and an imperial decree, in 1426, required the appointment of city physicians throughout Germany, whose duty it was to adopt preventive measures. A city ordinance of Nürnberg, in 1562, gives detailed directions as to the quality of bread, beer and wine offered for sale, the cleaning of streets and houses, the disposition of infected clothing

*Oration on State Medicine before the Fifty-second Annual Meeting of the American Medical Association, at St. Paul, Minn., June 4-7, 1901. Published synchronously by courtesy of George H. Simmons, M.D., editor *Journal American Medical Association*.

and bedding, the fumigation with sulphur and straw of pest-houses, etc.

In 1685 Prussia established a central medical bureau, and appointments of health officers and privy medical counsellors were made, whose duties consisted in advising the men entrusted with the care of the government on matters relating to public health, and some of these titles are still in vogue in Europe. At the beginning of the eighteenth century, Prussia, upon being threatened with an invasion of the bubonic plague from Austria, created the "Collegium Sanitatis," popularly called the "Pest College," which was really the beginning of the present state board of health. In 1762 a sanitary council was established in every Prussian province, for the prevention of disease among man and animals. About the same time sanitary improvements in the way of widening streets for the purpose of supplying more air and light to the habitations, and better methods for the collection and removal of the wastes of human life were introduced, but, broadly speaking, at the close of the seventeenth century the habits of the people in Europe were generally filthy and in striking contrast to those observed among the most untutored savages of the present day.

In Madrid, we are told by Barcome, in his history of epidemics, "that not even a privy existed in 1760. It was customary to throw the ordure out of the windows at night, and it was removed by scavengers the next day. An ordinance having been issued by the king that every householder should build a privy, the people violently opposed it as an arbitrary proceeding, and the physicians remonstrated against it, alleging that the filth absorbed the unwholesome particles of the air which otherwise would be taken into the human body. His majesty, however, with commendable zeal, persisted, but many of his citizens, in order to keep their food wholesome, erected privies close to their kitchen fire-places."

With such unsanitary conditions we need scarcely be surprised that the mortality in towns was greater than their birth-rate and that the city population had to be recruited continually from the country. Toward the close of the eighteenth century many sanitary reforms were effected, however, especially in connection with infant and orphan asylums, and the management of schools and prisons. Of special importance is the brilliant discovery, or re-discovery, of vaccination by Jenner in 1796.

PROGRESS OF SANITATION IN THE NINETEENTH CENTURY.

The nineteenth century can boast of many advances in hygiene, particularly since the European invasion of cholera in 1830. The English towns which had been visited by this disease and those fearing similar scourges were willing to profit by their sad experience, and freely instituted sanitary reforms in the establishment of sewers, public water supplies, sanitary homes, etc.

The example of England was followed by all civilized nations, with similar results. The efforts of sanitation, as taught by Dr. Parkes, were demonstrated during the Crimean War and, as beautifully expressed by Virchow during our Civil War, reached "the highest point in humane efforts ever attained in a great war," and we may proudly add, have even been excelled during our late Spanish-American War.

PROGRESS OF SANITATION IN THE UNITED STATES.

While the people of the United States were not slow in adopting and originating sanitary measures of great value, our ideas of personal liberty, guaranteed to us by the Constitution, evidently prevented early legislation in matters of public health, for fear that such legislation might affect the personal habits of the citizen and lessen his freedom of action. Dr. Samuel W.

Abbott, in his masterly exposition of "The Past and Present Condition of Public Hygiene and State Medicine in the United States," records, however, the gratifying fact that the early colonists recognized the need of preserving their records, which constitute the foundation stone of public hygiene, by enacting a law in 1639 "that there be records kept of the days of every marriage, birth and death of every person in this jurisdiction."

The importance of vital statistics is not fully appreciated at the present day, and yet, as remarked by Dr. Billings, "when we wish to study the healthfulness of a city, whether it is getting better or worse, or judge correctly the effect of certain sanitary laws, we should not only know the number of deaths, but also the amount and character of the prevalent disease, together with accurate information as to the number of population at different ages." It is a matter of regret, therefore, that even now only 10 states, Connecticut, Delaware, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Rhode Island, and Vermont, have anything like a satisfactory system of vital statistics.

According to Abbott: "Up to the close of the eighteenth century and for several decades of the nineteenth, almost the only health legislation which was enacted in the different states in the Union consisted in a few laws relating to smallpox, since this pestilence was scarcely ever absent for many years at a time from any city or village, until after the general introduction of vaccination."

Dr. Waterhouse, of Cambridge, having secured a supply of vaccine lymph from Dr. Jenner, introduced vaccination in Boston in 1800, and Dr. Seaman in New York in 1801. In the same year President Jefferson received some virus from Dr. Waterhouse and was vaccinated by Dr. Grant, of Georgetown.

The invasion of cholera from Canada in 1832, and the epidemic of 1848-1849 here, as in Europe, aroused public interest in sanitary reforms, and the legislature of Massachusetts in 1849 appointed a commission to make a sanitary survey of the State, and we are told by Dr. Abbott "that this was done none too soon, for in that year the general sanitary condition of the State, as shown by the report of the commission, was deplorable and the death-rate unusually high. Only a few towns had then introduced public water-supplies. Cholera was beginning to appear again and dysentery and other infectious diseases were more destructive than they had been for many years."

HEALTH BOARDS.

New Orleans, having lost 8,000 victims of cholera in 1832, out of a population of about 55,000, and anxious to maintain a quarantine, secured the enactment of a law in 1855 for the establishment of a state board of health; in 1869 a more comprehensive board was established in Massachusetts, followed in 1870 by California, since which time nearly all of the states and territories—42 in number—have followed the example. *Pari passu* and in many instances preceding the establishment of state boards of health, sprang into existence our local boards of health, who adopted measures for the control and restriction of infectious diseases, for the abatement of local nuisances, for the sanitary inspection of the food-supply, schools, public buildings and institutions and tenements; street cleaning and removal of refuse, registration of vital statistics, supervision of burials and of municipal water-supply, sewerage, and sewage disposal, care of bathing establishments, regulation of offensive trades, etc.

EFFECTS OF VOLUNTARY ORGANIZATION ON SANITATION.

In September, 1872, the American Public Health Association was organized; in 1873, the Section on State Medicine of the American Medical Association

was created; since then the American Climatologic Association, the Sanitary Council of the Mississippi Valley, the American Sanitary Association, and the American Health Resort Association have been organized, and numbering, as they do, among their members some of the best minds in the profession, much good has been accomplished by these bodies, and the so-called "sanitary conventions" in molding public opinion and in framing and recommending health laws. There is no doubt, however, that all these organizations were stimulated into existence by the lofty tenets of our Code of Ethics,* in which the duties of the profession to the public were prescribed as early as 1847.

Indeed, the American Medical Association, according to Dr. N. S. Davis, Sr., gave prominent attention to State Medicine and sanitation from its first meetings. At the second annual meeting, in 1849, standing committees were appointed on forensic medicine and on hygiene and reported annually on these topics and on meteorology, medical topography and epidemic diseases until 1860, when work in sections was commenced. Dr. A. N. Bell, of New York, delivered the first address on State Medicine in general session of the Association in 1874, followed in 1875 by Dr. N. I. Bowditch,† of Boston. In this connection, I may say that there is need of reliable information on the geographic distribution of diseases like goiter, cretinism, etc., and county medical societies would contribute much to the common fund of knowledge by placing on record information of this character.

NATIONAL BOARD OF HEALTH.

The cholera epidemic of 1872 and 1873 resulted in the appointment of a commission by Congress. This, together with the yellow-fever epidemic of 1878 in the Southern States, affecting, according to Sternberg, over 74,000 persons, with 16,000 deaths, called attention to the necessity of some central sanitary organization. In March, 1878, Congress created a national board of health, whose duty it was to make investigations into the causes and means of prevention of contagious and infectious diseases, to indicate measures of national importance and to be a center of information for all matters relating to public health. For want of appropriation, this important body has ceased to exist, and since 1883 the duties relating to international and interstate quarantine have been discharged by the Surgeon-General of the United States Marine-Hospital Service; his bureau, apart from the management of hospitals and stations for the care of sick and disabled seamen of the merchant marine, has also undertaken the collection and dissemination of mortality statistics and sanitary information, scientific investigation into the causes of disease, the physical examination of immigrants under the law, excluding those affected with contagious disease—service in the office of consuls at foreign ports to assure the accuracy of bills of health—and other miscellaneous duties. Since Congress has failed to act upon the President's repeated recommendation and the petition of numerous medical societies for the creation of a national health establishment, there is no good reason why the scope of duties and powers exercised by the Marine-Hospital Service should not be enlarged. Indeed, the last Congress appropriated sufficient money for the erection of a laboratory "for the investigation of infectious and contagious diseases and

matters pertaining to the public health," which marks the beginning of a new era in national sanitary legislation.

NATIONAL AND INTERNATIONAL QUARANTINE.

The question of an efficient system of national and international quarantine against Asiatic cholera, yellow fever, smallpox, typhoid fever, bubonic plague, leprosy, has engaged the attention of sanitarians for years, especially since it became known that these diseases, particularly cholera, are generally carried along the highways of travel and commerce. Special efforts were made after the completion of the Suez canal and other rapid transit facilities, to guard Europe from the invasion of cholera from India, and since 1892 these efforts have been quite fruitful. At all events, with efficient quarantine regulations involving inspection of vessels, passengers and crew, the detention of the sick and disinfection of all others, including personal effects, cargo and vessels, and proper notification, we have been enabled to keep these diseases from our shores, and if other nations do the same, they should be restricted to their original home. General Wyman's plan, as outlined in his address before the Pan-American Medical Congress, contemplates an international system of sanitation; while his proposition refers especially to yellow fever in the Western Hemisphere, it is equally applicable to the home of cholera and the oriental plague.

In the light of the recent researches by Reed and Carroll as to the transmission of yellow fever by means of mosquitos, our views concerning quarantine and disinfection in this disease may have to be modified, but in the meantime the fight against the mosquitos will go on; whether this will be effectually accomplished by insecticides and screens, or the more rational method of drainage of the soil, remains to be seen; in either event malarial countries will likewise be benefited.

HAS HUMAN SUFFERING BEEN MITIGATED AND HUMAN LIFE GREATLY PROLONGED BY EFFORTS IN SANITATION?

Our answer is an emphatic "Yes." Professor Finkelnburg, of Bonn, estimates that the average length of human life in the sixteenth century was only between 18 and 20 years; at the close of the eighteenth, it was a little over 30 years, while today it is over 40 years; indeed, the span of life since 1880 has been lengthened about 6 years, as shown by statistics, in Mulhall's "Dictionary of Statistics" (fourth edition, London, 1899).

The mortality of London between 1660 and 1678 was 80 per 1,000 of inhabitants; from 1728 to 1780, 51 per 1,000; from 1801 to 1835 it was still 29, while at the present time it averages between 17 and 19 per 1,000.

INFLUENCE OF SEWERS AND PUBLIC WATER-SUPPLIES.

Without underestimating the brilliant achievements of Jenner's discovery of vaccination in 1796, which as a preventive measure has saved millions of lives, no 2 factors have contributed so much to the general result as the improvement of the air we breathe and the water we drink. Indeed, we have ample evidence that, with the introduction of sewers and public water-supplies, the general mortality in numerous cities, during the past 40 years, has been reduced fully one-half, the good effects being especially shown by a marked decrease in the number of cases of typhoid fever, diarrheal diseases and tuberculosis. The vital statistics of Great Britain furnish the proof. The mortality of Salisbury within the last 30 years has been reduced from 40 to 16 per 1,000; at Dover, from 28 to 14 per 1,000; at Rugby, from 24 to 10 per 1,000; at Croydon, from 28 to 15 per 1,000, and at Matlock, from 18 to 9 per 1,000.

The history of every sewered city shows a lessening of the typhoid death-rate subsequent to the construction of the sewers and that the typhoid rate is always higher in sections supplied with privy pits and box privies,

* Article 1, paragraph 1, reads: "As good citizens, it is the duty of physicians to be ever vigilant for the welfare of the community and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to matters especially appertaining to their profession, as on subjects of medical police, public hygiene, and legal medicine. It is their province to enlighten the public in regard to quarantine regulations, the location, arrangement, and dietaries of hospitals, asylums, schools, prisons, and similar institutions; in relation to the medical police of towns, as drainage, ventilation, etc., and in regard to measures for the prevention of epidemic and contagious diseases, and when pestilence prevails it is their duty to face the danger and to continue their labors for the alleviation of the suffering, even at the jeopardy of their own lives."

† Information kindly furnished by Drs. N. S. Davis, Sr., and George H. Simmons, letter of April 18, 1901.

than in the houses connected with sewers. In 1895 the speaker pointed out that typhoid prevailed in the city of Washington and suburbs in 1 of 81 houses with privies, and in only 1 in 149 of those connected with sewers, and the health officer of Nottingham has since then presented similar evidence. The only reasonable explanation for this is that sewers carry away the filth that otherwise would contaminate the soil and ground water, but even if there were no wells, these makeshifts are still a source of danger in so far as they favor the transmission of the infection by means of flies, nor can the possibility be ignored that the germs in leaky or overflowing boxes may reach the upper layer of the soil, and with pulverized dust, gain access to the system. This conclusion, and the agency of flies in carrying the germs from box privies and other receptacles from typhoid stools to the food-supply, was enunciated in my report in 1895 and appears to have found ample support in the experience of the late Spanish-American War.

INFLUENCE OF IMPROVED WATER-SUPPLIES.

According to Dr. Abbott, the number of towns in the United States before 1800 having a public water-supply was only 16, supplying about 2.8% of the existing population; in 1850 there were only 83 public water-works, supplying about 10.6% of the census population; in 1897 the total number was 3,196, supplying about 41.6% of the population.

A summary of the evidence on this subject reveals the significant fact that cities, both at home and abroad, in which there has been the most marked decrease in typhoid fever death-rate, are those in which a pure supply has been substituted for a preexisting contaminated one. Thus, for example, the typhoid fever death-rate in Boston in 1846-1849 was still 17.4 per 10,000; in 1890-1892 it had fallen to 3.2 per 10,000, the city having in the meantime expended \$25,000,000 on its water-supply. The typhoid fever death-rate in Chicago from 1890 to 1892 averaged 12.5 per 10,000. After improving the water-supply it fell with every step in improvement until last year it was only 1.9 per 10,000, a total reduction of 84.8 during the decade. The rate from this disease in Lawrence, Mass., for 5 years prior to 1893, was 12.7 per 10,000. After the establishment of sand filters, in September, 1893, the rate fell during the first 12 months to 5.2 per 10,000.

Munich was notorious for excessive typhoid fever death-rate, it being 29 per 10,000 in 1856. With the introduction of a pure water-supply and improved sewer system it has fallen to less than 2 per 10,000. The experience of London, Berlin, Vienna, Albany and a host of other cities has been precisely the same.*

SEWAGE DISPOSAL AND RIVER POLLUTION.

When we remember that in 1893, 41% of our population lived in towns having public water-supplies, and only 28.7% in sewered towns, we fear that the municipal authorities have failed to recognize the necessity that a system of public sewerage must go hand in hand with the public water-supply, the neglect of which simply compels recourse to the various makeshifts for the collection and removal of excreta, and leads to soil pollution and all the other evils already referred to.

In view of the fact that self-purification of rivers is a slow and uncertain process, and the streams once polluted with excrementitious matter can not be considered a safe water-supply, it is high time for civilized communities to take steps toward removing the danger to be found in rivers, which are the sewers and at the same time the sources of public water-supply.

We know, from statistics collected by the Marine-Hospital Service, that the towns and cities located on

*In 25 cities using unfiltered water the average typhoid death-rate is still 7.7 per 10,000; in 5 American cities supplied with water filtered by the American process, the rate is 5.5, against a rate of 1.1 per 10,000 in cities supplied with water filtered by the natural or English method. The average rate of 5 cities in Europe supplied with mountain springs or deep wells from unpolluted source is only 0.7 per 10,000.

the banks of the Ohio, Potomac, Mississippi, Merrimac, Connecticut, Missouri, the Red, the Columbia and Wabash rivers show a marked prevalence of typhoid fever, confirming what has elsewhere been proved, that this disease, as also cholera, dysentery and diarrheal diseases can be carried from one town or city to another by means of water-courses. There were probably no fewer than 35,000 deaths caused by typhoid fever alone throughout the United States last year and, based upon an estimated mortality of 10%, it is within reason to assume a yearly prevalence of 350,000 cases of this disease. The average duration of a case of typhoid fever is not less than 30 days. If we calculate that an average of \$1 a day is expended for care, treatment and loss of work, and that the value of a human life is \$5,000, we have a total loss in the United States of \$185,500,000 per annum, from one of the so-called preventable diseases. Reduce the prevalence of this single disease $\frac{1}{2}$, which has been accomplished in England, and the oft-recurring question: "How is it our fathers got along without these so-called modern improvements?" will be satisfactorily answered from an economic point of view.

One of the most pressing needs is an investigation into the pollution of water-supplies when such pollution affects or threatens to affect the sanitary condition of the people of more than one State, because the individual States are powerless to protect themselves against the misdeeds of their neighbors. Mr. Barthold's bill for the appointment of a river pollution commission was defeated; yet that same Congress appropriated \$40,000 for the extermination of the gipsy moth. England enjoyed the benefit of such a commission as early as 1855, and, in order to prevent, remedy and remove the danger of polluted water-supplies, adopted a comprehensive system for the disposal of sewage and water filtration, the fruits of which have already been referred to.

No community or individual has a right to pollute streams used for public water-supplies any more than a man has to contaminate his neighbor's well. This principle is very well appreciated by some of the nations in Europe. Thus the inhabitants of a town in Belgium suffered from the effects of a river polluted by the French, and the French Government not only compelled the offending town to dispose of its sewage by irrigation, but also granted a subsidy for this purpose.

In the interest of public health it is to be hoped that every State in the Union will take steps toward the prevention of the river pollution, except when towns are located close to the sea, and no lower towns are obliged to use the water for drinking purposes.

In 1878 the British Government appointed a committee to inquire into the several methods of sewage disposal and concluded that it can be best and most cheaply disposed of by the process of land irrigation for agricultural purposes, but as this is not always practicable, other modes of dealing with sewage have been proposed.

It is a gratifying fact that within the past 10 or 12 years over 100 communities in the United States have established plants for the disposal of sewage. The first attempt was made in 1872 at the State insane asylum, Augusta, Maine, since which time 78 plants for the disposal by irrigation, and 15 by chemical treatment, have been established, and over 40 more projected.

PURE FOOD AND DRUG LEGISLATION.

The first movement toward securing comprehensive legislation against the adulteration of foods and drugs in this country was made in 1879. This is all the more surprising because Dr. Mann, in his "Medical Sketches of 1812," remarks that "the bread on the Niagara was made of damaged flour, such as was either not nutritious or absolutely deleterious." It was believed also that the flour contained in some instances an earthy substance, and that this adulterating substance was

plaster-of-paris. Again, during the Civil War, as early as the winter of 1861-62, an extract of coffee furnished the troops in the vicinity of Alexandria produced nausea and vomiting, and subsequently a government contractor, for having practised food adulteration, was sentenced to a protracted imprisonment.

Instances, therefore, were not wanting pointing to the necessity of such laws; nevertheless, it was not until 1881 that 3 States, New Jersey, New York and Michigan passed laws to prevent the adulteration of food and drugs. The law in New York commenced in the summer of 1882. At the close of the year, 286 samples of food and drugs had been submitted to the public analyst for examination, of which 194 had been reported on. Of 119 samples of food, 50 were found adulterated; while of 75 samples of drugs, 32 were adulterated.

Since 1883 quite a number of States have enacted similar laws, but I regret to say that in spite of the absolute necessity for national legislation, which has been agitated ever since 1892, so far every bill presented to Congress has failed to become a law, and food adulterated in one State can be taken to another and sold. It would lead me entirely too far even to touch upon all the frauds which are daily perpetrated. Some adulterations are harmful, others are not. I will simply refer to a very universal article of food, viz., milk. New York City obtains its milk supply from 5 States, and amounted in 1896 to nearly 729,000 quarts a day. Analysis of the milk sold some years ago showed an average dilution with 33% of water. The State inspector found 12% water added and 20% of cream removed, the fraud amounting to over \$10,000 a day. The results in St. Louis, Chicago and elsewhere were similar, and indicated the desirability of stringent laws to protect the pocket of the consumer, but when we remember the frightful infantile mortality, and the fact that the speaker has recently presented his conclusions, based upon 195 epidemics of typhoid fever, 99 of scarlet fever and 36 of diphtheria, and that 52 of these outbreaks occurred in this country since 1882, we see at once that the milk traffic should be under strict sanitary control.*

LAWS REGULATING THE SALE OF DRUGS AND POISONS.

Forty-two States and territories have enacted laws to regulate the sale of poisons, but a careful study shows that they should be amended, and greater restriction placed on the sale of poisons generally. A recent investigation by a committee of the Medical and Surgical Society into the extent of the opium and drug habit in the District of Columbia developed some interesting facts, and led to the conclusion that one class of subjects have developed the opium habit by the use of the milder preparations of opium and some of the various proprietary or secret remedies commonly employed as domestic remedies, such as paregoric, McMunn's elixir, chlorodyne, blackdrop, soothing syrup, diarrhea mixtures, pain-killers, etc. Those of another class have evidently acquired the habit by the constant use of prescriptions containing opium, or its preparations, for the relief of pain, the individuals being at first quite unconscious of the enslaving nature of the drug. Still another class of persons belong to the moral degenerates of fast men and women who have acquired the habit by contact with opium habitues, including opium smokers, and through solicitation, invitation and persuasion, have fallen victims to the vice. Since the opium habit is often established by the unauthorized and indiscriminate renewal of prescriptions containing opiates, the New York Legislature very wisely enacted, in 1886, a law that no pharmacist shall refill more than once prescriptions containing opium or morphin, or preparations of either, in which the dose of opium shall exceed $\frac{1}{10}$ grain, or morphin $\frac{1}{10}$

grain, except with the verbal or written order of a physician.

It is clearly the duty of the State to close opium dens and restrict the sale of poisons, and in regard to the sale of patent and proprietary medicines containing poisonous drugs, the contents should be expressed on the label and the word "poison" added.

PATENT AND PROPRIETARY MEDICINES.

By the term patent medicine, as properly employed in this country, England and Europe generally, it must be understood that the composition is known and can be seen at the Patent Office. The proprietary medicine is a secret preparation protected by a trade mark in this country, and hence preferred by the owner, but both are vaguely termed by the public patent medicines. Up to December 10, 1900, the United States Patent Office had issued patents on the following: Disinfectants, 321; extracts, 250; hair dyes and tonics, 48; insecticides, 180; internal remedies, 376; plasters, 56; topical remedies, 371; veterinary, 78. Trade marks: Drugs and chemicals, 319; medical compounds, 5,974, and increasing at the rate of about 250 a year.

The proprietary medicines are subject to the control of the State authorities, and if containing alcohol in sufficient quantity to be intoxicants are subject to internal revenue laws; but so far as my knowledge extends, little or nothing has been done in this country and in England to control the sale of secret remedies. Dr. G. Danford Thomas, Coroner of London and Middlesex, before the International Congress of Hygiene, in 1891, very justly urged that all proprietary medicines should be under the patent laws, because the composition is at least disclosed; he would abolish licenses to sell them and confine the sale to chemists and druggists only. In these matters we could certainly profit by the example of the Japanese, Italian, French and German laws. In the interest of public health the profession should demand adequate legislation; as it is now, hundreds of these proprietary preparations, the compositions of which need not even be disclosed to the Patent Office, are advertised in medical journals.

INDUSTRIAL HYGIENE.

The relations of occupation to health and life were studied as early as 1700 by Ramazzini, an Italian physician, and since then numerous monographs have appeared. We know to-day that persons habitually engaged in hard work, especially in factories and indoors, present a higher mortality than persons more favorably situated, and that the character of occupations influences, to a great extent, not only the average expectation of life, but also the prevalence of certain diseases. We know, for example, that tuberculosis is much more frequent among persons engaged in dust-inhaling occupations, and that the sharp angular particles of iron and stone dust are more liable to produce lesions of the respiratory mucosa than coal, flour, grain and tobacco dust. We know, too, that certain establishments, like slaughter-houses, glue, soap and candle factories, chemical factories, etc., are more or less productive of noxious and offensive gases, and that workers in lead, mercury, arsenic, phosphorus, poisonous dyes, etc., suffer especially from the injurious effects, and that other occupations, such as mining, railroading and contact with moving machinery, involve special danger to life and limb.

For all these reasons the laboring classes need special protection, and in order to render this efficient, it must be provided for by the enactment and enforcement of suitable laws. In 1864, 1867 and 1870 England enacted the so-called factory laws. According to Miss S. S. Whittlesey's "Essay on Massachusetts Labor Legisla-

*The results achieved by the health officers of every large city, notably by Reynolds, of Chicago, Wende, of Buffalo, and Woodward, of Washington, in the reduction of infantile mortality amounting in some instances to over 50%, show the advantage of pure food legislation.

*Information kindly furnished by Dr. J. B. Littlewood, of the Patent Office.

†Information collected from files of the United States Patent Office, by the author.

tion," child labor, here as in England, was the first aspect to receive attention in legislation as early as 1836. The first law as regards safety and sanitation was enacted in that State in 1877, since which time, from information kindly furnished by the Hon. Carroll D. Wright, of the U. S. Department of Labor, 32 States have enacted similar laws, including legislation requiring seats to be furnished saleswomen in stores and shops. Indeed, in some of the States the latter requirement is the only sanitary regulation. As a result of these laws, the majority of which were enacted during the last decade, commendable progress has been made in the way of ventilation, heating, lighting, removal of dust and injurious gases, means of escape in case of fire and prevention of injuries by moving machinery.

It is quite true there are other factors which affect the health and longevity of wage-earners adversely. So, for instance, unsanitary dwellings, faulty nutrition—the results of badly prepared food and cold lunches—can not fail to lower the power of resistance to disease, especially when the individual, in consequence of these very causes, has also become a victim of the alcohol habit.

SANITARY DWELLINGS FOR WAGE-EARNERS.

No field affords better opportunity for philanthropic work than the erection of sanitary homes for wage-earners at reasonable rentals, the encouragement of cookery schools, the establishment of sanitary lodgings, model eating-houses and other betterments of industrial conditions.

The vital statistics of London show that the mortality in the improved dwellings for wage-earners is far below the general mortality of the city, the difference being specially marked in the infantile mortality; the general average during the five years ending December, 1890, was 153 per 1,000, while in the "George Peabody" and the "Metropolitan dwellings" it was only 136 and 121 respectively.*

RURAL HYGIENE.

When we consider the fact that over 70% of our population reside in rural districts, that the "bone and sinew" of these are engaged in agricultural pursuits, and that they do not enjoy the benefits of enforced sanitation by local health boards, we see at once the desirability of the family physician extending useful suggestions on healthful building sites and homes, disposal of house wastes, the importance of a pure water supply, wholesome and properly cooked food, etc. As it is now, the diet is faulty, especially the hot biscuits, greasy fried dishes, while wells and privies are often dangerous neighbors. The undue prevalence of typhoid fever in rural districts could be materially checked by disinfecting the stools with 3 times the volume of boiling water and the adoption of the earth closet system. This is all the more important since infection is often spread through the milk-supply, and many of our urban population contract disease in the country during the summer months. While prompt disinfection of the excreta is

*At a recent meeting of the American Social Science Association, held in Washington, April 18, 1901, Mr. J. H. Patterson, Dayton, Ohio, read a paper on factory sanitation and described a large manufacturing plant of which he is the head, and their close adherence to the principles of hygiene and the uplifting of mankind. The interior of the factory is painted in cheerful colors, extra windows were made to give light, forced ventilation to afford plenty of fresh air, and all dust and acid fumes are carried away by exhaust fans. Bath-rooms and well-furnished toilet-rooms are on all the floors. All seats have backs. Clean aprons are furnished by the company, and a dining-room where hot meals are served, and a course in domestic economy is conducted. The grounds around the factory, and the houses of the employes, are healthful and attractive. "We have demonstrated," said Mr. Patterson, "that this system pays the employe, the manufacturer and the buyer; in the health of one, profit of the second, and the improved quality of the product purchased by the third." Bulletin No. 31, Department of Labor, November, 1900, contains an article on betterment of industrial conditions, showing what has elsewhere been accomplished, every effort being in the right direction, except that free medical attendance is being furnished by certain companies, involving a contract system with physicians, which ought never to gain a foothold on American soil, because it has proved a bane to the profession elsewhere.

the only rational method, we should also make an effort to get rid of the flies by prompt disposal of the horse manure in which they breed, the abandonment of open privies and surface pollution, removal of garbage and other fly-breeding matter.

SANITATION OF PRISONS.

Most commendable progress has been made in the construction and management of modern prisons. The mortality at the close of the last century, among prisoners in some of the French prisons, was 250 per 1,000; between 1840 and 1849 it was still 80.2 per 1,000, at St. Gallen, while today it is less than 30 per 1,000. Tuberculosis, typhoid fever, diarrhea, croupous pneumonia and mental disorders are the most prevalent diseases, but much will be done in future to reduce the excessive mortality by improved lighting, heating, ventilation, good food, bathing facilities, etc.

In some of the damp, dark and gloomy prisons of Germany over 50% of all the deaths are from tuberculosis. In the Millbank Prison of London, from 1825 to 1842, there were 175 deaths, of which no less than 75 were due to tuberculosis. Besides, 90 prisoners were set free on account of being hopelessly afflicted with pulmonary tuberculosis. In the Illinois State Prison, at Joliet, during the year 1895, 39 deaths were reported from tuberculosis; in 1900 only 8 occurred. This decrease appears to be due directly to segregation of tuberculosis subjects.

HOSPITALS, SANITARIUMS AND DISPENSARIES.

Perhaps no country in the world can boast of better hospital facilities than our own. Indeed, many of our institutions are perfect in sanitary architecture and equipment. There are in the United States no less than 1,776 hospitals, including 35 special hospitals for consumptives; 308 sanitariums, 213 dispensaries, and over 8,000 mineral springs, of which 727 are health resorts. Unfortunately the liberality with which medical charities have been supplied has given rise to shameful abuses, and persons who would shrink from seeking charity in any other form have abused the privileges offered by hospitals and dispensaries.

Correction of Abuses.—In 1896, speaking of the city of Washington, no fewer than 21% of the population received free medical treatment; the medical association in 1897 adopted certain rules compelling the attending staff of hospitals and dispensaries to require evidence of dependency; as a result of this system there has been a gradual but positive decrease in the number of charity patients, amounting to over 9,000 last year. It is the simplest, most just and effective remedy for the correction of this evil.

SCHOOL HYGIENE.

During the year ending June 30, 1900, there were 15,341,220 children enrolled in the common schools of our country. When we consider that the mental and physical vigor of a nation depends largely on the environments of childhood and youth, it seems strange that up to within 40 years little or no attention should have been paid to the hygiene of schools. The occurrence of so-called school diseases is not surprising when we reflect that children, on beginning school, enter upon a new life and environment. Up to this time they have been allowed to run and play in the open air, exercise the body and senses, without restraint, but now without a period of transition they are obliged to remain for several hours a day in close and sometimes unsanitary school rooms, taxing their minds and straining their eyes for near objects. Experience teaches and statistics confirm the conclusion, that quite a number of children suffer from certain physical defects and diseases, which because rarely observed before the school period, may be justly attributed to the school environments. Among the most common of these affections are myopia, lateral

curvature of the spine, dyspepsia, anemia, muscular debility, headache and nose-bleed, nervous affections and tuberculosis. Ware, of our own country, as early as 1812 called attention to the fact that myopia was most frequently developed in the school room, and during the past 40 years we have been enlightened as to the cause of this and other defects, and many excellent monographs have been written on the construction of school buildings, arrangement of recitation-rooms as regards light, ventilation, adjustable seats and desks, proper type for text-books, and more rational methods of mental and physical training. This, together with a commendable zeal on the part of the authorities to correct existing evils, has resulted in many reforms, the fruits of which are already apparent in a decrease of the diseases referred to.

Medical Inspection.—I cannot enter into details concerning the prevention of the spread of infectious diseases among school children, but desire to emphasize the necessity of medical inspectors, whose duty it should be to visit the schools, examine pupils, and give such directions as will reduce the dangers of spreading contagious diseases to a minimum; they should also make sanitary inspection of the buildings and present such recommendations as are necessary in the interest of the health of both the pupils and teachers, and as the physicians were perhaps the first to recognize the fact that "the system of education should be made to fit the child, not the child the system," the teachers may derive much aid from such consultations; among the cities that have inaugurated such inspections since 1894 are Boston, New York, Brooklyn, Chicago, Milwaukee, Louisville, St. Louis, Philadelphia, Jersey City, Brookline, Mass., Buffalo, Minneapolis and Salt Lake City, and they have proved of inestimable value.

SMALLPOX AND COMPULSORY VACCINATION.

In this connection, attention is invited to the undue prevalence of smallpox in the United States; the total number of cases reported to the U. S. Marine-Hospital Service during the past fall and winter, up to March 29, was 11,964, as compared with 7,279 cases for the corresponding period of the preceding year, and it is doubtless due to neglect in vaccination. Dr. Abbott estimates the vaccinated portion of the inhabitants of the United States at not far from 90%, and the revaccinated portion at probably 50%. With the introduction of glycerinated animal lymph every vestige of prejudice against vaccination should cease, and compulsory laws should be enacted in every State, so that smallpox here, as in the German army, may become practically unknown. While quite a number of States have enacted laws requiring that unvaccinated children shall not be admitted to the public schools, it is believed that these laws are not rigidly enforced.

VENEREAL DISEASES.

A careful perusal of Dr. Prince A. Morrow's article on the "Prophylaxis of Venereal Diseases" (*Philadelphia Medical Journal*, April 6, 1901) should stimulate our efforts in the prevention of diseases which affect not only the offender, but innocent wives, the offspring and not infrequently even the medical attendant. According to Fournier, one-seventh of the population of Paris is syphilitic, and Morrow, from statistics gathered in New York, believes it is quite possible that Fournier's figures, with some modification, may apply to New York. Neisser holds that gonorrhoea is, with the exception of perhaps measles, the most widespread of all diseases. Other German authorities have computed that fully three-quarters of the adult male population and one-sixth or more of the adult females have contracted gonorrhoea; that 80% of all deaths from disease of the uterus and its adnexes are of gonorrhoeal origin, while blennorrhoea neonatorum contributes a contingent to our asylums for the blind estimated at from 10 to 20%—from

40 to 60% before the Créde method was instituted—to mention the destructive effects on the procreative functions. Dr. S. M. Burnett, of Georgetown University, believes that 15,000 of the 50,000 blind persons in the United States lost their sight from this cause, which, according to his calculation, involves a financial loss to the commonwealth of 7½ millions annually.

The measures which have been proposed for the control of the social evil and the prevention of its consequences are numerous enough, but not so easy of practical application. On the whole, I believe the remedy lies in public education, and the task as usual falls on the medical profession, especially the trusted family physician. Public lecturers on the purity of man commit a serious mistake, however, when they picture the consequences of the social evil, without offering a suitable remedy. We should make a strong plea in favor of continence, and tell our young men that while the sexual passion is very strong it can be accelerated or delayed, excited or lowered by the influence of the will. We should assure them that by the cultivation of pure thought, removal of temptation, normal, mental and vigorous physical exercise, continence may not only become possible, but easy. And we can hardly go astray if we follow Dr. Parkes in advising a poor young man to make his home, after the age of 21, and thus secure himself both from the temptations and expenses of bachelorhood.

THE MANAGEMENT AND CONTROL OF INFECTIOUS DISEASES.

It is in the field of infectious diseases where preventive medicine has and doubtless will continue to achieve its greatest triumphs, and there is ample room, when we consider that during the census year of 1890 there were not less than 102,199 deaths from tuberculosis, 74,496 from pneumonia, 74,711 from diarrheal diseases, 41,677 from diphtheria, and 25,058 from typhoid fever. In spite of centuries of groping after facts, we knew nothing of the real nature of infectious diseases until the middle of the present century, and even 25 years ago the text-books still discussed the subject of miasma and contagions, whose nature had never been demonstrated to our senses. With improved microscopic lenses and the development of bacteriology, more especially the discovery of the anthrax bacillus by Davaine, Pollender and Brauell (1849-1855), scientific medicine had its birth, and today we know that such diseases as tuberculosis, glanders, leprosy, cholera, erysipelas, wound and puerperal infections, gonorrhoea, pneumonia, cerebrospinal meningitis, typhoid fever, diphtheria, malaria, influenza, dysentery, bubonic plague, and possibly carcinoma, are caused by living organisms, capable of reproduction within and without the body, and this is a strong argument in favor of the microbial nature of other infectious diseases, in which the specific organism has not yet been isolated.

The eradication of preventable diseases is the highest aim of scientific medicine today. The public should be made familiar with the nature and causes of infectious diseases, and be taught that many are a source of danger, against which it is entitled to be warned by proper notification through the health officer. This notification should be made compulsory in cholera, yellow fever, smallpox, chickenpox, typhus and typhoid fever, diphtheria and membranous croup, scarlet fever, tuberculosis, cerebrospinal meningitis, leprosy, glanders, bubonic plague, whooping-cough and measles. And let me say that a prompt and correct diagnosis is the first and most important step in preventive measures. The health department should have competent medical inspectors and a clinical laboratory for the verification of the diagnosis, and have the power in certain of these diseases to display warning signs, enforce isolation and disinfection, and to take such other steps in the way of immunizing agents as may be deemed necessary to limit their spread.

Isolation, to be effective, should extend to all persons

who have come in intimate contact with the patient, but this is rarely enforced except in smallpox, in the case of the attending physician, and the wage-earners of the family, but it is clearly their duty to take special precautions in the way of clothing and personal disinfection. Matters of this kind ought never to be left to the discretion of the family, nor the attending physician, for even members of the profession often entertain widely opposing opinions on the subject of quarantine and disinfection, but the principles which ought to be carried out, apart from being a matter of conscience, should be accepted in a practical sense and embodied in effective laws.

Disinfection.—Scientific disinfection had its inception with the labors of Koch and Sternberg some 20 years ago. Although, as we have seen, certain physical and chemical agents were used empirically for ages, now we know from laboratory experiments that they are effective, because they destroy the vitality of the germs. We also know that, in most of the contagious diseases, the infective matter is given off by the patient chiefly through the secretions and excretions, and it is evident that disinfection to be of value must be directed to these and all the media with which the patient has come in contact.

"IF CERTAIN DISEASES ARE PREVENTABLE, WHY ARE THEY NOT PREVENTED?"

My answer is, that while every scientific physician familiar with biologic research knows full well that if the methods of prevention recommended by sanitarians, including the prompt disinfection of the dejecta of every typhoid fever patient, the expectoration and excretions of diphtheria and tuberculosis patients, for example, were adopted, these diseases would be reduced to a minimum and probably eradicated in the course of a few years. The facts are, these recommendations have not been generally adopted, because the knowledge gained by experimental medicine is not sufficiently diffused. Nor are we responsible for the fact that so many of our States still permit every charlatan to practise one of the most difficult and responsible of all professions without a uniform and rigid system of examination. However, we owe it to ourselves and to humanity to take positive steps in behalf of higher medical education and laws regulating the practice of medicine. So long as we permit the existence of irregular and incompetent practitioners, so long will the public be deceived and will we be obliged to compete with incompetent men, and so long as we tolerate the exponents of so-called "Christian Science," osteopathy, and other quacks, infectious diseases will be spread as the result of ignorance and neglect.* A strong organization, such as is proposed for the American Medical Association and the various State medical societies will speedily accomplish this and other reforms.

FORECAST OF THE RESULT OF THE CENSUS WORK UPON THE MORTALITY STATISTICS.

Notwithstanding these and other disadvantages in the way of defective sanitary legislation, the American medical profession has reason to be proud of its work in the century's progress of hygiene and preventive medicine. It may be truly said that every hospital or

other medical charity owes its foundation and success to the activities of the medical profession. Nay, every law inscribed on the statute books, in the interest of public health in this and other countries is the work of our noble profession. Acting upon the lofty principle that the education and betterment of the people in sanitation is not less humane than the healing of the sick, the American medical profession has filled the measures of its philanthropy by advocating laws to "regulate the health and physical wellbeing of communities," and thereby lessen its own income, but the results attained during the last 10 years are sufficient recompense. By the courtesy of Mr. William A. King, Chief Statistician of the U. S. Census Bureau, I am enabled to give you a forecast of the result of the work upon the mortality statistics at the close of the century.

The mortality returns for the twelfth census, which relate to the year beginning June 1, 1899, and ending May 31, 1900, have not yet been tabulated in full, but sufficient progress has been made to permit a comparison of the preliminary results with the figures for 1890 for a portion of the country.

Considering these results for these States in which the returns were secured from registration records in both 1890 and 1900, there appears to have been an absolute decrease in the general death-rate of about 1.5 per 1,000 of population. This decrease seems to be most marked in the rates due to scarlet fever, whooping-cough, diphtheria and croup (combined), typhoid fever, malarial fever, tuberculosis, diarrheal diseases, and diseases of the nervous system, the decrease in the mortality from diphtheria and croup amounting to more than 50%. On the other hand, the rates due to carcinoma and tumor (combined), Bright's disease, heart disease and dropsy (combined), and pneumonia are apparently greater than in 1890, the increase being most marked in case of Bright's disease, carcinoma and tumor, and pneumonia.

The death-rate by age periods in the registration States has not yet been computed as the population figures are not yet available, but the effect of the decrease in the rates due to the causes specified is shown by a decrease in the proportion of deaths occurring at each period up to 30 years.

The results in the decreased rate of diphtheria, croup, scarlet fever, typhoid fever, whooping-cough, tuberculosis, malarial fever and diarrheal diseases are the direct outcome of preventive medicine and are as gratifying as they are striking. We note with regret the increased rate in Bright's disease, heart disease, dropsy and pneumonia, and may well pause to inquire whether our ever-increasing "National Drink Bill," averaging 17.68 gallons per capita, may not be a factor in the development of these diseases, especially since there is reason to believe that the habitual and immoderate use of alcohol, apart from increasing the connective tissue and causing cirrhosis, also produces fatty degeneration, especially of the heart, liver and arterial coats, probably because it promotes the conversion of albuminoids into fats.

Without wishing to underrate the brilliant achievements in surgery of the brain, stomach, intestines, liver, gallbladder and other abdominal organs, and even wounds of the human heart which have been successfully sutured in 4 of the 9 cases reported, what after all are the ultimate benefits compared with the results obtained by improved methods in sanitation?

Since our knowledge of the nature of infectious diseases has been more and more defined, scientific methods for their prevention have been applied. We have learned, too, that in addition to the germ there must be a suitable soil for its proliferation and that sanitation will not only destroy the environments for its development without the body, but also place the system in the best possible condition to resist its toxic action.

The application of this knowledge has saved millions

*During the year 1900 there were 119 regular medical schools in this country, with 1,079 female and 21,673 male students; of these 22,752 students, 2,327, or about 10%, had degrees of A.B. or B.L. Number of graduates last year, 4,720. The homoeopathic schools had 1,584 male and 325 female students, and the eclectics, 500 male and 52 female students. The number of registered physicians in the United States in 1900 shows an average for the whole of about 1 to 636 inhabitants. In 31 States and Territories, according to D. McIntyre, an examination is required, in 9 certain diplomas are accepted, all others must be examined; in 5 only a diploma is required, and in 5 the laws practically impose no restriction. In 1900 there were 150 National and State medical societies, 1,097 county and local medical societies, and 282 medical journals, of which 28 were exclusively devoted to hygiene and public health.

of lives besides an incalculable amount of human suffering and distress, not to mention the economic aspect of the question. When we remember all this and the fact that Jenner's discovery at the close of the last century of a fundamental and practical method of producing artificial immunity has been far eclipsed in the last 20 years, and that we possess today not only curative but also protective serums for diphtheria, erysipelas, tetanus, plague and possibly cholera, tuberculosis, typhoid fever, pneumonia, and a number of other immunizing agents for diseases of man and lower animals, we have reason to believe that the solution of the problem of immunity is only a question of time, and we may indeed expect great possibilities in our battle against infectious diseases.

To the solution of this problem, the labors of Salmon and Smith, Sternberg, Welch, Osler, Councilman, Reed and other Americans engaged in experimental medicine, have contributed their full share. Progress has crowned our past, we will not retrograde. Let our conduct raise no blush on the cheek of posterity. Let us hand in hand with heart and mind join in promoting the welfare of American medicine, until she has reached the proudest pinnacle in the world of science, until she has become the fountain-head of knowledge for the benefit of mankind. Then when at last we are called upon to pass through the portals beyond, Minerva Medica, in her sweeping robes of state, will proudly but reverently present us to the Supreme Healer of the Universe as types of the true physician.*

INTERNAL MEDICINE IN THE NINETEENTH CENTURY.†

BY

N. S. DAVIS, JR., M.D.,

of Chicago.

It is one of the duties of those who address you, as I do today, to review what has been newly discovered in the field of medicine or in some limited department of it. At this first meeting of the American Medical Association in the twentieth century, it seems most natural to review what has been accomplished in the last 100 years. The time at my disposal is too brief to read to you a complete history of the achievements of this wonderful epoch, for more of genuine advancement has been made in medicine during it than during all the preceding centuries together. It is only possible for me to point out some of the reasons for the rapid development of medicine, to recall to your minds some of the most important discoveries and applications of them.

A century is not so long a time as we are apt to think. Our grandfathers were vigorous men in the prime of life when the nineteenth century was born. Yet changes so great that they seem miraculous have occurred since then. In 1800 this great country was a wilderness, unknown even to the inhabitants of the few straggling settlements upon the Atlantic coast. Our land contained no great cities. There was little travel from place to place. There were no steamboats or railways; no telegraphs or telephones. Information traveled slowly by packet ship, canal boat and stage coach. The discovery of the wonderful properties of the x-ray could not then have been flashed over the world in a day and its genuineness and utility confirmed within a few weeks by experiments made simultaneously in all parts of the

world, as did happen at the close of the century. Today all civilized peoples are so united that knowledge has become the common property of them all. In former epochs geniuses delved alone, inspired only by their own enthusiasm. Often it was many years before their discoveries became widely known or appreciated; and many more before another genius standing upon land already found ventured upon its exploration.

All this has been changed. Learning is not possessed by a few, but by many. In earlier epochs men of genius towered above their contemporaries in learning. Today thousands crowd about their shoulders, so much higher is the average of learning. All scientific workers are now linked together by the rapid dissemination of news, so that no matter in what part of the world they may be, they are kept conversant with what is being thought and done in every other part and they are thereby inspired to greater mental efforts.

Knowledge is no longer isolated. It is cultivated in centers too numerous to count. Even in this new land universities with great libraries, finely-equipped laboratories, and corps of brilliant teachers and seekers after new knowledge are found in every part of it. Medical societies have been organized in every State and city, and in many counties and towns. But at the beginning of the century there were only 4 medical schools in this country, and 4 State societies, organized for the advancement of medical knowledge.*

These changes have been effected chiefly by the rapidity of communication which has been established in all civilized lands and by the greater concentration of the people in large cities.

But it is not in the United States only that the population has increased and concentrated. In 1801 the total population of England and Wales was less than 9,000,000. Of this number more than half lived in the country. At the end of the nineteenth century the population of the same countries was more than 29,000,000, and only one-fifth of this number lived in rural districts. These figures attract our attention to the social changes which have occurred in all civilized lands—changes which have effected not only a greater diffusion of knowledge but have also modified the conditions which produce and limit disease.

At the opening of the nineteenth century, "Cullen's Practice of Physic," written late in the preceding century, was the standard textbook. A glance at its contents will give us the clearest conception of the state of medical knowledge at that time. In an edition of this work printed in New York City in 1806 I find no description of structural diseases of the heart; even as a complication of rheumatism heart disease is not mentioned. A single page is devoted to nephritis, but in its description there is no mention of the chemie and microscopic changes in the urine upon which we depend to recognize it and to distinguish its forms. The affections of the respiratory organs were described with similar crudeness, under such chapter headings as "Of Catarrh," "Asthma," "Pneumonic Inflammation," "Peripneumonia Notha," and "Phthisis Pulmonalis," but the catarrhal inflammations of the nose, pharynx, trachea and bronchi were not differentiated from one another, nor were catarrhal and croupous pneumonia, brown induration, hypostatic congestion and edema of the lungs described.

The hypothetic explanation of diseases and their causes which prevailed at that time is well illustrated by the conclusion reached by Noah Webster, who in his "History of Epidemics and Pestilential Diseases," writes that typhus and nervous fever are due to "conversion of the perspirable fluids of the body into septic matter."

*In the preparation of this address I have been greatly aided by the Library of the Surgeon-General's Office, the historic monographs on hygiene, by Professor Kinkelburg, of Bonn, now deceased, and by Dr. S. W. Abbott, of our own country. I am also greatly indebted to Dr. W. T. Harris, the Commissioner of Education, and Dr. A. E. Miller, of his Bureau. Other acknowledgments have been made in the text and are gratefully renewed.

† Annual oration in medicine, delivered at the fifty-second annual meeting of the American Medical Association, held at St. Paul, Minn., June 4-7, 1901, and published synchronously by courtesy of Dr. George H. Simmons, editor *Journal American Medical Association*.

*The colleges were medical departments of Pennsylvania, Columbia, Harvard and Dartmouth (founded 1797). The societies were New Jersey (1766), Massachusetts (1781), Connecticut and New Hampshire (1791).

Nothing will help so much to make clear the progress made in medicine in the last century as to compare the resources at the disposal of physicians of our day with those commanded by our grandparents. At the opening of the nineteenth century medical men knew nothing of the clinical thermometer, of percussion, auscultation, urinalysis, clinical microscopy, laryngoscopy ophthalmoscopy, of the sphygmograph, or Röntgen rays.

It was not until the year 1808 that Corvisart spread widely a knowledge of percussion as a means of discovering the physical status of the viscera, although the work of Avenbrugger which he translated, and which was the original description of percussion, had been published nearly 50 years before. The work of Avenbrugger and Corvisart was supplemented in 1819, when Laennec published the result of his labor with the stethoscope which he invented 4 years earlier. From this time dates our clinical knowledge of diseases of the lungs and heart.

In 1827 Bright pointed out the relationship of albuminuria, dropsy and diseases of the kidneys. At this point clinical chemistry may be said to begin.

At the beginning of the nineteenth century, compound microscopes were almost useless, for the images which their lenses made were so distorted and colored that they could not be properly interpreted. In 1812 Dr. William Hyde Wollaston combined 2 plano-convex lenses so as to correct the spherical aberration which a single double-convex lens produces; and nearly 20 years later Joseph Jackson Lister discovered the utility of combining lenses of crown and flint glass in order to produce an image in the microscope relatively free from distortions and fringes of color. The more recent invention of the oil immersion lens has made bacteriology possible and has solved many of the problems of infectious diseases which puzzled even our fathers in the fifties and sixties.

The dependence of medicine upon ancillary sciences is well illustrated by the sudden birth and rapid development of new branches of medical knowledge which are dependent on the perfection of the microscope.

This instrument has made histology, embryology, modern pathology and bacteriology a possibility. These departments of science are altogether products of the last century.

It was at the beginning of the century that Bichot divided the structures of the body into what he called "tissues" and showed that there were only a few of them. It is surprising that the great anatomists before him did not make the same discovery.

As modern anatomy has been dependent upon the microscope in order to explain structures, so physiology has been dependent upon experiments on living animals to explain function. It is true that in earlier epochs at considerable intervals of time experiments upon living animals were made, notably by Harvey, when he studied the circulation of the blood, but they were never made systematically until the discovery of anesthesia in the nineteenth century made them painless. No wonder, therefore, that the explanations made by physiologists in 1800 seem to us extremely crude. Haller, for instance, whose printed lectures formed the textbook of most students at that time thus describes the nature of blood: "Hydrostatic experiments demonstrate in the blood first a kind of volatile vapor or exhalation which immediately and continually flies off from the warm juice with a sort of fetid odor coming betwixt that of sweat and urine. This vapor, being caught and condensed in proper vessels, appears of a watery nature joined with a small tincture of an alkaline disposition."

A few pages further on what he says of the blood gives us an idea both of the state of physiologic and pathologic knowledge at that time: "For the blood in a sound healthy state, not injured by putrefaction or too violent a degree of heat, is neither alkaline nor acid, but mild and gelatinous and a little saltish to the taste; yet in some diseases it is sharp enough and comes near

to a state of putrefaction, as for instance in the scurvy, when it corrodes through its containing vessels, and in those who have ascites or dropsy whose waters are often much of an alkaline and corroding nature."

At the close of the eighteenth century the part which gland cells play in forming secretions was not comprehended. It was believed that "the albuminous or hardening juices are separated almost anywhere from the arteries themselves, into continuous excretory canals, with any intermediate organ or machine betwixt them." It was believed that all excretions existed primarily in the blood.

The physiologists of this period appreciated the importance of the lungs and the act of respiration, but their exact use they did not comprehend. Haller enumerates several possible functions which they might perform, yet he did not feel sure that any one of them was the real one. For instance, he says: "Our blood acquires its heat principally in the lungs, for that all animals which have lungs and 2 ventricles in the heart have the heat of their blood commonly twice that of the atmosphere. But does not this arise from the alternate extension and contraction, relaxation and compression of the pulmonary vessels by which the solid parts of the blood are perpetually rubbed together and closely compressed in the attrition that is made during expiration, as it is more rapidly moved and ground together during inspiration."

Our forefathers 100 years ago often endeavored to hide their ignorance in long names and resounding phrases, a common practice, indeed, in all times and not wanting to-day, for how much ignorance will our successors find hidden in words now so commonly used as are metabolism and auto-intoxication!

Pathology as a distinct department of scientific medicine originated in the nineteenth century. It was not until 1860 that Rudolf Virchow demonstrated conclusively his famous dictum: "*Omnis cellula e cellula.*" His studies of cells in disease laid the foundation and did much to rear the superstructure of cellular pathology. So rapidly has a knowledge of this subject grown that we can unhesitatingly say that we now possess very accurate and detailed information as to the anatomic changes which disease effects. The insight of physicians was so greatly extended into the nature of morbid processes by these pathologic studies that enthusiastic devotees of them felt that the application of the microscope to the study of disease would dispel its mysteries. Increasing information, however, soon demonstrated the limitations which exist as to knowledge derivable from a study of morbid anatomy. Most of us remember how, soon after the birth of bacteriology, it was also hoped that from it at least we would learn the true essence of disease. But we know now that in most ailments after the bacteriologist has discovered the offending microorganism the chemist must help us, for it is usually a product of its growth, not its physical presence in the tissues, that causes disease.

The production of disease by parasites imbedded in the tissues of the human body was suspected from early times, but was not demonstrated until the end of the first third of the nineteenth century, when James Paget, then a medical student, found unusual nodules in the muscles of a man whom he was dissecting. These Richard Owen demonstrated to be the cocoon of a minute animal which he called *trichina spiralis*. In 1847 Dr. Joseph Leidy, of Philadelphia, found them also in pork, and soon thereafter it was shown in Germany that men could become infected by eating pork containing *trichina*, and that in consequence there developed in them a definite train of symptoms.

In 1837 Latour in France and Schwann in Germany, almost simultaneously propounded the view that fermentation and putrefaction are due to the growth of microorganisms. Liebig, with all the weight of his authority, antagonized this belief in a "vitalistic"

explanation of these phenomena. Pasteur undertook to settle the dispute by methods of research, which proved to be the foundation of a new department of science—bacteriology. The results of his experiments were published between 1857 and 1869. He proved that without microorganisms there could be no fermentation, no putrefaction, no decay. These studies prompted many investigators to attempt to demonstrate the suspected relationship of microorganisms to disease. In 1863 Devaine succeeded in showing that the organisms, seen by him in 1850 in the blood of animals which had died of anthrax, were its cause. This, as some of those before me will remember, aroused a storm of controversy which was not settled finally until after my own student days.

Formerly such vague terms as "miasm," "humor" and "virus" were used to explain the communicability of contagious diseases, but they have had to be discarded or to be newly defined by the bacteriologist. It was in the sixties that Lister made his studies upon the relationship of microorganisms to wound infection. The brilliant, revolutionary results of those studies are too well known to you to require elaboration, besides they belong to the history of the nineteenth century surgery rather than to the history of internal medicine. They were, however, so important in settling the relationship of invisible parasites and diseases that they must be mentioned.

It was at this time, too, that Pasteur and Tyndall finally settled the controversy over spontaneous generation which had raged from time immemorial. The world at last felt convinced that even microorganisms could not exist where an antecedent organism had not been.

It is needless to recapitulate the long list of discoveries rapidly made from this time onward of the causes of infectious diseases, by such men as Koch, Klebs, Löffler, Fraenkel, Laveran, and many others.

Although medical men have been incited to search for the causes of disease in order that they might understand their nature better and therefore be able to treat them better, such studies naturally led more directly to the prevention than to the cure of disease. That is why the recent epoch-making bacteriologic discoveries have greatly stimulated the study of preventive medicine. It is true that the prevention of disease has engaged the attention of medical men and statesmen since the earliest times, but the subject was not studied systematically before the last century.

Hygiene as a separate department of medicine, with a literature of its own, was created only in the nineteenth century.

While, in the eighteenth century, much was done to improve the hygienic state of individuals, and as a result there began before its close to be a reduction in the mortality rate, which has continued up to the present time, public hygiene or attempts to prevent the spread of disease by State and civic interference, was not fairly established until very recently. Even today small communities have no health officers or sanitary inspectors, and few regulations which are intended either to inform the people as to the relative healthfulness of towns and hamlets or by which the spread of disease is to be lessened. These facts show how new and undeveloped as yet the field of public hygiene is. The mortality statistics which have been gathered in cities since the middle of the last century make it possible to point out which among them are the healthiest, and which diseases are the most destructive. It is to be hoped that these statistics in the future will be supplemented by reports of the kinds and amount of illness whether fatal or not, that may exist in a given place.

The knowledge recently acquired of infections and their spread has already been applied to their prevention. Such diseases as erysipelas, septicemia and tetanus no longer torment surgeons when they can make clean wounds. But as late as 1870 the first of these ailments

was common in the hospitals of France. Puerperal fever is today as rare as it was common formerly. Typhus fever no longer exists in America, although not uncommon at the beginning of the last century.*

Indeed, it is rarely seen in any civilized country today. At the beginning of the nineteenth century, smallpox was so common that few persons reached adult life without having had the disease, and the mortality from it in childhood was great. What is the status of this disease today? I venture to say there are many physicians in this audience who have never seen a case, and that a majority of them have not treated more than 4 or 5 cases during their whole professional experience. In the early days of this nation's history yellow fever spread to Philadelphia and New York, and provoked much discussion, for it was feared that it would prove as great a pest as cholera. A careful study of the disease and a consideration of the possibility of preventing it were referred to a committee of the New York Medical Society, which reported that yellow fever may be produced in any country by pestilential effluvia. How different is this conclusion from that of recent students of the subject, who assign to it a specific cause, which is transmitted from man to man by the mosquito, which is its host.

Cholera has been brought to our shores several times in the last few years, but its spread has been prevented in each case. In Europe it has also been limited to comparatively small areas. Within a year the plague has been found in this country, in Great Britain and France, but has caused little alarm, so great is the confidence that it will be successfully suppressed. (Let us hope that this confidence is not misplaced.)

What has been accomplished during the last 100 years by internal medicine the following statistics will show in part, although it must be remembered that mortality statistics gathered before the middle of the century are not reliable. It is estimated that in 1805, in New York City, from 35 to 40 deaths occurred in every 1,000 inhabitants. During the last decade it has averaged 20 in 1,000, and has been as low as 19 in 1,000. In 1847 the mortality in London from zymotic diseases was 23.26%; during the last 2 decades, 19% to 20%. In 1846 the deaths from tuberculosis were 12.67%; now approximately 9%. The mortality from diseases of the respiratory organs has been reduced in the same time from more than 12% to about 7%, and the mortality from diseases of the digestive organs has diminished from about 6% to less than 5%. In Chicago the mortality rate has fallen, with small fluctuations, from 46 and 64 deaths per 1,000 inhabitants in the cholera year of 1852 and 1854 to 14 in 1898. The following diseases are among those in which the deathrate has fallen progressively: Cholera infantum, erup, diarrhea, diphtheria, dysentery, malaria, measles, scarlet fever and whooping cough. These are ailments the spread of which has been controlled either by isolation or by insuring the people purer food and water. Although the general mortality of Chicago, which is typical of the great cities of civilized countries, has improved, there are some diseases which are increasing in prevalence, notably nervous diseases, heart diseases, cancer, Bright's disease, bronchitis and pneumonia. To the discredit of my native city must it be said that the mortality from typhoid fever reached its highest point at the close of the century, during 1890, '91 and '92, although its cause and its mode of dissemination, as well as its prevention, were well known.

The general lowering of the deathrate is due to the improved hygiene of communities. In what the improvement has consisted is best shown by recalling some of the conditions under which people lived in 1800. At that time few cities had an adequate public water supply. In London water could be delivered at any

*Typhus forms an item in the mortality reports of Chicago (and other American cities) as late as 1886. This is probably because it was confused with typhoid. Not during the first quarter, and rarely afterwards, genuine typhus occurred in this country.

house 3 times a week by one of the water companies; but most households depended upon wells. The sewerage system was quite as imperfect. Outhouses and cesspools were attached to each dwelling. The conveyance of sewage from houses by water did not become general until well into the last century. Ventilation of buildings, and especially of public halls, had attracted attention before the nineteenth century; but the real causes of danger from bad ventilation were not appreciated until bacteriology disclosed them.

In 1800, streets were not paved, and rarely cleaned. The habits of the people as regards eating and drinking were hestial. Excessively large quantities of food were consumed by all who could provide it. Alcoholic beverages were universally drunk, and generally in immoderate quantities. No disgrace attached to drunkenness; and it was customary for a man to drink several bottles of wine at a sitting.

Those who compose this audience appreciate how much illness must have been caused by these habits, and how much the relative abstemiousness or temperance of today has lessened the percentage of disease.

Prevention of diseases is only possible when a knowledge of their causes, their mode of dissemination, and methods for their suppression are possessed by all the people. Medical men alone cannot stop their spread, nor will the making of laws do it. Only the intelligent cooperation of those who are ill and those who are well can accomplish it. It must not be expected, therefore, that as soon as the cause of the disease is discovered, that ailment can be suppressed. Time is required in which to educate all classes of people on that particular subject. Unfortunately, many persons are so obtuse that they will not believe in methods of prevention even when the fullest demonstration of their success has been made. A noteworthy instance of this is seen in the recent repeal of laws in England which made vaccination compulsory. The ease with which drinking water may be become contaminated and the danger to health from contamination is not even now appreciated by the public. It is partly because such thorough knowledge is needed by the laymen that tuberculosis, diphtheria, pneumonia, typhoid fever, and similar troubles have not been better controlled in the past. In order that in the twentieth century the fruits of the great discoveries of the last may be gathered, all members of the medical profession must fit themselves to teach their patients what is known of disease and its prevention. Those who are especially adapted to do so must disseminate their knowledge by popular discourses and essays. When hygiene shall be regarded by all classes as necessary, and as much a matter of course as the use of the railroad, steamboat, the telegraph, telephone, and labor-saving machines, then, but not until then, striking results may be expected.

The wonderful, the revolutionary discoveries made by students of internal medicine during the nineteenth century are not always appreciated as they should be, for their results are often demonstrable only by statistics; and the dramatic rescue of individuals from certain death which the surgeon at times accomplishes, unfortunately cannot be effected by the therapist. It is not in the nature of his art. Great progress, however, has been made in the use of medicines and remedial procedures. Good reasons can be given for their employment, and their mode of action can be explained. Empiricism no longer governs their use as it formerly did. The placing of therapeutics upon a scientific basis began in the last century when the physiologic effect of drugs was first demonstrated by experiments upon animals.

No field of medical research needs cultivation so much or is more certain to yield a rich harvest than therapeutics. It is surprising that we have not a larger volume of accurate knowledge of the effect of drugs than we do possess. Of late pharmacology has been neglected

for studies which have temporarily been more enticing to experimenters, such as bacteriology and experimental pathology. Moreover, a knowledge of these subjects is essential to enable a clinician to apply his therapeutic resources to the mitigation of suffering, the support of strength, and the elimination or destruction of noxious substances. One can safely prophesy that the exact utility and the limitations of drugs and medical procedures will be defined in the present century.

To accomplish this, not only is more knowledge required of the physiologic action of drugs, but also better means of accurately measuring their effects when they are given to patients. We know when pain is relieved; we can sometimes measure effects produced upon the heart and bloodvessels and temperature. Beyond this we depend for knowledge upon the impressions of physicians, impressions which must be corrected and often reversed by a wide experience. Clinicians possess only a few appliances or methods for the exact study of the sick. It is to be hoped that more will be discovered, and that they will also make it possible to register with accuracy the effect of drugs. When this is accomplished, undoubtedly a smaller number of useful drugs will be employed, but these with greater exactness.

It is true that more drugs are used today than need be, because patients demand them as a fetish; but this will be changed when laymen learn that it is the function of the physician to teach them what to do to give nature the best chance to effect repair, what to do to make themselves comfortable and to preserve life. When they learn that it is a physician's function to teach them how to protect others from the same ailment, to foretell the possibility of recovery or death, and to avert or forestall complications. Medical men should include time and faith in their materia medica as important means of effecting a restoration of health. I do not mean faith in a fetish procured in an apothecary's shop, but faith in the wisdom, honesty and disinterested devotion of physicians which will enable them to accomplish all that can be done for the suffering.

Although the greatest discoveries in the field of internal medicine have been applicable to the prevention of illness in the masses, much has also been done to increase the chances of recovery of individuals who are sick. I need call attention only to a few of the improvements in treatment which have been effected to remind you of more. Typhoid fever, which has been a scourge in all civilized countries, and constantly present in all larger centers of population, has not only been greatly lessened, sometimes even suppressed by improved hygiene, but the chances of recovery of the one who is sick with it have been increased several fold by improved methods of treatment. Twenty-five years ago the mortality from typhoid fever in the hospitals of the world was from 20% to 35%; today it is from 5% to 15%. The better results are due to the cold baths which are used, to a more generous supply of fresh air, to proper feeding, and to protection against, or the prompt treatment of, complications.

One great therapeutic discovery has been made at the end of the nineteenth century—the discovery of antitoxins, the natural antidotes to the poisons of infectious agents. For a very long time it had been known that something developed in the human system during the course of many ailments which gave to the sufferer from them for a variable time immunity from a recurrence of the same disease. Until the existence of parasites and of poisons generated by them was proven, an antitoxin was of course unrecognizable. Moreover, the possibility of such a thing in diseases, one attack of which did not cause immunity to others, was not even suspected. But the diphtheria antitoxin, the most efficient of those of which we know anything, is one belonging to this last group of ailments. The chemical composition of antitoxins is yet to be discovered. Since antitoxin has been used the mortality from diphtheria has been reduced

about one-half. The most extensive collection* of statistics gathered from all civilized countries shows that when antitoxin is used on the first day of the disease, the mortality is 5%, increasing rapidly to 30% when used on the fourth day or later. Before its employment the average mortality of the disease was from 25 to 35%. To effect a still greater reduction in the deathrate from this ailment, it is necessary that it be recognized early, and that antitoxin be employed more generally as a preventive for those who have been exposed.

That tetanus antitoxin and plague antitoxin are valuable is admitted. Many others, such as pneumonia, typhoid, tubercle, scarlet fever, erysipelas and streptococcus antitoxins are still in the experimental stage. But even though it should be found that few natural antitoxins can be isolated for use as remedies, those already discovered confirm physicians in the hope that specifics will be found some day.

Another therapeutic discovery made at the close of the century which has thrown a flood of light upon some obscure points in physiology and pathology, and has restored to usefulness many who were formerly incapacitated and incurable, is that of internal secretions, and especially the role of the secretion of the thyroid gland. Ingredients in the thyroid, suprarenal bodies, and ovaries, produce as definite effects upon the living body as many extracts from plants or synthetic chemicals. The pituitary body, the thymus, and bone marrow may also have a value as yet undetermined. The rescue of those suffering from myxedema and cretinism by the administration of thyroid is one of the few happy dramatic incidents which fall to the lot of the practitioner of medicine.

That a much larger proportion of recoveries from tuberculosis occur today than formerly is evident from the statistics of this disease, but this lessened mortality is not due to prevention only. Trudeau has estimated that 18% of all persons have tuberculous lesions, because a reaction to tuberculin can be demonstrated in that proportion. This statement is confirmed by Councilman, who states that his autopsy statistics show that at least 17% of all who die have had this disease. But in spite of this prevalence the mortality from the ailment is lessening.

Rabies and tetanus are 2 diseases which, until recently, were thought to be incurable. Rabies can be suppressed by killing unknown dogs and by muzzling the rest. Upon this point the following statistics from England are very instructive. In 1887, 217 deaths occurred in Great Britain from rabies; in 1888, 160; in 1889, 312. A muzzling law was then enforced. In 1891 the deathrate from this disease fell to 129; in 1892, to 38. The muzzling ordinance was repealed, with the result that in 1894, 248 deaths occurred from mad dog bites, and 672 in 1895. Again muzzling was made compulsory. The deathrate once more diminished; in 1897 it was 151; in 1898, 17; in 1899, 9, and in 1900, none.

Pasteur's great discovery of a method of attenuating the virus of rabies and rendering those who have been bitten by mad dogs immune by rapidly accustoming them to stronger and stronger viruses has greatly reduced the mortality.

Tetanus, quite common in hospitals formerly, is now prevented by properly cleansing and protecting wounds. It has become so rare a disease that today most students do not see a case of it during their college course.

The nineteenth century will be known in the history of medicine as the century of experimental medicine, for it is in that field that the greatest discoveries of the age have been made. The names of Pasteur, Koch and Lister will forever be linked with it as representing its greatest achievements. But these achievements would not have been possible had not the physicist perfected the

microscope, and had not Virchow and his pupils explored the field of cellular pathology to its farthest limits. Around Virchow's name as a banner will historians gather the achievements in medicine during the early and middle portions of the century, and around Pasteur's those of its close.

If our greatest needs conditioned the growth of knowledge, we could prophesy what will be the great field of research of the twentieth century, but history teaches us that our needs can often not be met until some sister science has grown, or new methods of experimenting have been devised. Therefore, the future must remain a blank to us. However, we are more apt to accomplish what is needed if the problems are kept clearly in mind. We greatly need more exact methods of clinical study, more accurate knowledge of the effect of remedial agents and procedures, but more than all else we need a knowledge of the changes which take place in the living tissue in health as well as in disease.

The anatomist has resolved the cellular structure of the body; the physiologist, the laws which govern the action of its organs and the chemic changes which are wrought upon its surfaces; the bacteriologist has discovered the parasites that infest, and often destroy it; the pathologist has described the anatomic changes which disease produces; the clinician has linked all these facts together and has discovered ways of seeing with the intellectual eye disturbances of physiologic function, of determining their cause, and of anticipating the anatomic changes which they will produce. But this does not satisfy us; we want a knowledge of the atomic and molecular structure of cells, of the changes which take place in the atoms and molecules in health and in disease, and of the effect of medicines and remedial procedures upon them. This knowledge chemistry must give us. I feel sure that, standing as we do at the beginning of a new century, expecting greater developments in it than in the last one, we are halting before new discoveries in chemistry, waiting for new methods of studying metabolism in microscopic portions of tissue. When this knowledge is vouchsafed, medicine will make another stride as great as was made when, by the perfected microscope, cellular pathology and bacteriology became possible.

Let us look forward with confidence to the Virchow and the Pasteur of the future.

Good, Cheap Bread.—A society has been formed in Paris to promote the establishment of combination milling and baking houses in all the large French towns. It has for its object the production of 100 kilograms (220 pounds) of nutritious, digestible white bread from 100 kilograms of grain at the lowest cost, made by the Swiss system. Official analyses made by the National Agronomical Institute and by the Municipal Laboratory of Paris shows that Swiss bread contains more nutritive nitrogenous properties and more phosphates than ordinary baker's bread.

Carcinoma Inquiries.—At a recent meeting of the German Cancer Investigation Committee, held at Berlin, under the presidency of Professor von Leyden, it was reported that the material already accumulated was being analyzed and digested under the direction of Dr. Hirschberg, of the Berlin Statistical Office, and Dr. George Meyer, secretary of the Committee. It was further stated that an investigation on the lines of that organized in Germany had been undertaken in Holland, and that communications had been received by the Committee from England, America, Russia and Italy. The Berlin Assurance Institute had made a further grant of 500 marks for the year 1901. In his opening address at the German Surgical Congress recently held in Berlin, Professor Czerny, of Heidelberg, the President of the Congress, made the interesting announcement that Professor Levschin, of Moscow, has stated that a hospital for the care of cases of incurable cancer, with an institute for the investigation of the disease would shortly be established in that city. Funds to the amount of 700,000 roubles have been obtained by voluntary contributions. The results of the research carried out in the institute will be published in a special journal bearing the name of the hospital. Professor Czerny expressed a hope that a Meeenas might come forward and make the establishment of a similar institution possible in Germany. [*British Medical Journal*.]

1. Lower Uterine Segment and the Contraction Ring. W. J. SMYLY.
2. The Dangers and Diagnosis of Breech Presentation, and Its Treatment by External Version Towards the End of Pregnancy. HERBERT R. SPENCER.
3. Some Instances of Cystic Affections of the Breast, with Remarks. A. MARMADUKE SHEILD.
4. Some Remarks Upon an Analysis of 5,000 Cases of Death from Malignant Disease. E. N. NASON.
5. Erythema Multiforme and Vaccination. NORMAN WALKER.

1.—Smyly claims that the origin of the lower uterine segment is still uncertain, but that as labor sets in, the contrast between the 2 segments becomes more marked, the upper part being the contracting and the lower the distensible portion, allowing the fetus to descend; but so embracing the head, or presenting part, during the first stage of labor as to prevent the passage of anything between. This is one of its most important functions. When the lower segment does not thus embrace the presenting part, portions of the limbs or cord may be forced through, or it may cause funic prolapse. It is the unusual or abnormal development of the placenta in the lower uterine segment which leads to the dangerous condition of placenta previa. The lower segment of the uterus is the part most frequently involved in rupture. The constriction of the contraction ring may occur before, during, or after the expulsion of the fetus. But the most familiar example is the retention of the afterbirth by the so-called "hourglass contraction" of the uterus. The contraction which sometime occurs after the patient has been long in labor, is often a serious cause of dystocia and even danger. Smyly thinks it important that every practitioner should make a careful study of the lower segment and contraction ring and the dangers resulting from ignoring this subject. [W.K.]

2.—Spencer says the causes of the high rate of mortality of children in breech presentation are the low insertion of the cord leading to prolapse, sometimes asphyxiation and death, and injury to the soft thoracic and abdominal viscera from undue pressure, the soft buttocks not protecting them as does the harder head. He describes fully the method of diagnosing breech presentation by abdominal examination and its treatment by external version toward the end of pregnancy, preferably at the end of 7½ months. Contraindications to external version are multiple pregnancy, malformed uterus or placenta previa. This early diagnosis and treatment of breech presentation involves physical examination during pregnancy, and Spencer believes this examination should be a routine practice, as thus conditions may be recognized which can be obviated by timely interference. [W.K.]

3.—Sheilds reports 4 cases of cystic affection of the breast, with remarks on the diagnosis and treatment. Small deep-seated cysts often so closely simulate malignant disease that mistakes in diagnosis and treatment are not infrequent. Elasticity, variation in size and tenderness are important points in the differential diagnosis. The condition of the axillary glands is often misleading. As regards treatment, removal by dissection, followed by the establishment of sufficient drainage is preferable. Small cysts containing clear or straw-colored fluid may be treated by the injection into them of carbolic acid in glycerin. In doubtful enlargements of the breast the use of the exploring trocar and canula are advised. [J.W.M.]

4.—Nason points out what seem to be legitimate deductions from the analysis of over 5,000 cases of death from the various forms of cancer. Of these 62% occurred in the female and 38% in the male. The preponderance of female cases seems to be due to the frequency with which cancer attacks the uterus and female breast. In 40% of the female cases 1 of these 2 organs was affected. If the sexual peculiarities of both sexes be eliminated the inequality is reversed, 53% being male and 47% female cases. There is a general increase in cancer mortality and this increase is much more noticeable in males than in females. A table is given showing the percentage

in which the various organs are affected in males, females and persons. Of deaths from cancer in the male a large percentage is caused by cancer of the stomach and pylorus. Diagrams show the frequency with which the various forms of cancer occur at different ages. The following predisposing causes of cancer are mentioned: Prolonged local irritation; the immediate or after-effects of direct and sudden injury; syphilis and possibly other constitutional diseases which are associated with local tissue changes; the tissue degenerations of advancing years varying with the age; individual proclivity; the presence of fetal remnants, and the residence in the neighborhood of a sodden and sewage-soaked soil. [C.A.O.]

5.—Walker has had under observation 4 cases of erythema multiforme following a recent vaccination and all showing features which seem to make it certain that the vaccination was causally related to the eruption. The wound had entirely healed before the eruption appeared. Walker believes that a toxin is produced, which, circulating in the blood, produces erythema multiforme and especially that form described as erythema iris. [C.A.O.]

1.—Edmunds, in the second Erasmus Wilson lecture on the pathology and diseases of the thyroid gland, considers the results of removing the parathyroid glands only. From a mass of observations it seems that excision of the thyroid gland and the parathyroid glands produces enophthalmos with narrowing of the palpebral fissures; total parathyroidectomy seems to produce the same, and so also (if it produces symptoms) does excision of the thyroid gland proper; but certain operations not fatal at the time, and especially those in which the parathyroids are interfered with, may be followed by exophthalmos widening of the palpebral fissures. Experiments undertaken to ascertain whether the internal secretion of the thyroid is under the influence of the nervous system disclosed the fact that it is, and that interference with the nervous supply produces very serious symptoms; whence it follows that we must be prepared to admit the possibility of defective innervation being the cause of serious symptoms and pathologic changes. Finally, there are detailed the results of excess of thyroid gland in the body noted by different observers and by himself. [A.O.J.K.]

2.—Robinson reports some cases illustrative of thyroid gland surgery. The first refers to 3 cases of parenchymatous goiter, in which a general almost symmetrical enlargement of the thyroid gland occurs, giving rise to dyspnea on exertion and difficulty in swallowing. One case improved under thyroid extract; in the others the isthmus was removed and the lobes rapidly diminished in size. In both cases tracheotomy was necessary and in both thyroidism occurred, due to absorption of glandular secretion. He also refers to adenoma of the thyroid gland, which may be solid or cystic, bilateral or unilateral, usually the latter. The most satisfactory treatment is removal by enucleation, or by removing the entire lobe. Tapping, with the injection of iodine and drainage has been tried but is not recommended. [J.W.M.]

3.—Godlee reports the removal of a large pharyngeal pouch. The patient was a man 31 years of age, who 10 years ago first became conscious of a swelling on the left side of his neck, which moved up and down on swallowing. It disappeared and reappeared suddenly at varying intervals, and later gave rise to difficulty and pain in deglutition. By squeezing it a squeaking sound was produced and an uncomfortable sensation experienced while the tumor was reduced in size. It was tympanitic on percussion and the patient could inflate it slightly at will. It was removed by dissecting the pouch from the surrounding structures and invaginating the tubular pedicle. The communication with the pharynx was not found. These pouches arise from the incomplete closure of visceral clefts. [J.W.M.]

4.—Poore, writing of flies and the science of scavenging, advocates strongly the disposal of excreta in camps in narrow and superficial trenches, and insists that the burial of the feces must be done methodically and carefully, precisely as a gardener plants his seeds when intent upon raising crops. Some herbage may be grown and the waste water of the camp may be utilized to water the soil. He mentions many details that go to show that the method advocated is entirely practical. He believes that the presence of flies in large numbers should be a rebroach to us for not putting organic refuse to its proper use. [A.O.J.K.]

5.—Hann and Knaggs report a case of retinal detachment occurring during labor and associated with albuminuria, which condition is one of the causes of blindness during parturition. Retinal detachment during labor generally ends in recovery, while such an accident occurring during an attack of renal disease is usually a prelude to a fatal result. This accident is labor is explained as follows: During the pains the return of the venous blood must be retarded and a considerable back pressure exerted on the capillary circulation. [F.C.H.]

6.—Walsham, in an endeavor to determine whether the murmur of mitral stenosis is systolic or presystolic in rhythm, made use of combined examination by the x-ray, palpation and auscultation. He details first the x-ray appearances presented by the normal heart during the different phases of its cycle—there occurring with the auricular systole an advance to the left of the left border of the shadow, with an abrupt recession toward the median line with the ventricular systole. By the combined method of investigation it was found that the murmur in mitral stenosis begins at the moment when the shadow is advancing toward the left, that is, during the auricular systole, and that it ends abruptly when the shadow retreats toward the median line—that is, with the ventricular systole. Such examination in a number of cases of mitral stenosis have convinced him that both the thrill and the murmur are presystolic in time. [A.O.J.K.]

7.—Phillips prefers the term ophoterapy to organotherapy. The indications for the administration of thyroid, ovarian and mammary extracts are detailed. [F.C.H.]

8.—McBride discusses some questions with regard to acute otitis media, and reports a case in which an empyema of the antrum of Highmore seemed to be an important factor in keeping up a middle ear suppuration. Otitis media may arise from acute rhinitis or pharyngitis, adenoids, and the existence of adenoid tissue between and around the eustachian orifices. The treatment suggested in otitis media after spontaneous perforation, consists in the use of Politzer's bag, and in catheterization of the eustachian tube where drainage is difficult, and the nasopharynx does not contain infective material. In the question of mastoid operation, 2 conditions suggest its necessity: (1) Profuse discharge; (2) a small opening in a bulging membrane. [J.W.M.]

9.—Eve describes a form of electric light and heat bath, and reports 8 cases of osteoarthritis, in which its use was followed by the relief of pain and stiffness. The apparatus consists of 3 32-candle power lamps fixed on an aluminum base, and protected by a wire cage. A wire connects it with any lamp-holder. It may be used to heat a single limb or the entire body. The temperature of the chamber, formed by covering the cradle with several blankets, can be raised in 30 minutes from 200 to 250°, and, as a rule, the body-temperature rises 2 or 3°, especially

when the whole body is treated. The following advantages are claimed for the apparatus: (1) Little cost; (2) lightness and portability; (3) no odor; (4) high temperature; (5) the current can be obtained from the domestic electric light; (6) the production of intense light as well as heat, which is of sudorific and therapeutic power; (7) by changing the cradle the one apparatus can be used for different parts of the body; (8) the patient can be treated at his own home. [J.W.M.]

1.—The normal movement of the kidney varies from 2 to 4 cm. The technic of palpation and the 3 degrees of mobility are described. The usually mentioned etiologic factors of movable kidney are shown to have little or no influence. The essential cause lies in a particular body form. The measurements of Becker and Lenhoff are not sufficient to give a correct idea of this. More reliable results are obtained by dividing the jugulo-symphysis distance by the abdominal circumference at the level of the lowest point of the tenth rib. A more accurate index still is obtained by dividing the lateral diameter of the lower plane by that of the upper plane bounding the middle zone of the body cavity. The chief characteristic of this body form is marked contraction of the lower end of the middle zone with lessened capacity. This depresses the kidney so that the constricted outlet comes above the center of the organ and all acts, as coughing, lifting, etc., which adduct the lower ribs press on the upper pole and crowd it still further downward. Repetition of these internal traumas gradually produce movable kidney. It is never the immediate result of external trauma. The measurements of 153 patients in whom the kidney was palpable are tabulated. In cases requiring operation the tendency has been to fix the kidney too high up. This may cause recurrence or, if not, more severe symptoms than the original condition. The selected location should depend on body form. The author's operation for contracting the pouch in which the kidney moves is described. [H.M.]

2.—The presence and character of the cecum and vermiform appendix in various mammals, birds, reptiles and fish are noted. Carnivora, as a rule, have an appendix. Herbivora possess a rather large cecum. The continued presence of the latter in the higher orders of vertebrates is nature's attempt to use an organ that has lost its original function. The anatomy of these organs in man with the greater development of the appendix in infancy and of cecum in middle life is described. [H.M.]

3.—American medical schools should give the same recognition as the European in their curriculum or requirements to the practical and intimate relation of zoology to disease and public hygiene. As in the fields of chemistry and botany special attention is given to toxicology and bacteriology, so should we have courses on animals which produce disease including lectures and laboratory work. This would include lectures on the protozoa of various fevers, etc., and disease-producing worms and insects. Knowledge of these is of added importance, owing to the growing dissemination of tropic diseases. The subject of animal parasitism should be treated either by a professional zoologist or by a physician with general zoologic training. [H.M.]

4.—The paper opens with an account of the discovery of **antipneumococcal serum**. Conflicting opinions are quoted, but it may be concluded that it is not a bactericide but prevents the development of symptoms due to the formation of pneumotoxin, either by rendering it inert or by counteracting its effects. It is prepared much the same as diphtheria antitoxin and treated with trikresol. The statistics of cases treated are reviewed and 6 new cases reported. When those with complications, etc., are excluded, the mortality is 4.7%. Its value is indicated by the increase of leukocytes in the blood. It will prevent toxic symptoms if given before the advent of the pneumococcus in the blood which occurs on the third to fifth day. It does not affect the lung except possibly preventing involvement of new areas. [H.M.]

5.—Statistics of these injuries are given, showing their frequency. Ligaments are rarely torn and never stretched. There is rupture of areolar and connective tissue around the joint and contusion of the lining. In muscular **sprains** there is rupture of the tissue elements. Muscles continue functioning when immobilized, and waste products should be removed. In **sprains** there should be passive exercise the first few hours or days and active exercise after that. In the majority of cases active exercise is indicated from the first. Plaster casts should be used only when needed to maintain proper position after fracture. Ice compresses the first few hours, followed by hot fomentations or the Scottish douche are of great value. Static electricity with massage is the best treatment for a strain. The average time for recovery from ankle sprains is from 6 to 12 days. [H.M.]

6.—In **children** the **symptomatology of appendicitis** is more complex and indefinite than in later life. The position of the cecum is more indefinite, its lax attachment to the iliac fascia allowing greater range of motion. In childhood, intussusception and tubercular peritonitis are the 2 diseases most likely to be confounded with it. Floating kidney, perinephritic and psoas abscess, and typhoid fever are also mentioned. Umbilical abscess is generally of appendiceal origin. Pressure on the ureter, or perforation into the bladder, may lead to wrong diagnosis. Examination of the blood has no practical value in diagnosis. Physical examination reveals flexion of the right leg, abdominal distension is generally present, and with peritonitis the respirations are frequent and shallow. In most cases tumefaction is made out. Deep puncture is unreliable. By rectal examination under an anesthetic any localized fulness below the umbilicus may be made out in a child under 10 years. The constitutional symptoms are those of peritonitis. The disease often begins with symptoms of obstruction. Three types or stages, with symptoms and physical signs, are described: Acute appendicitis in the congestive or plastic stage; appendicitis with gangrenous, ulcerative perforation and suppurative typhlitis; and perforation of the appendix directly into the peritoneal cavity. In the first type, free evacuation of the bowels and bladder will often establish convalescence. The second type seldom presents urgent symptoms except when there is fecal extravasation or great quantities of pus burrowing into the retroperitoneal tissues, or bursting of the pyogenic membrane into the peritoneal cavity, when the patient may sink from toxemia in spite of operation. In the third, could we always determine when perforation occurs, probably every life might be spared. [H.M.]

7.—In 632 cases of **tuberculosis** seen by Kinney in private practice, with the exception of those following pneumonia, 88% gave a history of gastric or intestinal disturbance existing from 3 months to several years before involvement of the lung. In the remaining 12%, cases of over 3 years' duration, there was marked digestive disturbance. The trouble was intestinal in 78% and gastric in 22%. The history is often difficult to elicit owing to the absence of pain, especially in the intestinal cases, patients being unobservant frequently of other symptoms. The essentials of perfect digestion are a proper anatomic and physiologic condition, proper foods and applied nerve force to run the digestive apparatus. Depleted conditions result from improper proportions and quantities of foods and from eating in conditions of physical exhaustion. The practitioners should always think of food before medicine and give it the place of

importance in his directions. In the treatment of tuberculosis the nitrogenous foods are essential. The importance of the early diagnosis of digestive disturbances, of the study of dietetics and of the education of patients and public are considered in relation to prophylaxis.

Medical Record.

June 1, 1901. [Vol. 59, No. 22.]

1. The Diagnosis and Surgical Treatment of Prolapsed Kidney, with Demonstration of a Simple Method of Examination for its Detection. AUGUSTIN H. GOELET.
2. The Climate of Long Island. LE GRAND N. DENSLOW.
3. Superheated Air in the Therapeutics of Chronic Catarrhal Otitis Media. GEORGE W. HOPKINS.
4. Three Cesarean Sections: Recovery. J. F. BALDWIN.
5. Ether as an Anesthetic. EDWARD JUDSON WYNKOOP.
6. A Few Observations from the Lorenz Orthopedic Clinic. LEONARD W. ELY.
7. Case of Membranous Angina, due to Streptococci, followed by Paralysis of the Soft Palate. MOSES KESCIENER.

1.—Goelet believes that the **examination for the detection of a prolapsed (movable) kidney** should be made with the patient standing and with the body inclined slightly forward so as to relax the abdominal muscles. The examiner sits in front and a little to the right of the patient, grasps the right loin with his left hand, with the 4 fingers behind the right lumbar region and the thumb in front just below the border of the ribs. The patient is now directed to take several deep inspirations and to expire to the extreme limit. When expiration is complete he presses the thumb well into the abdominal wall under the ribs, depressing it as much as possible so as to reduce the space between it and the fingers posteriorly. If the kidney is out of position, it must be below his thumb, and he can feel the kidney slip into position as it is pushed upward by the fingers of the right hand. His observations have led to the following conclusions, viz.: (1) That prolapsed kidney is more frequent than is generally supposed; (2) that it is often not suspected, because it does not always give rise to symptoms directly referable to the kidney; (3) that frequently it is not discovered because, by the usual methods of examination, only an expert can detect it unless the kidney is much enlarged or the subject is thin and the abdominal wall relaxed; (4) that palliative measures are of no avail and therefore useless and unwise if the degree of prolapse is sufficient to produce symptoms; (5) that lumbar fixation is the correct method of treatment when there is no contraindication; the operation being simple, devoid of risk, and successful when properly executed and the patient is given careful preparation and proper attention during convalescence, extending over a period of several months. [C.A.O.]

2.—Tables of mean temperature, frost, precipitation, sunshine, cloudy days and relative humidity for many **health resorts** on the Eastern and Western coasts and interior of the United States are given, showing the marked advantages of Eastern and Southern **Long Island** in these respects. The geologic conditions with reference to drainage and pure water supply are also shown to be very favorable. Its best field would be in heart, lung, kidney and rheumatic troubles in which a sunshiny, dry, slightly stimulating climate at a low level is desirable, in which from May till October almost every day may be passed out of doors with comfort. [H.M.]

3.—**Superheated air** was first used 4 years ago by the author in a case of **ankylosis of the ossicles** and since then in 62 characteristic cases with but 4 failures. The ear is cleaned, packed with gauze, a gauze pad placed externally, and then covered with a canvas-sleeve hot air conductor, and the temperature gradually raised to 400°; a gas or oil room-heater and a funnel shaped top being used. There must be a perforation in the sleeve near the ear for the removal of dead air. The contraindications are arteriosclerosis, serous effusion into the tympanum and perforation of the latter. The intense heat seems to stimulate the circulation, causing absorption of articular deposits, removing atrophy and relieving rigidity of the tensor tympani. [H.M.]

4.—Baldwin reports 3 cases of Cesarean section: the first, in 1889, was by Porro's method, the first operation of the kind in

Ohio. In the other 2, the incision was made transversely across the fundus, the child delivered, incision sutured, and fallopian tubes removed into the horn on each side so as to prevent future pregnancies. The children all lived and the mothers recovered. [w.k.]

5.—Wynkoop, in discussing the subject of ether as an anesthetic, arrives at the following conclusions: (1) Ether from its physiologic action is the safest of anesthetics; (2) more care is necessary in preliminary examinations, and more care in regard to the position and condition of patients during narcosis; (3) a good inhaler, the simpler the better, is needed, with fresh ether made by a reliable firm, and for this purpose the small ½-pound cans are the best; the ether is to be added in small quantities frequently, beginning the narcosis with the inhaler a short distance from the patient's face and gradually bringing it down; (4) the more detailed study of this important subject is called for in our schools and hospitals; (5) the presence of a trained anesthetist at all operations is necessary. [C.A.O.]

6.—Ely gives a few observations from the orthopedic clinic of Lorenz in Vienna. He says many of our well-established ideas are ridiculed, and appliances adopted which we would consider clumsy and unscientific. Where we use plaster Lorenz uses a brace, and for our brace he substitutes plaster. In spinal caries he advocates the use of a corset made of perforated celluloid, strengthened by metal bands. In the treatment of diseases of the other joints, plaster is the favorite material. A plaster spica is used in hipjoint disease. Lorenz is particularly noted for his treatment of congenital dislocations. Much of his work is done without the use of the knife, and the results are at times brilliant. He looks forward to the time when these patients will be brought earlier for operation, and believes that failures then would be few. [C.A.O.]

7.—The patient presented the classic symptoms and signs of local diphtheria, with profound systemic infection shown in maniacal delirium. Repeated examinations at the hospital and New York Health Department excluded the Klebs-Loeffler bacillus. Paralysis may have been due to pressure from the inflammatory process, or from a toxic neuritis generated by the streptococcus. [H.M.]

Philadelphia Medical Journal.

June 1, 1901. [Vol. 7, No. 22.]

1. Two Successful Cases of Secondary Suture, 1 of the Posterior Interosseous Nerve and 1 of the Median and Ulnar Nerves. W. W. KEEN.
2. Pancreatitis. A. W. MAYO ROBSON.
3. The Examination of the Blood in Relation to Surgery of Scientific, but Often of no Practical Value, and May Misguide the Surgeon. JOHN B. DEEVER.
4. Complicated Fractures, Their Diagnosis and Treatment. THOMAS H. MANLEY.
5. Pityriasis Versicolor, with Special Reference to Allen's Iodin Test. JACOB SOBEL.
6. The Biceps Tendon Jerk in Locomotor Ataxia. MOSES BEHREND.

1.—Keen reports 2 successful cases of secondary suture of nerves. In the first case there was division of the posterior interosseous nerve and common extensor muscle of the fingers, followed by total loss of extension of the fingers; suture after 3 months; entire restoration of function. In the second case the median and ulnar nerves were divided; secondary suture after 6 months; entire recovery. [C.A.O.]

2.—See page 335, Vol. 1, No. 8, AMERICAN MEDICINE.

3.—See page 292, Vol. 1, No. 7, AMERICAN MEDICINE.

4.—Manley discusses the following points in speaking of the diagnosis of complicated fractures: (1) History of case; (2) inspection of patient; (3) posture, attitude or position; (4) manipulation, palpation, pressure, torsion, and traction; (5) narcotic relaxation of the muscular system; (6) x-rays; (7) exploratory incision; and (8) a consultation. In the treatment of those fractures not attended with marked displacement, he does not use splints, and reports most satisfactory results. [C.A.O.]

5.—Sobel, in his paper on pityriasis versicolor, says the old theory that only hidden parts are affected is no longer tenable.

He believes Allen's iodine test to be of great value not only for class-room demonstration and for bringing into relief pale and hidden lesions of pityriasis versicolor, but also for differentiating parasitic or presumably parasitic skin affections from those of a nonparasitic nature. Recurrences are in the main due to the overlooking and nontreatment of the suprapubic region and to the use of desquamative agents to the exclusion of penetrating ones. Both must be combined if a cure is desired. Tuberculous subjects, while affected in great measure on account of the hypersecretion of sweat, do not form the greater part of these patients. It occurs in all degrees of health and disease, a marked hyperidrosis, however, predisposing towards it. Children and the very old are occasionally, though rarely, attacked. It may occur in all shades from a very light pink to almost coal black (pityriasis nigra), the color being influenced by the condition of cleanliness, the circulation of the skin, the occupation of the patient, and the color of the underclothing. [H.H.C.]

6.—In an article on the biceps tendon jerk in locomotor ataxia, Behrend states that the ataxia in the arm is, as a rule, more marked when the biceps tendon jerk is absent and is usually marked when the same is found in the legs. In these the biceps tendon jerk is absent. In the presence of the biceps tendon jerk with slight ataxia in the arms, ataxia in the legs is invariably well marked. Sensation is usually normal in those cases with normal biceps tendon jerk, and the sensory losses are usually found when the biceps tendon jerk is absent. Arthropathies are only found in the advanced cases and astereognosis is only present in the markedly ataxic. The loss of the sense of position is almost constant in the advanced cases of tabes and the shooting pains in the arms bear no relation to the degree of ataxia. The marked ataxics seldom show the loss of weight sense. The intensity of the symptoms is not dependent on the duration of the case, but rather upon the extent of the sclerotic process. [H.H.C.]

THE PUBLIC SERVICE

Health Reports.—The following cases of smallpox, yellow fever and plague, have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended June 1, 1901:

Changes in the U. S. Marine-Hospital Service for the 7 days ended May 30, 1901:

CARTER, H. R., surgeon, to inspect the local quarantine station at Baltimore, Maryland—May 25, 1901.
 WOODWARD, R. H., surgeon, granted 2 weeks' extension of leave of absence from May 26—May 25, 1901.
 VAUGHAN, G. T., surgeon, detailed as delegate to represent the service at the meetings of the Association of Military Surgeons of the United States, May 30; and American Medical Association, June 4, at St. Paul, Minn.—May 27, 1901.
 COBB, J. O., passed assistant surgeon, relieved from duty at Fort Stanton, N. M., and directed to proceed to Portland, Oregon—May 29, 1901.
 WERTENBAKER, G. P., passed assistant surgeon, detailed to represent the service at meetings of the Association of Military Surgeons of the United States, May 30; and American Medical Association, June 4, at St. Paul, Minn.—May 27, 1901.
 GARDNER, C. H., passed assistant surgeon, detailed to represent service at meeting of the Washington State Medical Society at Seattle, Wash., June 16 to 20, 1901, inclusive—May 27, 1901.
 DECKER, G. E., assistant surgeon, granted leave of absence for 10 days—May 28, 1901.
 HOB DY, W. C., assistant surgeon, to proceed to Thomson, Ga., for special temporary duty—May 27, 1901.
 HARGIS, J. W., acting assistant surgeon, granted leave of absence for 4 days from May 26—May 27, 1901.
 OLSEN, E. T., hospital steward, granted leave of absence for 15 days from June 13—May 22, 1901.
 SPANGLER, L. G., hospital steward, to proceed to Delaware Breakwater, Del., and report to medical officer in command for duty and assignment to quarters—May 28, 1901.

Appointment.

SPANGLER, LEWIS G., of Ohio, appointed junior hospital steward in the United States Marine-Hospital Service—May 27, 1901.

Changes in the Medical Corps of the U. S. Navy, for week ended June 1, 1901:

DIXON, W. S., medical director, commissioned medical director from April 28, 1901.
 HERNDON, C. G., medical inspector, commissioned medical inspector from April 28, 1901.
 ARMSTRONG, E. V., passed assistant surgeon, detached from the Vermont, May 20, and ordered to the Key West Naval Station for duty with detachment of marines at Dry Tortugas, Fla., as relief of Assistant Surgeon R. B. Williams.
 LIPPITT, T. M., assistant surgeon, ordered to the Washington Navy Yard, June 1, as relief of Assistant Surgeon W. M. Garton.
 WILLIAMS, R. B., assistant surgeon, detached from duty at Dry Tortugas, Fla., June 3, and ordered home and to hold himself in readiness for sea duty.
 IDEN, J. H., assistant surgeon, ordered to duty at the naval hospital, Chelsea, Mass.
 MORRIS, C. Jr., assistant paymaster, detached from the Abarenda, upon reporting of relief, and ordered home and to wait orders.
 GOODHUE, E. E., assistant paymaster, detached from the Mare Island Navy Yard, June 10, and ordered to the Abarenda, as relief of Assistant Paymaster C. Morris, Jr., via the Philadelphia.
 COSTIGAN, J. F., passed assistant surgeon, detached from the Yorktown and ordered home and to wait orders; resignation to be accepted after arrival home.
 GARTON, W. M., assistant surgeon, detached from the Washington Navy Yard, June 1, and ordered to the Indiana.
 IDEN, J. H., assistant surgeon, appointed assistant surgeon from June 4, 1901.
 SHIFFERT, H. O., assistant surgeon, ordered to the Nashville.
 THOMSON, E., assistant surgeon, detached from the Petrel and ordered to the Solace.
 MCCLANAHAN, R. K., assistant surgeon, ordered to the Culgoa.

Changes in the Medical Corps of the U. S. Army for the week ended June 1, 1901:

The following assignment of medical officers is ordered: Major John R. Hereford, surgeon, to duty at Balanga, province of Bataan; Major Wm. H. Cook, surgeon, to duty at Santa Ana, province of Pampanga; Captain Frank W. Dudley, assistant surgeon, to duty at Orani, province of Bataan.
 LONG, Captain CLARENCE H., assistant surgeon, will proceed to Carangan, province of Nueva Ecija, P. I., for duty.
 COMEGYS, Major EDWARD T., surgeon, is relieved from command of the 1st reserve hospital, Manila, P. I., and is granted leave for 3 months on surgeon's certificate, to take effect upon arrival in the United States.
 GLENNAN, Major JAMES D., surgeon, now in Manila, is assigned to the command of hospital No. 3, Manila, relieving Major John S. Kulp, surgeon.

HEIZMANN, Lieutenant Colonel CHARLES L., is granted leave for 1 month and 14 days, with permission to visit Japan.
 BRATTEN, Captain THOMAS S., assistant surgeon, is relieved from duty on the transport Indiana and will report for duty at the Santa Mesa Hospital, Manila, P. I., for duty, relieving First Lieutenant Percy M. Ashburn, assistant surgeon, who will report at 1st reserve hospital, Manila, P. I., for duty.
 BARTLETT, COSAM J., contract surgeon, will proceed to the Presidio, for duty at the Army and Navy General Hospital.
 MOSES, HOMER C., contract surgeon, will proceed to the Presidio for temporary duty.
 GARRETT, NEVIL M., contract surgeon, Fort McDowell, will proceed to his home, Frankfort, Ky., for annulment of contract, at his own request.
 LAINE, Major DAMASO T., surgeon, is granted leave for 1 month, with permission to go beyond the limits of the department of Cuba.
 HENDERSON, CLINTON F., hospital steward, Fort McDowell, will be discharged by way of favor.
 BELL, JOSEPH L., contract surgeon, is granted leave for 15 days.
 PLUMMER, Captain G. R., assistant surgeon, is granted leave for 1 month, with permission to go beyond the limits of the department of Cuba.
 KENDALL, Major WILLIAM P., surgeon, having reported his arrival in New York City, will repair to Washington, D. C., on business pertaining to the medical department of the army, and upon the completion thereof will proceed to Fort Slocum.
 HATCH, HERBERT W., contract surgeon, is relieved from duty in the department of Alaska, and will proceed to San Francisco, Cal., and report by letter to the surgeon general of the army for annulment of contract.
 COLLINS, First Lieutenant CHRISTOPHER C., assistant surgeon, is relieved from further duty at the United States general hospital at Presidio, and will proceed to Fort Bayard and report at the United States general hospital for duty.
 SMITH, ARTHUR B., contract surgeon, is relieved from duty at the United States general hospital, Fort Bayard, to take effect upon the arrival at that hospital of First Lieutenant Christopher C. Collins, assistant surgeon, and will then proceed to his home, Ravenna, Ohio, for annulment of contract.
 STONE, FRANK P., contract dental surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report for transportation to Manila, P. I., where he will report for assignment to duty.
 HESS, First Lieutenant LOUIS T., assistant surgeon, is relieved from further duty at the United States general hospital, Presidio, and will proceed to Fort Bayard, and report at the United States general hospital at that place for duty.

AMERICAN MEDICINE

1321 Walnut Street Philadelphia

Cable Address—AMMEDIC, Philadelphia

Subscription Price - - - - Four Dollars a Year in Advance

Postage in the United States and Canada, Mexico, Hawaii, Guam, Porto Rico, and the Philippines, free; foreign postage, \$2.50. Subscriptions may begin at any time. Volumes end with the last issues of June and of December.

News.—Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to members of the medical profession. We shall be glad to know the name of the sender in every instance.

Original Papers.—Articles are accepted for publication with the understanding that they are contributed solely to this journal.

Correspondence on all matters of clinical interest, particularly with reference to therapeutics, will be welcomed. Unobjectionable questions concerning formulas, treatment, etc., will receive attention in the department of Practical Therapeutics.

Copyright.—Matter appearing in AMERICAN MEDICINE is covered by copyright, but usually no objection will be made to the reproduction of anything appearing in its columns if the author's consent is obtained and proper credit is given.

Illustrations, such as half-tones, zinc etchings, etc., as in the judgment of the editor are necessary to illustrate articles, will be furnished when photographs or drawings are supplied by the author.

Reprints (250) of Original Papers will be furnished gratis to authors making the request. Covers to these and extra reprints will be furnished at net cost.

Advertisements.—Advertising forms go to press 8 days in advance of the date of issue. Therefore, in sending in copy, time should be allowed for setting up advertisements and for the sending and return of proofs. The advertising-rate is one dollar per page per thousand of issue. Double prices for preferred positions.

Change of Address.—In ordering a change of address it is important that both the old and new addresses be given.

Remittances.—Remittances should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to American-Medicine Publishing Company. Address all correspondence to 1321 Walnut Street, Philadelphia.

JUNE 15, 1901

\$4.00 PER ANNUM.

The St. Paul Meeting of the American Medical Association was the best that has ever been held. We know that the elation following each annual meeting makes such praise habitual, but there is a unanimity and emphasis this year that we have never seen equalled. This feeling is undoubtedly due to the acceptance of the new Constitution and By-laws prepared by the committee on reorganization, and to the limitation of the number of papers on the programs, whereby there was gained more time for the consideration of each, with a resultant improvement of the entire scientific work. There was a thorough leveling-up of the standards most gratifying, and this is better than the straining after brilliant discovery or incomplete research. Those who attended the section-meetings came away with a consciousness that much indefiniteness had been cleared up and many perplexing questions, if not settled, at least put in the way of decision. There was everywhere manifest the desire to limit the social features, and the politics and discussions of the general sessions, and to regret that the section-work had to be interfered with. Under the new order of proceedings next year this will be done, as after the first day the general sessions will not interrupt section-work. The profession of St. Paul and Minneapolis greeted the Association members with a hospitality and perfection of arrangements which insured the gratitude of every visitor.

The Reorganization of the American Medical Association, according to the recommendations of the Committee, is a cause for profound gratification. The long labors of the Committee, motivated by the sincerest desire to put the Association upon a basis that would insure reform and progress, ended in a wise general plan and a perfection of detail that disarmed criticism and reduced opposition to a minimum. Before the session had convened that so quickly adopted the new Constitution and By-laws, hardly anyone supposed the body would have so soon found its mind and heart at once, but when the strongest opponents, feeling that the inevitable was upon them, seconded the motion for adoption, there were few negative votes left. The chief advantage of the new business arrangements is that the real legislative work of the Association will hereafter be confined to a compact body of about 150 delegates, elected for that purpose by the local State organizations. The Association will thus get its work done, the legislation and business by men selected directly as representa-

tives and sitting uninterruptedly for those ends, while the scientific programs will be carried out by those who come to the meetings with such objects in mind. Dr. Reed has been an exceptionally able and effective President, and under him has been instituted a reform which will, we prophesy, vastly increase the power and growth of the Association.

Success in Desperate Cases by Conservative Treatment is the lesson often repeated, and yet never quite sufficiently learned by any physician or surgeon. The infinite ingenuity behind the healing processes, the never-renounced struggle toward normality is an ever-renewed source of wonder. All that is needed to elicit it is confidence in it, delay in doing anything radical, watchfulness to follow up the hints to action as they begin to show themselves. We know of a living and happy patient who ten years ago had albuminuric retinitis from long-existing Bright's disease, despite what all the textbooks say as to "two years" in such cases. "Don't do the irrevocable thing until forced to do it," is the warning that has saved many organs and lives. Above all, never proceed with surgery ("the despair of medicine") until physiologic and medical methods have been exhausted. The *Wiener klinischer Wochenschrift* tells of the success of Herr Heller, director of an asylum for the blind, in educating the remnant of visual power retained by a "blind" child. There was only perception of light in a narrowed field left, but this, by education, was made to yield such indications to the eager mind that after fourteen months of endeavor the boy has very useful vision, can distinguish colors and forms, and even can read. There are possibly thousands of blind people who have renounced vision instead of cultivating it to a degree that would render the blind types useless.

The Selection of Summer Clothing is a matter of considerable importance not only from the influence it may have in comfort, but also in promoting health. Yet this is a matter to which most people give comparatively little attention, and the question of style and appearance is certainly more considered than the effect on health. From the hygienic standpoint we are concerned with the questions of what form and quality of clothing will maintain the proper body-temperature, protect from changes of temperature and absorb the sweat with the excretory products contained in it. In both summer and

American Medicine

winter, as a general rule, too much, too heavy, and irrational clothing is worn by most people. This keeps the body overwarm, and promotes free sweating, thus the skin is most of the time kept covered with moisture, but a condition in which it reacts most readily to changes of temperature and which is liable to become suddenly chilled. The frequent summer coughs and colds, most of them, arise in this way. Besides weight of clothing, the ventilation of it is very important. Goods of loose texture, loosely fitting, and without constricting collars or bands allow free circulation of air and escape of perspiration vapor. Clothing which is not properly ventilated retains a layer of steam-like perspiration which gives a feeling of oppression. The sweater is an example of a properly ventilated garment, and every athlete knows how warm and comfortable a sweater is. Its loose mesh permits of free escape of perspiration, the skin dries rapidly, but without becoming cold. Very little clothing is needed to maintain the bodily temperature in summer, but it is necessary to protect against sudden changes in our changeable climate. Wool, cotton, linen and silk each have their enthusiasts and advocates. Experience has very certainly shown that woollen garments are better adapted to protect those whose occupations subject them to very sudden and considerable changes of temperature, especially if accompanied with much exertion. But it is unfortunate that practically no light loose mesh woollen undergarments are to be had that have any durability; and thus for persons engaged in sedentary occupations the lighter cotton and linen mesh are better adapted. For both cleanliness and health very frequent changes of undergarment are needed, thus keeping the skin in the very best condition to eliminate as much waste matter as possible, and this is fully as important as the material of the garment worn.

Less clothing, looser mesh garments, fewer stiff collars and constricting bands are needed reforms in summer clothing for our hot cities. If sensible people will demand such clothing, the demand will not long remain unsupplied and what sensible people wear soon becomes to a certain degree at least, the fashion. A better perception of light and heat is to be had by wearing less clothing.

Major surgery should be done in hospitals; few will question this, though at present there is still a good deal of work done by some surgeons with large private practices in the homes of their patients. A surgeon of great reputation and experience recently made the statement that within a month he had been able to save the lives of two patients who would certainly have died had they not been operated upon with all the facilities of a hospital immediately at hand. In the surgery of the present day, perfect aseptic technique is the factor of greatest importance. For the proper preparation of dressings, sponges, sutures, ligatures, etc., for the sterilization of instruments, the preparation and after care of the patient, and for a thousand other details, the busy surgeon must chiefly depend upon his assistants. Most operators have their own special methods which they prefer for preparing supplies for operation, and few care to depend upon the sterilized materials which are everywhere for sale. Trained assistants accustomed to the

operator's methods and specially prepared materials are hard to find outside of hospitals, and on these depends much of the most important part of operative technic. The management of large public institutions for the selfish interests of a few men is an evil not infrequently seen, but because some men misuse the opportunities entrusted to them for the public good is no reason why such public institutions should not exist. In our large cities the hospital facilities are for the most part of a good as any in the world, and even in smaller towns of ten thousand inhabitants many little cottage hospitals are

being built. More of these smaller hospitals are specially needed to provide for emergency cases such as acute appendicitis, intestinal obstruction, or ruptured extrauterine pregnancy, in which the delay necessary to transport patients to a distant city would prove fatal. If properly administered, such hospitals will be not only a means of saving lives, but will be a convenience and a help for the entire profession. It is difficult to understand how a surgeon can consent to operate in a critical case at the patient's home if it is possible to take advantage of the conveniences of a good hospital. I refer to no papers on the subject of the program of the Chess Club. The mental breakdown of three of the world's greatest chess players suggests queries as to the value of chess as a game and especially as to the evil of exhibitions (and match games). There is something highly abnormal in the powers demanded in championship games. Clearly the game of chess is not worth the candle of sanity and life. The military, medieval, and royal types of life upon which the imitation battles are founded, are, moreover, no longer desired in modern civilization. Evolution has gone beyond all that, and the commercial, scientific, and democratic ideas of civilization are so different that the mental exercises that mimic and stimulate the old and outworn phases of human activity are precisely those that do not conduce to progress and success. Peasants are no longer pawns; castles are in ruins; and if a king is checkmated, why, there are thousands of better men fitted to rule under the title of President, Governor, etc. Physiologic or biologic problem-solving is not helped by the peculiar intuitions and ingenuities of the chess player.

A resolution according to the recommendations of the Association of the Little Knowledge of the History of Vaccination would extinguish the rabidity of all but the wildest antivaccinationists. Will not some one write such a history designed for popular use and scatter it broadcast over the world? Every year intelligent legislators and governors have to fight the shameless attempts of the fanatics to enact laws for breeding smallpox and killing the innocent by bit. Yet a half-hour's reading of the history of smallpox and its ravages before the time of Jenner should deny in any but those of unsound mind that the vaccination of the world has been free from its greatest curse. In 1707 for instance, 86% of the inhabitants died of smallpox in London; from 1660 to 1679 it killed 14,170 per million, and remained at about this figure for over 100 years. Similar figures or estimates are made for the whole world. Serpents and crawling people could not get employment if they had not had the disease. How is it with us now? In Russia where

vaccination and revaccination has been compulsory since 1874 the mortality has been reduced to 7 per million and in the army where the law is absolutely carried out there has been no smallpox mortality at all for many years. The only answer the cranks have to such facts is that the disease is a filth-disease and that its cessation is due to sanitation, etc. Of course we know that all the filth in the world could not generate the disease without the specific poison. How the argument of sanitation and isolation worked in Gloucester, England, in 1895-6 is well known to all. In a largely unvaccinated town of 42,000, there were 1,979 cases and 434 deaths. If the antis could only be allowed their will on themselves without endangering the rest of the world the logic of fact would soon be most convincing!

Coffee and Tobacco.—If we form a comparative table of the average number of pounds of tobacco and coffee consumed per inhabitant we find the figures as follows:—

Country.	Tobacco.	Coffee.
Holland	6.92	23.00
United States	4.40	10.55
Denmark	3.70	15.00
Belgium	3.15	11.00
Germany	3.00	6.00
France	2.05	4.00
England	1.41	1.00

We thus see that as a general rule the consumption of coffee and of tobacco increases in nearly a uniform ratio throughout the civilized world. The apparent exceptions would probably disappear with more accurate statistics. The figures suggest some intimate physiologic law or necessity of the organism underlying the fact, and this is made apparent when one observes the money the world spends in these two items. Of coffee alone, there is annually consumed about 1,500,000,000 pounds, of which our country uses more than one-half, *i. e.*, more than all the rest of the world.

The Cause of Cancer.—By a curious coincidence, there have appeared almost simultaneously two important articles, or monographs, on the cause of malignant tumors; one in the United States, by Gaylord, of Buffalo, the other in Germany, by Schüller, of Berlin. This remarkable synchronism reminds us of the discovery of Neptune, accomplished almost at the same moment, but independently, by Adams and Leverrier. Whether the observations of the two pathologists will bear the scrutiny of time as well as the discovery of the two great astrophysicists is not altogether removed from the realm of doubt. We have already referred to Gaylord's studies, and shall at this time speak primarily of those of Schüller.

In a brief communication dated March 15, 1900, Schüller announced that by a happy circumstance he had succeeded in cultivating from sarcoma and carcinoma a well-defined parasite, probably animal in nature. By selective methods of staining, he had also been able to demonstrate the presence of this parasite in all tumors examined, and had undertaken animal experiments; but at the time of the preliminary communication these were not in a state of completeness, and a further

detailed report was promised. This has just appeared in the form of a monograph of 128 pages, with three plates and 64 text illustrations. It contains a description of the parasite discovered by the author, of the methods of cultivation, and of the results of animal experiments.

The failure of others to discover the cause of cancer Schüller ascribes to improper methods of study. He cultivated the organism in the tumor tissue itself, in the following way: Immediately upon the removal of the tumor, while the latter is still warm, a piece is cut out of the center and placed in a sterile glass vial, which is at once transferred to an incubator and kept in the dark at 37.50° C. In his earlier investigations, Schüller introduced the vial into the peritoneal cavity of an animal, but found that a well-regulated incubator would satisfactorily replace the living body. After a few days colonies appear on the sides of the bottle, in the form of fine, sago-like granules or droplets. Under the microscope these colonies are seen to be made up of large, golden-yellow capsules, occurring singly or in chains or masses; and of small, spherical bodies, having a dark greenish-yellow or greenish-brown color, and a radially striated margin. There are only minor differences between the capsules obtained from carcinoma and those from sarcoma. Those from the former appear to be a little smaller, and their walls are less thick. In the protoplasmic contents of the capsules a nucleus can sometimes be seen. The contents of some are granular, of others made up of small angular or rounded bodies. These latter increase in size and stretch the capsule until it bursts at one or more points, giving the bodies their freedom. This represents a cycle of development, and the small bodies are the young organisms of the parasite. In the hanging drop the small bodies are golden-yellow, and invariably strongly lustrous. The border is double-contoured, and presents a radial striation. The organisms also possess cilia, by means of which they keep up a constant wavy motion. Peculiar appearances are produced by the degeneration and disintegration of the parasites. The cultures may be kept alive for months by the addition of fresh normal human blood. On the addition of rabbits' blood the organisms die. Careful studies of organisms suspended in human blood were made by means of the hanging drop. Various phases of development could be traced by that way. The color of the organism, which seems to be an invariable characteristic, is produced by a ferruginous pigment of the nature of hemosiderin. By the examination of teased preparations, on a warm, sterile slide kept upon a warm stage, the organisms could always be demonstrated in fresh tumor tissue. The parasites were also found in the urine of a patient in whom a carcinoma of the uterus had ruptured into the bladder. For the demonstration of the parasite in sections, it seemed most satisfactory to clear the tissue in one of the ordinary oils (especially oil of lavender) without preliminary staining. For purposes of staining, hematoxylin-alum was most serviceable. The striking features in all sections are the large capsules, which occur in rows or as a meshwork throughout the tissue, often forming honeycomb-like structures. In some carcinomas what appeared on superficial examination to be trabeculas of connective tissue, on careful study proved

to be made up of compact rows of capsules. In the neighborhood of the capsules young organisms are found in abundance. In the hardened tissues the form of the latter is considerably altered by pressure and contraction. They frequently permeate the tissues in long rows, and occur between as well as within the cells. They are found not alone in the original tumor, but also in the regional lymph-glands, even in such as present no macroscopic alteration. Schüller thinks that they may be carried to the lymph-glands within epithelial cells, the multiplication of which they stimulate in the new environment; yet he is inclined to revive the long-abandoned hypothesis of a metaplasia, and to assume that the parasites are capable of causing a transformation of connective tissue cells into epithelium. Numerous parasites in the capsular and the free stage are constantly found in the pearly bodies of the epitheliomas. Studies of the border zones of carcinomas give an insight into the earliest phenomena of cancer development, and show that the parasites bear a most intimate etiologic relation to the tumor growth.

The animal experiments, the details of which are only briefly given, were made with the sterile cultures obtained in the manner previously described. In order to exclude the possibility of transplantation of tumor tissue, the material was taken from vials in which the cellular elements had been entirely destroyed and dissolved. One experiment, in which the injection was made directly into the kidney, gave rise to the development of a carcinomatous nodule in the organ. The cells of the growth contained the young parasites, as well as the capsules. Even the appearance of epithelial pearls was produced. In the same animal, the lymphatic glands in the neighborhood of the portal vein showed alterations that could be interpreted as incipient carcinoma. In some of the animals which had received intraperitoneal injections, the pancreas was the seat of carcinomatous transformation. Even the regional lymph-glands showed epithelial cell accumulations. The livers of the animals contained the parasites in large numbers, but there was no actual development of carcinoma. One animal received an injection of sarcoma culture into the peritoneal cavity. The liver was filled with parasites of the same nature and having the same pigment as those of the original tumor—a pigmented giant-cell sarcoma of the jaw. The interlobular connective tissue showed distinct transformation into sarcoma.

Regarding the nature of the parasites discovered, Schüller is noncommittal. They are not yeasts, nor are they to be identified with Plimmer's bodies, which on culture present the appearances of blastomyces. The biologists of Berlin, to whom Schüller has shown his cultures, were unable to classify the supposed organisms. Schüller leans to the view that that they are protozoa. After discussing the mode of entrance of the organisms into the human body, the monograph closes with a few brief remarks regarding prophylaxis. The illustrations, although somewhat crude, are truly startling, particularly those depicting the changes, *i. e.*, the malignant tumors, produced in experimental animals by inoculation with the parasite.

On the face of things it must be admitted that Schül-

ler's discovery fulfils all the requirements that could be demanded of a parasitic agent. He found it in the primary disease, cultivated it (of course, only after a fashion), reproduced the original disease in the lower animals, and recovered the organism from the experimental lesions. Whether it is the cause of cancer and sarcoma, however, can be demonstrated only by the corroborative testimony of other, unprejudiced, investigators.

An interesting question at this time is, What relation do Schüller's bodies bear to those described by Gaylord? So far as we can determine from reading the respective articles, they are not identical. Gaylord identifies the organisms discovered by him with Plimmer's bodies; but it seems to us that the bodies found by him in the fresh tissue and in cancerous fluid are entirely different from the parasites observed in the stained sections, and are, perhaps, the same as those depicted by Schüller, differing from them principally in the absence of color. As mentioned above, Schüller finds that his parasites are different from those discovered by Plimmer. If the bodies described by Gaylord and by Schüller are not identical, they cannot both be the cause of cancer. As far as Schüller's bodies are concerned, no one in this country has, presumably, checked his observations by personal examination, nor are we aware that Schüller has presented his specimens to any medical society. Until then, an attitude of scepticism is eminently justifiable. It is different with Gaylord's observations. His work has been more or less constantly under the eye of other authorities, and has been freely submitted to the scrutiny of disinterested men. His recent article, however, is silent concerning the appearances of the parasite on culture, and as to the results of animal experiments with the organism in a pure state. Plimmer claims to have isolated his parasite, and the cultures are those of a yeast; yet it is maintained by Gaylord that the organism discovered by him—identical with Plimmer's body—is not a yeast. We are thus left in doubt as to the nature of the organism, and must defer judgment until the impatiently awaited appearance of Gaylord's second article.

Trusts not organized for money-making but for philanthropic purposes, a new product of our times, are fortunately growing more and more common. The last is a public house trust in London to reduce the consumption of alcohol by the restriction of licenses, lessening the profits of the liquor sellers, etc. Prohibition, most desirable for the individual, has, in the belief of many, increased the evil it would kill, or has engendered other and worse ones.

There is still danger that the Legislature of Pennsylvania may "amend" the anatomy act in the interests of so-called "friends" of the deceased. There is no injustice whatever to the real friends in the present law. It should be remembered that bodies have often been offered and perhaps have been sold by "friends" before death has taken place, and a possibility of great abuses will be opened up by the pernicious laxity of the proposed change of the law.

AMERICAN NEWS AND NOTES

GENERAL.

The Jamaica Hospital has hitherto had a mixed staff of 10 physicians, 7 regulars, and 3 homeopaths. Recently the homeopaths were requested to resign. It is reported that strong protests against the action of the board will be made by friends of those who resigned.

Plague on an Army Transport.—The War Department has been advised from Nagasaki that the delay in the departure of the transport Kintuck from that place had been due to a discovery of a case of plague on board. The vessel carries Company D of the Forty-third Volunteer Infantry.

Tuberculous Immigrants Debarred.—An order has been issued by the Superintendent of Immigration debarring tuberculous immigrants from all ports of the United States. The supervising surgeon of the Marine Hospital recently declared tuberculosis of the lungs to be a dangerous contagious disease and the law required such to be debarred. Under the old ruling they were debarred only when they were likely to become public charges.

Manila Hospital.—Surgeon-General Sternberg, of the Army, has been advised of the shipment from Manila of a complete model of Hospital No. 3, an admirably equipped and well managed institution which has been under the command of Major John S. Kulp, surgeon of volunteers and captain of the medical department of the Regular Army. It is intended to place the model in the Army Medical Museum in Washington. The model is built upon a single square of Narra wood, and is built to the scale of 1 to 250, showing all elevations, drainage and sanitation. The model includes, besides Hospital No. 3, the hospital corps company of instruction and the hospital corps camp of casuals, which are adjacent and under the same command. The details are made from the original material of the buildings and walls which they represent.

The Army Board which has been in session in Washington for the examination of candidates for appointment in the medical corps of the Army, will hold its final meeting during the week of June 17, and then adjourn till September. The results of the board's work has been disappointing in the few candidates who have met all the requirements. Since February, not more than 40 young physicians have proved their ability to receive commissions as assistant surgeons, and some of these were acting assistant surgeons in the service in the Philippines. The report of the board at Manila has been received at the War Department, and after all the appointments have been made, there will remain still 80 vacancies in the 129 new positions, which are created by the Army law of February 2.—[*Army and Navy Review*.]

Food for American Soldiers.—Major G. W. Ruthers, in a report on the conditions governing the subsistence of troops in Northern Luzon and the best foods adapted for the soldiers, says that the supply of frozen beef has been sent to every point possible. On one line it leaves the railroad and goes by bull carts 60 miles into the interior. From another line it is carried in carts and then for 20 miles over mountains by pack mules. Wherever beef goes 100 pounds of ice for each company is supplied. The troops endorse this frozen beef as the finest beef in the world. The beef stew, with vegetables, is the finest component of the ration ever put in the hands of troops. With the addition of some hard-tack, coffee, sugar, salt and baked beans, you could cut an army loose from its transportation for some time. The standard emergency ration has given very good satisfaction. The use of it alone has enabled the commands to operate during the constant rains and to go through water and mud up to their necks. Experience shows that the American soldier serving in these islands needs the full army ration, including the full allowance of fresh beef; his health cannot be maintained without it.

Obituary.—J. L. Acomb, of Tidiloute, Pa., aged 70.—BART BYRD, of Lexington, Miss., June 2.—JAMES MURRAY STONE, of Govanstown, Md., June 5, aged 80.—SETH B. SPRAGUE, of Jersey City, aged 61.—W. MERGLER, of Chicago, May 18.—HUGH STOCKDELL, of Petersburg, Va., May 23, aged 66.—W. S. WITHAM, of South Lebanon, Ohio, May 24, aged 23.—D. C. THOMAS, of Adrian, Mich., May 30, aged 66 years.—R. B. ARCHIBALD, of Purdy, Mo., May 31, aged 53.—J. A. HEALD, of Denton, Tex., May 29, aged 80.—J. W. ALLEN, of Guthrie, Ky., May 28, aged 45.—WILLIAM H. DALY, of Pittsburg, Pa., June 9, aged 59.—A. A. BLOCH, at Denver, Colorado, June 8, aged 34.—E. P. SALE, of Memphis, Tenn., June 8.—W. S. CALDWELL, of Freeport, Ill., June 7, aged 69.—HARRY SMITH, of Northampton, Mass., June 9, aged 39.

EASTERN STATES.

Worcester City Hospital will be closed to all patients, as far as possible, until June 23, because of smallpox. Patients needing treatment will be taken to St. Vincent or Memorial Hospital.

Hospital for Chronic Diseases.—A petition of Mayor Thomas N. Hart and others was presented to the Massachusetts House, May 20, asking that the act of 1858, authorizing Boston to establish a city hospital, be amended by providing that the city be authorized to erect and maintain a hospital for the treatment and care of persons suffering from chronic disease.

Cigaret Smoking not Injurious.—Dr. William J. Robinson, of New York City, says that cigarettes are not any more injurious than cigars and when used in moderation in cases of extreme nervousness and irritability they produce a distinctly soothing effect. In one case where he prescribed cigaret-smoking as a remedial measure it gave more relief than the bromids or valerian.

Hospitals for Contagious Diseases.—The Connecticut Board of Health in its argument for the necessity of every town having a hospital where contagious disease patients can be isolated and receive proper treatment, draws attention to the fact that in that State in 693 cases of typhoid fever, there were less than 7% of deaths, while in 1,163 cases under private treatment there was a mortality of 20%.

Summer Home for Children.—St. James' parish, of New York, has built a new summer home for children at East Norwalk, Conn. The home cost over \$11,500 and will accommodate over double the number that the former house could. It is now hoped that every child in the parish needing it will reap the benefit of at least 1 week's outing in the pure air. The old house used for this purpose will be sold.

The Little Sisters of the Sacred Heart, a French Community, has established a branch at Springfield, Massachusetts. These sisters will nurse the sick in their homes, care for the homes during the sickness of the inmates, and help the families of the sick while in need of household assistance. They give their services to any who need their help, irrespective of religion, the remuneration depending on the ability of their patrons to pay.

\$1,950 for Preserving a Leg.—In the Superior Court of New Hampshire recently a druggist secured a verdict of \$1,950 for preserving in alcohol the amputated leg of the late John H. Pearson, a wealthy resident of Concord. In 1887 the druggist was instructed to preserve the leg, in 1899 it was buried with its owner, and the druggist sent a bill of \$3,450 to the executors of the estate. They refused to pay the bill and the verdict is the result.

NEW YORK.

West Point.—It is said that 25% of the young men who have applied for admission have been unable to meet the physical qualifications.

A Bronze Statue in memory of Dr. A. J. C. Skene is proposed for Prospect Park, Brooklyn. Effort is being made to raise \$25,000 for that purpose.

Cornell University Medical College.—The third annual commencement was held recently. The degree of M.D. was conferred on 26 graduates, many of them women.

Mid-air Cremation.—Lieutenant James M. O'Kolley is the inventor of the Navohi, a peculiar balloon-like apparatus, the object of which is to cremate bodies high in mid-air.

Bellevue Hospital's insane pavilion will be abolished and the necessary legislation will be made to secure a separate hospital under the supervision of the State where mental and nervous diseases may be treated.

The New York State Hospital for the care of crippled and deformed children was formally opened at Tarrytown, May 17. Bishop Potter, the President of the Board of Managers, presided and made the opening speech.

Williamsburg Hospital.—The festival of the Plattdeutscher Volksfest Verein, of Brooklyn, was opened recently in Ridgewood Park, L. I. The greater part of the proceeds will go to the new German Hospital at Williamsburg.

Emergency Hospital.—The Brooklyn Rapid Transit Company is contemplating the establishment of an emergency hospital for the immediate use of passengers injured on the company's lines. An ambulance trolley service will also be provided.

Death Due to a Camphor Ball.—Carl Gondeck, 3 years old, of Flushing, L. I., mistook a camphor ball for candy and swallowed it. The ball lodged far down the throat and caused death in a short time. A physician was called but was unable to remove the ball.

The Medical Society of the County of Rensselaer, at the annual meeting held May 15, at the Court House, Troy, N. Y., elected the following officers: President, George A. Bradbury; vice-president, Aaron D. Davidow, secretary, H. E. DeFreest; treasurer, Reed B. Bontecou.

Oleomargarine Dealers Convicted.—For selling oleomargarine as butter in New York, 4 wholesale dealers of Jersey City were recently convicted by the Court of Special Sessions. The punishment imposed was a fine of \$150, or 60 days in prison to 3 of the offenders, and the fourth was sentenced to 3 months imprisonment.

Playroofs.—In the downtown portion of New York the children of janitors, who have charge in the unusually high buildings, find fresh air and recreation on the roofs. These are often fitted up with swings, doll houses, etc., and these, with the view before them of Staten Island, Long Island and the grand march of the river to the sea, are wonderful indeed to these little ones, who cannot play on the surface streets.

Free Medical Library.—The Medical Society of Kings county, N. Y., has opened its library, founded in 1845, to the public daily (Sundays and legal holidays excepted) from 10 a. m. to 10 p. m. The library contains over 30,000 volumes, 15,000 pamphlets and some 500 current medical periodicals, and appeals for contributions to a permanent library endowment fund and for gifts of medical books from authors and publishers.

Mount Sinai Hospital.—The corner-stone of the new buildings of the Mount Sinai Hospital, Fifth Avenue and One Hundredth Street, was laid May 22 by Isaac Wallach, president of the hospital. It will consist of 10 large fire-proof buildings, each 5 stories high, all separate and distinct from one another, yet connected by passageways, under and overhead. The total cost will be \$1,335,000, the present site having been bought for \$532,000.

Smallpox.—It is reported that Dr. A. S. Zabriskie, Health Officer of Suffern, Rockland County, N. Y., is being investigated by the State Commissioner, with a fair prospect of removal, for diagnosing a number of cases of smallpox as Cuban itch. The Anchor liner Britannia, recently from Genoa, Leghorn, and Naples, with 654 Italian immigrants, is detained at Quarantine owing to smallpox among her steerage passengers. The surgeon reports 5 cases of the disease in a mild form. Steamer Tartar Prince is in quarantine because of 1 case of smallpox among the steerage passengers. The Queen's County grand jury is investigating the alleged negligence of the health authorities in the case of John Chariton, of Woodside, who, while suffering from the smallpox, was allowed to remain 52 hours at his home before being removed to the pest-house. The Health Department officers declare that they are badly handicapped there, having no ambulance and no reception hospital. Since the outbreak, 5,182 school children have been vaccinated. The whole number of persons vaccinated is 10,213. The number of cases of smallpox in Queens reported up to yesterday is 53.

PHILADELPHIA, PENNSYLVANIA, ETC.

Memorial to Dr. Bartine.—The citizens of Merchantville, N. J., propose to perpetuate the memory of the late Dr. D. H. Bartine, who practised his profession in that town for 35 years. The tablet will cost \$1,000.

Swallows False Teeth.—A lady in Scranton recently swallowed her false teeth. X-rays at the Lackawanna Hospital located the plate in her stomach. An operation will be performed for their removal.

Infectious Diseases.—The health report for the week ended June 9 shows 120 new cases of typhoid, scarlet fever 77, diphtheria 63. Diphtheria is widespread on the west side. For the week there were 410 deaths.

Allentown Hospital.—At a recent meeting of the trustees of this institution a letter was read from James K. Mosser, announcing that he would contribute \$33,000 for the erection and completion of the west wing of the building.

Pure Milk Supply.—The Philadelphia Pediatric Society has appointed a commission of its members—C. J. Marshall, veterinary inspector; M. P. Ravenel, bacteriologist, and Henry Leffmann, chemist—to inspect the milk submitted to them by dairymen and certify the result of such examination. It will be examined in relation to percentage of proteids, fat, sugar, mineral matter and water present, as well as tested for the number and nature of contained bacteria. The veterinary inspector will have oversight not only of the health of the cows and the nature and quality of the food given them, but also of the health of the employes on the dairy farm and of the care and cleanliness observed in milking and of the utensils employed. Satisfactory methods of delivery will be used and guarantees that the milk furnished is of the proper standard.

SOUTHERN STATES.

Dr. Kunst has been appointed to succeed Dr. Stathers as superintendent of the Hospital for the Insane at Weston, W. Va. He will take charge of the institution July 1.

The Bedford County Medical Association met at Shelbyville, Tennessee, June 3. The future meetings are to be held the third Thursday of each month. At the next meeting, Dr. J. M. Cunningham will present an essay on smallpox, and Dr. J. S. Newlin one on dysentery.

First Volunteer.—Dr. Charles F. Rand, of Washington, was the first volunteer to enlist for the Civil War in response to Lincoln's call for 75,000 men, and he possesses the first medal of honor ever presented by Congress for gallantry on the battlefield.

Medical Examination for School Teachers.—On May 9, the School Board of Louisville, Ky., adopted a measure prohibiting the employment of teachers who suffer from deafness, tuberculosis or contagious diseases. Medical examinations will be made whenever it is considered advisable.

Home Doctoring.—The tendency of the people to drug themselves with patent and proprietary medicines has been commented upon by the Louisiana State Medical Society. It is stated that the manufacture of these medicines, the composition of which is generally kept secret, has increased 500% in the last 10 years.

The Progress of the Negro Race in Washington is shown to be commendable by a recent investigation made by the Union League into the status of the colored population in business and in maintaining organizations. Among them are 53 physicians, 12 trained nurses and 10 dentists, and among their organizations are a medical society, a dental society and a society of trained nurses. Of the colored families, 15% own their own homes.

The location of the Lepers' Home on the Gustine plantation, Louisiana, lately bought for that purpose, is so strongly opposed by the citizens of Jefferson and St. Charles parishes for 7 miles around that they met in a mass meeting and adopted resolutions asking that it should not be established in so populous a vicinity. It is stated that there never have been more than 20 lepers in the home, while, according to recent returns, there are not less than 400 at large in the State living in various parishes and many of them moving about at pleasure.

Mental Therapeutics.—The Secretary of State of North Carolina has refused to charter a new "College of Science and Healing"—the first institution of the kind proposed in the State, and he is sustained by the Attorney General. The purposes of the college, as stated in the application, are as follows: "To educate and graduate its students in the science of treating disease without the use of medicine or surgery; to practise the same and educate and authorize them to teach and practise the same; to confer upon each of said students, as its faculty think proper, any or all of the following degrees, namely: doctor of psychotherapeutics, suggestive therapeutics, mental therapeutics, massage therapeutics, magnetic therapeutics, hypnosis therapeutics, anatomy, diagnosis, professional nurse, psychologic therapeutics, and metaphysic therapeutics."

A Remarkable Case of Combustion.—A case that must certainly prove of interest to the medical world generally is contained in a letter from Dr. B. C. Wilson, of Soldier, Ky., to Dr. Samuel E. Woody, professor of chemistry at the Kentucky School of Medicine. It relates to a case of spontaneous combustion in connection with the customary treatment of severe burns. His letter, in part, is as follows: "A child 4 years old was burned on the fire. The burns in each locality being of moderate severity and strictly superficial were not sufficient to have caused a fatal result. The burns were dressed in the following manner: First dusted with subnitrate of bismuth, then linseed oil was freely poured on, and the parts wrapped in cotton batting and a sheet wrapped around it, and, lastly, a quilt was wrapped around this. The child was put to bed and instructions were given not to remove the dressing. The child complained bitterly all night long, the parents thinking that the suffering was due to the original burn. About daylight they saw smoke arising from the bed, but, being very ignorant people, thought it was the 'fire leaving the burn,' and did not remove the dressing until later, when the child was dying. Upon removing the dressing they found the inner aspect of the sheet was scorched, the cotton batting burned almost entirely up (over the abdomen) and still smoldering. The child was burned into the intestines in 3 places and died in a few minutes. There was not the least evidence or the remote possibility of the second fire originating from the outside, and there was absolutely nothing used but the bismuth and linseed oil." Dr. Woody said in reply: "Under the circumstances it must have been spontaneous combustion of the linseed oil. The bismuth subnitrate and cotton divided finely, distributed the oil and exposed a large surface to the action of the oxygen of the air. The warmth of the body added to the heat and hastened the oxidation, and the covering confined the heat until the oxidation became an actual combustion."

WESTERN STATES.

Hospital for the Tuberculous.—The citizens of Chicago who are interested in this movement have already collected \$22,983.

Excision of Lung.—Reports come from Santa Anna, California, that doctors have successfully removed the entire lung of a patient suffering from pulmonary tuberculosis.

Iowa State Hospital for the Insane.—Dr. C. F. Applegate has been appointed superintendent of this institution at Mount Pleasant. The vacancy was made vacant by the death of Dr. F. C. Hoyt.

Michigan University will have a psychopathic ward for the treatment of acute mental disorders, as Governor Bliss has recently approved the bill appropriating \$50,000 for its establishment.

Public Hospital.—Cedar Rapids, Ia., will have a public hospital. Abraham Slinner, of Waverly, has agreed to duplicate, up to \$50,000, whatever sum the city may raise. Already \$25,000 has been secured.

Beautifying Back Yards.—Several of the Women's Clubs of Wisconsin have initiated movements to interest the children of the cities in beautifying the back yards of residences and keeping them clean.

Western Reserve University is the recipient of \$12,000 from H. M. Hanna, a brother of Senator Hanna, to establish a research fellowship in its medical school in the departments of pathology and physiology.

Tuberculosis Among Cattle.—The State authorities have found many cases of tuberculosis among the cattle in the neighborhood of Chippewa Falls, Wisconsin. The disease was carried there by cattle shipped in.

New Hospital.—Staubenville, Ohio, is the recipient of a fine hospital, fitted with the latest improvements at a cost of \$35,000 through the gift of Congressman J. J. Gill. The public is expected to maintain the hospital.

New Medical Building.—The authorities of the University of Michigan have decided to expend \$100,000 for the erection of new medical building. On account of its historic associations the old structure will be retained and will be connected with the new building by a tunnel.

Gift for Hospital.—It is said that P. H. Anderson and John Brynteson, 2 missionaries who have made fortunes in the old fields of Alaska, will give \$25,000 to build a hospital. The site for the institution has not yet been definitely determined, but Chicago will in all probability be chosen.

Glucose and Honey.—Merchants of San Francisco petitioned the Board of Health recently to be allowed to use glucose in storing honey, as it, they claim, prevents granulation of honey. The decision of the board was that it had no power to revoke the law prohibiting such adulteration.

Physicians Appointed.—In accordance with the recent actment creating a State board of medical registration, the Governor of Kansas appointed as members Drs. O. T. Lewis, George F. Johnson and S. W. Williston. From the homeopaths, Drs. H. W. Roby and D. P. Cook. From the eclectics, Drs. H. Hatfield and E. B. Packer.

Clean Streets for Chicago.—Prominent men and women of Chicago have consented to act as volunteer inspectors of streets and alleys under the new clean-city ordinance and great enthusiasm is manifested in the work which is vigorously prosecuted by millionaires, merchants, bankers, judges, society women, physicians and a venerable bishop.

Cincinnati Hospital.—The exinternes celebrated their fiftieth anniversary as an association June 1. One member was on duty in the hospital in 1849. An interesting program was carried out, and the following officers elected: President, A. E. Thrasher; vice-president, W. W. Vinnedge; secretary, A. E. Frieberg; treasurer, J. C. Oliver.

Arrest of Development.—A remarkable instance comes to us in the death of Aurelis Rodriquez, June 4. He was born August 10, 1879, in Eagle Pass, Texas, and was an ordinary healthy baby. A few months after birth he ceased to grow, and at 22 years he remained a baby. He never talked or walked, never developed any muscular power, could not turn over in bed, and was always fed liquid food.

Chicago Chronicle Sued.—John Murdock recently entered suit against the Chicago Chronicle Company for \$5,000 damage for an alleged libelous publication relative to his degree as a physician. The Chronicle, it is charged, in its issue of June 5, published an article in which it called the Metropolitan Medical College of Chicago, a "diploma mill," and in the same article it spoke of Dr. Murdock as a graduate.

Gastric Ulceration.—The physicians of Chicago assert that gastric ulceration is markedly on the increase. They blame our methods of hasty lunch eating. Though known to the profession but a few years the increase has been 200%.

Dust in Chicago Streets.—So much dust follows the efforts of the street cleaners of Chicago that doctors are discussing this menace to public health and the City Commissioner has determined to abate the nuisance. Orders have been issued that all sweeping be done after the crowds have left the streets and that sprinkling precede sweeping. It has been suggested that asphalt pavements should take the place of the granite blocks.

Faith Curists Responsible.—Exhumation of the remains of Mrs. Emma L. Judd showed that her death and that of her infant were due to neglect. Her husband, 2 nurses and "Dr." Dowie, of the Christian Catholic Church of Chicago, all of them faith curists, were held criminally responsible. Evidence showed that ordinary medical treatment could easily have saved both the lives of mother and child. The men were each held in \$10,000 bail and the women each under \$5,000.

The Lane Lectures, consisting of 10 lectures delivered yearly on 5 consecutive days at the opening of the Cooper Medical College in San Francisco, were inaugurated about 5 years ago, and since then have been held by Mr. Christopher Heath, Dr. Clifford Allbutt, and Sir Michael Foster, while Mr. Malcolm Morris is the lecturer appointed for the present year. Mr. C. B. Ball, Regius Professor of Surgery in Dublin University, has been appointed "Lane Lecturer" for 1902; his subject will be "Diseases of the Rectum."

Necessity for a Hospital.—The officers of the Cleveland Society for the Relief of Crippled Children say that hospitals for efficient work are greatly needed. They ask the cooperation and support of the people of Cleveland for this necessary work. Arrangements have been made by which as many beds in other hospitals as can be supported are at the disposal of the society. Six beds are already occupied, but there is a large list of little ones waiting to be helped. These will be taken care of as soon as the adequate funds have been provided.

To Nurse Lepers.—Mrs. Laura Schwichtenberg, of Detroit, has decided to devote her life to the leper colony on the island of Cebu, one of the Philippine archipelago. Some time ago she received, at her urgent request, appointment, as government inspector of hospitals in the Philippines, at which time she visited the leper colony, declaring that her commission took that in, as the whole colony was a hospital. She was greatly impressed with the lack of sanitary conditions prevailing and with the hopeless condition of the 30,000 lepers congregated here.

Pauper Practice.—The physicians of Pana, Ill., have entered into an agreement, signed by every physician in the city, that they will not bid for pauper practice and that they will not attend the paupers at a less rate than the regular established and recognized fee bill of Pana. It is also understood that no one physician shall be favored in the distribution of pauper practice, but that the patient shall be given the privilege of choosing his own physician. This agreement has been published in the 2 daily local papers and the consensus of opinion is with the doctors.

Indiana Mortality and Morbidity for May, 1901.—Reports to the State Board of Health show 2,556 deaths in May, a rate of 11.9. For the preceding month 2,839 deaths were reported, a rate of 13.7. For May, 1900, 2,536 deaths were reported, a rate of 11.4. According to ages, there were deaths, under 1 year, 347; 1 to 5 inclusive, 151; 65 years and over, 640. From important causes: pulmonary tuberculosis, 354; other forms of tuberculosis, 48; typhoid fever, 33; diphtheria, 21; scarlet fever, 7; measles, 35; whoopingcough, 15; pneumonia, 250; diarrheal diseases, under 5, 13; cerebrospinal meningitis, 27; influenza, 40; puerperal fever, 17; cancer, 76; violence, 136. All cities, representing a population of 847,302, reported 1,023 deaths, a rate of 14.3. The country, representing a population of 1,669,160, reported 1,523 deaths, a rate of 10.8. The tuberculosis rate in the cities was 186.6 per 100,000, and in the country 155.5. Typhoid fever had a rate of 16.7 per 100,000 in cities, and 14.8 in the country. Influenza, cities 17, country 23; puerperal fever, cities, 4.1, country, 9.8; cancer, cities, 35, country, 41; pneumonia, cities, 116, country, 134. Special morbidity reports show a decrease in sickness of about 10% as compared with the preceding month, and the mortality reports sustain the conclusion. The decrease appeared in pneumonia, typhoid fever, scarlet fever, measles, croup, cerebrospinal meningitis, influenza, whoopingcough and puerperal fever. Diphtheria increased slightly, also diarrheal diseases. Smallpox appeared in 19 counties, at 60 different points. The number of cases was 238, with 3 deaths.

CANADA.

The Militia Department, in its arrangements for opening camps is taking the utmost precautions that none of the companies or corps in districts where smallpox is prevalent shall be called out.

FOREIGN NEWS AND NOTES

GENERAL.

South Africa.—It is reported that the casualty list of the British Army in South Africa for May included 25 officers and 709 men, who died either from military operations or disease.

Obituary.—ARTHUR LLOYD MACLEROY, at South Devon, England, May 19, aged 49; ROBERT SKIMMING, of East Molesey, England, May 23, aged 58; ROBERT WEBB WATKINS, of Towcester, England, aged 76; JOHN D. WILLIAMS, at Cardiff, Wales, May 21, aged 36; ROBERT JOHN SPRAKELING, at Bootle, Liverpool, England, May 9, aged 68; WILLIAM HAY, at Zyrardow, Poland, May 12.

GREAT BRITAIN.

Gift to Universities of Scotland.—The annual income of the gift of £2,000,000, made by Andrew Carnegie to the Universities of Scotland, is £104,000. Half of this income will be expended in strengthening the faculties of science, medicine, history, modern languages, and literature, until these become as strong as similar faculties in the universities in Germany and the United States. The second half will probably be expended in paying the ordinary class fees of Scottish students, female as well as male. Any surplus will be spent in extending lectureships at evening schools outside the universities.

Glasgow Smallpox Epidemic.—The outbreak is practically at an end. A new case is an exceptional event and the number in hospital has fallen to 45. The minutes of the Health Committee contained a recommendation that a new smallpox hospital should be erected and that the committee should be authorized to visit and to inspect sites suitable for this purpose. This was approved.

Housing of the Poor.—In Bristol several years ago a committee was established to promote the better housing of the poor. Great good has been accomplished in the way of obtaining the repair of dilapidated cottages and the closing of those beyond repair. A warning note has been raised with regard to the provision by municipalities of working-class dwellings, the rental of which were not sufficient to pay the interest and repayments on the original outlay.

The Croonian Lectures on the "Chemical Side of Nervous Activity," will be given by W. D. Halliburton, before the Royal College of Physicians of London, on June 11, 13, 18 and 20. The Goulstonian Lectures on "Certain Mental States Associated with Visceral Disease in the Sane," will be given by Dr. Head on June 26, 27, and July 2. The subject of the Bradshaw Lecture on Prognosis in Relation to Diseases of the Nervous System, will be delivered by Dr. Judson Sykes Bury.

Cost of Smallpox.—In Glasgow where the epidemic is steadily decreasing, there being only 75 patients under treatment on May 13, the cost of the measures used in stamping out the disease has been estimated as follows: The cost of treating the patients in hospital and of isolation, £5,000 to £6,000; the cost of erecting reception houses and temporary pavilions, £7,000; the cost of prophylaxis, including vaccination and revaccination £30,000 to £35,000.

A Psychologic Department has been established in connection with the Pathologic Laboratory of the London County Council Asylums at Claybury, with W. G. Smith, M. A., Edin., Ph. D., Leipzig, in charge. It is proposed to study the problems of pathologic changes in mental states, such as memory and association of ideas, especially in those suffering from alcoholic dementia and the phenomenon of reaction time in normal and abnormal individuals as studied both by the measurement of the duration of mental processes and by analysis of the motor phenomena by the graphic method.

CONTINENTAL EUROPE.

M. Laveran, the discoverer of the hemozoon of malaria, has been elected a member in the section of medicine of the French Institute to succeed the late Prof. Potain.

"The Medical Echo" is the English title of a trilingual monthly review of medical literature, edited by Dr. S. A. Arany, which has come into existence lately in Budapest.

Leprosy.—Brittany and Savoy, according to the report of Dr. Besnier of the Académie de Médecine, are centers of leprosy, a disease which 20 years ago was scarcely known in France.

Röntgen Ray Therapy.—An institute for the light treatment and Röntgen ray therapy has been opened in the Dermatologie Clinic of the University of Berlin and E. Lesser named as director.

Education of Criminals.—At the Pan-Russian Congress of Criminologists, held recently in the Moscow University, a compulsory law for the education of adult criminals was decided upon.

The University of Paris.—It is reported that Prof. Brouardel, who is an ardent nationalist, and who is at present dean of the medical faculty, has resigned his position because Pozzi, the celebrated gynecologist and republican senator has been recently made full professor.

A League Against Syphilis has been founded recently in Paris with Professor Fournier for president; M. Bérenger, Professor Brissaud and M. Pileur, vice-presidents, and Dr. Barthélemy, secretary-general. Among the members are Drs. Barbe, Emery, Bizard, Balzer, Champetier de Ribes and Gaucher.

Remedy for Mosquito Bites.—Professor Voges, the Director of the National Board of Health at Buenos Ayres, according to German papers, has found by accident that naphthalene neutralizes the poison of mosquito bites even when the spot bitten is greatly inflamed, and when applied to fresh bites no swelling occurs.

Sulphur Water.—Armand Gautier, the French chemist, is reported to have announced to the Paris Academy of Sciences his discovery that pulverized volcanic stones treated by water at a temperature of from 250° to 300° C. yield a liquid identical in composition with the ordinary sulphur water of mineral springs, except that it is stronger.

Virchow's Eightieth Birthday.—Preparations are being made for a suitable celebration by most learned societies of the scientific world. The Austrian Aergtekammer has refused to take part, however, the reason given being that Virchow, as a member of the German Reichstag, favored laws permitting unrestricted medical practice and thus used his influence against the best interests of the medical profession.

Antimalarial Campaign.—The Italian Red Cross Society has succeeded in collecting by voluntary subscription the greater part of the sum necessary for renewing the summer campaign against malaria in the Agro Romano. Some 5,000 lire are still needed to make the scheme practicable, and an appeal for funds is being made to the Government by the society and others interested in the undertaking.

Cremation in Basel is said by the *Luzerner Tagblatt* to be free for the citizens of Basel. The number of cremations is not increasing, however. In 1898 there were 17 cremations, and in 1899 only 14, with 1,689 burials. This is thought to be partly due to prejudice and partly to the fact that the person concerned must express the wish to be cremated, though the wishes of the relatives are usually respected by the Sanitary Department.

Texas Fever, previously known only among the cattle of Texas, Roumania, Finland and Sardinia, has been identified recently by Dr. Ziemann, in the Neuenburg district of Oldenburg in North Germany, where it has been known throughout the Ammerland district for more than 100 years under a local name. The disease, which is due to a bacillus, is ascribed by the local veterinary surgeons to the eating of poisonous plants, as it usually proves fatal.

To Regenerate the Human Race.—Count Alexander Louis St. Ouen de Pierrecourt, lately deceased, left among other bequests to his native city of Rouen, 50,000 francs a year to the 2 healthiest children in that city and 100,000 francs paid yearly to the healthiest pair of young giants who shall marry and have children. The will specifies that candidates for the prize must be proved by medical examination to be perfect specimens of the human race, and that the legacy shall be divided equally between the contracting pair. The Count's testament sets forth that the amelioration and increase in size of the human race is a needed work.

Colors and the Nerves.—French scientists have made some very interesting experiments in connection with the effects of certain colors on the nervous system. M. Henri de Parville, of Paris, asserts that the red end of a spectrum excites the nerves, while violet, green and blue are calming. Dr. Donza goes further and attempts to cure nervous diseases by the use of certain colors. Melancholia he treats with red, violent mania with blue, and nervous prostration with violet. The very grave question arises as to how the woman already nervous will regard unbecoming color. Dr. Dor, another experimenter, has brought on vertigo in patients by the use of red lights, and relieved the symptoms by changing the ray from red to green.

Leprosy Increasing in France.—The report read by Dr. Besnier at a meeting of the Académie de Médecine revealed the disquieting fact that leprosy—which 20 years ago was practically unknown in France—has within recent years become so prevalent in this country as to convince the public authorities that urgent measures are imperative to prevent its further spread. In Paris alone there are 14 lepers in treatment at the Hôpital St. Louis, and in parts of Brittany and Savoy there are localities with recognized leper centers. Dr. Besnier in his report states that the suppression of the foul contagion in France can only be secured by the most complete isolation and by taking effective measures against further possible leper importations.

SOCIETY REPORTS

AMERICAN MEDICAL ASSOCIATION.

ANNUAL MEETING AT ST. PAUL, MINN., JUNE, 1901.

[Specially reported for AMERICAN MEDICINE.]

General Session.

FIRST DAY.

The Session was called to order by the President, Dr. Chas. A. L. Reed, at 10 o'clock. After prayer by Bishop H. B. Whipple and an address of welcome by Mayor Smith, the presidential address was delivered by Dr. Reed. The address (published in the issue of AMERICAN MEDICINE for June 8) was most heartily applauded.

Dr. Pennington presented an oil portrait of Dr. N. S. Davis, "The Father of the Association," who is now 85 years old and still in the practice he entered upon 65 years ago. Upon motion a committee was appointed to secure, without expense to the Association, the portraits of all the ex-presidents of the Association.

The Secretary's report, by Dr. Simmons, showed that there are now about 10,600 members, an increase during the year of between 1,500 and 1,600.

The report of the Executive Committee, by Dr. Bulkley, showed that this year there are 391 papers upon the program, a great reduction over the number of previous years. But there have been presented only 196 abstracts of these papers, and the committee recommends that hereafter no title be printed unless an abstract of the paper should also have been furnished. This recommendation was adopted.

The report of the Board of Trustees was read by Dr. Happel. The report showed a profit for 1900 of \$13,344.91. The Board also reported that they ordered enough money invested to make the investment, when added to the \$10,000 in United States bonds, about equal to the sum of \$25,000 par value. Toward securing a permanent home for *The Journal*, there is invested in gilt-edged securities \$25,000, which yearly grows by the interest at least. The sum total of the items mentioned, viz., pressroom, proofroom and office furniture and fixtures, and machinery and plant, less 5% for wear and tear, after all additions, amounts to about \$21,000. The office, with the addition of 1 or 2 small motors which the editor was authorized to buy, is almost complete, and can now do all of its own work. Its quarters are crowded, and for that reason some things cannot be done to the best advantage. There has been a steady growth in *The Journal*. An effort has been made by the trustees and editor to increase the quantity and quality of the reading matter in *The Journal*. It should be the best medical journal published in the world. With the support of a united profession it can be so made. The following comparative statement indicates the increase in advertising collections during the past 12 months: Collections for 1899 were \$33,760.82; for 1900, \$44,060.70; showing a gain of \$10,299.88. The advertising collections for 1898 were \$23,629.71, thus indicating an increase of \$20,430.99, nearly doubling the revenue from this source in 2 years. The frequent changes made in the program of the work of the sections, all of which work is done in *The Journal* office, adds much to the expenses incident to printing of the *Journal*. It has been deemed best to instruct the editor to make no changes in the program after May 4 of each year. It is suggested also that too many papers are on the programs of some of the sections, and many of them are read only by title, and yet they must be treated and published, as if read and discussed by the section. The board suggests that such papers should be treated as volunteer papers, unless the writer can give a satisfactory excuse for not appearing to read his paper. Especially should this apply when more than one paper is furnished by the same author at any annual meeting. In arranging the programs of the work of the different sections the board suggests that the secretaries give preference to those who write for only one section, over those who have furnished or propose to furnish, papers for 2 or more sections. This will limit the number of papers, and will tend to improve the quality. This course will become a necessity in view of the increased number of sections, and the fact that each section will be furnished a reporter so that all discussions can be reported in full. Under an order from the Board of Trustees, all stenographers will be employed by the editor, to enable him to control all papers, and abstracts of the same. The board having directed an enforcement of Section 7 of the By-laws, in regard to the publication of papers, no paper will be published in *The Journal* which has appeared in full or in abstract form in any other journal, and no stenographer will be reemployed who furnishes any such abstract to any other journal. Unless some curtailment of the number of papers to be published in *The Journal* can be obtained along the lines just suggested, the publication of many valuable papers read at our annual meetings must of necessity be delayed for nearly a whole year, a thing pleasant neither to the writer nor editor. The Association might come to the relief of the editor by limiting by by-law or otherwise the number of papers

in each section to 35. In order to still further improve the quality of the material, to eliminate as far as possible all that would be of little value to our readers, and to fix the responsibility for all that is admitted to the pages of *The Journal*, the trustees suggest that hereafter no paper presented to any section shall be printed until it has received the approval of the 3 members of the Executive Committee from that section, evidenced by their signatures to said paper.

The recommendations of the Board were adopted.

The report of the Committee on National Legislation, by Dr. JOHNSON, was read and adopted.

The report of the Committee on Reorganization, the essentials of which were published in AMERICAN MEDICINE May 25, was read by the chairman of the committee, Dr. McCORMACK, and after a somewhat excited debate was by motion referred to a joint committee, consisting of the Executive Committee and the Committee on Reorganization, a meeting of which was held at 3 p. m., for the purpose of considering all arguments for or against the plan proposed by the committee. The joint committee is to report to the Association at to-morrow's general session. Adjourned.

SECOND DAY.

The meeting was called to order at 11 a. m., by President REED. Governor Van Zant was introduced and in a witty and patriotic speech he welcomed the Association to the State.

The report of the Joint Committee, to whom was referred the report of the Reorganization Committee, was called for. Dr. WALKER reported that the Joint Committee unanimously advised that the report as a whole be adopted. Dr. WALKER then read the draft of the Constitution and Bylaws as made by the Reorganization Committee. The essential portions of this Constitution and Bylaws were printed in AMERICAN MEDICINE, issue of May 25. After the reading, Dr. HARRIS (New York) moved that the Constitution and Bylaws be adopted.

Dr. BULKLEY, who had been opposed to the recommendations of the Reorganization Committee, stated that he was now in favor of their acceptance, and he seconded the motion for their unanimous adoption. The motion carried, and thus after the close of the present session the new Constitution and Bylaws become the future law of the American Medical Association. In order to avoid bringing up the question again at this session, Dr. McCORMACK moved that the vote should be reconsidered and laid upon the table.

The new Constitution was ordered to be printed and sent to every member of the Association.

Dr. WYETH, of New York, then read the address of surgery, which was printed in the issue of AMERICAN MEDICINE for June 8.

The reports of several Standing Committees were read and adopted.

A resolution against the abolishing of the army canteen was laid upon the table, and the subject was referred to the Committee on National Legislation.

THIRD DAY.

The meeting was called to order by President Reed at 11 o'clock. After the reading and approval of the minutes of yesterday's session, Miss Susan B. Anthony and Rev. Annie B. Shaw were by courtesy allowed to address the association in behalf of *The Suppression of Vice in the Philippines and Other New Possessions of the United States as Regards the Soldiers*. They earnestly sought the sympathy and cooperation of the association and of the medical profession in the regulation and suppression of vice.

Dr. SEAMAN (New York) protested that the ladies were misled, that since the suppression of the army canteen the number of cases of venereal disease had doubled.

Dr. McCORMACK (Kentucky) moved that the association endorse the plan of reorganization so far as it applies to State and county societies, and that the secretary shall be instructed to open correspondence with the officers of these societies, and report the results at the next annual meeting.

Dr. GOULD moved that the Board of Trustees be authorized to expend \$400 for the necessary expenses of the Committee on Reorganization.

Dr. BULKLEY (New York) read the report of the Executive Committee, and by vote the recommendations of the committee were taken up singly.

A committee was ordered to draft commemorative resolutions concerning the deaths of the ex-presidents, Drs. Stille, Sayre, McGuire, and Cole.

A resolution authorizing the procuring of the portraits of the past presidents of the association without expense, was passed.

The incorporation of the association was ordered.

It was moved that the resolution that a committee of 3 be appointed to revise the code should be laid upon the table. To ensure the voting only of delegates, Dr. HAPPEL (Tennessee) moved that the roll call of the delegates should be made. This would have consumed several hours, and Dr. BISHOP (Pennsylvania) moved that the roll-call should be postponed for 1 year. Carried.

A resolution disapproving of the action of Congress in degrading the rank of the medical department in the army corps was passed.

The Committee on Scientific Research, Dr. WELCH (Balti-

more), chairman, was voted \$500 for the expenses of their work during the coming year.

The project of a psychophysical laboratory, advocated by Dr. MACDONALD (Washington), under the Department of the Interior, was endorsed.

Several recommendations of the Committee on Legislation were approved.

The fusion of the 2 sections on Physiology and Dietetics, and on Pathology and Bacteriology, into a single section, was ordered.

The Committee on Pathologic Exhibits was voted \$500.00 for its expenses during the coming year.

The oration on Medicine, by Dr. Davis, of Chicago, published in our present issue, was then delivered.

The recommendations of the Nominating Committee were as follows: For President, Dr. John A. Wyeth, of New York; First Vice-President, Dr. Alonzo Garcelon, of Maine; Second Vice-President, Dr. A. J. Stone, of Minnesota; Third Vice-President, Dr. A. E. Jones, of Nebraska; Fourth Vice-President, Dr. John R. Dibrell, of Arkansas; Treasurer, Dr. Henry P. Newman, of Illinois; Secretary, Dr. George H. Simmons, of Illinois; Librarian, Dr. George W. Webster, of Illinois.

Board of Trustees, term expiring 1904: Dr. W. W. Grant, of Colorado; Dr. John F. Fulton, of Minnesota; Dr. T. J. Happel, of Tennessee.

The oration in Surgery, Dr. Harry Sherman, of California; the oration in Medicine, Dr. Frank Billings, of Illinois; the oration in State Medicine, Dr. J. M. Emmert, of Iowa.

The place of the next meeting, Saratoga, N. Y. The Chairman of the Committee of Arrangements, Dr. G. F. Comstock. Adjourned.

FOURTH DAY.

The session was called to order at 11 o'clock by President Reed. After the reading of the minutes of the previous session, the oration on State Medicine, published in June 8 number of AMERICAN MEDICINE, was delivered by Dr. GEORGE M. KOBER.

Upon the recommendation of the Executive Committee, a vote of thanks was tendered Mr. Rockefeller for his gift of \$200,000 for scientific research, under the charge of Dr. William H. Welch.

Adjourned.

Section on Practice of Medicine.

FIRST DAY.

Address of the Chairman.—Dr. J. M. ANDERS (Philadelphia) pointed out a few lines on which organizational and professional progress must be conducted. He believed that if the American Medical Association hopes to be one of the great powers of the country, that it was of great importance that the proposed reorganization scheme should be promptly affected, and due efforts made to establish and maintain proper respect and forbearance between the various sections to the end that they may work in perfect harmony with one another.

Appendicitis.—Dr. JOHN B. DEEVER (Philadelphia) read a paper in which he stated that the appendix was the most vulnerable of the abdominal organs, and this for several causes, as follows: It is a structure in the progress of retrograde metamorphosis. It is deficient in blood, nerve, and lymphatic supply. It is long and its caliber is small, hence its drainage is easily interfered with. It is subjected to traumatism by the movements of the psoas muscle upon which it lies. It is apparent that the appendix may easily become the target for the destructive microorganisms when from any cause these are incited into activity; and it is specially noteworthy that a hollow glandular organ remains intact only so long as the production and evacuation of its secretions continues normally. When this function is deranged there are serious results: (1) Retention, stagnation, and decomposition of the appendix contents; (2) pressure, leading to impairment of the appendix wall; (3, and most important) the bacteria, especially the colon bacilli, are so increased in number and virulence that they are able to penetrate the coats of the appendix and set up their irritant processes in varying degrees. Such he considers to be the brief pathogenesis of appendicitis. The following classification was suggested as convenient and well founded:

Acute Appendicitis:	First—Catarrhal.
	Second—Interstitial.
	Third—Ulcerative.
	Fourth—Gangrenous.
Chronic Appendicitis:	First—Catarrhal.
	Second—Interstitial.
	Third—Obliterating.

He frankly admitted that we could not always distinguish between the different pathologic varieties of appendicitis. Apparent inconsistencies were explained by the fact that most symptoms were due to peritoneal inflammation by extension. The majority of appendix inflammations are chronic in nature, and many of the so-called acute cases represent exacerbations, a relighting of a quiescent focus. He had never seen much good from the efforts of nature to cure. The abscess itself, by its tendency to infect the peritoneum, is a grave menace and even if the abscess ruptures into a hollow viscus the situation is not much better. A short sketch was made of certain features

of the pathology of appendicitis and 2 points were specially emphasized: First, the practical nonexistence of any form of inflammation which by obliterating its lumen renders the appendix harmless; second, the appalling rapidity and suddenness with which the appendix may suffer bacterial invasion and necrotic degeneration with resulting general peritonitis. Upon these facts he based proper treatment and the justice of claiming appendicitis as a purely surgical affection. The following word of caution was made: No frequent disease presents its signs and symptoms in such varied form and locality as appendicitis. Make it a rule, therefore, in all abdominal cases to first exclude appendiceal irritation, because careful examination will often reveal as due to it affections otherwise apt to be classified as "enterocolitis;" "acute dyspepsia;" "cholera morbus," etc. In all inflammations of the appendix not entirely chronic there are 3 cardinal symptoms, viz.: pain, tenderness and rigidity. Pain is in every variety by all odds the most significant; so much so that he regarded with suspicion every clinical history with bellyache, inflammation of the bowels, neuralgia of the stomach and similar terms. But the pain of appendicitis has certain characteristics. Above all it is paroxysmal, cramp-like and colicky and may at intervals almost disappear. It is usually first referred to the umbilical and epigastric regions, becoming localized in the right iliac fossa, only after the lapse of several hours and that not in all cases. First examine away from the seat of disease, and slowly and gently approach the tender area. A localized spot of extreme tenderness he considered to be the surest indication of pus formation; conversely abrupt cessation of such pain is apt to denote complete gangrenous change and a paralysis of peripheral nerve filaments by toxin absorption. After considering briefly some of the other symptoms of appendicitis he said that he did not depend to any extent upon blood-examinations; a leukocytosis of over 20,000 indicates pus usually unless either shut off by adhesions or the individual is overwhelmed by septic absorption. The symptoms of appendicitis were seldom in proportion to the appendix lesions; therefore it should suffice to diagnose early the inflammatory involvement, which is of itself proper enough indication for rational treatment. There is but one treatment for appendicitis, the aseptic scalpel of a surgeon, and it should be called upon as promptly as the diagnosis is made.

Discussion.—DELANCEY ROCHESTER (Buffalo, N. Y.), made a strong plea for the value of the blood count in the diagnosis of these conditions during the acute inflammatory state and particularly during the development of pus. Another interesting point he made was in reference to the variation of the temperature with the blood count; when there was an elevation of temperature there was a higher leukocytosis. He believed the aseptic scalpel to be the only treatment for appendicitis when operation was possible.

Dr. J. B. KELLEY (Philadelphia) did not think that any medical man should treat a case of appendicitis after the first 24 hours.

Dr. J. A. WITHERSPOON (Nashville, Tenn.), said that if the medical treatment of appendicitis is Christian Science that any man with a little pain in his belly and with a little elevation of temperature and with very few local signs who submitted himself to operation is as brave as Julius Cesar with the faith of a Daniel. We should realize that appendicitis is both a medical as well as a surgical condition. There were many cases in this disease that get well, not by medical treatment, but by placing a man in bed at once, stopping all nourishment, applying ice bags over the belly, and keeping him perfectly quiet.

Some Phases of Malaria.—Dr. J. B. McELROY (Stovall, Miss.) read this paper, in which he cited a case in detail in order that he might discuss some of the phases of malaria suggested by it.

Perniciousness in Malaria. It is well known that in these infections the estivoautumnal parasites are found in exceedingly large numbers. There are usually two predominating broods of parasites in the blood of patients with pernicious fever, but Marchiafava and Bignami report cases in which the viscera, as well as the peripheral circulation, show a very small number of parasites. So it is evident that we must look for the causes of malignancy in another direction than merely in the large quantity of parasites. These causes may be found in what has been termed the biologic characteristics of the estivoautumnal parasites. The first of these is their capacity for rapid propagation. It is another characteristic of these parasites to disappear from the peripheral circulation to complete their cycle of development in other vascular areas. We should take into account another factor in the other forms of pernicious malaria, the virulence of these parasites. Many attempts have been made to demonstrate a malarial toxin, and there is good evidence to believe that such a malarial toxin exists, although it cannot be demonstrated. Therefore, it is probable that this property of the estivoautumnal parasites, more than any other, accounts for malignancy in malaria. Another proof of the great virulence of these parasites is the occurrence of hemoglobinuria in these affections. But the blood offers other evidences of malarial infections than the parasites in it, viz.: the presence of pigmented leukocytes and the characteristic leukocytic variation of malarial infection. In all the cases studied by him there were pigmented leukocytes. After considering this subject quite in detail, he said that if pigmentation and leukocytic variation are evidences of malarial infection when the parasites

are few or absent in the peripheral circulation, hemoglobinuria must be malaria, and, being malaria, is a most striking evidence of the extreme virulence of the estivoautumnal parasites. Phenomena occurring in these infections after the disappearance of the parasites, which have been termed postmalaria, are also evidence of the toxin theory. Not infrequently it has been stated that the negro is relatively immune from malarial infections, and sometimes that he is absolutely so. These statements were not in accord with his experience of 8 years with the negro in the southern Mississippi valley. On the plantation where he resided there were 24 whites last year, and, of this number, 41% were infected with malaria. Of this number, however, 5 who did not have malaria were away from home during the greater part of the malarial season. So, excluding these, the percentage of malarial morbidity would be about 53% amongst the whites. There were 184 blacks, and of these 61 were infected. Professor Osler classifies 3 groups of gangrene: First, in connection with Raynaud's disease; second, multiple spontaneous gangrene, in association with the acute infections, like measles, typhoid fever, typhus fever, scarlet fever, diphtheria, and malaria. Multiple spontaneous gangrene of the limbs in young and middle-aged people may occur without any obvious cause. The case he reported was one of multiple gangrene in estivoautumnal infection. He saw another case of spontaneous gangrene last year which from the clinical history he regarded as one in association with malaria. He then gave an abstract of the case.

SECOND DAY.

The Chemic and Microscopic Examination of the Blood: Dr. W. D. KELLY (St. Paul, Minn.) said the blood-serum containing serumalbumin and serumglobulin is subject to chemical change in puerperal septicemia, and in febrile disease serumglobulin is less subject to change than serumalbumin. The pathologic variation in the phosphates of the serum is but slight; of the chlorids not very great, although this principle is chiefly responsible for the isotonic relations of cells in serum. A high percentage of chlorids is usual in anemia. The larger the proportion of plasma the greater is the percentage of chlorids in the blood. Sodium salts are principally found in the plasma, being usually increased in the watery blood. Potassium found in the red cells is diminished in hydremic conditions. Seegan, Chauran, Cavazanni and others found in normal blood traces of glucose, which was increased by a diet of carbohydrates and diminished by muscular exertions. The diastase ferment of blood is found in the red cell and serum is found by Preeka and others to have the power of coagulating the blood; it is inhibited by the nuclein and increased by sodium sulfate and chlorid. Fat has been demonstrated in the blood after a hearty meal. The occurrence of free fat both in health and disease has been frequently observed. Acetone has been found in fevers. Jaksch demonstrated fatty acids in the blood of leukemia, acute atrophy of the liver, and infectious diseases. The poisonous symptoms developed in cholemia have been referred by most authorities to the presence of biliary acids. Isotonic tension and increased resistance of the red cells are peculiar characteristics of red blood in jaundice. Bile acids affect the union of hemoglobin and with the stroma of the red cells, rendering hemoglobin more easily soluble; this accounts for the solution of red cells in jaundice, as well as in other conditions. Icteric blood has also an increase in the nitrogenous bodies. Well-marked cholemia may be detected by the inspection of serum or foam on heating to 50° C. Bilirubin may be changed to biliverdin by that process. By the intravenous injection of glacial acetic acid in the rabbit he has been able to get an acid reaction several hours afterward by the phenolphthalein test. The specific gravity of the blood may be increased by sweating, lack of food, muscular exertion, and may be decreased by freely imbibing water or fluids. Homberger found that albumins, phosphates and chlorids behave differently after changing osmotic conditions. When a little acid is added to blood, albumin and phosphates pass from red cells to serum, while chlorids pass from serum to cells; but when alkali is added the opposite transfer is induced. In order to make a satisfactory examination of the blood the following things are necessary: Apparatus must be absolutely clean. The various stages of the process must be performed rapidly because the cell coagulation of the blood will interfere with any of the tests. The work must be done accurately. By making large quantities of the stain and keeping some in glass-stoppered bottles, will standardize the solution, and so one will receive minimum variations in intensity of stain. Fixing a specimen by continuous heat, with a slight degree of variation in distributing the heat as possible.

Pernicious Anemia: Report of a Series of Cases: Dr. THOMAS McCRAE (Baltimore) read this paper, which was a report of 40 cases that have occurred in the service of Dr. Osler, at the Johns Hopkins Hospital, in Baltimore, in a period between 10 and 11 years. During the same time there were about 12,500 medical patients. Of the 40 patients, 32 were males and 8 females. Two were colored. The ages varied from 10 to 70 years, the largest number occurring in the fifth decade. As to the etiology, worry and mental strain were only present in 3 cases. Pregnancy was associated in one instance. Oral sepsis was not invariably present in the recent cases. Among the symptoms the most frequent were weakness, change of color

and loss of weight. The latter occurred in more than one-half of the cases, and emaciation was marked on examination in 10 of the series. Pigmentation of the skin was found in 8 and petechia in 4 instances. In the abdomen the liver was felt in 2 cases and the spleen in 6, but in none was the enlargement at all marked. When the cases first came under observation the hemoglobin averaged 30%, the red corpuscles 1,560,000, and leukocytes 6,920 emm. Of the 16 cases with a count below 1,000,000 only 4 recovered. The average differential count for 36 cases was polymorphonuclears, 61%; small mononuclears, 31%; large mononuclears and transitionals, 4%; eosinophiles, 2% and a fraction of a percent of myelocytes. The average number of nucleated reds per 1,000 leukocytes was 37, of which 23 were normoblasts, 5 were megoblasts and 9 were intermediary forms. In a comparison of the fatal and the nonfatal cases the average percentage of small normoblasts was rather higher in the cases that recovered, but the number of megaloblasts was 11 times greater in the fatal cases. There were nervous manifestations in 14 cases. These varied from slight sensory disturbances only to complete paraplegia. It was not possible to group the cases under any division as the symptom varied so. The prevailing type, however, was of a more or less spastic condition, with some incoordination and marked sensory disturbances. In some, the nervous symptoms seemed to vary with the state of the blood. As to diagnosis, the distinction from gastric cancer may be difficult. In this the higher count of the red cells usually found, lower color index, lower percentage of small mononuclear and absence of megaloblasts are all important factors. Certain cases showing some features of splenic anemia are hard to place, of which 3 were cited. They had a prolonged course, markedly enlarged spleen, ascites in 2, and the general blood conditions of pernicious anemia. They were not included in this series. The average duration of 17 fatal cases was 12 months. In 8 the course was under 6 months. One patient recovered and came under observation 7 years later with cancer of the stomach and one is in good condition 6 years after the onset. The treatment given may be summed up as rest, fresh air, good food and arsenic.

The Leukocyte Count in Hemorrhage: Dr. GEORGE DOUGLAS HEAD (Minneapolis) wished to place on record some experimental work upon the leukocytes in hemorrhage which gave results somewhat different from the generally accepted views. In his experiments upon dogs the same law seems to govern the increase or decrease of leukocytes in the circulating blood as in man. There is a leukocytosis of digestion and one following septic infections in dogs as in the human being. The variation of leukocytes in the circulating blood of man is the same as in dogs. In all probability the conclusions arrived at from his experiments in dogs would apply equally well to human beings. He formulated the results of his work as follows: (1) In dogs a diminution in the number of white cells in the circulating blood immediately follows a profound hemorrhage; (2) this initial leukopenia is followed sooner or later by an increase in the number of leukocytes in the circulating blood; this is the so-called posthemorrhagic leukocytosis of all writers; (3) this leukocytosis of hemorrhage continues for at least 7 days, and in some cases much longer. The writer believed that what he had demonstrated in dogs is equally true for human beings. Namely, that in human beings, immediately following hemorrhage, there is an increase in the number of leukocytes in the circulating blood which has hitherto been overlooked because hematologists have failed to make their counts early enough after the hemorrhage took place.

Discussion.—Dr. W. T. HIGGINS (Courtland, N. Y.) says that some of the gentlemen were inclined to doubt Hunter's theory and the importance of the mouth conditions in pernicious anemia. Hunter's success in the treatment of this disease seemed to offer something in favor of his theory. He had treated one very marked case on the lines laid down by Hunter with complete recovery. He was impressed with the securing aseptis, not only of the mouth, but of the nose and upper air passages, as well as the teeth.

Dr. W. D. KELLY (St. Paul) referred to the importance of keeping the air from the veins of rabbits; if air gained an entrance death would ensue in a few seconds.

Dr. McCRAE, in closing, said that he agreed with Hunter in his theory, but he also believed that it was important to pay attention, too, to the intestinal tract. Brilliant results had been obtained from the use of arsenic. One patient he had had in 1880 who is alive today. Another patient treated returned 6 years later with cancer of the stomach. He has now one case under observation for 6 years. He had seen cases recover when treated by rest, fresh air, good food, Epsom salts and arsenic. He emphasized the importance of oral aseptis.

Osmotic Pressure and its Relation to Uremic Manifestations: Dr. HEINRICH STERN (New York) read this paper and stated that he thought we were laboring in the wrong direction when we tried to fasten the origin of uremia and kindred affections upon a purely physiologic-chemical basis. Most of the effete products *per se* are little toxic. Potassium, it seems, exerts the greatest poisonous qualities. Intravenous injection of urine for experimental purposes has shown what we did not know before, namely, that uremia is *not* the consequence of one, but of the retention of all those substances which normally enter into the composition of urine. We do not encounter in the blood of uremia any other factors but those prevalent in the normal state. The only difference is the quantity. *Uremia is,*

therefore, rather a physical than a chemical anomaly. **Osmotic Pressure in the Body Fluids:** All organic matter is saturated with water. The cells of the body are more or less permeable for water. If the contents of the organism are soluble salts and, in water, remain unaltered, so that for a certain period neither salts nor water are introduced nor eliminated, all the watery constituents of the organism would become one homogeneous liquid, and the same osmotic pressure would prevail over the entire system. The molecules of a number of compounds, when dissolved, are divided up, are dissociated into "ions." The higher the dilution the more perfect the dissociation, as a general rule. There is no vital process in which diffusion, or osmosis, does not participate. Conditions for the evolution of osmotic pressure always exist in the organism, for whenever 2 solutions come in contact by means of a semipermeable wall, osmotic tension is displayed. When the excretory activity of the kidney is materially interfered with, the products of catabolism are retained in the blood. The great number of molecules dissolved in the plasma exert a high osmotic tension, and tend to diffundate (?) toward the less concentrated body liquids. Ultimately all the fluids of the body exhibit a similar degree of concentration. This degree of concentration is accompanied by a series of manifestations coordinate and successive, which have been grouped together under the name of "uremia." *This is really, if we may call it so, a mechanical intoxication, not one of chemical origin, but one due to an abnormal increase in osmotic tension of the blood plasma and the fluids of the body.* The phenomena which occur in the blood after the injection of large amounts of concentrated salt solution are the same as those in uremia; they make their appearance, together with the increase in the concentration of the blood, when the elimination of the accumulated substances from the blood, on account of the extraction of the resorbative qualities of the tissues does not occur any longer. Noss already noticed in dogs tonic and clonic convulsions after intravenous injection of 10% sodium chlorid solution, and in such events that the blood had attained twice its former concentration.

Circulatory Disturbances Accompanying Cirrhosis with Inosulation of the Portal Branches with Systemic Veins: Dr. CHARLES G. STACKETON (Buffalo, N. Y.) read this paper, from which some practical conclusions may be drawn from the data given, some of which it would not seem necessary to call attention to but for the fact that they appear to have been somewhat overlooked. First, the normal blood-pressure in the portal vein is low; when it is raised suddenly it is apt to be followed by symptoms of toxemia, and these symptoms may be primarily relieved by purgation. The second important conclusion is that when the vascular changes, and the raised portal blood pressure, that permit the passage of the portal blood into the systemic veins, are brought about gradually, and then the subject is better able to resist toxemia, becoming as it were immunized to the offending portal blood, hence the symptoms are less striking, and with proper care as to diet and laxative, may be practically overcome.

Cirrhosis of the Liver due to Metallic Poisons: Dr. VICTOR C. VAUGHAN (Ann Arbor, Mich.) said that lead and copper are the substances which should be considered among the metallic poisons, so far as their effects upon the liver are concerned, and especially upon the changes in the connective tissue of the liver. Alcohol is one of the most important factors in the production of the cirrhosis of Laennec. The metallic poisons, lead and copper, generally, if not always, produce changes in the liver-cells, which are characterized here by a fatty degeneration or fatty deposits in the liver-cells. There has been considerable discussion as to whether the first changes take place in the hepatic cells or in the connective tissue. But so far as the metallic poisons were concerned, he thought that the changes in the liver-cells were prior in time to the changes in the connective tissues. They are certainly recognizable earlier than the other changes. For instance, if hours or days after the administration of these metallic poisons in not immediately fatal doses fatty deposits may be found in the hepatic cells, it is not presumable that the changes in the connective tissue takes place so rapidly. He had seen a number of cases of cirrhosis of the liver due to lead poisoning, some occurring in house painters who are careless in their habits, having unclean hands. Other cases of this occur in workers of lead fumes. It is not often that we see cases in the early stages of liver changes at autopsy. Therefore we must rely on animal experimentation in our endeavors to trace the relationship of these changes. In a number of the cases of metallic poisoning there occurs subsequently an overgrowth in the connective tissue in the liver. Another poison in which he was much interested was aluminum; the effects of this upon the human liver he did not know much about, but when the soluble salts of aluminum were administered to animals hypodermatically or intravenously, the changes can be speedily detected in the hepatic cells and subsequently in the connective tissue.

Treatment of Cirrhosis of the Liver: Dr. JOHN H. MUSSEN (Philadelphia), spoke on this topic. He divided the cases of cirrhosis of the liver into those in which no symptoms occurred during life, the cirrhosis having been found at autopsy, the patient dying from other causes, and into those cases that were not suspected until such an accident as hemorrhage made it apparent, *i. e.*, latent cirrhosis of the liver, and again into cases with the symptoms of portal obstruction and, on the other hand, biliary obstructions. The lines of treatment

were largely dietetic and hygienic, great care being taken to see that the functions of the gastrointestinal tract were kept in action all the time, and that the renal secretions were properly regulated as well as the action of the skin. He raised a word of caution in regard to the presence of hemorrhoids. Many patients are operated upon without careful investigations, and it was his misfortune to see 2 or 3 deaths occur following the operative treatment upon hemorrhoids; at autopsy cirrhosis of the liver was shown to be present. In all cases of hemorrhoidal disease, a thorough knowledge of the state of the liver should be known before any operative measures are advised. The management of ascites, occurring in cirrhosis, is interesting because of the late attempts at treatment through surgical intervention. In the treatment of ascites there were medicinal and surgical measures. He was accustomed to the use of mild purgation, and the use of calomel from time to time; he also used calomel in $\frac{1}{10}$ of a grain doses given every 3 hours as a diuretic. He also relied upon the old-fashioned pill of digitalis, squills, and calomel. He also had considerable confidence in the oil of copiba. In any case of ascites he did not wait long to determine whether these drugs would be of use, but he resorted to tapping early and frequently. One should not be appalled at the frequency of tapping required in some cases; 1 case was cited in which tapplings were done 190 times. He then considered the question of permanent drainage, and stated that Dr. Frazier had operated upon a case, opening the abdomen, scarifying the peritoneum, and attaching the omentum to the abdominal walls; this was done 12 months ago, and the patient is cured of his ascites, there being no recurrences. Among 20 cases that have been operated on in Philadelphia, a very large percentage were relieved or cured.

Cirrhosis with Pigmentation: Dr. THOMAS D. FUTCHER (Baltimore), read this paper. The association of pigmentation of the skin and tissues with a form of hypertrophic cirrhosis of the liver, rather than with the atrophic form was emphasized. He discussed at length the pigmentation associated with the hypertrophic cirrhosis of the liver, which occurs in the disease described by von Recklinghausen as "Hemochromatosis." He also dwelt with the source, chemical composition, and distribution of the pigment. He endeavored to show that diabetic cirrhosis with bronzing of the skin, *diabète-bronzé*, was probably identical with von Recklinghausen's hemochromatosis. So far as he knew, only 4 cases of cirrhosis of the liver with general pigmentation (hemochromatosis) have been reported from this country.

Rheumatic Stimulants: Dr. JAMES J. WALSH (New York) said that there were 3 terms in medicine that have indefinite signification—rheumatism, gout and catarrh, and curiously enough these terms are descriptive of the same idea. Acute rheumatic arthritis we have come to realize as being an acute infectious disease of microorganismal origin. Its very similarity to gonorrhoeal rheumatism points strongly to the microbial origin of the disease. He referred to a series of joint-symptoms that occurred in connection with certain toxemias. Observations were made, pointing to the fact that there might be serious involvement of joint structures without their necessarily being any microbial metastasis. Painful affections around a joint point to 2 facts, (1) the nervous mechanism supplying joints, owing to its greater use than most of the other groups of nerves, makes it extremely sensitive to disturbances of the circulation; (2) tissue in the neighborhood of joints being much used and subjected to injury are liable to take on chronic inflammatory conditions. Certain observations were made in a series of cases in the service of Professor Katzenbach at the New York Polyclinic. These cases presented painful symptoms which were usually referred to the neighborhood of joints and which had been diagnosed as rheumatism. When the patient was not able to give a straight history of acute rheumatism with red swollen joints, fever and sweating, the case was at once assumed not to be rheumatic in character and very seldom was it necessary to retract this assumption. Among 40 cases presenting, 15 had so-called rheumatic symptoms of the lower limbs, due to flatfoot. This proportion, a little more than $\frac{1}{3}$, represented, he thought, very nearly the ratio in which flatfoot symptoms are mistaken for rheumatism. Very often the symptoms are worse on rainy days or damp weather, probably from the fact that on damp, muggy days these patients are apt to wear old shoes which furnish a much less support to the foot than do the well-fitting new shoes. Again, nerves are much more sensitive when there is much dampness. In speaking of occupation neurosis, he said that there was no occupation that involved a frequent repetition of muscular movements but what might produce it. For instance, so simple an action as sweeping, if done as a regular occupation and constantly performed with a broom in the same hand, will, in individuals who are run down, give rise to painful feelings, either in the shoulder, if the broom is grasped too high up to enable the person to take advantage of the proper leverage in making the sweep, or in the leg if the body is constantly supported on one leg during the process of sweeping. The brachyalgia that occurs in connection with frequent and badly directed use of the small muscles on the forearm is well known, occurring in telegraphers, in writers, in penmen, in typewriters, in piano players, in violin players, etc. As a result of a sort of sympathy with the lower arm, the upper arm and shoulder, often suffer from a decided ache, and it is surprising how often this ache is treated as rheumatism. He referred to many other cases of

occupation neurosis in which antirheumatic treatment had been administered.

A Case of Akromegaly Presenting Features of Unusual Interest: Dr. CHARLES LYMAN GREENE, (St. Paul, Minn.,) presented a case of a young man, 25 years of age, who had had no fixed occupation, but for some years prior to the development of the disease had spent the winter months on the ice, a point of some importance, inasmuch as the history of many of these cases has strongly suggested the influence of long exposure to cold and dampness as a predisposing or exciting cause. The family history was negative. Syphilis was denied. Three years ago he suffered from a swelling of the kneejoint, from lassitude and general weakness. Two years previous to this (5 years ago) he noticed a rapid enlargement of the hands and feet and the members of his family noticed a change in his physiognomy. The enlargement of the hands and feet steadily continued and progressed quite rapidly up to the time that he presented himself 3 years ago. At this time the hands and feet were enormous, the wrist and ankles free from inflammation, but bulky, thick and in strong contrast with the forearms and legs. He complained of languor and weakness, but has had none of the severer vertical pains so common in akromegaly, nor did he complain of pain in the lumbar region or limbs. There were no signs of disturbance of the special senses nor of the nervous system. The skin is nearly normal and lacks the harshness of myxedema. The appearance of the face was especially interesting, the skin being thickened and hypertrophied though not rough. Both upper and lower eyelids are thickened and the ears appeared clumsy and tumid as also is the nose. The nasal arch is prominent, the malar bones project and the lower jaw is apparently enlarged both from the angle to the symphysis and vertically. The enlargement of the upper jaw had no doubt masked the changes in the lower jaw, depriving the case of one of the so-called typical signs of the disease. The tongue is large, the larynx is enlarged and its cartilages appear to be the seat of hypertrophy. The radiograph demonstrates the remarkable enlargement both in length and thickness of the bones. The feet presented the same typical characteristics as the hands. There were no marked enlargements of the great toes. The hands and feet were not the seat of pain nor are their movements much restricted. A feature of especial importance is the marked increase in the bulk of the overlying tissues which present the appearance and sensation of a hard edema exactly like that of myxedema. The treatment had been solely by thyroid extract, the result being an immediate and marked amelioration of the disease.

Election of Officers. For chairman, Dr. FRANK A. JONES, of Memphis, Tenn.; for secretary, Dr. ROBERT B. PREBLE, of Chicago.

THIRD DAY.

Modified Treatment of Typhoid Fever: Dr. T. B. GREENEY (Meadow Lawn, Tenn.) advocated the use of acetanilid with quinin, which, he claimed, had a soothing and quieting effect, and prevented the possible irritating effects of the latter. He had never observed any depressing effects of the drug upon the heart. The dose was increased or diminished according to the rise or fall of the temperature.

Mental Shock: Dr. O. T. OSBORNE (New Haven, Conn.) did not wish to advocate the use of the term medical shock for conditions of failing heart due to distinct pathologic conditions, or due to a gradual breakup in the system by very acute or prolonged intense processes; he thought the term was justifiable when a badly-acting and gradually weakening heart was the most urgent cause for anxiety and its weakness was out of proportion to the pathologic conditions or symptoms present. He believed that we were justified in using the term medical shock as we are in using the term surgical shock. The symptoms of this are a more or less rapid heart, irregular, perhaps dirotic, or intermittent pulse, incomplete inspirations without much actual dyspnea, interspersed with frequent sighs, and the subjective symptoms of precordial oppression. The temperature is generally low, the flesh cool and clammy, and if quick relief be not obtained death will soon take place by heart failure or medical shock. He believed that medical shock was just as certainly a vasomotor paralysis as in surgical shock and, as a consequence, the major part of the blood is to be found in the abdominal veins. The blood flows slowly into the dilated, and therefore nonelastic arterioles, hence slowly into the capillaries, and returning slowly in the veins and imperfectly fills the heart cavities. The heart contracts irregularly, incompletely, and arrhythmically. The aorta has not the pressure ahead or the forcible quota of blood from behind, and consequently does not give enough elastic rebound to force blood properly into the coronary arteries, and the heart muscle is improperly nourished. By the lowered blood pressure all the functions of the body begin to fall, all digestive processes are impaired, and molecular death begins to take place, at least almost unaccountably gradual failure of body and mind occurs until death closes the scene. Severe acute nerve pain will, if continued, give a lowered vasomotor tension, and if too long continued or too severe, vasomotor paralysis or shock perfectly similar to that due to profound injuries of these nerves, or surgical shock. In acute feverish processes our aim should be to make the elimination at least equal to the production of decomposing and fermenting products and to prevent the absorption of these products if possible. Keep the emunctories all in good order.

In all diseases or conditions where there is a piling up in the blood of absorbed poisons, be they from typhoid fever, or dysenteric ulcers, from pus collections, from malarial plasmodia, or hemoglobin debris, from cancerous disintegration, or from catarrhal unhealthy, edematous mucous membranes, etc., any treatment which hastens the evacuation of the excreted bile impregnated with toxins, will prevent systemic and nervous poisonings and ultimately vasomotor disturbances and mental shock.

Coughing a Means of Disseminating Tubercle Bacilli; a Study of 50 Cases: Dr. L. NAPOLEON BOSTON (Philadelphia) said the conditions which prompted him to investigate as to the degree with which tubercle bacilli were disseminated by coughing were, first, that from the mouth of an inmate of the Philadelphia Hospital he noticed that fine droplets of sputum were ejected with each act of coughing, and second, that coughing was often excited by eating. He thought that this was a potent factor in the dissemination of tuberculosis, and possibly explained why patients in the early stages of tuberculosis did badly in this institution where every possible attention was given to ventilation, light, and the disinfection of sputa. The spray was collected by a mask, the essential features of which were that it was made from German silver wire, one piece of which was moulded to fit the face, resting on the nose, cheeks and chin. To prevent irritation it was covered with rubber tubing. Suspended from this wire was a second oblong portion provided with 2 lateral grooves, which served to accommodate 2 microscope-slides. When the mask was in position the slides were held directly in front of the mouth and nose at a point 3 inches distant from the lips. The piece is held in position by an elastic band. The patients were allowed to wear the mask with clean slides from 1 to 1½ hours, and only during the day when he coughed less, and they were instructed to remove it during a paroxysm of coughing. Of the 50 specimens obtained from 50 patients, 38 were found to contain tubercle bacilli in variable numbers, 4 to 6 being the smallest found in any specimen. Of the 12 negative cases explanations were given. In 3 of these the patients were so very weak and did not talk while wearing the mask. It was shown that the secretions of the mouth and respiratory tract are atomized and given off in the form of spray, in both health and disease, and that this spray contains bacteria and other cellular elements known to be common to such secretions, and therefore it was reasonable to suppose that many other diseases were conveyed by this medium, and that the work accomplished through the study of consumptives is but a step in a direction which bids fair to modify the hygiene of infection. Conditions affecting these organs and consequently their secretions must of necessity be spread in this way; especially was this true of diphtheria, tonsillitis, and possibly smallpox, measles, scarlet fever, whooping cough, mumps, etc. Droplets alighting on clothing must serve as a favorable means to convey the disease from house to house; and that men may become infected by the spray projected by horses, cows, and other domestic animals suffering from glanders, tuberculosis, and similar affections, appears to be highly probable.

The Value of Throat Cultures in Diphtheria: Dr. M. H. FUSSELL (Philadelphia) said that the following statements could be proved: (1) True cases of diphtheria may have few or no clinical symptoms; (2) cases of tonsillitis or pharyngitis may have severe symptoms and be serious, but not true diphtheria being present, not due to the Klebs-Löffler bacilli and consequently not able to transmit diphtheria; (3) a diphtheric exudate may be easily detached and leave no bleeding surface; (4) an exudate due to some other organism may be a true membrane impossible to detach from the mucous membrane. He said that cultures can most surely and with less risk of mistake be made in the laboratories, but that they could be made at home and should be made there if we intend to keep pace with the rapid strides of recent medicine.

Genitourinary Examination by the General Practitioner, with Demonstration on Patient: Dr. FERD. C. VALENTINE (New York) made practical demonstrations upon patients before a large and interested audience. It was his desire to show (1) that all genitourinary examinations should be painless; (2) the operator should conduct no examinations unless his arms are bared to above the elbows and his clothing protected by a gown and apron; (3) during every genitourinary examination the physician should protect his eyes with spectacles (not eyeglasses), even if he has no visual defect; (4) ideal examinations are made in the morning, before the patient has passed his urine; (5) the amount and character of a urethral discharge can be estimated only by correct technic in expressing the urethral contents; (6) the color of the urethral discharge changes when it dries upon the patient's garments; (7) the meatus should be cleaned before passing urine for examination; (8) the manner of urinating is often pathognomonic; (9) the epithelium found in the urine is indicative of the locality of the lesion; (10) examination of the urethral adnexa is a necessary part of the steps for complete diagnosis; (11) no instrumental ingression of the urethra should be attempted without most thorough efforts at rendering it aseptic; (12) the technic of striving at urethral aseptics is neither complicated nor difficult; (13) the soft bougie-a-boule is the only instrument that can be used for tactile exploration of the urethra; it is a purely diagnostic instrument; the rigid sound is wholly a therapeutic instrument; (14) urethroscopy with a modern

instrument is not difficult; (15) the general practitioner is perfectly competent to examine the vast majority of genitourinary cases; (16) such examinations only exceptionally require extraordinary skill or a large armamentarium; (17) the pathology of genitourinary diseases in no wise differs from that of other affections.

Clinical Observations in Pericarditis: Dr. FRANK BILLINGS (Chicago) stated that pericarditis is essentially a secondary process, occurring in the course of some general infection. The local manifestations may be so slight as to escape observation, and the general symptoms to which the local disease may give rise may be obscured by the constitutional disturbance of the primary general infections. Therefore it often happens that the diagnosis of pericarditis is more often made at autopsy than clinically. The histories of several cases were given which illustrated pericarditis of several varieties, etiologically considered which presented clinically, as far as the heart and pericardium were concerned, practically the same signs and symptoms. The cases further illustrated the importance of the 3 cardinal signs of pericarditis, namely the pericardial friction rub, the form or outline of the precordial dulness, and the position of the apex beat especially in relation to the left border of precordial dulness. The pericardial friction rub is doubtless present in every case of pericarditis in some period of its course. It is practically the sole local sign in plastic pericarditis. It may not be recognized in pericarditis with effusion although it is present in every case at an early stage of the disease, and in cases of recovery after the disappearance of the effusion; it may be present too during the stage of effusion. The form of this outline of dulness in pericardial effusion is also characteristic. The pear-shaped outline with the base downward; the dulness, even in the early stage of effusion, in the fifth right interspace close to the sternum, obliterating the resonant angle formed by the lung, heart and liver; the dulness over the sternum extending to or above the second rib, together with the outline of the left border dulness, are easily recognized and are almost pathognomonic. It is also true that a greatly enlarged heart with all the chambers dilated from myocarditis and a weak diffusible apex-beat, may present an outline of dulness which so nearly resembles that of pericarditis with effusion that it may be impossible to differentiate between them without puncture. The location of the apex-beat in pericarditis with effusion is characteristic. When it is perceptible it will always be found that the left border of dulness is relatively far removed from it, as it is not in any other cardiac disease. In large effusions it may be obscured, and at other times the right ventricle may strike the chest wall in the region of the nipple, or undulatory waves may be seen as the only evidence of the heart beat against the chest wall. However, it matters not how the apex beat or the impulse of some other part of the heart against the chest wall be ascertained, it will be found that the point of contact of the heart against the chest wall is always relatively far removed from the left border of precordial dulness as compared with the relations of the apex beat to the left border dulness in all other conditions. The relatively rapid respiration and dyspnea, the signs of compression of the left lung evinced by the left subscapular dulness and bronchial breathing, the rapid heart action, the pulsus paradoxus and the asymmetry in size of the pulse of the radials, the irregular type of temperature, the paralysis of the left recurrent laryngeal nerve, the unequal pupils, the disturbed mental state of the patient, and still other phenomena, are signs and symptoms not so characteristic as the 3 cardinal signs first named, but are important and significant when present. Pericarditis is an easily recognized condition. Frequent, careful, systematic examination of the precordium should be made in all infectious diseases, and if this is done by the clinician, pericarditis will not escape him.

Pathology and Pathogenesis of Pericarditis: Dr. JOSEPH McFARLAND (Philadelphia) said that it is more frequent in men than in women, probably because they were more exposed to its causes. Concerning the relative frequency authors vary. It is customary to divide the cases into those which are primary or idiopathic and those which are secondary or metastatic. **Traumatism as a cause of pericarditis** is of importance only as it affords an avenue of entrance for microorganisms, or produces conditions favorable to their colonization in the tissues. Lymphogenous metastasis may occur in many of the local affections in which no actual traumatic lesions existed. In this manner disease of the mediastinum, plura, etc., may occasion pericarditis. Hematogenous metastasis is seen in nearly all of the infectious diseases, but especially in rheumatism, pyemia, septicaemia, pneumonia, chorea, scarlatina, etc. There is no specific microorganism of pericarditis. Breitung collected 324 cases of pericarditis among the autopsies of the Berlin Charité between the years 1866 and 1876 and found them distributed as follows: Pericarditis, serofibrinosa, 108; pericarditis hæmorrhagica, 30; pericarditis purulenta, 24; pericarditis tuberculosa deuteropathia, 24; pericarditis tuberculosa idiopathica, 2; pericarditis adhesiva partialis, 111; pericarditis adhesiva totalis, 23; pericarditis ossificans, 2. It is an error to think of these names as referring to distinct forms of the disease; they are for the most part stages of the same process. In 39 cases studied by Louis the exudates were, serous, 9; purulent, 7; seroanguinolent, 10; seropurulent, 13. The effect of pericarditis upon the heart is of great importance; no considerable disease of the epicardium is possible

without involvement of the heart. The superficial layers of muscular fibers usually show cloudy swelling, later hyaline or fatty degeneration. In cases with purulent exudate the pus may also gradually work its way between the muscular bundles. The changes that thus take place during the height of the disease predispose to acute dilation of the heart and a fatal termination of the disease may thus be brought about. If this does not occur and if the patient recovers from the pericarditis, the regenerative cicatricial processes that go on lead to fibroid interstitial changes in the wall of the heart.

The General Etiology of Pericarditis: ROBERT B. PREBLE (Chicago) made the following conclusions: (1) Cases of acute pericarditis, clinically primary occur, but are rare; (2) diseases to which pericarditis appears as a complication are in order of their frequency: pneumonia, 34%; rheumatism, 23.36%; chronic diffuse nephritis, 11.2%; tuberculosis, 10%; sepsis, 4.7%; aneurysm, 2.6%; typhoid, 1.7%; (3) the more extensive a pneumonia, the greater the danger of this complication; (4) the danger is somewhat greater with left than with right-side pneumonia; (5) When only 1 lobe is involved, the danger is least with a right upper lobed pneumonia, and greatest with a right middle or left upper lobed pneumonia; (6) with a unilobar pneumonia the chances of a pericarditis are 1 in 40; with a bilobar or trilobar, 1 in 10; with a quadrilobar, 1 in 5, and with a pneumonia of the entire left lung, 1 in 8; (7) the mortality of pneumonia with pericarditis is 92.4%; (8) rheumatic pericarditis is complicated by endocarditis in 60% of the cases, *i. e.*, 3 to 4 times the normal rate of cases of endocarditis; (9) the danger of pericarditis complicating rheumatism is the greater the younger the individual and is somewhat greater with males than with females; (10) so far as acute pericarditis is concerned, the site and extent of the endocarditis is apparently of no importance; (11) pericarditis appears as a complication of all forms of nephritis, but particularly the chronic diffuse nephritis with contraction; (12) it is an extremely ominous thing for 22, *i. e.*, 84.6% of the cases died; (13) it is still uncertain whether the pericarditis is toxic or infectious; (14) tuberculosis excites only $\frac{1}{5}$ of the cases, and when one considers the extreme frequency of tuberculosis, tuberculous pericarditis must be regarded as a rare complication; (15) pericarditis may be a part of a generalized acute tuberculosis, but is more often the result of a chronic tuberculosis of the lungs or mediastinal glands; (16) septicaemia and pyemia contribute a very considerable number of cases of pericarditis, and the primary focus may be remote or close to the pericardium; (17) aneurysm of the aorta causes 2.6% of all the cases, a very high figure when one recalls the comparative infrequency of aneurysm; (18) typhoid fever, which is rarely complicated by inflammation of the serous membranes, other than the peritoneum, contributed 4 cases, which is 1.7%; (19) the cases of obliteration of the pericardium are due to the following causes arranged in order of importance: endocarditis, tuberculosis, chronic nephritis, aneurysm; (20) more than $\frac{1}{2}$ of the cases, in which the cause was clear, were due to endocarditis, or rather to some cause common to both the endocarditis and the pericarditis, and more than $\frac{1}{2}$ of these cases showed a combined aortic and mitral endocarditis; (21) relatively, 6 times as many cases of obliteration of the pericardium occur with aortic and mitral endocarditis than with either lesion single; (22) tuberculous causes but few cases of obliterative pericarditis; (23) pericarditis accompanying nephritis is not always fatal, but may apparently end in the formation of adhesions.

Adherent Pericardium: ROBERT H. BABCOCK (Chicago) stated that adherent pericardium was encountered in 2 forms: first, in which adhesions between the 2 layers of the sac but not of the pericardium to the surrounding parts, pericarditis *interna*; and second, the pericardium adherent to the epicardium and also to the neighboring structures, pericarditis *interna et externa*. He then considered the effects on the heart and general circulation, with special consideration of its effect on the liver, leading to the so-called pseudotrophic cirrhosis of the liver. Diagnosis in the first form mentioned was usually very difficult and often impossible. He then made a cursory enumeration of signs. If the adhesions are limited to the 2 layers of the sac, and if they are unassociated with valvular disease, the result may be only hypertrophy of the heart and the circulation will be carried on adequately and no subjective symptoms are produced. If pericarditis leads to adhesions while the heart is in dilation from endocarditis, then the heart is prevented from ultimately returning to its previous size and the symptoms are likely to occur, *viz.*, those to stasis. In the second form mentioned the diagnosis was often easy in consequence of the signs resulting from the pulling of the adhesions upon the surrounding soft parts.

Tuberculous Pericarditis: C. F. MCGAHAN (Aiken, S. C.) stated that this disease was much more prevalent than had heretofore been generally accepted. He believed that a great many cases of obscure heart troubles occurring in the anemic when we could find no valvular disease, without marked symptoms of pericarditis, but where we have certain masked symptoms of the disease, is due to tuberculous pericarditis, particularly if later the patient begins to lose weight and assume a cachectic appearance. This condition usually progresses insidiously and he believed that it was communicated to the pericardium through the lymphatics, arterial and venous systems, and from all that tends to cause tuberculous troubles in the peritoneum. The symptoms of tuberculous pericarditis are

those that we would get from enlarged heart, and from an adherent heart together with the general symptoms of malaise and more disturbance of the general system than would be found in a simple pericarditis, or that secondary to rheumatism, or one of the exanthematous diseases.

Cardiac Lesions as Observed in the Negro; With Special Reference to Pericarditis: FRANK A. JONES, (Memphis, Tenn.) made the following recapitulation: (1) aortic regurgitation in the negro was the most frequent and most dangerous of all valvular lesions; (2) the next most frequent, aortic stenosis; (3) the next, mitral regurgitation; (4) mitral stenosis had not been diagnosed in the cases he reported from the physical signs and symptoms; (5) tuberculosis and syphilis acted both as exciting and predisposing causes in the production of muscular and valvular lesions; (6) syphilitic history in mitral regurgitation was more frequently found than that of rheumatic; (7) the murmur of aortic regurgitation was most frequently musical.

Some Points in the Treatment of Pericarditis: FRANK PARSONS NORBURY (Jacksonville, Ill.,) said that it behooved us in the treatment of rheumatism, acute infectious fevers and septic processes to keep ever in mind the possibility of pericarditis as an aftermath and govern ourselves accordingly by insisting upon absolute rest and quiet until this danger is past. Each case must be treated upon its individual merits. There must be enforced rest and quiet surroundings; this is important because it "curbs the symptoms and places the patient under the most favorable condition for speedy recovery." Milk is the most suitable diet. It should be given in small quantities every 2 or 3 hours. It is well to remember that most all cases of rheumatic pericarditis get well, if we will let them alone; keep them at rest and carefully meet indications as they arise. For the relief of pain a blister over the pericardium will be sufficient, or if it continues, cold applications, cold cloths or an ice bag used as needed. When other means fail morphin should be given, guarding it with proper cardiac support. For the restlessness he preferred bromid of soda given usually during the day, usually commencing about noon, again at 4 or 6 in the afternoon and at bedtime. For the sleep he used trional. If combined with sulfonal its effects are prolonged. For the cardiac distress strychnin may be given or, if necessary, digitalis with strophanthus. To properly care for the effusion is one of the prime essentials of treatment. If moderate, unless septic, it will be absorbed, and even if large, the chances are that with cautious use of diuretics and purgatives it will disappear. The indications for surgical interference are, according to Osler, "dyspnea, small, rapid pulse, dusky anxious countenance," and we will add the physical signs of extensive effusion.

[To be concluded.]

Section on Surgery and Anatomy.

FIRST DAY.

After expressing his appreciation of the honor done him in electing him Chairman of the Surgical Section, Dr. A. J. OCHSNER proceeded to give the usual address of the Surgical Section, on **The Cause of Diffuse Peritonitis Complicating Appendicitis, and Its Prevention.** Impressed with the fact that an unfavorable outcome in any given case of appendicitis means that the infection which was originally confined to the small space occupied by the appendix, has first invaded the tissues surrounding, and then been deposited over the entire peritoneal cavity, Ochsner has adopted a new form of treatment since 1892. At first, this treatment was employed only in selected cases; later, more and more generally, as its value was shown by clinical results. His idea is that the peristaltic motion of the small intestines is the chief means of carrying infection from the perforated or gangrenous appendix to other portions of the peritoneum, changing a circumscribed into a general peritonitis. This can be prevented by prohibiting the use of every kind of food and cathartics by the mouth and by employing gastric lavage in every case in which there are remnants of food in the stomach or in the intestines above the ileocecal valve, as indicated by nausea, vomiting or meteorism. The patient can be supported by the use of concentrated, pre-digested food, administered as enemas, not oftener than once in 4 hours, and not in larger quantities than 4 ounces at a time. This form of treatment, when instituted early, will change the most violent and dangerous form of acute perforated or gangrenous appendicitis into a comparatively mild and harmless form. Cases of perforated or gangrenous appendicitis in beginning general peritonitis, can usually be carried through the acute attack safely with this method. In all of this class, gastric lavage should be practised, in order to prevent the absorption of decomposing material from the alimentary canal. In cases of doubtful diagnosis, this form of treatment should always be employed. It will prevent a large proportion of troublesome complications and sequels, such as ventral hernia and extensive adhesions. The patient should be permitted to recover fully from his acute attack before an operation is performed, especially in cases not encountered within the first 36 hours after the beginning of an attack, or in cases with the formation of a superficial, circumscribed abscess. It often requires but a small amount of food to change a harmless, circumscribed peritonitis into a

dangerous, diffuse peritonitis. The treatment does not prevent a subsequent attack; it does not contraindicate the removal of the diseased appendix before the septic material has extended beyond this organ. It is indicated in all intraabdominal conditions in which it is desirable to prevent the absorption of septic material by means of peristaltic motion. The laity should be taught to stop feeding and giving cathartics to patients suffering from intraabdominal diseases. Ochsner states that his mortality in cases of perforated and gangrenous appendicitis, with diffuse peritonitis, is less than $\frac{1}{4}$ as high as it was in cases operated upon at once, upon making a diagnosis; and even in advanced cases of diffuse peritonitis, there has been a marked decrease in the mortality. From January 1, 1898, to May 1, 1901, he has operated in the Augustana Hospital in Chicago, on 565 cases, which he divides into 3 groups: Those suffering from diffuse peritonitis on entrance; those suffering from gangrenous, perforated appendicitis; those suffering from recurrent appendicitis, or at the beginning of a recurrent attack, when the infectious material was still confined to the appendix. Of the first class, 18 patients were treated, with 10 deaths, a mortality of 55.5%. Of the second class, 179 cases were treated, with 9 deaths, a 5% mortality. Of the third class, 368 cases were treated, with 1 death, or 33% mortality. In the total 565 cases there were 20 deaths, a mortality of 3.5%. These statistics include all patients who entered the hospital suffering from appendicitis, even those who died from general peritonitis a few hours after admission. Of classes 2 and 3, all were operated upon, so there can be no doubt concerning the diagnosis. Of class 1, all but 4 were operated upon and these were in an absolutely hopeless condition when they came to the hospital. Judging from the mortality rates quoted by other writers, Ochsner believes that these results are extremely encouraging. Krogins, who has compiled statistics for 58 authors, gives a combined mortality of over 70%. Ochsner believes that these results justify a further adoption and trial of this method of treatment.

Remarks on the Surgery of the Spinal Cord: ANDREW J. MCCOSH (New York). There are quite as urgent reasons for rapid relief in cases of pressure on the cord as there are in cases of depressed fractures of the skull, though perhaps it must be said the results of operation for the relief of fractured vertebra are less satisfactory than are those for fractured skull. Early operation is of the utmost importance. The patient may be in a condition of shock due to severe injuries of other organs. In such an event it is wiser to wait until it be determined that the case is not one which under any circumstances must end fatally. Again, it is sometimes difficult to determine that the symptoms are not due to mere contusion of the cord, or to more pronounced hemorrhage within the substance of the cord, or to hematomyelia. A certain time must often elapse before this point can be determined. In these cases the symptoms are apt to be of an irregular type. The muscular paralyses are not complete and often the muscles of the same group may not be equally affected; the anesthesia is only partial and paresthesia with patches of hyperesthesia is common. The symptoms of irritation are apt to be less pronounced though there may be mild twitching at first of certain muscles. The reflexes are not apt to be abolished though they may be altered. On the other hand, when there is definite pressure of bone on some portion of the cord the parts supplied from this center are apt to be more distinctly and more decidedly affected. The paralyses are generally complete and more regular as to grouping, the anesthesia also is apt to be complete with or without a band of hyperesthesia. The reflexes are apt to be abolished.

Generally within a few hours the differential diagnosis between these 2 conditions can be made. If in doubt a delay of 12, 24, or even 48 hours can do little harm. If then there still be question as to the cause of the paralysis, it seems to be wiser to do an exploratory operation. In the severer cases, where the symptoms indicate a fracture or dislocation, the question then will be: Is the injury to the cord one that can be relieved by operation. In order to answer this, we should first determine whether the damage has already been done by the springing apart of 2 dislocated vertebrae, with resulting pinching, bruising or complete disintegration of the cord, the vertebrae having immediately afterwards sprung back into their original position, or whether the symptoms produced are by the pressure of bony fragments or of an unreduced dislocation. In the former case, operation is not indicated. In the latter case it is urgently demanded. It is very difficult, often impossible, within the first few hours to determine which of these conditions exist. A short delay will probably settle this point, but it is exactly such delay which makes recovery hopeless.

As yet we have not sufficient experience or knowledge to make any definite statement concerning the early symptoms which indicate complete destruction of the cord. We do know, however, that if certain symptoms are allowed to persist for days or weeks that the case will be hopeless. It has been stated more than once that where there is complete loss of sensation, motion and patellar reflexes in both lower extremities that these symptoms indicate a complete crush of the cord, and that the case is absolutely hopeless. This view, however, is not correct, as has been shown by more than one case where all these symptoms have been present, and yet where, after removal of fragments of bone, recovery has resulted. The following case is to be added to this list:

The risk of an operation on the vertebra is very slight. The

shock should not be great. The operation should not consume more than half an hour. While it is true that the mortality has been great, it is not the operation but it is the conditions found which cause the large death rate. It would doubtless be larger were the operation not performed. In the 159 cases collected by Lloyd there were 59 deaths following immediately after operation and 32 at a later period. The so-called operative mortality was 49%. Of McCosh's own laminectomies for fractures of the spine, 6 in number, 2 have recovered and 4 have been fatal.

Operations for spinal tumors have generally been more satisfactory than those for cerebral tumors and offer better promise for future operative successes.

Spina Bifida or Hydrorrhachitis.—EVE says that Spina bifida, caused by an arrest of ossification of the vertebral arches, is situated in the lumbar region in about 50% of all cases.

At present there are recognized 3 distinct varieties: meningocele, meningomyelocele, syringomyelocele, the central canal of the spinal cord being dilated, thus forming the cavity of the sac.

This is a very fatal affection, few children surviving longer than 5 or 6 months after birth, many dying before that time. Death usually occurs from convulsions, or ulceration and rupture of the sac.

On account of the very fatal termination of the majority of these cases, the surgeon is warranted in pursuing any treatment which promises a prolongation of life or a radical cure. This treatment we can readily divide into palliative and radical.

Eve believes from the statistics gathered from the treatment by tapping followed by the injection plan, the results of which have been most unfortunate, we are warranted, in this aseptic age of surgery, to treat this affection by operation especially when the tumor is small and peduncular. He reported the case of a child operated on when less than three months old; the tumor was rapid in its development, and threatened rupture was imminent; the pedicle was small and consequently easily dealt with. The child made an uneventful recovery, and was dismissed entirely well.

The Methodical Exploration of the Brain for Fluid: CHRISTIAN FENGER (Chicago) reviewed the literature of traumatic brain abscesses, and spoke of the efficacy of the aspirating-needle. He described a case having a previous history of suppurating disease of the ear, and an attack of appendicitis subsequently, of short duration, and then swelling of the elbow-joint. He explored the brain methodically, going from one place to another. There was a cicatrix behind the ear which was the only guiding point. After exploring the brain on the affected side of the head with no results, he then tried the opposite side, where the pus was found, and the patient recovered. The methodical exploration of the brain was preferable to all others. Puncture is harmless, as Spitzka proved by the needle-tracings in the brain, which were aseptic.

The Immediate and Remote Effects of Brain Injury: D. S. FAIRCHILD (Clinton, Iowa). Fairchild discussed this subject at considerable length, reporting several interesting cases, and in closing offered the following conclusions: Violence of no great intensity may cause a fracture with only momentary displacement, or a rupture of the middle meningeal artery, with or without fracture, may occur. An injury which may lead to fracture without displacement, does not, as a rule, cause a serious termination if early and judicious surgical treatment is employed. A fracture may occur without brain displacement and yet it may cause irritative changes, which either may be immediate or there may be remote secondary changes resulting in epilepsy or mental impairment. A blow on the head may produce extensive laceration of the skull without any serious results, but a fall from a height or a rapid-moving train usually results in contusion or laceration of the brain tissue with serious immediate or remote results; or such serious injuries may also disturb the cerebrospinal fluid, causing more or less mental disturbance. A wound of the brain may heal with a scar tissue, which results in cystic or other degeneration with serious remote effects. In absence of definite symptoms to indicate the nature of the lesion, the extent of the force applied is of great value in reaching a conclusion as to the nature of the injury to the brain. Fairchild omitted for the most part ordinary, simple and compound fractures, and considered only such varieties of injuries as those which occur within the cranial cavity, and the immediate and remote results which may follow. In such doubtful cases, exploratory operation is usually advisable.

Discussion.—KEEN (Philadelphia). He believes that Eve has taken the proper stand with regard to the treatment of spina bifida; the old treatment by injection should be abandoned and operative measures adopted in these cases. He is disappointed that Fenger would limit aspiration to diagnosis of the cases with pus. Over 10 years ago Keen formulated methods and described various routes for tapping the ventricles of the brain for withdrawing collection of fluid. This paper which was read at the German Surgical Association was lost by the secretary, and has consequently never been published in full. Keen does not consider opening the ventricles a dangerous operation. In discussing Fairchild's paper on "Fractures of the Skull," a case of a man was reported who fractured the posterior part of his skull in 1892. Epileptic symptoms did not develop until 7 years later. On trephining, nothing was found to account for the symptoms. An incision was made into the brain substance, and to his surprise, Keen found, after a slight

incision, that the lateral ventricle was open. He drained this with a small drain for 24 hours, and twice on later occasions was obliged to evacuate fluid. The patient recovered from the operation, but sufficient time has not elapsed to determine what the permanent results will be. The case is interesting as showing not only the lack of danger in open ventricles, but from the fact that the symptoms developed very late, 7 years after the accident. Keen agrees with Fairchild that in many cases operation is imperative in the treatment of fractures. In certain cases of hemorrhage following injury there is no stage of unconsciousness, and the symptoms may be misleading. A case of a man is reported, who fell from a hayrack. No fracture was discovered, even upon exploratory incision. The man developed severe symptoms of pressure, however, with stertorous breathing, but no paralysis. There was no reaction of the right pupil to light, and but very slight reaction of the left pupil. A trephine was performed and both branches of the medical meningeal artery were found to be ruptured. In this case there was no loss of consciousness in spite of the severity of the injury. In certain other cases unconsciousness may develop from the injury, producing hemorrhage very long after the injury. A case was cited in which consciousness developed 6 weeks after the injury, and upon trephining, a very large clot was found. Keen believes with Fairchild, that it is necessary to operate in many of the doubtful cases.

FRAZIER (Philadelphia) advocated a new method of operation for trifacial neuralgia. His method is really a combination of the methods of Abbey and Cushing. He goes in by the temporal root as Cushing advanced and divides the central root, but does not remove the ganglion.

WEIR (New York) has recently become more radical in his views regarding the necessity of operating for fractures, and he thinks it a question if we should not operate in nearly all cases of fracture of the skull. In case of fracture discovered on exploratory incision after a severe injury, it is sometimes a question whether we should operate or not, but of late Weir has adopted a radical course and feels safe in doing so. On several occasions he has seen decided advantage result from this course. In cases in which we trephine and leave a gap in the skull, especially if this is below the hatband, or where the depression is unsightly from a cosmetic point of view, Weir uses a celluloid plate to fill the opening. In operating for the removal of the ganglion, Weir uses the Hartley and Krause method. He has performed 4 such operations during the past year with good success. He finds this method very satisfactory, and sees no reason to change. He can see no advantages in the method adopted by Cushing, but several disadvantages; the smaller incision makes the operation more difficult, and with the incision through the temporal root and consequent damage to the muscles, for this reason mastication will be decidedly interfered with. There is very little trouble in evading the medical meningeal artery with the Hartley-Krause method.

FRANK (Chicago) said he had good results in tapping the ventricles for severe headache following trauma in one case, as suggested by Fenger, but in most cases he does not think this operation is necessary, and sometimes the pressure may be removed by lumbar puncture and evacuation of the cerebrospinal fluid by this route.

EARLES (Milwaukee) agrees with Fairchild that very radical measures are necessary in the treatment of fractures of the skull. He now thinks that in nearly all cases we should trephine and examine the brain before closing the wound. In no other class of cases does the surgeon consider himself justified in closing the wound before it is determined definitely the condition of the viscera. In over 70 cases occurring in his own practice, Earles has found injury to the brain in about 87%.

MOORE (Minneapolis) believes that McCosh has given an entirely satisfactory statement of the best methods of the indications for the operation of langeneotomy. He believes with Eve that we should operate in cases of spina bifida and would even operate in the larger percent of the cases which were suggested by Eve. He mentioned several cases in which he had obtained satisfactory results from operation and gave several suggestions as to the technique of the operation.

DAWBARN (New York) mentioned a case which occurred in his practice 10 years ago. A man had been struck on the right side of the head and developed hemiplegia. Dawbarn trephines as was indicated by the local symptoms. The ventricle was tapped and a small amount of fluid withdrawn. The symptoms were not relieved, however, and the patient died about a week later. At the necropsy a blood-clot the size of a hand was found on the same side as the injury. In this case Dawbarn followed the suggestions of the neurologist in operating. Upon more thorough examination it was found that the motor fibers did not cross as is usually the case. He questions whether these cases are so rare and believes that in certain cases if we do not find a clot on trephining according to local symptoms, we should trephine on the side of the injury. Dawbarn has used the celluloid plate as suggested by Dr. Weir, for filling openings. The camphor in the celluloid is somewhat irritating and he has devised a new composition for a plate containing urea instead of common camphor, which he thinks is advantageous.

BERNAYS (St. Louis). Fenger's suggestion to trephine and examine both sides of the cerebrum and cerebellum with an aspirated needle is probably a new suggestion and one of great importance. With regard to technique, Bernays suggests that it is necessary to use a large trephine, and a good sized burr may

be used with good results without leaving so large a defect in the skull.

Discussion.—CRILE (Cleveland) did not think there was any difference of opinion as to what to do in any case of incomplete paralysis due to traumatism of the cord, but there is question as to the diagnostic feature as to complete cross-lesion of the cord.

BALDWIN (Salt Lake) in speaking of the celluloid plates, mentioned one that had absorbed and become flabby; that, instead of acting as a protection, it produced irritation.

McCOSH, in closing, emphasized the simplicity of laminectomy.

Dr. MEANS (Columbus) believes that McCosh's suggestions with regard to laminectomy are very valuable. Means operates only in case of injury to the spine with symptoms of pressure. He believes that there is a possibility of obtaining relief, even after the symptoms have existed for some time. He reported a case in which there was considerable following the operation 2 years after the injury.

SECOND DAY.

The Mortality of Appendicitis.—JOHN B. DEEVER (Philadelphia) stated that in 1900 he operated upon 268 cases of appendicitis in the German Hospital of Philadelphia. Of this number 144 were suffering from an acute attack and 124 cases were chronic. Of the patients operated upon during the acute attack of the disease, 26, or 17%, died, either from the disease or intercurrent trouble. One patient died from diabetes, 1, who was suffering from advanced tuberculosis, died from peritonitis; 1 died of postoperative pneumonia. Deducting these 3 cases of diabetes, of tuberculosis and pneumonia, the mortality of the series is 15.9% for appendicitis without intercurrent disease. In 7 cases there was purulent peritonitis. In 7 other cases, purulent peritonitis occurred subsequent to the operation. In 8 cases, septicemia was the cause of death. One patient died of shock, 1 of shock from a second operation for intestinal obstruction, due to adhesive bands. In the 7 cases of postoperative peritonitis, the appendix was removed in every instance. It was postcecal in 3 cases, and by its removal, unsuspected abscesses were discovered and opened. In another case, the appendix was behind and to the outer side of the cecum in a mass of infected exudate. In a sixth case, the abscess was found immediately on opening the abdomen, and the contents escaped into the general peritoneal cavity. In the seventh case, the appendix lay to the cecal side of the abscess wall and was not a portion of it. Of all these 7 cases with purulent peritonitis, in only 1 had the attack lasted but 12 hours before the operation; in the others the operation was from 1 to 21 days. In nearly all there was nephritis after operation. One death in chronic appendicitis occurred, in which there was an ovarian cyst adherent to the appendix and complicating appendiceal operation. Deever considers septic peritonitis the most important factor in the causation of mortality in appendicitis. This arises from the migration of organisms through an ulcerated appendix, or through the wall of the appendix without rupture, or through a gangrenous pouch. Another common cause of trouble is obstruction of the bowel from adhesions which form and which are apt to localize the infection. In certain cases, death results from the deposition of septic material in distant parts of the body, such as the liver, lungs, brain and heart. Very rarely, an abscess rupturing into the bladder, causes fatal cystitis, or pyelitis. In the fulminating variety of appendicitis, a fatal termination is unavoidable. Deever especially emphasized the importance of immediate operation as soon as the diagnosis of appendicitis is made. Delay in operation is responsible for more deaths than all the other factors which have to do with the disease. Barring some cases of the fulminating variety, there are no cases, which, if operated upon within the first few hours of the disease—at the latest, from 18 to 24 hours—that cannot be saved, and these patients are not only saved, but they are prevented from disagreeable complications such as fistula, fecal fistula, adhesions, the danger of intestinal obstruction and semiinvalidism from pain.

Some Unusual Features of Appendicitis and Their Treatment.—ERNEST LAPLACE (Philadelphia) reported 4 cases illustrating some conditions seldom met with in appendicitis. In the first case, there was pain of a reflex character, which the patient insisted was on the left side. The abdominal muscles were rigid on the right side, and, depending upon other symptoms, the operation was performed and a gangrenous appendix was found and removed. A good recovery followed. This case illustrates the deceptive nature of reflexes and reflex pain in these cases. In a second case, a man of 42 was supposed to have an abdominal tumor on the right side, but on operating, it was found that the appendix had sloughed off and formed a large, inflammatory, indurated mass. In cases of abdominal tumor of uncertain diagnosis, an exploratory operation should be undertaken, as in this case. In the third case, there was slight induration in the right iliac region, with considerable jaundice and pain. On operating, a gangrenous appendix with pus about it was found, also cholecystitis. The patient, in this case, had been suffering from typhoid fever. Both appendicitis and cholecystitis were relieved by this single operation. In the fourth case, a man suffering from gastrointestinal irritation and symptoms of dyspepsia suggesting the

possibility of floating kidney, but on opening the abdominal cavity, the true nature of the disease was discovered. In the treatment of cases complicated by general peritonitis, Laplace advocates continuous irrigation of the abdominal cavity with normal salt solution at a temperature of 100° F. A glass tube is introduced into the pelvis, and is connected by a rubber tube with a basin under the bed. A small tube is introduced at the superior extremity of the wound and placed in connection with the irrigating apparatus a few inches higher than the patient. The wound is tightly closed between the 2 tubes and continuous irrigation is kept up for a varying time, according to the necessities of the case.

The Knot within the Lumbar Region in Intestinal Surgery, with Report of Cases.—F. GREGORY CONNELL (Chicago). This form of suture Connell had previously described, so he limited himself to discussing the cases in which it had been used and in discussing its advantages.

The method was employed for the following conditions: Fecal fistula, 4; benign stricture of the pylorus, 3; malignant, 3; laceration of rectum, 1; gunshot wound, 2; carcinoma, large bowel, 1; strangulated hernia, 1; fistula bimuscosa, 1; invagination of ileum, 1; biliary fistula, 1.

The various operative procedures have been: circular enterohaphy, 8; longitudinal, 4; pylorotomy, 3; pyloroplasty, 3.

He gives the chief advantages of this suture:

1. Less danger of peritonitis through leakage at stitch hole.
2. No yielding of stitch.

And among other commendable points which may only be mentioned now are:

3. Adhesions diminished.
4. Small diaphragm.
5. Less danger of gangrene.
6. No foreign body. Suture material will all pass away.
7. Decrease in time.

In no case can death be attributed either to the method of suture employed or the manner of applying it.

In closing, he drew the following conclusions:

Yielding and leakage are the most frequent causes of failure in enterohaphy.

To include all coats of the bowel wall removes the danger of stitch-yielding.

To place the knot within the lumen diminishes the danger of capillary.

The square loop stitch is more reliable than is the circular loop stitch of Mamesele.

The relative thickness of the needle and the submucosa surrounds the procedure of "penetration without perforation" with great uncertainty.

To fail to include the submucosa leaves an insecure stitch.

To perforate the submucosa is practically to open into the lumen.

To penetrate into the submucosa of the duodenum is practically to perforate the submucosa.

It is not only possible but practical and advantageous to place all the knots of an enterohaphy in the lumen.

The ideal location for the knot is outside of the peritoneal cavity.

Discussion.—STEELE (Chicago) was glad that there is a hospital in the country where in every fatal case of appendicitis there was held an autopsy, as in the German Hospital, Philadelphia. Steele often was compelled to say, "I do not know why that man died," because of the fact that a necropsy was not accorded. He related the case of a little girl who had swallowed a shawl pin, which simulated appendicitis, but the pin was found and the case proved not to be appendicitis.

As to Laplace's irrigation in septic peritonitis, he did not see why normal salt solution, now applied to septic joints, could not be extended to the abdomen.

He had had an opportunity of observing the advantages of Connell's method described.

MURPHY (Chicago) commended Dr. Deever on his work, a debt of gratitude which the profession will never be able to pay. He considered that the question as to whether it is possible to make a diagnosis of the pathologic conditions within the peritoneal cavity from the symptoms presented was a very vital question. In the fulminating type he did not believe that one could tell from the outside whether it is progressing to that stage where it manifests its virulence.

KNIGHT (Connecticut) emphasized the importance of the estimation of the leukocytes in appendicitis and referred to a number of cases in which these furnished valuable diagnostic information. In case the peritoneum is infected he advises flushing freely.

MAXWELL (Keokuk, Iowa) emphasized the importance of irrigation in the treatment of these cases.

ANDREWS (Chicago). There are 3 zones in the region of the perforated appendix. One case in which the infection expanded to involve the entire peritoneal cavity, the zone contained clear pus; in the second case it contained cloudy serum, and in the third, clear serum alone. If the peritoneal cavity is flushed, there is danger of carrying the infection into areas not already contaminated. Recovery of the pelvis is possible only when part of the peritoneal cavity is affected but not if there is a true general peritonitis. He believes he can cite as many cases in which favorable results have followed simple drainage, as Knight can in favor of treatment of irrigation. Andrews advo-

eates the Trobis position and has seen astonishing results follow its use. He also commended Connell's method of suturing the intestine with the knot within the lumen.

HARRIS (Chicago) believes that in some cases leukocytes estimation is of absolutely no value, notwithstanding the use of the blood-count, as it is frequently impossible to tell from diagnosis what is within the abdominal cavity. Considering the dangers of early operation was advocated.

MOORE (Minneapolis) believes that it is dangerous to teach students and general practitioners that every case of appendicitis should be operated upon as soon as diagnosis is made. In the practice of Dr. Deaver and other experienced surgeons, with the advantages of large hospitals, this may be the wisest practice, but with inexperienced operators and less favorable facilities, it is not the wisest course. Moore believes that the appendix should be removed in most cases, and if it is not readily found in the pus cavity, extensive search should not be made for it. The estimation of leukocytes is of special diagnostic value in but comparatively few cases.

MORRIS (New York) compared an inflamed appendix in the peritoneal cavity to a match in a haystack. In many cases the fire might go out spontaneously, but it is always dangerous to trust to such a result, and clearly dangerous to trust appendiceal inflammation subsiding spontaneously. Morris advocates operation in every case as soon as diagnosis can be made by a competent man. Leukocytosis is of scientific interest in these cases, but it is not of determining importance when we are deciding the necessity for operation. In treating cases of general peritonitis, Morris believes that it is better to make a small incision, washing out the toxin particularly clean and leaving the patient alone instead of employing continuous irrigation as is suggested by Laplace. We are coming to appreciate more and more the importance of leukocytes as a protective agency, and washing the peritoneum disturbs this natural process. Both Clark's position, with the pelvis elevated, favoring absorption by the peritoneum, and Fowler's position favoring mechanical drainage, have been used with excellent results. Morris believes that it is still a question which position affords greatest advantages. He emphasized the value of intraphine transfusion of normal sterile saline solution in the treatment of cases suffering from considerable shock or aseptic pains from absorption of toxins.

SMYTH (Memphis) advocates early operation and removal of appendix.

DEAVER (Philadelphia) would not in routine make the blood count, and believes with Morris that it is better not to employ continuous irrigation of the peritoneal cavity.

A Method for the Study of Relational Anatomy: C. M. JACKSON (University of Missouri).—The relative inefficiency of the present courses of instruction in anatomy is largely due to the lack of a practical method of studying the topographic relations of the various organs. For this purpose, sections are necessary. The method of frozen sections is unsatisfactory. Jackson has obtained excellent results by sectioning bodies hardened by arterial injection of formalin. A detailed account of this method as applied in teaching relational anatomy in the University of Missouri was given, and a new apparatus for making rapid and accurate drawings of sections described. The possibilities of this method for teaching anatomy and surgery, and also for the study of relational anatomy by the practitioner are very great.

The Surgical Aspects of Carcinoma; the Nature of the Cancerous Process: ROSWELL PARK (Buffalo). The various theories as to the nature of carcinoma were reviewed, the dietetic, embryologic, irritation, and parasitic theories being especially considered. The dietetic theory is important only in case we succeed in maintaining the parasitic nature of the disease, when it may become a question as to whether raw, or uncooked food may furnish some of the parasites. The embryologic theory has explained many anomalous growths, but this hypothesis can never explain the peculiar behavior of cells which constitute the nature of malignant growths. The relation of irritation and trauma figures today as prominently as it ever did, but the relation is an indirect one, and, while accounting for certain predispositions, does not account for the active disease. The parasitic, or infectious theory of carcinoma, Park believes is the only one that satisfies the needs of both the pathologist and clinician. The disease must be studied by the pathologist, the chemist, the histologist and the clinician, all working in close association. The man who knows the disease solely from what he has learned from dead-house preparations, is in poor position to explain its course; whereas, the man who has simply watched the disease during life, may have strong views about its infectious nature, which, however, he can justify by nothing more than by analogy. The combination of clinical observation with experimental and laboratory work, is sure to solve this problem, if it is not already solved. Park believes that there are several arguments in favor of the parasitic hypothesis. The analogy in the lower vegetable forms in which the galls and zylomata are invariably caused by parasites. Comparative pathology furnished many other arguments. Again, in the matter of metastases, there is no known infectious disease characterized by metastases, and it is well known that cancerous disease often follows the track of such instruments as the trocar. Park believes that he may state that in the Buffalo Laboratory, Gaylord and others have absolutely produced adenoma carcinoma by inoculation in a

number of animals, and that this can now be produced in such a way as to afford unmistakable evidences of the infectivity of the disease. A minute description of the organisms cannot yet be given, but they belong to the protozoa, or some lower and less known form of animal life. They are seen to undergo ameoboid movement upon the warm stage, and they are seen to undergo anomalous changes somewhat slowly. This would appear to take them out of the realm of the vegetable kingdom. They can be cultivated and successfully inoculated, however. They grow best in weak solutions of ordinary media. The most successful way yet devised, is to deposit them in collodion sacs in living animals. They stand dessication as does vaccine lymph. There is absolute resemblance between the results obtained in the Buffalo Laboratory and those of Schüller, working independently. Nearly every statement is corroborated. Park believes that the statements of Schüller in connection with the work at Buffalo, take away the last element of doubt which can remain as to the parasitic nature of carcinoma. It is as yet too early to discuss treatment, but if it is found that we have to do with a parasitic disease, it is not too much to hope that some agent, vegetable or mineral, or animal antitoxin may be discovered, by which the ravages of the disease may be checked or prevented. Drugs destroy the protozoan that cause malaria, and let us hope that something may be found which will have the same destructive effect on the parasites producing carcinoma, without injuring the animal body. Until this can be done, carcinoma is a surgical disease, and Park believes that if recognized early, in accessible parts of the body, and if it can be removed thoroughly, it can be absolutely cured.

The Present Status of the Carcinoma Question.—SENN (Chicago) considered this the most important topic for research of today. Carcinoma results from a typical proliferation of epithelial cells. As carcinoma originates in epithelial cells its development is impossible in mesoblastic tissues. Histology does not support the parasite theory. The progressive extension of a tumor into the adjacent tissues is proof positive of malignancy. This is by the lymphatics only. The increase of carcinoma is more imaginary than real. There is more basis to heredity than is believed by the profession at large. The age is important, although usually over 40 it may be below 20, and in these cases it is almost always extremely malignant.

Carcinoma of the Cecum: W. J. MAYO (Rochester, Minn.). Carcinoma of the cecum occurs in 7% of all cancers of the intestines and is of the columnar cell variety. Colloidal changes are frequent. It is usually annular in form but may present a well marked tumor. Glandular infection occurs in less than 1/4 of the cases dying from this malady. Age is not so important a feature as in carcinoma of other organs, it is not infrequent in the comparatively young. This disease may be confused with chronic appendicitis, tuberculosis of the cecum, fecal impaction and so forth. Its course may be marked by symptoms of chronic obstruction of the bowels, with colics, alternating diarrhea and constipation, cachexia and wasting, or the first symptom may be an acute attack of obstruction. In the latter case an ileocolostomy should be performed. This procedure rapidly drains the small bowel giving the same relief as an artificial anus and can be left permanently, the malignant parts being excised at a secondary operation with closure of both ends of the intestine. If the symptoms are not acute the ileocecal coil should be resected. An incision through the right rectus muscle gives easy access to the operative field and as the blood-vessels are to a large extent terminal, ligation is not attended by great risk to the vascular supply of adjacent bowel. The peritoneum is divided along the outer side of the ascending colon and after the cecum is liberated posteriorly the colon is divided and the distal end sutured, the ileum being cut across when the parts are ready to unite. The end of the ileum should be anastomosed to the side of the ascending colon. The results of radical operations both immediate and remote, are good and compare favorably with cancer in other situations of the body.

A New Method of Treating High-seated Cancers of the Rectum: ROBERT E. WEIR (New York). Weir first opens the abdominal cavity and detaches the peritoneum around the rectum. With his fingers he freely liberates the entire contents of the sacral curve down nearly to the tip of the coccyx posteriorly, and in front to the edge of the prostate. This gives ample room to tie around the bowel, some 3 inches from the anus, a couple of iodoform tapes about an inch apart, these tapes being situated below the tumor. The intestine is then divided and raised out of the abdominal wound, and the tumor excised. The lower end of the rectum is seized by forceps, by an assistant, and drawn down and out of the anus in an everted condition. The tape that closed this everted bowel is then divided and a pair of long forceps is carried up into the pelvis and the lower end of the upper segment of the bowel is brought down by this forceps and out through the anus. The invaginated ends of the bowel are then sutured near their margins. This gives a union with all the knots inside the intestine. After suture, the bowel is replaced and the peritoneum is closed so that the abdominal and pelvic cavities are separated from each other by a peritoneal shelf. The drainage is then provided below through an opening just in front of the coccyx. Weir has performed this operation in 3 cases. One patient died, not from peritonitis, but from persistent diarrhea without elevation of temperature. The 2 other patients recovered and there are no evidences of

recurrence 18 months and 9 months respectively after the operation. Weir considers this a much more satisfactory operation than that devised by Kraske, for the removal of high-seated cancers of the rectum. In the Kraske operation, the disadvantages are the depth of the wound, difficulty in drawing the upper portion of the bowel satisfactorily, jagged invasion of the peritoneal cavity, and annoying hemorrhage. Weir states that the operation which he has described is very satisfactory.

The Treatment of Malignant Disease: FREDERIC S. DENNIS (New York) discussed the various unsurgical methods which have been proposed in the treatment of malignant disease, such as electricity, caustics, toxins, and drugs. He believes that experience has shown that surgical intervention is the only resource, since all these methods have proved of practically no value. Surgical operation is successful only when it is performed early, when it is radical in its character, and if there is recurrence, it should be repeated. Cases should not be considered cured unless at least 3 years has elapsed since operation, and by some this period is estimated as far too short. Dennis insisted upon the importance of educating physicians as to the necessity for early operation, as an essential feature of the cure. Microscopic examination of every growth is also very important as the only means to obtain accurate information for the future study of malignant disease. Every case should be carefully recorded and the subsequent history followed. Dennis gave the results of his own extensive experience: Eighty-seven patients are well from 3 to 22 years after operation for the extirpation or removal of malignant growth, without recurrence. These results reported to prove the value of surgical intervention over all other methods of treatment. In his cases there was no mortality in amputation of the breast for carcinoma or sarcoma, or from any other cause, with the exception of 2 cases of hemophilia. There was no mortality in the operation for removal of epithelioma or sarcomata of the skin; glandular sarcoma; sarcoma of the superior maxilla. There was 1 death from excision of malignant disease of the intestine, and 1 death following amputation of the hipjoint. Up to 1891, his percentage of cures for carcinoma of the breast was 45, and in his last series of 15 cases there has been 83% of cures of over 3 years' standing. He now has 20 cases in which the patients are living after a period of from 4 to 13 years after the operation, without recurrence or metastases. The patients have been carefully watched in all cases, and great pains have been taken to trace them for years. Dennis has had 5 cases of sarcoma of the superior maxilla, all of whom are living, with no mortality in from 8 to 18 years. In 7 cases of glandular sarcoma there was no mortality, and a permanent cure of from 8 to 21 years. In sarcoma of the skin, 22 cases; in 7 cases a permanent cure has resulted, existing from 8 to 16 years. In sarcoma of the breast, 6 cases were permanent cures of from 7 to 22 years. Dennis has had 8 cases of sarcoma of the leg, with permanent recoveries of from 6 to 13 years. He states that these statistics are not entirely up to date, but are being collected for future publication. The results in these cases are very encouraging, and show the value of surgical intervention, for the patients could not have been saved in any other way.

Discussion.—BERNAYS (St. Louis) believes that the prophylactic treatment of carcinoma is impossible until we learn the nature of the disease. He believes that in most cases, carcinoma is the degenerative process occurring in other tumors, while in other cases a new growth arises from some other cause.

RODMAN (Philadelphia) inclines to the belief that the parasitic theory offers the most satisfactory explanation of the etiology of this disease. Contrary to the experience of Dennis, his results in the treatment of sarcoma of the lower jaw have been very satisfactory.

FUTERER (Chicago) does not believe in the parasitic origin, but is inclined to favor Virchow's theory of mechanical origin. For years he has tried transplantation experiments without success, but he still believes that these attempts should be continued. Specimens of natural transplantation in the body, are by no means uncommon, and there is much evidence in favor of this theory.

MASSEY (Philadelphia) believes that carcinomatous tissue can be destroyed by the electric current without injury to the surrounding normal cells, and he advises this method of treatment.

DAWBARN (New York) agrees with Bloodgood in the opinion that all suspicious lumps should be removed. In operating for carcinoma of the mouth, he does not find it necessary to ligate the carotid in all cases, nor does he consider it best to pack the wound, for the gauze soon becomes saturated with saliva. Frequent irrigation keeps the wound in a more cleanly condition. He places the patient, not sitting up, but with the head lower than the feet, to avoid swallowing saliva and getting inspiration pneumonia.

POWERS (Denver) believes that the favorable results obtained at the Johns Hopkins Hospital have attracted more patients there than would ordinarily come to a general hospital, and hence, that the proportion of 3% of carcinoma in all cases, as stated by Bloodgood, is too high. He considers Weir's operation probably a better one than that of Kraske in the treatment of carcinoma, and believes that the mortality might be lessened by adopting it.

MAYO (Rochester, Minn.) mentioned a case in which on

operating for appendicitis he found a carcinoma in the region of the cecum.

The Nominating Committee suggested the names of Dr. DE FOREST WILLARD, of Philadelphia, for chairman, and Dr. JAMES B. BULLITT, of Louisville, Ky., for secretary, for the ensuing year. The secretary was instructed to cast a unanimous vote for these officers.

[To be concluded]

Section on Obstetrics and Diseases of Women.

FIRST DAY.

The chairman, Dr. H. P. NEWMAN, delivered his annual address, reviewing **The Progress of Gynecology** during the past year, and comparing the relative value of new methods and procedures, and forecasting the trend of the future progress of this specialty.

A paper by Dr. J. CLARENCE WEBSTER (Chicago) on **Methods of Incision for Vaginal Section**, and one by Dr. RUFUS B. HALL (Cincinnati) on **Indications for Vaginoabdominal Hysterectomy** were read by title.

Dr. A. H. CORDIER (Kansas City) read a paper on **Postoperative Intra-peritoneal Hemorrhage**. He described 1 case lost by the slipping of a catgut ligature. He believes that the use of unstable ligature material on large pedicles in localities where the same is absorbed quickly has regularly resulted in death. Postoperative hemorrhage demands early recognition and quick surgery. The use of drainage was advocated in all cases where hemorrhage is to be feared. He believes that the tube does no harm if left in for a few hours. Too much confidence is reposed in nature to control bleeding within the peritoneum. He considered the question in differentiating diagnosis between secondary shock and internal hemorrhage. If hemorrhage is suspected, a single parietal suture should be cut and sterilized forceps passed in to determine the true condition within the peritoneal cavity. He spoke of the value of saline solution employed intravenously in the treatment of hemorrhage, and considers that there is little danger of air in the vessels. The fluid should be employed hot and in large amounts. The value of complete examination in diagnosis was commented upon.

Discussion.—Dr. McMURTRY (Louisville) spoke of the prevention, diagnosis and treatment of postoperative hemorrhage. This, when due to the slipping of the ligature, the material used has little to do with the accident. The method rather than the material is important. He employs silk for ligature material. Intravenous injections of saline solution should not be employed as it will increase the blood.

Dr. GORDON (Maine) has used catgut sutures for 17 years, and has never had a case of intra-peritoneal hemorrhage. He does not consider that the use of the drainage-tube would be any protection against hemorrhage and would advise against its use.

Dr. H. A. KELLY (Baltimore) cited a case of hemorrhage from the uterine artery occurring 8 days after the operation from the too rapid absorption of the catgut ligature. He employs fine silk ligatures and objects to the use of the interlocking suture. He thinks it is important to leave a good pedicle above the tie and to apply 2 ligatures on the cardinal vessels after the operation is completed, and that the field should be thoroughly reviewed and all vessels examined to see that hemorrhage is completely controlled.

Dr. MARCY (Boston) spoke of the value of absorbable suture material. Drs. Wiggin, Frederick, Harris and Massey also participated in the discussion.

Dr. J. G. CLARK (Philadelphia) read a paper on the **Contributing Factors in the Production of Peritonitis**. He presented the following conclusions in regard to the Elimination of Peritoneal Infection and the Prevention of Surgical Peritonitis: (1) The peritoneum has an enormous absorbing function, being capable of taking up in an hour 3% to 8% of the entire body weight; (2) minute solid particles are carried in an incredibly short time from the peritoneal cavity through the diaphragm into the mediastinal lymph-vessels and glands, and thence into the blood-circulation, by which they are quickly distributed to the abdominal organs and to the bone-marrow; (3) the granular bodies are at first largely transported as free bodies, swept along by the lymph currents, but later the leukocytes act as the carriers; (4) there is, normally, a force in the peritoneal cavity which carries fluids and foreign particles toward the diaphragm, regardless of posture, although gravity may greatly favor or retard the current; (5) after the introduction of microorganisms into the peritoneal cavity there is a great decrease in their number within the first hour, both through their intra-peritoneal destruction and through their rapid absorption into the general system, where they are dealt with, and there is, therefore, no possibility of limiting free infectious matter to any part of the peritoneal cavity by mechanical means; (6) vigorous streptococci which remain behind develop within 6 hours a repellent or destructive quality for leukocytes, and the lethal combat is, therefore, inaugurated and well under way before drainage, as ordinarily employed, can possibly exercise any beneficial action, and hence in many cases in which surgical drainage is employed the patient recovers in spite of and not because of it; (7) a moderate amount of even virulent organisms carried by the blood to the lungs, liver, spleen, kidneys, gastrointestinal tract and bone-marrow may be destroyed or eliminated without the least harm to the patient,

whereas if the same amount of infectious matter is detained about a surgical field in the abdominal cavity, or stagnates in a dependent pocket, they may generate myriads of others, and thus overwhelm the patient; (8) in many cases, therefore, drainage as ordinarily employed, is superfluous or even dangerous, and the rational method is to remove all possible debris and infectious matter by thorough irrigation and then leave 1 liter of salt solution (0.6%) in the abdominal cavity, and in order to promote and hasten natural drainage, supplement this by an enema of a liter of salt solution given while the patient is well under anesthesia and in the Trendelenburg position; (9) under this plan the patient is generally stimulated, shock is minimized or averted, the urinary excretion is greatly increased and thus toxic matters are more easily eliminated without irritation to the kidneys or bladder, peritoneal infection is quickly eliminated while yet minimum in amount, thirst is alleviated or entirely prevented, intestinal peristalsis is promoted and consequently tympanitis is of less frequent occurrence, and the early action of the intestines evacuates infectious matter thrown out into the canal by the bloodvessels of the villi. All of these factors combine to reduce mortality after abdominal section, to decrease pain, discomforts and complications of the first 48 hours, and finally to hasten the recovery of the patient.

Discussion.—Dr. KELLY said that in nothing does the progress of gynecology show more than in the status of drainage from the past to the present time. He only drains in case of general peritonitis due to appendicitis, and says that it is rather for the sequestration of purulent foci rather than for the purpose of drainage. Baldy, of Philadelphia, opposes the use of large amounts of saline fluid in the peritoneal cavities, he considers it unnecessary and harmful.

Dr. CARSTENS alluded to the advantage of vaginal drainage. He believes that almost immediately after the operation is performed, adhesions are formed closing off the pelvis from the general peritoneal cavity, and that the only effective mode of drainage is through the incision in the posterior vaginal fornix.

Dr. DEEVER protests against the tendency to do away with drainage.

Dr. GORDON (Maine) indicated a marked difference between appendicial and pelvic pus.

Dr. DUDLEY (New York) employs transfusion before opening the abdomen to produce a current in the lymph channels through the abdominal cavity in septic cases.

A paper on the **Advantages and Disadvantages of Drainage after Abdominal Section**, Dr. HUNTER ROMM (Cleveland), was read by title.

Dr. MATTHEW D. MANN (Buffalo), by invitation, described a **New Operation for Removal of Cancer of the Rectum**. He pointed out that so far, 3 routes had been proposed for the removal of cancer of the rectum, the latest operation being the one perfected by Dr. J. B. Murphy, viz. removal through the vagina. Mann proposes to operate through the abdomen, the patient being in the Trendelenburg position. The technic as follows: The abdomen being opened, the rectum is cut off above the cancer and clamped. The sigmoid and rectum are then pulled out of the pelvis, the mesorectum being cut if necessary. The lower end of the rectum is cut below the growth and the latter removed. The lower cut end of the rectum is then pulled up and $\frac{1}{2}$ a Murphy button is put into it. The other half is put on the upper cut end, and the 2 ends are brought together. Union takes place even if the lower end is not covered with peritoneum, as was the case in 3 instances. Mann reports 5 cases operated on in this way with 1 death. In 2 of the cases the growth extended below the cervix uteri.

Dr. JOHN B. DEEVER (Philadelphia) read a paper on the **Accidents and Complications of Pelvic Surgery and their Treatment**. He treated of the difficulties which the gynecologist is compelled to face, and that the occasional operator under ordinary circumstances does not meet the cases which present anomalous complications, and as a rule is not prepared to deal with them or dispose of the accidents which may occur as a consequence of a complicated operation for disease of the pelvic organs. The variety of complications he groups as follows: (1) Those resulting from adhesions; (2) large growth involving other organs which may be damaged in the attempt at removal; (3) malignant growths involving other viscera by extension of the disease; (4) complications secondary to a ruptured extrauterine fetation; (5) pus in the pelvis; (6) hemorrhage. He called attention to the injuries produced by inefficient operators, and the harm resulting in the many so-called minor gynecologic operations of dilation, curetment, and trachelorrhaphy. He believes that many of these operations are performed unnecessarily when contraindicated and are positively harmful.

SECOND DAY.

The paper on **Uterine Fibroids**, by Dr. THOMAS S. CULLEN (Baltimore) was read by title; the second paper, also read by title, was on **The Complications and Degenerations of Fibroid Tumors as Bearing on the Treatment of these Growths**, by Dr. CHARLES P. NOBLE (Philadelphia).

Dr. EDWARD E. MONTGOMERY (Philadelphia) read a paper on **How Shall We Deal with Uterine Myomas?** He presented the following conclusions: (1) Small uterine myomas which do not cause symptoms are subperitoneal or interstitial and may be permitted to go untreated, but the patient should be kept under observation, and any increase in size should

indicate operation, as continuous growth may result in destruction of the uterus; (2) small growths which cause hemorrhage are submucous or interstitial, and should be removed through the vagina; they may be made accessible by tents or incision through either the posterior or anterior lip; (3) multiple growths or small growths inaccessible by the vagina causing symptoms, should be removed by abdominal incision; the uterus should be preserved wherever practicable; (4) when the growths are large, or render extirpation of the uterus necessary, the entire removal of the organ, as described in the text, is the simplest and most expeditious procedure.

Discussion.—Dr. EASTMAN (Indianapolis) compared the past and present methods of dealing with uterine fibroids. He considers that the evolution of the treatment is remarkable and gratifying. Degenerative changes are apt to occur at the menopause and he hesitates to leave a patient with a fibroid tumor at this time. He alluded to the danger of infection of myometomy, in which case the use of the serre-noud is necessary.

GORDON believes that when a woman has a fibroid tumor which is producing symptoms, whether it be large or small, whether she be near the menopause or not, it should be extirpated by hysterectomy. WATTEN (Louisville) believes that it is best to do full hysterectomy in these cases as it is possible for a cancer to develop in the neck of uterus after supravaginal hysterectomy. Dr. DUDLEY (New York) thinks there is room for conservative work in this field; that it is a duty of the gynecologist to perform myometomy if there is a possibility of preserving function and leaving the woman with healthy appendages. Dr. MASSEY (Philadelphia) argued in favor of electricity in treatment of these cases.

Dr. J. M. BALDY (Philadelphia) read a paper on **Cancer of the Uterine Neck**, which will be published in **AMERICAN MEDICINE**.

Dr. J. WESLEY BOVÉE (Washington) read a paper on **The Relative Merits of the Different Methods of Uretero-ureteral Anastomosis**. He referred to the frequency of injuries to the ureter in abdominal surgery. He considers that nephrectomy is often necessarily performed. He reviewed the different methods of performing ureteral anastomosis and described a case of anastomosis in which the upper end of ureter was invaginated into the lower by the method of Pozzi. In comparing the relative value of the different methods that have been suggested, he considers that the transverse end-to-end is preferable so far as the length of the ureter is concerned, except when the ends are already cut obliquely, in which case the oblique method would be most economic; next would come the end-to-end method of Pozzi with oblique end-to-end; next, the Robson modification of Pozzi, which is the least valuable; and the Van Hook is practically inapplicable when more than $\frac{1}{2}$ inches of the duct has been cut away. When the upper end of the ureter alone is dilated, the oblique end-to-end and side-to-side are clearly the best plans to adopt. He considers that the end-to-end or the end-in-end are applicable in every case in which the end-in-side or side-to-side plans can be used with one single exception and can be accomplished as safely and in even less time. It may therefore seem that the ingenious plan of Van Hook would scarcely ever be needed. With the end-to-end plan as most practicable and the end-to-end of Pozzi, it would seem that a surgeon should be able to repair any injury to the ureter.

Dr. A. PALMER DUDLEY (New York City) read a paper on **Some Results of Ovarian Surgery**, with a report upon intraimplantation of ovarian tissue. He reviewed the work done along this line since 1887, and considers that this is no longer experimental. During the past 14 years he has operated upon 190 cases requiring operations upon the uterine appendages. In selecting the method of operation he considers the age of the patient, her social position, previous family history, and the patient's preference in the matter. His records show that plastic work was done upon both ovaries in 128 cases; 1 ovary and tube removed in 60 cases; gonorrhoeal tubes examined and $\frac{1}{2}$ removed in 5 cases; vaginal sections for drainage in 14 cases; hysteroraphy, 73 cases of pregnancy at full term, and 5 cases of miscarriage which have occurred subsequently to this operation. He described the method of ovarian implantation of large cysts, implanting the ovarian tissue in the center of the fundus uteri without severing it completely from its ligamentous attachment. By this method the ovarian tissue is nourished by its own circulation until such time as collateral circulation can supply it. The proper nervous supply of the ovarian tissue is not cut, and should the ovarian tissue subsequently give trouble, it is in the cavity of the uterus where it can be quickly reached with a sharp curet, and removed without danger to the patient.

Dr. HOWARD KELLY (Baltimore) gave a lantern demonstration, illustrating **The Various Incisions Appropriate to Different Renal Operations**. Three incisions were indicated. First, best incision for suspension of the kidney; second, the incision to be employed when the kidney is enlarged and the operation is liable to be attended with difficulty; third, incision for the removal of the kidney with the ureter. His plan for the nephroureterectomy avoids an extensive wound which would weaken the support of the abdominal walls made by the long incision from the back down to the symphysis pubis. He discussed thoroughly the anatomy of the renal region and the best method of operating upon renal lesions with the least injury to nerves and muscles.

Dr. THIENHAUS (Milwaukee) reported a case of **Atresia Hymenalis, Hematokolpos, Hematometra, and Duplex Hematosalpinx**, each of the size of a man's fist, in a girl of 14, and presented specimens. At the close of his paper he emphasized the following conclusions: (1) the origin of gynatresias in a simple genital tract may be twofold; (a) caused by an inflammatory process (the majority of cases); (b) caused by congenital malformation; (2) the practitioner must pay attention to every case of birth in which he suspects a gonorrhetic infection of the maternal genital tract, not only to the eyes of the newborn, but in the same manner to the vulva and vagina, and, if he finds an infection of these parts he should treat them carefully with a 5% protargol solution 3 times daily, as advised and recommended by Siebert, or by other methods; (3) in all infectious diseases during childhood possible inflammation of the genital apparatus must be taken into consideration; (4) the physician must enforce a thorough examination in all cases of polymenia menstrualia with absence of menstrual flow; (5) if he finds an atresia somewhere in the genital tract as the underlying cause, that he must not cut blindly into the hematokolpos or hematometra, but must direct his method of treatment after the question: is there hematosalpinx present or not? (6) if the latter is diagnosed, laparotomy must be performed first and then the hematometra or hematosalpinx opened by the vaginal route.

Dr. A. GOLDSPOIN (Chicago) presented a paper on **Results Immediate and Remote of Conservative Surgery**, with these conclusions: 1. The patients who are not near the menopause, and who are not tainted by tuberculous or malignant disease, 1 or a part of 1 or both ovaries should be preserved, with or without the retention of the corresponding tube, in the following conditions: (a) In follicular cystic degeneration or cirrhotic induration due to inflammatory processes or other circulatory disorders; (b) in extirpating dermoid tumors and in removing fibroid tumors with or without the uterus; (c) with great caution in the extirpation of nonpapillary glandular cystomas that are devoid of surface papillomas and other evidences of malignancy. 2. Necessary for success in the resection of the uterine adnexa is the exercise of asepsis of the highest degree, and the use of a minimum amount of a fine and readily absorbable suture material exclusively and judiciously as to tension. 3. A generous median ventral incision provides the best access for the conservative treatment of the adnexae, in cases where septic accumulations in the parts are not certainly absent, and when extreme fixations of the parts abound. When these more extreme complications are not present, and a retroversion of the uterus exists, the resection of the adnexae is most auspiciously and easily effected via the dilated internal inguinal rings in conjunction with a thorough Alexander operation. 4. Vaginal celiotomy does not provide a favorable access for conservative surgical treatment of ovaries and tubes. It does frequently admit of ignipuncture, but is not auspicious for resection of ovaries. 5. Resection, with the care and technic above mentioned, is the more ideal and most conservative measure, and should be preferred when the parts are sufficiently accessible without undue traction upon the lateral supports, and when asepsis in the surrounding wound and in the general execution is reasonably assured, otherwise thermo-cauterization is probably better.

Dr. A. J. DOWNES (Philadelphia) read a paper on **Electrothermic Hemostasis in Abdominal and Pelvic Surgery**. He defined the ideal method of hemostasis as one which not only occluded the bloodvessels, but did so without adding a complication to the case either immediately or remotely. He says that none of the usual methods fulfills the definition. He referred to the use of ligatures and the angiatribe. He referred to Keith's method of hemostasis by pressure and heat with crude appliances and gave Skene credit for originating the electrothermic hemostasis and indicated the imperfections in his instruments and method. He believes that the essential requirements in this method are: first, pressure, and then the proper amount of heat in the compressing blade. He pointed out the dangers and insisted on the necessity of mathematic exactness in the use of the current, and exhibited an electrothermic angiatribe, electrothermic forceps, and electrothermic artery-forceps. He reported 20 cases and some multiple operations, including 11 appendicectomies, hysterotomies, 1 ovarian cyst, and 5 salpingo-oophorectomies. He claimed for the method, general hemostasis without ligatures; its ideal use in appendicectomy. He believes in the use of a nonadhering and sterile clamp, and claimed for the method a shortening of time for hemostasis and great practicability.

A paper by Dr. L. H. DEMMING (Indianapolis) on **The Uses and Abuses of Morphine in Abdominal Surgery** was read by title.

[To be concluded.]

Section on Diseases of Children.

FIRST DAY.

The Chairman's Address. SAMUEL W. KELLY recommended that either the office of Secretary be made more continuous than at present, or that the secretary be provided with an assistant; also the custom which, it appears, expects the chairman of the section to act as toastmaster at the section din-

ner undergo a revolution. The advancement of the surgical side of pediatrics is very important, and has been slower in its developments than was medical pediatrics. Its advance may be measured in many different ways, by the recognition of the necessity and importance of it; by the increase of actual knowledge concerning it; by the spirit of knowledge through textbooks and teaching; by the extent and the manner in which this knowledge is applied in practice; it becomes evident that many of the most prominent writers on surgery have given inadequate attention to the surgical side of children's diseases. At the present time the knowledge of anatomy, physiology, pathology, and the history of diseases has reached such a point in the observations of practical physicians and surgeons that the diseases of children, their peculiarities and their importance, can no longer be quite ignored by the surgical side of the profession. There is now needed no elaborate argument to prove that there is a department of surgery as distinct from that adult life, as the medical diseases of children differ from those of their elders. In the cases of children abnormalities are found, and the same diseases that occur in adults are marked by different phenomena when occurring in children. We are aware what peculiarities surround operative work upon children,—how ill they bear hemorrhage, cold, or prolonged shock, and how wonderfully they recuperate once the stress of the storm is past. In medical journals, medical societies, and medical teaching, too little attention is paid to the surgical subjects. There should, if necessary, be children's surgeons as well as children's physicians; or at least the surgeon should be required to extend his knowledge to diseases of children.

Measles.—J. B. GARBER said that the prime cause of measles is, no doubt, a specific poison, the nature of which has not been fully determined. The poison spreads by contagion from one person to another and is given off by the breath and secretions. No age is exempt from an attack of measles. Recurrence of the disease is not uncommon, especially among children. The pathology of the disease is not marked. The period of incubation is now well established, and is found to be about 14 days from the time of exposure. The prodromal symptoms last about 3 days, and are associated later with catarrhal symptoms. Fever is always present, coming on as early as the second day; often remitting and rising again just preceding the eruption; laryngeal cough, drowsiness, loss of appetite and vomiting usually occur; sometimes convulsions. On the third or fourth day, eruptions appear, usually preceded by the Koplik spots which disappear as the eruption progresses. When the rash begins to disappear, if the fever continues, look for complications; for in complications lie the danger of measles. Bronchopneumonia, intestinal catarrh, hemorrhages from the mucous surfaces, and otitis media may occur as complications. The diagnosis is not usually difficult but occasionally puzzling in isolated cases. Cases without eruption have been reported; malignant forms sometimes occur; marked typhoid symptoms accompany some of the fatal cases; it may awaken a dormant tubercular condition; the mortality is low, except in complicated cases; the treatment should be rest, hygienic and symptomatic.

Discussion.—Dr. SLAGLE stated that he rarely found the Koplik spots. Second attacks of measles have not been common in his experience, usually when a second attack is diagnosed as measles, it has been found that it was German measles.

Dr. SCOTT thinks rubella a distinct disease; very much more prevalent than measles, but very easy to confound with the second attack.

Dr. J. M. POSTLE was sure that he had seen true measles undoubtedly recur, in several cases, and had found benefit in the treatment of measles from the internal administration of suprarenal capsule.

Dr. BARBER called attention to the danger of endocarditis following measles. Dr. TOWNSEND pointed out that the enlargement of the postauricular glands was pathognomonic of German measles.

Pathology and Treatment of Pertussis: J. M. POSTLE. Pertussis is a toxic neurosis produced by a bacterium, probably by that of Czuplewski, Hensel, and Koplik. Working in the tissues beneath the mucous membrane of the respiratory tract, these bacteria produce a toxin which has as the point of special selection for attack those nerve-cells governing expiration. These nerve cells are depressed, with resulting clonic spasm of the expiratory muscles. Excess of carbon dioxide in the blood produces powerful stimulation of the nerve-cells governing inspiration, at the same time, partially or completely destroying the toxin. Children, therefore, when playing around gas-works have whoopingcough lightly. Dr. Rose, of New York, has treated pertussis by rectal injection of carbon dioxide, and this experiment has seemed to ameliorate the symptoms. The whooping sound is produced by inspiration before the laryngeal muscles are fully relaxed. There is a prompt return of the expiratory cells to normal when the toxin has been destroyed by rational therapeutic immunization, and recovery is complete in from 1 to 3 weeks, depending on how near to the full physiologic effect the patient is kept while under the influence of the remedies used. The treatment consists of the administration of suprarenal glands, strychnin or any preparation of nuxvomica which may be given hypodermically or by the stomach, and should be pushed almost to the full limit or slightly toxic effect.

The Antenatal Treatment of Hemophilia was the title of a paper by J. W. BALLANTYNE (Edinburgh, Scotland) read by Dr. DARNALL. Cases in which the effect of antenatal treatment can be tested are rare. It is clearly and persistently hereditary, and shows a family prevalence. The probability is that male offspring will be hemophilic, though the female offspring usually escapes. There is a presumptive diagnosis then of antenatal hemophilia when a hemophilic woman is pregnant with a male infant. The following case is reported: Mrs. C., 34 years of age, third pregnancy, tall, well built, rather spare, with black hair, sallow complexion, has always lost much blood at her menstrual periods, and had postpartum hemorrhage after both confinements. She had a distinct family history of hemophilia; the first child at birth was anemic, is still alive, but is a marked "bleeder," having nearly succumbed several times during the cutting of teeth; the second pregnancy ended in the birth of a male child, and was also associated with a postpartum hemorrhage. The infant showed hemorrhage from the umbilical cord at birth, and died at the age of 12 months, during dentition, the cause of death being returned as cerebral hemorrhage. The mother was now pregnant for the third time. Calcium chlorid might safely be given to the mother; the drug would pass through the placenta and reach the fetal tissues, although theoretically the hopes of success were small; also iron, arsenic and strychnia might be administered in order to improve the general health, increase the tone of the uterine muscle, and lessen the risk of postpartum hemorrhage. This treatment was carried out for 3 months; on October 3, 1900, a male child was born, red and mottled and healthy in appearance, indeed, in all respects normal; there was no hemorrhage from the cord, no postpartum hemorrhage for the first time in the mother's obstetric history, and she was able to nurse her infant. The labor was easy, and the whole process normal. Since that time the infant has never had any bleeding, and did not bruise like his brothers. He has also cut a tooth without a hemorrhage, while it may be noted that his eldest brother still suffers with a bleeding tendency very markedly. This may be a coincidence, but if so a very remarkable one, and we cannot accept the conclusion that it is merely a coincidence. There are circumstances which encourage the opinion that after all the treatment in this case may have something more than a coincidental relation to the healthy state of the third infant.

SECOND DAY.

A symposium on typhoid fever in children signaled the morning session, the following being abstracts of the important papers read:

Symptoms of Typhoid Fever in Infancy and Childhood.—J. P. CROZER GRIFFITH reviewed a number of articles that have appeared on typhoid fever in the last few years. The symptoms of typhoid fever in children differ in many respects materially from those in adults. To insist that the cardinal symptoms must always be present would lead us into frequent errors in diagnosis. The affection is far from rare in infancy and the failure to recognize it is rapidly disappearing because we are more on the alert for it, and have the serum reaction test to aid in the diagnosis. The peculiarity of the onset of typhoid in children is its indefiniteness. The great degree of malaise and fatigue is absent. There is loss of appetite, slight indisposition, and some headache. The temperature does not abate, and, although the child scarcely feels ill, the diagnosis of typhoid fever may be made by exclusion. The child is sent to bed on general principles, and not because it wants to go. In the second class of cases the onset is sudden, with vomiting and with fever from the start, and the rash is discovered. In infants the symptoms are vague because elevation of temperature is common from slight or undiscovered causes. Perhaps only the Widal reaction will differentiate the disease from indigestion, enteritis or influenza. Another peculiarity is that the course of the disease is shortened, from 14 to 20 days being, perhaps, an average length. Abortive cases are common, and it is milder than in adult life, and the mortality lower. Children under 5 are less liable to die from it. The roseola is quite as common as in adults. In a few cases he had seen herpes labialis. Desquamation is described by the French writers as occurring frequently. Enlargement of the spleen is usually present, but not usually discovered. There is perhaps nothing peculiar in the respiration. The pulse is often unusually slow as compared with the rate which one would expect for the same elevation of temperature in other diseases. The temperature-curve is similar to that in adults. Not infrequently it rises rapidly without the step-like ascent. Often it remains high without the tendency to morning fall. Towards the end of the attack it falls, often with much greater rapidity than in adults. Indeed the fall may be almost critical at times. The tongue is not as liable to become dry and parched. Vomiting is a very common initial symptom. It is sometimes troublesome even later in the disease, sometimes directly producing death. Diarrhea is more liable to be absent than present. Abdominal distension is not often a troublesome symptom, though often present. Hemorrhage is of rare occurrence. When it does occur it is usually in later childhood. Perforation is also of uncommon occurrence, the infrequency of these 2 symptoms probably being due to the less pronounced development of intestinal lesions. One of the characteristics is the tendency of nervous symptoms to predominate over intestinal symptoms.

Extreme torpor, coma, vigil and carphologia occur much less often than they do in adults. Slight delirium is common, especially at night. A certain degree of apathy is very common, especially in very young children. A condition sometimes seen is that of pseudomeningitis. This sometimes causes confusion in diagnosis. Meningitis symptoms, it is true, do occur in adult typhoid also, but certainly less characteristically. As a rule the diagnosis can be easily made, but sometimes typhoid fever begins in children with all the appearances of acute leptomeningitis and lead for a time to an entirely erroneous diagnosis. Aphasia is a nervous symptom rather to be considered as a complication and occurs probably more frequently in childhood.

The Diagnosis of Typhoid Fever in the Laboratory: JOHN LOVETT MORSE protests against the separation of laboratory and clinical methods in the diagnosis of typhoid fever. Both are to be used, both are fallible, and both have their limitations. The value of the various laboratory tests are unequal. Some are easy to carry out, some are more difficult. The Widal reaction is present in 95% of all cases of typhoid fever. It seldom appears before the second week of the disease. In a small number of cases it may not be present, and in some it may be intermittent. Repeated negative tests are a strong evidence against the presence of typhoid fever. The reaction may persist in the blood for a period of at least 20 years after the patient has had typhoid, hence a positive reaction in the absence of other symptoms is not diagnostic of typhoid, unless one can be sure that the patient never had typhoid. A negative reaction followed by a positive reaction in a dilution of 1 in 50 is absolute proof of typhoid. In children, the reaction appears under the same conditions as in adults, but appears earlier, is feebler, and persists for a shorter time. It is of less value in infants than in older children, because it may be transmitted to the blood through the mother. Examination of the feces is of nearly equal value as the Widal reaction, but requires much expert knowledge and a complete laboratory, and is therefore not practicable. Typhoid bacilli are found in the urine in from 20% to 30% of the cases, but as a rule they do not appear until late in the disease. Recent observers have shown that in about 80% of the cases the blood shows the presence of typhoid bacilli. On account of the complicated processes necessary, this test is hardly practicable to the general practitioner. The rose spots in a series of comparative tests invariably showed the presence of the bacilli. The spots must be carefully incised under antiseptic precautions, however, and requires much technical knowledge. The diazo reaction is simple and can be made by anyone. It is obtained in most of the cases and usually appears early. Its value is vitiated by its being also present in tuberculosis, septicemia, and other febrile diseases, the very conditions with which typhoid fever is oftentimes confounded. The leukocyte count is important. It is subnormal throughout the entire course of the disease. The average is 5,000 per cm. or less. An increase above normal means the onset of some complication, such as hemorrhage, inflammation or some outside influence, such as cold bathing. The value of the leukocyte count is only seen when the diagnosis lies between 2 diseases, one of which has leukocytosis, and the other does not, as in typhoid and septicemia, the latter having leukocytosis and the former not having it. In the cases of malaria and meningitis, where the diagnosis is uncertain, the examination of the blood for the plasmodium of malaria, or lumbar puncture in meningitis, will clear up the doubt. The author concludes that the Widal reaction and the leukocyte count are the most important tests because easiest carried out, and therefore more practicable.

Report of a Case of Typhoid Fever in an Infant: FRANCES E. BARRETT first discussed the slowness of the profession to recognize the existence of typhoid fever in young children. The report of this case is of interest on account of the age, which was 2 years and 4 months, and the physical condition of the child. Also, the absence of many of the common symptoms, such as enlarged spleen, rose spots, coated tongue and prodromal symptoms, and the continued high temperature without morning remissions. The recovery was uneventful.

A paper on **The Treatment of Typhoid Fever in Children**, by HENRY E. TULEY, was read by title, as also was one on **The Dietetic Treatment of Typhoid Fever**, by LOUIS FISCHER.

Case of Multiple Gangrene Associated with Cholangitis Complicating Typhoid Fever.—I. A. ABB related the case of a female child aged 21 months which came under observation on the fourth day of its illness. The father is at present ill in a hospital with typhoid fever. Examination on admission shows the tongue coated, the abdomen tympanic, the spleen palpable and enlarged. The Widal reaction was positive, temperature 103 F., and a slight edema of the extremities. About 10 days after admission furuncles appeared on the scalp and over the shoulder blade of the left side. After the child had been ill about 2 weeks an eruption appeared on the back of the neck and extremities. At first papules appeared, these became pustules, and in a very short time became areas of gangrene. Summing up the features of the skin the following are interesting points in the order of occurrence; red macules, papules, flaccid vesicles and blebs. There were also postulated or crusted papules, umbilicated vesicles, and ulcers with a dirty, grayish, moist slough. The ulcers have steep margins, are mostly oval in shape, and vary from the size of a split pea to a penny. The whole eruption impresses one as a multiple

embolic process in the vascular system of the upper corium leading to gangrene of the type called infectious multiple gangrene. The autopsy showed the gangrenous areas in the skin which have already been described. The pericardial sac contained fluid. The myocardium was pale and flabby. The lungs were edematous. The spleen was enlarged and showed the presence of infarcts. The kidneys were negative. The liver was large, light-brownish in color, and distinctly soft. Over the entire surface there were a large number of whitish areas about the size of a pin. These were surrounded with a red border, and were scattered irregularly throughout the organ. Microscopically these areas are seen to be due to a necrosis of the parenchyma adjacent to the interlobular vessels. A study of these sections from the liver shows an inflammation of the bile passages, and angiocholitis. The liver also shows the presence of an adenoma.

Treatment of Typhoid Fever, with Special Reference to the Intrarectal Injections of Normal Salt Solution. E. STUVER holds that it is the toxins generated by typhoid bacilli which are responsible for the pathologic lesion and the characteristic symptoms of the disease. These toxins seem to be very penetrating and reach every organ, tissue, and cell of the human body. The treatment must, therefore, aim at first inhibiting the activity of the bacilli, so that the manufacture of toxins will cease, then in eliminating these toxins from the organ's tissues and cells of the body, as well as clearing out the bacilli. At the same time attention must be directed also to the conserving of the bodily forces. This is accomplished by the administration of calomel and other laxatives to keep the bowels open. Calomel is also a well known antiseptic, and this and other intestinal antiseptics serve to inhibit the activity of the bacillus of Eberth. Intrarectal injections of normal salt solution serve admirably as an antipyretic if given cold. At the same time the action of the skin and the kidneys is so stimulated by its use that these eliminative organs much more rapidly rid the system of the bacterial toxins, thereby preventing some of the serious degenerations and complications of the disease. Cold baths and cold sponging should be employed, and the very best possible sanitary conditions and hygienic surroundings should be secured. On arranging the diet liquid and nourishing food should be selected, but at the same time food that is easily digestible. The patient should not be stinted with water. It should be drunk freely and often throughout the whole course of the disease.

The Treatment of Temperature by Drugs: EDWIN ROSENTHAL. Collective statistics of typhoid fever in children have placed the mortality rate at or near 5%. The thermometer retains the first place as a diagnostic implement. In young children, the febrile progress is often only from 8 to 14 days; the average course under 10 years is 19.3 days. After the age of 10, this course is much like that of adults. Typhoid fever is, perhaps, the only disease in which the temperature runs higher in older than in younger children. If the fever be high and long continued, it will do much harm by its influence on the nervous system. If the temperature suddenly drops, it is of the same significance as in the adult—a case of hemorrhage. If the fever continues longer than the average time, it is significant of a complication. A thorough knowledge of the febrile movement, its cause and its dangers, is as necessary as the drugs to be used. In the choice of remedies, one must use a surprising amount of common sense. The bad influence of too much drug treatment cannot be questioned. It is a misleading delusion to say that we can avoid it. Careful investigation proves that no special specific virtues can be designated; for this reason I cannot find one drug which has stood the test of time in an impartial judgment. While all the ordinary coal tar derivatives have been thoroughly tried, none of them are allowable; and while they may influence the fever, that is, reduce its height, no particular virtue can be claimed for them. The same conclusion may be reached with regard to the Woodbridge treatment, which has proved to be a failure as far as limiting the disease is concerned. These so-called specific remedies perhaps have little or no influence. Quinin also proves perfectly inert; it does not influence the fever, and sometimes does more harm than good; in children it should never be used, though it has never shown that influence which the coal tar products always exhibit. One must have a distinct understanding of the meaning of the fever in typhoid. The chief question is, not what drugs to use, but when is it necessary to interfere. It is conceded that the fever is but a protective reaction of nature. A long continued hyperpyrexia will produce tissue degeneration; that it will do it sooner in adults than in children is a well known fact. Lacking the ideal way of interference—an antitoxic serum—Brandt's hydrotherapy is the next best thing. Other antipyretics included in the line of drugs, and which have been mentioned above, have only been mentioned to be condemned, since they possess no specific virtue.

Discussion.—Dr. VICTOR C. VAUGHAN drew attention to the fact that typhoid fever occurred less frequently in children than in adults, and explained this fact by the child's not getting around and drinking water from so many sources as an adult; the same reason why typhoid infection occurs less frequently in women than in men. It has also been said that typhoid fever occurs less frequently in cases of pregnant women; cases of typhoid fever seem to be less severe when the infection is a mixed infection; for when there is a mixed infection with the colon bacillus an irritative diarrhoea is set up which causes the

intestinal canal to be regularly drained of its poisonous contents. Mixed infections are more likely to occur in the case of children; just why typhoid fever is milder in children, is a question for which there is no positive explanation. The death rates seem very hard to get at. In hospital practice it has been found to be 8 or 9%; but in a series of 20,000 cases, which were selected, the deathrate was between 16% and 17%. In children, perhaps, the reason for a lower deathrate may possibly be found in their better elimination through the skin, kidneys and other organs of toxic products. It is high time to stop experimenting with drug antipyretics. If these dangerous drugs are to be used, let us make our experiment on animals and not on human beings. The only way to reduce temperature is by the cold bath. The occurrence of multiple gangrene is an exceedingly interesting matter, and has been found in malaria, small-pox, etc., as well as in typhoid. The fact of being able to diagnose these things by a positive discovery of the bacillus given us now a clearer insight into the diseases. Dr. CLIFTON SCOTT referred to the view held by some that cold baths caused internal congestion, but had not found it so in his experience.

Dr. CHAS. DOUGLASS found the medicinal treatment of typhoid fever very unsatisfactory; temperature may be controlled entirely by the baths and proper regard to the diet. The diet should always be kept down to the point where there is perfect digestion, then both less baths are necessary, and less medicine; he does not agree with the popular idea with regard to the use of calomel in small doses; his experience is, that cases which are allowed to preserve quiet bowels, continue to a steady recovery; the temperature goes steadily down without purgation if proper care is used in the diet. Feeding should be such as to make the stools normal in character and free from any bad odor. Odor, color and consistency of the stools are the things to guide in the feeding. Anything may be given the patient that he can properly digest; milk, broths, the white of eggs and starch water may all be given if the quantity is regulated in accordance with the conditions present. Abdominal complications and tympanites give no trouble when this is looked after; and patients may frequently go from 1 to 7 days without a movement from the bowels, and no bad effects follow. Calomel or other forms of purgation are not necessary if the diet is steadily cut down, when the bowels usually take care of themselves.

Dr. F. WOOD thought we frequently feed our typhoid patients too much; less food, less medicine and more water give better results than over feeding; it is very important to provide perfect quiet for these cases; don't allow them to become restless, talk too much, or be bothered; don't urge them to eat at all unless they want to eat. Oftentimes injudicious use of milk will cause tympanites. If hemorrhage occurs, perfect quiet should be maintained by the use of morphin. Quiet is more important in this complication than any medicine.

Dr. HEAD pointed out the great value of the leukocyte count as an aid to the differential diagnosis between meningitis and some of those forms that come on like appendicitis.

Dr. ROSENTHAL'S paper on **Prolonged Intubation** has been published in AMERICAN MEDICINE, Vol. I, No. 5.

Discussion.—Dr. SHURLY referred to 240 cases of diphtheria with a mortality of 60. Of this number 8 were intubated. Prolonged intubation may be classified as those cases in which the tube remains in position more than 6 days; ordinarily it should be removed on the fourth day. In these cases 3,000 units of antitoxin are always given immediately. Of the 8 cases intubated, all recovered except 1. The causes of bad results are usually traumatism or cicatricial bands. Plated tubes should be dispensed with.

Dr. GOLDAN uses the suprarenal glands whenever there is edema. A small piece of silk thread is always attached to the tube so as to easily withdraw it. It is often not necessary to withdraw the tube because the child will cough it up or pull it out.

Dr. I. A. ABT thinks the sooner the tube can be taken out the better it is for the child. It should be removed every morning; to allow it to remain in continuously causes edema, trauma, etc. His custom is to remove it in 24 hours if possible. There are cases in which a tube cannot be introduced into the larynx. This may sometimes be due to the fact that all of the tubes sold at the shop are not properly made.

The Prevention of Pulmonary Tuberculosis in Pre-disposed Children: JOHN A. ROBISON said before the discovery of the bacillus hereditary tuberculosis was supposed to be of great importance, but in the light of modern scientific inquiry infection has supplanted heredity. Direct transmission is extremely rare. Cases of tuberculosis occurring during childhood are in nearly all cases due to direct infection, so many statisticians claim, though an equal consideration of the two factors, heredity and the bacillus, I think must be maintained. Healthy individuals possess certain degrees of immunity to tuberculosis as well as other infectious diseases and this immunity is transmitted to the offspring. If one parent is tuberculous the immunity is weakened. If both parents are tuberculous, the immunity is lessened to a greater degree and there is engrafted on the progeny a cellular nutritional weakness. Children of tuberculous parents are easily affected both directly and indirectly. Preventive treatment should commence with the ancestors. The education of the people would mean the improvement of the coming generations. A child should never

be suckled by a tuberculous mother. As the babe grows the diet should contain more fat. Early a taste for hydrocarbons should be cultivated. Pure candy in moderation is beneficial to growing children if given after, not between meals. Children do not drink water enough which is a great aid to nutrition and acts as a solvent for the effete material in the body. The diet should contain plenty of nitrogenous food. The period of puberty is a critical one. Enforced ignorance of the sexual laws oftentimes allows youth to fall into vices which weaken the cellular and organic structure of their bodies. The youth should be educated in such necessary physiologic laws as tend to preserve the integrity of all the tissues and maintain nutrition at its highest point. Better hygiene should be secured in our schools. Those with a tendency towards tuberculosis should choose vocations which necessitate them to be out of doors a large part of the time. The question of clothing is a most important one, especially if the patient be a girl. The patient should be warmly and loosely clad. A child with predisposition towards tuberculosis should not wear a corset, since this cannot help interfering with the processes of nutrition and a development of the respiratory functions of the lungs. Thin shoes, insufficient head covering or deficient underclothing are the stepping stones to tuberculosis. Cleanliness is a great preventer of germ infection. Hydrotherapy is of great value. Perfect hygienic surroundings with a maximum of fresh air and sunshine are prerequisite. Parents should be warned as to the danger of neglecting such diseases as the measles, whooping cough, influenza, tonsillitis, adenoids, etc. The feeble-minded are especially liable to tuberculous disease.

Discussion.—Dr. WOOD thought that there was a great necessity for the stricter enforcement of laws regarding the marriage of tuberculous people. Dr. WORK referred to the supreme importance of proper clothing. People should change their clothing as the weather changes. The two great objects of clothing are equal warmth and equal pressure. Dr. SLAGLE pointed out that tuberculosis begins in the stomach through the influence of impaired nutrition, with the consequent weakening of the power of resistance.

Protracted Influenzal Pneumonia in Infancy: FRANK X. WALDS says that it has been observed that infants are in a high degree immune from influenza. Influenza, however, in infants, frequently runs into protracted pneumonia. Nursing children are almost absolutely immuned, even though their mothers be seriously stricken with the grip. This immunity is explained by assuming that a potent antitoxin is eliminated in the maternal milk. Infants artificially fed are more susceptible to this disease than others. COMBY reports a case of grip in an infant only 17 days old. Relapses among children are not rare. The symptoms often come on very much like severe gastrointestinal infections. Later involvement of the respiratory track occurs. Cough is at first short, but later increases in intensity until it is paroxysmal and continuous, similar to that of pertussis. Breathing is rapid and hurried, and jerky. More or less coryza is present in most of the cases. Oftentimes inflammation of the middle ear, rupture of the drum, and discharge of mucus complicates matters. The sputum was examined in all cases, and the influenza bacilli were demonstrated. The pneumonia was clinically lobar. The consolidation was slow in development, with diffuse bronchitis over the remainder of the lung. The nervous system was signally exempt in the cases coming under the author's notice. The occurrence of an exanthem closely simulating the scarletina rash, which has been pointed out by many authors, was wanting in the cases under consideration. A diagnosis is sometimes difficult, and may easily be confounded with gastrointestinal infections, ordinary bronchopneumonia, malaria, sepsis, or miliary tuberculosis. There is no specific treatment for influenza, but the little patient should be kept quiet and be fed on a nutritious diet suitable to the digestive capabilities of the infant. Nauseating cough mixtures should be avoided. In the event of cardiac or respiratory failure, stimulation should be given as indicated. Cold applications to the skin frequently act in a happy manner in cases of threatened suffocation.

Congenital Malformations: CARL BECK presented a very interesting paper, and showed numerous x-ray photographs to demonstrate the cases reported. The most frequent abnormality of the upper extremity is polydactylism. Congenital deficiencies are naturally hard of correction, but even in such cases surgery is not without resources. Eiselsberg has successfully transplanted, for instance, a toe to the hand. The x-rays are manifestly of great value in determining just what are the conditions present.

Membranous Colitis: CHARLES DOUGLAS says that membranous colitis occurs most frequently in infants over 6 months old and less than 2 years. The stools resemble those of catarrhal enteritis, except in the amount of blood. The only feature which establishes a diagnosis is the occurrence of the pseudo-membrane. The severity of the attack and the gravity of the prognosis are in proportion to the amount of mucus passed daily and the length of time it continues. If longer than 10 days, the prospect of recovery is not good. It is rarely seen in nursing infants. A microscopic examination of the membrane shows that it is structureless and like a mass of fibrin, with no mucous or epithelial cells. The cases presented showed that different bacilli have the power by their irritative qualities and the result of their toxins to form this false membrane on the mucous membrane of the bowels. It is important to recog-

nize that the character of the food is the principal etiologic factor in the beginning of this trouble.

A Case of Ureteral Calculus.—In the case reported by W. W. KEEN the calculus was accurately located by the x-rays before the operation was performed. The patient gave the usual history of stone in the ureter and since a recent attack of scarlet fever the paroxysms of pain on the left side have been more frequent and severe. The patient was 10 years old. On admission the left side of the abdomen was so painful that a diagnosis was impossible as to location of the stone, though the diagnosis of calculus which had already been made by his physician was perfectly clear. The photograph shows a calculus about $\frac{1}{2}$ the size of the last joint of the little finger. In the left ureter, a little below the level of the pelvic brim near the bladder, there was considerable difficulty in finding the ureter at the operation as it was imbedded in a hard mass in which the ureter was apparently lost. On an examination the stone was found to be dark in color with a reaction for mucin, the shell is of calcium phosphate with a trace of organic matter. On the opening of the ureter about $\frac{1}{4}$ of an ounce of urine escaped from the somewhat hydronephrotic kidney. The ureter was packed with iodoform gauze which was removed on the second day and recovery was uneventful.

Discussion.—Dr. C. L. LEONARD stated that he had skia-graphed 47 cases of stone in the ureter. In most of these cases the stone had been subsequently passed so that it is advisable to wait in most cases, unless the stone be large, rather than resort to surgery, since the surgical operation is difficult and nearly always if the calculus is small it passes of itself.

Dr. CLIFTON SCOTT agreed to the extraordinary value of the x-ray in these cases, but thought its value was negative as well as positive. He had operated on a case diagnosed as calculus from the clinical symptoms. The diagnosis seemed perfectly clear, but at the operation it was found to be an endothelial growth and no calculus at all. Dr. KEEN also referred to 4 cases on which he had operated for stone and the stone had not been found.

[To be concluded.]

Section on Materia Medica, Pharmacy and Therapeutics.

FIRST DAY.

Experimental Work in Intraorganic and Venous Injections and Blood Extracts in the Cure of Acute Organic Diseases, the subject of a paper by Dr. W. BYRON COAKLEY (Chicago) whose aim was to show that while exaggerated statements were often made as to the possibilities—in the way of prolonging life and otherwise—that could be accomplished by means of saline solutions, they had a very definite and useful place in practical therapeutics. Studying the history of the subject, he had found that the remedial effects of salt were referred to in a work of great antiquity. In the fifteenth century efforts were made to place its use on a scientific basis, and similar efforts had been made at various times since, but without any satisfactory results until experiments on animals were recently instituted. Meanwhile, the profession had taken up other liquids for the purpose of making injections. Distilled water, milk and blood were all tried, but the last had been abandoned, partly because of the difficulty of obtaining human blood in sufficient quantity, and partly because the benefits were counterbalanced by the dangers. None of the other things that had been used had produced the same good effects as a solution of sodium chlorid. The author reported a number of experiments he had made on dogs, their effect being to show that when the animals had been reduced to the point of showing only a slight flutter of the heart, the injection of the saline solution restored them to vitality in a remarkably brief space of time. Instruments for blood-letting and transfusion were shown, together with needles for making injections into the lungs and other organs. The author added that he had only 1 clinical case to report. It was a case of lobar pneumonia, and the patient recovered.

Dr. GEORGE F. BUTLER (Chicago) followed with a paper which appeared on the program as **Modern Therapeutics**, but which he said should have been entitled **The Neglect of Valuable Therapeutic Measures**. Having described how new medicines were introduced and boomed, enjoyed great popularity for a time, and then as often as not disappeared from sight, he said that some preparations of decided merit were thrown into the background because of prejudice and the influence of commercial interests. The fact was that therapeutics, like most other things, was markedly under the influence of fashion. Blood-letting, which was based on the old idea of removing toxic products and supplying blood serum with water, had fallen into disuse largely as a concession to prejudice. Now, however, it was commencing to assume its old place again. Practically the same theory prevailed in regard to the use of normal salt solutions. Again counterirritation had ceased to be generally used because of popular prejudice against pain, and yet alienists had observed that traumatism sometimes exercised a marked, though for the most part but too short, benefit in insanity, and cases had been reported in which fractures of the skull had been the means of curing idiocy, giving rise in one or two notable instances to the disclosure of remarkable genius. The great effects of counterirritation were shown in the results

obtained from the constitutional effects of operations *per se* irrespective of the location or indication of the operation. The author proceeded to show that, in spite of the prejudice against them, complex prescriptions founded on the control of objectionable features of a drug, still gave good results, and after speaking of the use of emetics as eliminants and of the use of the vegetable uterine tonics, he expressed his strong belief in the efficacy of hydrotherapy, massage, mechanotherapy, dietetics, suggestive therapeutics, and physical culture, when properly used. His experience led him to say that if he had to choose between the two therapeutic measures, exercise and baths, he would prefer exercise in the majority of cases, and especially exercise in the open air. Exercise, baths and suggestive therapeutics were all matters that should receive more attention, as should also the equally important matter of diet. If proper consideration were given to these neglected therapeutic agencies, and care taken to utilize them scientifically, there would be less room for Faith Curists and Christian Scientists.

A third paper bearing more or less on the same subject was read by Dr. O. T. OSBORNE, the particular phase of it which he discussed being **Therapeutic Indications Presented by the Conditions of the Blood in Disease.** His object, he said, was to stimulate the more careful study of the blood in the treatment of all diseases. He thought they had become too pessimistic of late in regard to therapeutics. Still, it was a mistake, on the other hand, to place a blind faith in particular remedies. Every case must be treated individually, and they must treat the disease plus the individual who had it. His reason for pleading for greater attention to the blood was founded on his belief that in it there might often be found to linger the doubts as to whether a patient would or would not get well.

Chronic Myocarditis. A paper on this subject was read by Dr. J. H. MUSSER (Philadelphia). A large proportion of patients who suffered from this disease were men who had great responsibilities, and nothing was more difficult than to decide what line of life should be recommended for them to pursue. They required to be guided by the circumstances of each case, and by the individual's capacity for exertion, his ability to digest food of a kind likely to assimilate, his recuperative power, and so on. They must also pay attention to the matter of bathing, and consider carefully the kind of baths suited to each case, though as a rule the warm bath at night and a cool bath in the morning were sufficient to indicate. In regard to drugs, if the affection of the heart could be traced to some other disease, such as syphilis, specific treatment must be resorted to. Apart from this he found good results from the use of purgatives, which he thought were too much neglected. There was, too, a certain class of cases in which he got good results from potassium iodid. He had tried to find the special indications for the use of this drug, but he regretted to say that he had not succeeded, and so must admit that he gave it empirically, though he could tell generally the kind of cases in which it was likely to do well. When a case had advanced so far as to have paroxysms of angina pectoris, the treatment in the intervals between the paroxysms was very important. A patient who had reached this stage must give up business cares, follow the most hygienic life possible, and take nitroglycerin or nitroglycerin and potassium iodid, or something else that would keep down the arterial pressure. He was opposed to the use in such circumstances of digitalis, which would increase the blood-pressure. The nitroglycerin ought to be taken in large doses, and the doses increased from time to time to the point of obtaining the physiologic action of the drug. These patients had to be put on a lower plane of existence than that on which they had been living. They could not live up to the normal blood-pressure without suffering injury and running danger. In many cases of dyspnea, on the other hand, cardiac stimulants were indicated. There was, however, no general rule to be laid down in regard to chronic myocarditis. Every case had to be dealt with individually, and that not only with reference to local conditions, but to all the functions and structures of the body.

Discussion. Dr. HENRY BEATES (Philadelphia) agreed with the author of the paper as to the treatment he recommended along the line of prophylaxis, but he joined issue with him as to the medical treatment. He was opposed to the use of arterial depressants and contended that stimulants were indicated in the class of cases described. Some remarks in regard to the paper were also made by Dr. S. E. SOLLY (Colorado Springs) and others.

The Treatment of Obesity.—The author of this paper was Dr. HENRICH STERN (New York). He defined obesity, classifying its different kinds and pointing out the complications that frequently accompanied it. As a rule it was to be regarded as symptomatic, hence the necessity of ascertaining its character and cause in each case. After discussing the Banting, Ebstein, and Oertel-Schweninger symptoms of treatment, the author describes his own methods, which consists of dietetic, physical and medical treatment.

The Treatment of Neurasthenia.—Dr. HAROLD N. MOYER (Chicago) contributed a paper on this subject. There was, he admitted, nothing new that he could advance in regard to the treatment of this disease, but its widespread prevalence made it of the greatest consequence that the subject should receive more attention than it did. The importance of correct diagnosis could not be too strongly insisted on. There was a general misapprehension in the profession as to what constituted

neurasthenia. From his association with his colleagues at the bedside and elsewhere he found that there was a disposition to confound hysteria, neurasthenia, and hypochondria. There would be no objection to this confusion of these complaints if the treatment of the conditions were the same, but he believed that the failure to make a proper differentiation between these diseases accounted for the large number of failures that took place in the treatment of neurasthenia. He was sure that none of those who heard him would say that the general treatment of neurasthenia was satisfactory. In his opinion, the central symptom of neurasthenia was fatigue. He believed that where there was no fatigue symptom there was no neurasthenia. He meant by fatigue the exhaustion state that followed motory activity or sensory stimuli. If this fatigue symptom were kept definitely in mind it would enable physicians to differentiate neurasthenia from hysteria and hypochondria. Hysteria never presented the fatigue symptom, and in the case of the hypochondriac there was never any basis for his belief that he had a definite ailment—it was a pure delusion. Hence the importance at the very outset of making a correct diagnosis, which must always be arrived at by process of exclusion. Every convalescent from acute disease was for the time being more or less of a neurasthenic. Many internal disorders and constitutional diseases were accompanied or followed by neurasthenic conditions. Therefore, he would distinguish between primary and secondary neurasthenia, and he would never make a diagnosis of primary neurasthenia until all possibility of secondary affection had been eliminated. The number of primary cases was comparatively small. When he had a case of the kind to deal with the foundation-stone of his treatment was rest. He followed this up by other measures. The rest might be partial or complete. The rest cure had become very fashionable of late, and it was being exploited largely by persons who did not belong to the profession. Much that was splendid that had come from Weir Mitchell in the way of therapeutic teaching was thus being misdirected, the consequence being that a great deal of harm was done. It was only in cases of primary neurasthenia that he would prescribe the rest cure. In other cases a large proportion of cases were made worse by the rest treatment. Women might sometimes do well under it, but it was generally quite otherwise with men. Modified rest was a very different thing, and as a rule did well with one sex as with the other. It was important also to regulate the habits of neurasthenics, and hydrotherapy ought never to be neglected. In respect to drugs, he differed very much from some of his colleagues, inasmuch as he made strychnia his sheet anchor. He gave it in very large doses—from a sixteenth to a twelfth of a grain 3 times a day. It often did well, as did likewise cannabis indica, which was another drug he used. His object in giving these drugs was to produce a psychical state in the patient; he did not believe they served any other use than that. They were not specifics in any sense. Still they frequently gave the patient a start to recovery. It was a species of suggestion, and it was only in that way that he used the drugs. In this connection he expressed the opinion that in the case of neurasthenics the larger the dose of the doctor and the smaller the doses of medicine they got the better it would be for them. He no longer used hypnosis, and he regretted some of the instances in which he had used it. But the extraction of a promise from a neurasthenic that he would pay implicit regard to the instructions of the doctor, coupled with the suggestion that thereby he was sure to get better, generally did much good. At the same time the patient should be told not to discuss his symptoms with anyone but his physician, and if he was asked how he was getting on, always to reply that he felt better—irrespective altogether of whether he did so or not—also had a beneficial effect. The keeping by the patient of a record of his daily life, with details of his treatment and symptoms, was likewise of much value. By simple means of this kind the author had many successes that were very gratifying.

Discussion.—Replying to questions, Dr. MOYER said that hysteria might lead to neurasthenia, and cases thus developed were peculiarly difficult to deal with. In regard to diet he would not attempt to lay out a table for any group of cases. It was necessary to individualize and experiment. However, he used none of the patented or prepared foods. He depended largely on milk, using modified milk, the same as they did with children, when milk in its natural condition could not be assimilated. He had had experience of 2 cases in which temporary exposure to cold had had good results.

SECOND DAY.

Standardization and the Pharmacopeia formed the subject of debate at the morning session. It was introduced by Dr. C. F. WAHRER (Fort Madison, Iowa) who read a paper entitled **A Plea for More Uniformity and Strength in Our Armamentarium.** The subject, he remarked, was far from being new, and the objects aimed at might seem utopian, but it was only by keeping eternally at it that any good could be accomplished. His main desire was to impress on general practitioners the importance of certain facts. In regard to some phases of their work, they were better equipped and could do things better than in previous days. They were better able to make a correct diagnosis. They knew more of etiology. And not only were they reasonably proud of these facts, but they

were apt to think themselves peculiarly blessed in being permitted to live in such an advanced age. But, on the other hand, had therapeutics kept pace with the advances in other branches of medical science? He believed he must answer negatively, and this not because the pharmacist had been idle, for many new remedies of much value had been introduced, but because sufficient attention was not given to the quality of the drugs they used in fighting disease. Even the pharmacopœia failed in this respect that it did not make adequate provision for the uniformity and strength of remedies that were officially recognized. If combined with this circumstance they took into account the cupidity and dishonesty of many manufacturers of medicines, and the ignorant and careless making up of prescriptions, they would admit that the outlook for the sick man was anything but cheerful. What was the use of making a careful diagnosis, and knowing the proper remedy to prescribe, if they were ignorant of the quality of drugs that were to be used in making up their prescriptions? It was necessary to have drugs made according to a uniform standard by a pharmacist who should not only be an honest man, but should feel that his calling was a high one. At present not a few manufacturers had only commercial interests in view, and therefore physicians had to limit themselves to the prescription of drugs which could be easily tested, or which came to them with the guarantee of a house of high standing. Why should physicians allow manufacturers to prescribe what remedies they should use in the treatment of their patients? Yet this was what was being done every day. Thousands of mixtures were continually being forced on their attention as specifics, and what was worse, the profession bought these mixtures, and even wrote testimonials in their favor. Among the members of the profession who were found endorsing nostrums were professors in medical institutions with pretensions to high standing. No matter who they were, he thought they should be dismissed from their positions, and allowed to devote all their time to the exploitation of the so-called remedies with which they had permitted their names to become associated. Of course, there were a few firms of repute that were doing all in their power to supply drugs of the requisite quality and strength. They aimed at what was called standardization, and their work in this respect was deserving of all encouragement. A body like the American Medical Association, however, could also do something to assist in bringing about a better condition of things. It seemed to him that a committee should be appointed to impress on the body having charge of the revision of the pharmacopœia the necessity of making more satisfactory provisions for standardization, and to memorialize Congress with the view of getting legislation passed that would at least ensure to the public the possibility of getting their drugs as free from adulteration as they could now rely on getting their butter and other commodities of daily use. All the skill and knowledge of physicians would continue to be thrown away so long as they had to depend on inert drugs and manufacturers of doubtful honesty.

Dr. A. B. LYONS (Detroit, Mich.,) who had the next place on the program with a paper entitled **Standardization of Crude Drugs and Galenical Preparations**, said the excellent paper they had just heard made superfluous a good deal that he had prepared to say. He then proceeded to speak of the natural division of drugs into 2 classes—those that could be tested by chemical process and those in regard to which they had to depend on physiologic experiment. He proceeded to give illustrations of the extent to which vegetable drugs varied in medicinal activity, and said that scientific medication required that preparations made from them be brought to some uniform standard of strength. Individual manufacturers supplied standard preparations, but many of their assay methods were confessedly imperfect. An imperfect method, he admitted, was often better than none. The *Pharmacopœia* of 1890 furnished standards and assay processes for opium, cinchona bark and nuxvomica. In the revision of 1900 this list would be greatly extended and the assay processes rendered more precise. Unfortunately standardization by physiologic experiment had been ruled out. The question vitally interesting to the physician was what standard shall be established? He should insist that the standards give him preparations identical therapeutically with those he had been accustomed to, when these were prepared from an average sample of good drug. In passing the author commented on the fact that the pharmacopœia was far behind the processes adopted by the leading pharmacists of the country for obtaining uniformity of quality and strength. In so far as standards were established, it was the duty of physicians to see that drugs conforming to them were used in making up of prescriptions; the enterprise of competing manufacturing houses of ethical character might be depended on to do the rest.

The chairman, in inviting *discussion* on the papers, said the subject was one of the greatest importance, and one in regard to which those aiming at uniformity in the strength of drugs should have the moral support of the profession.

Dr. HALLBERG (Chicago) said that the question, if not the burning one of the day in so far as therapeutics were concerned, was one of the most important that could be brought before them. Until the revision of the pharmacopœia, in 1880, there was no alkaloidal standard for any drugs. In the decade preceding that revision a great deal of work in the line of alkaloidal assay had been done by Dr. Lyons and others, and

it was thought that the principle of fixing the alkaloidal strength would be quite largely adopted, but by the time the Revision Committee got to work in Washington, it was found that the progress made was not sufficient to warrant the application of the principle to more than 3 drugs, opium, nuxvomica and cinchona, with preparations of the first 2. Since then this work had been going on apace. A number of the medical schools of the country—notably the University of Pennsylvania and the University of Michigan—had been devoting attention to the subject with the view of ascertaining the best processes that could be adopted for assaying drugs that could not be tested chemically. But whether the principle could be extended to every drug of alkaloidal or glucosidal character was still an open question. He was inclined to believe that it could not until the active principle of certain drugs, such as aconite and digitalis, were more clearly defined. Until this was done it would be a pretty difficult problem to know how to formulate a process and fix a definite standard of value for the drugs mentioned, as well as many others. No doubt the principle could be extended beyond the 3 drugs to which it at present applied, but he did not think it could be extended to a great many, except in a limited way. The physician ought certainly to have a criterion to go by whenever it was possible, and considering the number of competent men on the Revision Committee, he had no doubt that everything possible would be done towards supplying this.

Dr. F. J. WULLING (Minneapolis), speaking as a practical pharmacist, admitted that they were not yet in a position to adopt many of the assay processes that had been recommended. At the same time there was much that might and ought to be done in the direction of standardization. If they could not attain the ideal, they might at least take a step towards it. Much had been said about the lax methods of pharmacists in making up prescriptions, but it should not be overlooked that many physicians were equally lax in preparing them. The physicians referred to would do well to make themselves more familiar with the contents of the pharmacopœia. Of late many preparations had taken the place of drugs recommended in the pharmacopœia, and he knew of no good reason for this save the matter of convenience, and the fact that so many doctors did not know enough about the constituents of the medicines they prescribed. A physician who had included potassium iodid in many prescriptions had confessed to him that he had never seen the drug, and the same was true in regard to many members of the profession with respect to drugs in general. He thought that more attention should be given in the medical schools to the teaching of *materia medica and pharmacy*, and that the pharmacopœia should be made one of their textbooks. A recommendation to this effect from a body like the American Medical Association would carry much weight.

Dr. A. M. WILSON (Kansas City) said he had recently been invited to examine some students who had passed their prescribed time in the study of medicine, and he found that there was not a man of them who could tell the difference between a tincture and a fluid extract. The subject under discussion was one in which he had been interested for many years, and he was fully acquainted with the existent necessity for more uniformity. Some drugs varied so much in strength that one dose of what was bought in one store was sufficient to kill a dog, while that obtained in another store was almost if not quite inert. At the same time, looking at the matter from the standpoint of a teacher, he was sure that they would never bring about harmony between the druggists and the prescriber until doctors got to the position of knowing when they first came out of college what drugs were. It was too common a mistake in the profession in these days to think that if they could make a correct diagnosis, everything else was plain sailing. There was too little in the way of rational practical therapeutics in the textbooks used in most of the medical colleges. They could never hope to get any settlement of this question until the doctor knew as much as the druggist along the lines of these essential facts. It was their ignorance of drugs that allowed so many of them to fall victims to the polite and suave representatives of houses which called themselves pharmaceutical, but which it was an insult to reputable firms to speak of under that designation.

Dr. W. L. DICKERSON (St. Louis) said students of medicine should spend a much longer time in *studying therapeutics and materia medica*, but at the same time the pharmacopœia should be arranged so as to prevent such variations as were now possible in the strength of drugs.

The chairman said they had wandered somewhat from the subject of the papers, but perhaps not without benefit, the matters that had been touched on being also of importance. As to standardization, to which he had given a good deal of attention for some time past, he agreed that it should be brought about as fast as possible. As a member of the Revision Committee he might be permitted to discuss the pharmacopœia a little more freely than others had done. He had always wished that it could be made of such a character that medical men could be interested in it, and come to make use of it as much as druggists did, his belief being that it should be the common standing ground of the two professions. The difficulty, however, was this, that it was made for the druggist, and was not particularly useful to the medical man. It con-

tained a great deal that every medical man was expected to know in his student days but for which he had no particular use afterwards. There were many in his own position. He never handled drugs at all. For years he had nothing to do with handling them. He only knew the effects he wanted to produce by their agency, and when these results followed he knew that he had got drugs of the proper strength. To do this, however, it was necessary for him to specify. If instead of doing so he left it to the druggist to decide which make he should put in prescriptions, the variations were liable to be so great that they could not be depended on. Other physicians had the same experience, and consequently they made a point of specifying the make of drug they wished. The pharmacopeia could be made more useful to medical men if its character could be modified somewhat. What they wanted to know about chiefly was new remedies, and these should be included in the work somehow, whether tested or not. They might be put in an appendix for that matter, but they should be included in the book somewhere, so as to make it an encyclopedia of medical information, of course with as many details as possible about tests and other essential facts. On the other hand the volume might be relieved of a great deal that it now contained in regard to old remedies which were still used in some parts of the country, but which the majority of physicians had ceased to employ. In regard to the subject of teaching, he was glad to observe that some of the leading schools were commencing to give courses of lectures in pharmacology, while in a few there were also courses on the physiological action of drugs. The result would be that the profession generally would be much better informed than it was now in regards to drugs.

The Treatment of Pulmonary Tuberculosis: This subject was discussed in a symposium of papers at the afternoon session. The first speaker was Dr. S. E. SOLLY (Colorado Springs), who dealt with **The Indications for and Utility of Altitude Treatment.** While acknowledging the good effects that were now produced by sanatorium treatment, he said the advantages to be derived from climate should not be forgotten. In speaking of altitude as a factor in the treatment of tuberculous patients they must first consider the physical conditions and then the physiologic effects. The first thing that distinguished high elevations from other places was the diminished barometric pressure, and the effect was that a patient was soon elevated from his anemic condition into one of general health. The effect of altitude was similar to that of iron, arsenic, and other therapeutic agents which were employed for the purpose of improving the blood. The effects on the circulation and respiration were both temporary and permanent. The immediate effect was to increase the rapidity of the action of the heart, and another effect was to cause the lungs to become more active. Chest measurements had been found to be increased by residence at high levels to a greater extent than by that at sea level. The change from day to night—cold or cool nights following warm days—was also found beneficial, acting like a cold douche after a warm bath. The aseptic conditions of the air at high altitudes has likewise to be taken into account. Altitudes might be divided climatically into 3 classes—those that were cold, those that were warm, and those that were hot relatively. This matter of temperature was almost entirely a matter of altitude modified by the distance from the equator. To find cold places equal to those in the Alps it was necessary on the American Continent to go to Canada, that was if they wanted them at the same altitude. Hot temperatures they got in Arizona and New Mexico. Colorado occupied a position between the 2 extremes. In considering the cases they should send to high altitudes, it was essential to consider how the persons became tuberculous. Although the bacillus was the central factor in the process of tuberculous degeneration, it acted differently in different people, and arose from different causes. The condition of the patient's general health, in other words, was important. Tubercular patients might be divided into 3 classes—the purely tuberculous, the catarrhal and the pneumonic. These terms were subject to misunderstanding and abuse, but they served to mark a convenient division, though of course they were all tuberculous and there was more or less catarrh in every case. The important point was to distinguish those cases that arose like lightning from a clear sky, without any apparent cause. These might be called cases of primary tuberculosis. Such cases did well, as a rule, at altitudes and in such a climate as Colorado. Catarrhal cases were peculiarly susceptible to weather, and this fact had to be borne in mind in selecting a climate. Pneumonic cases were not so well suited to the higher elevations; they frequently did better on lower ground and in a less dry atmosphere. Individual habits and predilections, financial circumstances and a variety of other considerations had all to be taken into account in deciding whether it was desirable or not to send a patient to a particular locality. He hoped that the new sanatorium might be the means of bringing about a better selection of the patients whom there was a possibility of doing the maximum of good for in different regions.

Dr. NORMAN BRIDGE (Los Angeles) read the next paper, which was on the **Adaptability of Southern California and Similar Climates to the Needs of Consumptives.** Among the advantages he claimed for Southern California were its relative dryness, the small rainfall, the large amount of sunshine, the fact that it had both high and low altitudes, and the mildness of the climate all the year round, which permitted

patients to spend as much of their time as they pleased, or their physician thought desirable, in the open air.

Dr. A. BURROUGHS (Asheville, N. C.) reported the conclusions he had drawn from 19 years' experience with **Creatosol in Tuberculosis.** He dwelt on the importance of using a pure creatosol made by a method which he described, and said it should be used in large doses and continued for 2 years after all symptoms had disappeared. He thought it had been proved to give better clinical results than any other medicine.

A paper on **Specific Therapeutics in Pulmonary Tuberculosis** was contributed by Dr. ARNOLD C. KLEBS (Chicago). He reviewed the culture products and serums used in the treatment of tuberculosis, their method of application and their results; criticised pharmaceutical preparations of alleged specific value, food preparations, etc., and concluded by describing sanatorium regime as practised in and outside of institutions. The conclusion he came to was that there were no drugs possessing specific virtues for the cure of the disease, and that the best treatment to be followed by the general practitioner was the closest possible imitation of the methods pursued in the sanatoria, always keeping in mind the advantages of climate when they could be secured without too great a sacrifice.

Dr. NORMAN BRIDGE, by request of the chairman, then read another paper he had prepared with the intention of reading it in the section devoted to **Hygiene and Sanitary Science.** It dealt with the **Proper Management of the Tuberculous Lung.** The profession he thought had been too ready to follow the theories of the lay public, and the consequence was that they had many rules of action that ought to be relegated to the rubbish heap. What was most essential, in his opinion, was to give rest to a sick lung, and this he thought could best be done by external fixation. Bandages of plaster-of-paris he found particularly useful.

The papers were discussed by Dr. DELANCY ROCHESTER (Buffalo), Dr. S. G. BONNEY (Denver), Dr. C. L. MINOR (Asheville, N. C.), Dr. R. C. MOORE (Omaha), and others, most of the speakers expressing dissent from the opinions advanced by Dr. BURROUGHS as to the great value of creatosol.

Treatment of Pneumonia.—Papers on this subject were read by Dr. DELANCY ROCHESTER and Dr. W. L. DICKERSON, the former contending that the most serious element in the disease was toxemia, and that in the absence of an effective antitoxin it should be eliminated by means of the skin and the bowels, while the latter entered a plea for the use of cardiac depressants, by means of which he said he was able to abort attacks when he was consulted early enough. In the course of the discussion which followed, Dr. Rochester said that as pneumonia was an infectious disease, and not an inflammation, he could not approve of the methods followed by the reader of the other paper. Dr. J. F. SPELLMAN (Anaconda, Mont.) Dr. MOORE (Omaha) Dr. HOFFMAN (St. Paul) and Dr. MARY MCCOY (Duluth) also spoke.

[To be concluded.]

Section on Cutaneous Medicine and Surgery.

FIRST DAY.

Address of Chairman:—Ancient and Modern Conception of Syphilis: W. L. BAUM traced the development of the conception of syphilis from fifteenth century to present time. In 1492 syphilis was called a new disease, due to such causes as influence of planets, unseasonableness of the air, and bites of venomous insects. No great epidemic of syphilis has occurred since the fifteenth and sixteenth centuries. The animalcule theory of the causation of syphilis gained credence in the seventeenth century and developed into the germ theory of today. The following century saw the clinical demarkation of diseases due to venery, and in 1852 the distinction was made between hard and soft chanere. Lues is now regarded as a specific disease whose toxin arrests development, and whose course is modified by constitution attacked. There remain as problems for the twentieth century, the early securing of a diagnosis where primary sore cannot be depended upon, the determination of the process which produces the serious symptoms of syphilis, and a satisfactory working out of the bacteriology of the disease. Treatment should not only include the constitutional effects, but also be directed to the overcoming of the marked mental depression.

Pathology and Treatment of Cutaneous Cancer, with Special Reference to its Nonparasitic Nature, was the next paper. M. L. HEIDINGSFELD: Only the portion of the paper dealing with treatment was read. Zinc chloride, white arsenic and caustics have been the old established remedies. Surgeon's knife has been used since introduction of anesthesia, but has not realized our fondest hopes, as 75% of cases are or become beyond the reach of the surgeon's knife. Statistics show that only 30% of cases are cured. This fact, coupled with nonchalance of the surgeon and skepticism of laity, accounts for success of cancer quacks. In a series of cases has had great success with a mixture of equal parts of arsenious acid and gum arabic, enough water to make mixture, consistency of butter, cocaine crystals to relieve pain, and 10% of glycerin to prevent drying. One application for 12 hours is usually sufficient. Follow by antiphlogistin or soothing preparations. This combination is prompt in action, is easily limited, spurs the healthy tissue and has a specific action against cancer. It is an

ideal remedy in mild cases, and has been successful in a series of 9 cases.

A paper on the Increasing Prevalence of Contagious Skin Diseases, by H. W. STELWAGON, was read by title.

Syphilis and its Relations to Blastomycetic Dermatitis.—H. G. ANTIPOY said that evidence up to the present time is not sufficient to warrant us to regard blastomycosis as a separate disease due to the yeast fungi. Lesions which others would classify under this head are probably forms of verrucous tuberculosis, or as suggested by the study of the case in literature, are one of the vegetating forms of syphilis. Carefully analyzing this case, one concludes that the character of the infiltration border, the size and rapidity of the development of the plaques, the histopathology of the lesion, the results of treatment, and the varied forms of yeast fungi found, do not permit us to regard blastomycosis as a disease *sui generis*. As now recognized it has no distinct entity but is a disease which only the minority can diagnose and cannot be picked out by the majority. A spirited discussion followed and the general trend of opinion was opposed to above.

A paper by W. S. GOTTHEL on Adenoma Sebaceum of the Nonsymmetrical Type of Darier was read by title.

Notes on a Case of Keratosis Follicularis (Parospermosis).—J. ZEISLER reported a case of this rare disease in a boy 21 years old. The eruption commenced when the patient was 8 years of age, and has gradually increased in severity until it now covers almost entire surface of body. Has been treating patient for 6 weeks and stimulates glands to throw off crusts by use of pilocarpin, carefully watching effect of drug on heart.

The motion carried that chair appoint a committee of 3 to draft a constitution and bylaws to govern this section, and to report at the next annual meeting.

SECOND DAY.

The Nominating Committee reported for president, H. W. Stelwagon; for secretary, R. R. Campbell. The secretary was instructed to cast a unanimous ballot for these candidates.

Demonstration of Cases—BURNSIDE FOSTER: CASE I.—Lupus vulgaris on the left arm of a man 27 years of age. Has been treated with hot air. Lupus erythematosus somewhat suggested by cicatrix, but following discussion did not support this view. CASE II.—A large congenital nevus pigmentosus on the back of a young man. Microscopic section resembles structure of melanotic sarcoma. CASE III.—Notes on a case of leprosy. This leper was born in Minnesota and has not been out of the State.

Lantern Slide Demonstration on Skin Cancer: M. L. HEIDINGSFELD. The present tendency is to ascribe causation of epithelioma to parasites. Clinical evidence does not warrant this. Incongruity between parasites in tissues and in cultures is a weak point. Successful treatment of blastomycetic dermatitis with potassium iodid strongly suggests syphilitic origin. Has not been successful in finding blastomyces in these cases. At present too many links are poorly forged or are entirely wanting in the chain of evidence which would establish the parasitic origin of cancer. A disturbance of the normal relation between epithelial cells and the restraining to connective tissue affords a better hypothesis. A stimulus epithelial cells, a weakening of the restraining power of the connective tissue, or both of these factors combined are the main factors in the etiology of cancer.

Lantern Slide Exhibition Showing the Clinical, Pathologic and Bacteriologic Features of 11 Cases of Blastomycosis of the Skin, by J. N. HYDE and F. W. MONTGOMERY. The slides shown were prepared from cases in all of which, with one exception, blastomyces have been demonstrated, both in tissues and in culture. In that one case the fungus was not found in the tissues but was subsequently demonstrated in culture. Blastomycosis is a chronic disease, attacking the more exposed regions of the body, and now has a recognized organism. A clinical picture of the disease was established by a series of slides, showing character, location and extent of lesion. Blastomyces were shown in tissues and in culture and compared. There is a bare possibility that these organisms are saprophytic, but an overwhelming mass of evidence leaves no reasonable doubt but that they are the cause of blastomycosis.

Lantern Slide Demonstration of the Exanthems, from Original Photographs, by W. T. CORLETT. **Variola.** Slides showed seat of eruption and various stages of disease. Present epidemic characterized by mildness of attack. Eruption appears first on forehead, nose, on the backs and palms of hand. Induration on second day is very characteristic. Characteristic features of lesions are induration, umbilication in some place and at some time, and frequent involvement of nape of neck. **Varicella.** Diagnostic points are multiform appearance of lesion, noninduration, wide area of erythema, transparent vesicle, and the appearance of the eruption at first on the back and trunk.

Lantern Slide Demonstration of Variola: POLITZE (New York).—Period of umbilication is short and often is not recognized. The eruption in adults appears on palms of hands and soles of feet. The eruption of varicella never appears in adults in these localities, but may in children. Lesions are more marked where there is pressure or irritation. Soles of feet show characteristic eruption after it has disappeared from remainder of body.

Lichen Hypertrophicus: D. LIERTHAL.—Slides show pathologic changes in layers of skin.

Epidermolysis Bullosa Hereditaria: L. E. SCHMIDT.—The case has been under observation for 2 years. Microscopic findings are practically the same as in recorded cases, but findings in blood examination differ.

Report of a Case of Epithelioma of Long Duration and Beginning in Early Manhood: W. FRICK.—This carcinomatous lesion on back, between shoulders, has endured for 35 years. Patient is now 54 years old and has been under observation for 5 years. The lesion is not a typical carcinoma either clinically or microscopically.

[To be concluded.]

Section on Nervous and Mental Diseases.

FIRST DAY.

The Relation of Nervous and Mental Diseases to General Medicine.—In speaking of the tendencies of modern methods of investigation, Dr. H. A. TOMLINSON calls this the age of mechanics. Mechanical methods are more alluring to the average investigator, because they require less mental effort. Renal disease is most important in all forms of mental and nervous disease. In nearly all cases admitted to the hospital for the insane he found evidence of renal inadequacy. His observation as a consultant also confirms the belief that this condition prevails in private practice as well.

Dr. FRANK P. NORBURY (Jacksonville, Ill.), read a paper entitled **Etiology of Paretic Dementia.** The lesion of this disease is a meningoencephalitis; parenchymatous atrophy. The essential changes involved the cortex, the basal ganglia, and the chord. It has been claimed that there should be no doubts of the etiology in these days of the prevalence of syphilis, in fact, "where there is no syphilis there can be no paretic dementia." It is not primarily a syphilitic lesion. In a study of 200 cases under his observation a history of syphilis was present in 60%. Alcohol and overwork with other excesses should be considered as etiologic factors only. He cited 3 cases, in 1 of which paretic dementia followed malarial fever, in another typhoid fever, and in a third rheumatism. He believes that the acute infectious fevers are a common etiologic factor. These cases may have been purely coincident, but he believed them to be causative as above. He also believes that a vulnerable condition of the cell is necessary to its occurrence, and, therefore, that heredity occupies an important place as an etiologic factor. In summing up he stated that he believed syphilis to be present in all cases of paretic dementia, but that the infectious fevers and heredity are important secondary causes.

Discussion.—Dr. D. R. BROWER (Chicago) took issue with the essayist on the occurrence of syphilis in all cases of paretic dementia. He believes that heredity is very limited in its influence, if it acts at all as a cause. He cited a case in which paranoia and paretic dementia occurred simultaneously in the same individual as a complicating psychosis. In his experience, syphilis does occur in these cases in from 60% to 80%, but in many instances he believes that mere overwork, stress of life, or excessive indulgence in alcoholics, etc., are alone responsible for its occurrence.

Dr. CARPENTER believed with the last speaker that there are cases of paretic dementia in which it is impossible to obtain a history of syphilis, and that it is possible to find it as the result of other factors alone. He mentioned the fact that the negroes of the South did not have this disease until after the close of the Civil War. He believed that sexual excess, business stress and alcoholism are sufficient in one having a neuropathic constitution to produce this disease of themselves. He cited cases where great harm might be done the individual, as in life insurance examination, or army examination, where a diagnosis of preexisting syphilis were made because of the development of the dementia.

Dr. DEVEXY said that he had seen 6 or 8 cases in which it seemed possible to exclude syphilis altogether, unless the hereditary type were assumed, and this he thinks would not be fair.

Dr. SYDNEY KUH (Chicago) said there is a very large amount of evidence that syphilis is present in all cases of paretic dementia and also tabes, but as a matter of fact it is impossible to say that it is always present. The character of syphilis has changed very materially in the last 3 or 4 generations; it was formerly more in the nature of an acute infection and often caused death early. History seems to show that certain cases of syphilis have a tendency to attack the central nervous system; in other words, 2 or 3 men have been known to become infected from the same individual, and in each this disease of the central nervous system may develop.

Dr. MAYER (Pittsburg) was totally ignorant of cause of paretic dementia but believed that it must be based on more scientific grounds. When we study other diseases we take a different course as to their pathology, and do not state arbitrarily that they are due to this or that infection. It may be due to other causes; to toxemia, and even that traumatism may act as a factor in its causation.

Dr. TOMLINSON believes that because syphilis is present in these cases it is not necessarily the only cause; certainly, the syphilitic lesion cannot be demonstrated and is not present in many of the cases.

Dr. NORBURY, in closing, said that business stress and other excesses as a factor in the etiology do not hold good, for many cases come from the rural districts where such conditions are certainly not present. Caution in diagnosis should be exercised; the general practitioner is particularly liable to withhold his diagnosis too long, and the period at which treatment might be beneficial is passed ere the diagnosis is made. There is undoubtedly early in the history of these cases a circulatory disorder, as pointed out by Dr. Folsom, of Boston, some years ago, and at this stage we may reasonably hope for benefit from treatment.

Dr. F. SAVARY PEARCE (Philadelphia) then read a paper entitled *Symptomatology of Cerebral Hemorrhage*, going to considerable length into the considerations of symptomatology; he spoke of some unusual symptoms and stated that in 50% of all cases the hemorrhage occurred during the night, and that on awakening the patient found a varying degree of hemiparesis. All cases of suspected hemorrhage, however slight, should be kept absolutely quiet for a period of several days. He stated that spasticity in the part affected is greater in cases of ingravescent hemorrhage than in hemorrhage into the internal capsule.

Discussion: HUGH T. PATRICK said the question as to the mystery of the occurrence of cerebral hemorrhage being more frequent at night is like the problem of the jar of water containing the fish weighing exactly the same as when the fish is removed; the answer to the argument is that it is not so. This statement regarding cerebral hemorrhage came to light prematurely and was never visible anyway. The theory of neuron retraction has no basis upon which to rest, and is not an established fact, and Dr. Pearce has wasted a good deal of cerebral energy in dwelling upon these points.

Dr. PUNTON noted that the writer had failed to bring out the importance of coma as a symptom of cerebral hemorrhage. It is an important symptom, and the deeper the coma and the longer it lasts the more unfavorable the outlook; he agrees with the writer that the diagnosis of cerebrohemorrhage is at times very difficult indeed. Cerebral hemorrhage is occurring earlier than formerly; it is not at all uncommon nowadays to find it in individuals 30 to 35 years of age, whereas we were formerly taught that it was essentially a disease of middle life.

Dr. JONES (Minneapolis) states that to him the most puzzling cases are those with the symptoms of hemorrhage, but in which no hemorrhage is found at postmortem.

Dr. CARPENTER said that he had seen a number of cases of ingravescent hemorrhage within the past year, and he had noticed an early tendency to sleepiness and drowsiness, gradually passing into coma, and he believed this to be a characteristic of large surface hemorrhages.

Dr. PEARCE, in closing, said the inclusion of thrombosis and embolism make it still possible that it occurs in the majority of cases at night, while it is true that the neuron retraction theory is not established, yet it is satisfactory to cling to a theory so fascinating until something more definite shall take its place. A definite diagnosis in cerebral hemorrhage is one of the most difficult things in neurology.

Dr. PORTER (Chicago) read a paper entitled *What Can Be Done for the Epileptic in a Medical Way*. He dwelt at length upon the usually unsatisfactory results of treatment, and took the ground that by a careful and painstaking attention much better results may be obtained. The primary cause of epilepsy, he believes to be due to malnutrition of the brain-cell, brought on by constant congestion of the cerebral blood vessels; he claims that sensitive areas on the scalp which may be definitely outlined in nearly all cases are due directly to this congestion, and that remedies applied or administered to relieve such congestion are the rational treatment for epilepsy.

This paper was discussed by Drs. PUNTON, KUH, PATRICK, RIGGS, PEARCE, MOYER, WARNER and DEWEY, all of whom took issue with Dr. PORTER as to the etiology and pathology of epilepsy, and all agree that the treatment is usually unsatisfactory, and that there is but one remedy, viz., the bromids, which has any appreciable effect upon the course of the disease.

SECOND DAY.

Dr. C. E. RIGGS (St. Paul) read a paper on *The Treatment of the Acute Psychoses in Private Practice*. The various forms of mental perversion usually come first under the observation of the general practitioner. As for the acute insanities their prognosis varies in proportion to their early recognition and treatment. He believes that the causes of insanity are not confined to the central nervous system, but that they are primarily due to a general physical condition. It is only a short time since it was thought that the State Hospital or the private institution were the only places where the insane persons could properly be cared for. He is convinced from large experience that home care in properly-selected cases will shorten the attack by a period varying from a few weeks to several months. No person should be sent to a State hospital who can properly be cared for at home. He does not mean to antagonize the State hospitals; they are excellent institutions and are doing splendid work in their particular field, but there is a considerable class that can with great advantage be cared for at home. Early recognition and prompt treatment is very important in all cases of acute insanity. Properly adjusted rest and exercise, the administration of large quantities of milk (140 ounces per day)

together with eggs, beef juice, malt extract, etc., supplemented by whisky and strychnia to overcome excitement, is in brief outline the treatment recommended. The nurse is another factor of utmost importance in the care of these cases; she should possess special knowledge, as well as proper personality in order to be successful. The recommendation is often not only a mistake but a crime; cases of paranoia are always harmed by it, as are also many cases of melancholia.

Discussion.—Dr. DEWEY (Wisconsin) said it was his experience that the general practitioner seldom tries to care for cases of insanity at home; more often the opposite mistake is made of sending away cases which could more properly be cared for at home. Patients with melancholia are not benefited by travel, because they are incapable of being interested in their environment.

Dr. PUNTON (Missouri) emphasized the isolation of the patient as of great importance in the treatment of these cases. This point should be impressed upon the general practitioner and an early diagnosis always sought. Harm is often done by sending such patients to the ordinary city hospital where the surroundings are such that they cannot be properly cared for.

Dr. NORBURY (Illinois) emphasized the idea that insanity is a problem of internal medicine.

Dr. DREW (Massachusetts) took exception to Dr. Riggs' free use of whisky in the treatment of the acutely insane.

Dr. EVERTS (Ohio) concurred in the main in the views of the writer.

Dr. TILLER (Iowa) is opposed to the home treatment of the insane, since under his observation it has proven a failure, because of the lack of intelligence and the means of the relatives to carry it out properly.

Dr. LANGDON (Ohio) who has had neither hospital nor sanitarium experience, is inclined to favor the home treatment, although in the great majority of cases poverty will prevent this being carried out.

Dr. PEARCE (Philadelphia) endorsed the method of forced feeding by means of the stomach tube when food is refused.

Dr. TOMLINSON (Minnesota) believes that the idea that it is harmful to insane persons to keep them together is not true; on the other hand, it even results in benefit to them; the chronic cases having a quieting influence over the acute. It may be true that acute cases can be cared for successfully at home, but the majority of cases do far better in the institution. The thing that prompts people to send the patient to the hospital is not the welfare of the patient, but the convenience of the family.

Dr. KIERNAN (Chicago), from an experience in both hospital and private practice, favors the institution; the only feature of home care which he would commend being the avoidance of commitment.

Dr. RIGGS, in closing, said the distinction between the neurologist and the alienist is a thing of the past. He further emphasized the importance of forced feeding, and defended the free use of whiskey to quiet excitement for a limited time in selected cases.

A symposium on *Syphilis of the Brain* was presented by Dr. HUGH T. PATRICK (Chicago), RICHARD DEWEY (Wisconsin), and F. W. LANGDON (Ohio). Dr. J. T. ESKRIDGE (Colorado), being detained at home by illness, his paper was read by title only.

Dr. PATRICK began by presenting 7 general postulates regarding popular fallacies relative to syphilis of the brain: (1) Brain syphilis occurs most frequently in the first year after infection, next in frequency in the second year, next the third, next the fourth, next the fifth year and so on; (2) in diagnosis the absence of the history of infection should be accorded little, if any importance; (3) the term syphilis of the brain is not synonymous with gumma, indeed, the condition is not gummatous at all; (4) the lesion is most frequent in arteritis, next in meningitis, and least frequently gummatous; (5) paralysis caused by brain syphilis outside of the cranial nerve is very irregular in its distribution; that is, it may be hemiplegic, monoplegic, or any irregular type; (6) a very high proportion of cases are not at all amenable to treatment; (7) it is never a system-disease. Headache occurs in 75%, and is usually severe. Transient attacks, dizziness, etc., are frequent; these occurring between the ages of 20 and 40 should always awaken suspicion. A somnolent, semistuporous condition occurs more frequently in lues than in any other brain disease.

Dr. DEWEY presented the *Psychoses in Cerebral Syphilis*. He raised the question whether any psychographic changes characteristic of this disease may exist; going carefully over the subject by other writers he draws the conclusion that we have not yet sufficient evidence to assume that they do. Too much has often been taken for granted in claiming syphilis and then connecting mental symptoms with it. It is necessary to exclude also other complications before this conclusion may be reached, the disease being proven and other things excluded it is still necessary to connect psychopathic history with findings at the postmortem. Our knowledge is, as yet, too insufficient to admit of deductions of value on this point.

Dr. LANGDON (Ohio) presented *Syphilis of the Nervous System, its General Pathology, with Remarks on Treatment*. In describing the initial lesion he describes it as a primary, localized parenchymatous and interstitial neuritis. A wound plus an infection. A secondary or tertiary lesion, he describes as an exudative root neuritis. The early or febrile period is a generalized toxemia. Locomotor-ataxia and paresis

are usually associated with syphilitic disease, but may occur without this infection. He referred to the method recently suggested of treating this disease in the acute stage by means of serum taken from the individual in the tertiary stage. The production of an artificial antitoxin was also mentioned. These papers were discussed by Drs. Norbury, Carpenter, Punton, Moyer, Kuh and the essayist in closing.

Dr. A. J. PRESSEY (Cleveland, O.) presented a paper entitled **Suggestions for Lessening the Frequency of Relapse After-treatment of Morphinism.** Authorities have variously stated that from 50% to 95% of all cases relapse after so-called cure, but the writer believes that the former figure is more nearly the truth, and that if the cases of degeneracy be eliminated the percentage would be reduced to even 25% or less. Some of the commoner causes of relapse are the inability of the physician to retain his patient sufficiently long under treatment; the frequent use of alcoholics, of tobacco, and of other narcotics. Do not despair of cure in any case in which the patient shows a desire to recover; on the other hand, some of the apparently most hopeful cases do relapse. The drug should be very gradually withdrawn, and that not steadily and continuously, but increasing and diminishing according to the patient's comfort, until it is reduced to the minutest fraction of the grain before being discontinued altogether. Static electricity is mentioned favorably as a factor in treatment. Careful and minute personal attention to details of control are absolutely necessary. Institution life has good effect upon these cases.

Dr. CROTHERS (Connecticut) in discussion took issue with the writer upon the gradual withdrawal of the drug. He believes that in most instances it may, with benefit, be abruptly or rapidly withdrawn. The system does not absorb more than 4 grains at a time, even though the dose be 20 grains. The needle fascination is the hardest feature to overcome. By means of hydrotherapy, suggestion, and substitute drugs the patient may be sustained and kept comfortable while a cure is being effected.

Dr. LAMBERT OTT (Philadelphia) presented a paper entitled **Injuries, Feigned and Real, with their Differentiation and Medical Legal Aspect.** Injuries are of 2 classes, visible and invisible; the effects of invisible injuries are usually sensory, while those of the visible are motor and trophic. Subjective pain is not easily discovered, but the results of pain are many times easy to discover. The pulse-rate while pressure is being made over the painful area is a valuable means of diagnosis. The frequency with which modern attorneys and physicians bring cases of this type into the courts constitute a species of modern robbery; $\frac{1}{4}$ of the cases of personal injury are of this type. Corporations should employ a physician to guard their interests, watching all cases of personal injury throughout their course. A jury of medical men to determine the exact physical condition, and also to determine the amount of damages is recommended.

Dr. MOYER, in discussion, thought that these measures would require the elimination of a good portion of the Magna-Charta and also the revision of the State Constitution, if not that of the United States as well.

Dr. CRAFTS (Minnesota) took issue with the writer as to the frequency with which personal injury cases are fraught with rascality. He believes from the tone of the writer's paper that he must be a corporation surgeon, and called attention to the fact that as there is more money on the side of the corporation the influence upon the expert is likely to be greater upon this side than the other.

Dr. DEWEY emphasized the importance of suggestion in these cases, even when there is no intention of deception on the part of the patient; the examination of the physician in itself is liable to produce such suggestions.

Dr. GASSES (Wisconsin) said that so long as we have our present system of subjective and objective pain there will be this confusion; there is but 1 pain, and that is pain; the pulse is the best index of any condition arising from pain.

Dr. KIERNAN (Chicago) agreed with the premises of the essayist.

Dr. OTT, in closing, invited those who disbelieved the rascality exhibited in the average case for personal injury to come to Philadelphia for a short visit, where he feels they will be converted.

[To be concluded.]

Section on Ophthalmology.

FIRST DAY.

The chairman, Dr. J. A. LIPPINCOTT, delivered a short address of welcome. The report of the committee was heard after which the reading of the papers was taken up.

Treatment of Strabismus; Measures other than Operative.—Dr. EDWARD JACKSON (Denver, Col.). In order to secure the desired results, treatment is required whether the case comes to operation or not. When the strabismus is detected treatment should begin immediately. There are many grades of binocular vision and may exist with amblyopia or squint. When development is interfered with by the strabismus, means must be taken to overcome the defect. We must first make it possible for the eyes to act in unison,

second, establish normal enervation, third, remove all obstacles to binocular vision, and fourth, to assist and train binocular vision. The correction of the ametropia was dwelt upon at length and impressed as the most important measures at our command. A full correction is necessary, preferably made by retinoscopy. Other important measures urged are: (1) Bandage excluding fixing eye; (2) use of cycloplegics for long periods of time in fixing eye; (3) stereoscope; and (4) reading bar.

Treatment of Strabismus; Operative Measures.—Dr. C. F. CLARK (Columbus, Ohio) said that the first effect of tenotomy is over-correction, which rapidly diminishes and in 3 or 4 days is overcome. The operation for advancement is much more tedious than tenotomy, but with a careful procedure an over-correction is seldom met with and the ultimate result is satisfactory, while relapse is a frequent occurrence after tenotomy. Even though falsely directed the deviating eye moves in harmony with the other, and to tenonize one of this group of muscles would be an absolute loss of power, while an advancement or resection would be really adding strength to the muscle involved. The writer's method of resection was described in detail.

Strabismus; its Treatment.—Dr. A. E. DAVIS (New York, N. Y.) This paper was read by invitation and took up most of the modern approved methods of treatment of strabismus, both operative and nonoperative. Panas' method of tenotomy was described and when surgical interference was necessary this method was used to the exclusion of all others, even in low degree of squint. In nonoperative methods the careful correction of any refractive error was paramount.

The Cosmetic and Visual Results in Squint: Dr. J. M. RAY (Louisville, Ky.): In 100 cases of convergent strabismus, observed in private practice during the last 4 years, 76 were monocular squint and 24 alternating squint. The early age at which many of these cases are seen prevents a study of the visual acuteness. In all cases where the objective test could be made, a cycloplegic was used and the refractive error corrected with almost immediate improvement. In some cases after correction the amblyopic eye improved, while the fixing eye became worse. Rarely was it possible to produce binocular vision. Glasses were invariably prescribed before any operative interference was attempted. Cosmetic result may be good and still one eye be amblyopic.

Discussion: Dr. SAVAGE (Nashville, Tenn.) said that if either advancement or tenotomy alone was done, then do an advancement. He believed, however, that a complete tenotomy of a rectus muscle should never be done. He advocated advancing one muscle and cutting the other.

Dr. BAKER (Cleveland) was in favor of the exclusion bandage and the midriatic, surgical procedure always being the last resort.

Dr. HORTZ (Chicago) believes in dividing the effect of operative treatment on both eyes to preserve the harmonious action of the eyes. In alternating strabismus he does a single tenotomy with cure.

Dr. BLACK (Denver) has done Panas' operation, except that he did not cut the muscle, simply stretched it, with good results.

SECOND DAY.

The Origin and Development of the Instrument, Together with a Description of the Historic Exhibit of the Ophthalmoscopes and the Publications on Ophthalmoscopy, prepared for this meeting by H. Friedenwald, of Baltimore, Md. This interesting paper was written to commemorate the fiftieth anniversary of the invention of the ophthalmoscope. The experiments which led to its invention, a description of the original instrument, and the many improvements which have led up to the modern instrument was treated in a most pleasing manner. In the exhibit hall was a valuable collection of very old and rare historic instruments, charts, papers, and manuscripts, which have been loaned to the writer. In closing the paper the writer desired to thank particularly Dr. C. A. Wood for his assistance in gathering the collection, also to many other doctors and instrument houses. It was his earnest wish that the Surgeon-General be urged to establish a permanent museum of ophthalmologic apparatus at Washington.

The Life of Helmholtz: Dr. CASEY A. WOOD (Chicago, Ill.). The sketch on the life of Helmholtz seemed a most fitting close to the previous historical paper in which he played so prominent a part.

Tarsadenitis Meibomica: Dr. M. F. WEVMAN (St. Joseph, Mo.,) defined this condition as a subacute or chronic inflammation of the meibomian glands and tarsal cartilage. In enumerating the subjective symptoms he laid stress upon the smarting and itching of the lids and a tendency to lachrymation, and the objective symptoms of tumor, drooping of the lid, nipple-shaped gland-mouths and the alligator-skin appearance of the conjunctiva. Many chalazios that undergo suppurative extend between the layers, one to the other producing a fistula containing much granulation tissue which he thought was a cause of many relapses. Treatment was thorough curetment and 5% protargol injections.

Report of a Case of Retroflexion of Iris: Dr. A. A. HUBBELL (Buffalo, N. Y.) described the case of a man who fell from a wagon striking on the side of the head. The patient never had previous disease or injury to the eye and vision was

acute. When first examined, the cornea was hazy, tension diminished and anterior chamber filled with blood. No rupture of any tissues of the eye. Later the blood absorbed leaving a few shreds which in time also completely absorbed. Ophthalmoscopic examination failed to reveal either the iris or lens. In a few weeks' time tension was normal and aside from aphakia and loss of iris, the eye looked normal. The theory is that the lens was dislocated and absorbed, while the iris was forced back and turned in against the ciliary body where it was retained by the hemorrhage until it was permanently anchored. With a spherical lens vision was $\frac{1}{12}$. The writer could find but 7 more cases recorded.

The Nominating Committee presented the names of Dr. Frank Allport, of Chicago, for chairman, and Dr. C. A. Veasey, of Philadelphia, for secretary. The report was accepted unanimously.

Nonoperative Treatment of Heterophoria: Dr. G. M. GOULD (Philadelphia) believes, properly speaking, there is no operative treatment for heterophoria. In his private practice, heterophoria was, in a large majority of cases essentially innervational in character, and hence required no surgical treatment. The nonsurgical treatment consists of accurately correcting the ametropia, combining a prism with spherical lens, if necessary, and gymnastic exercise. He declares he has not a dozen patients wearing prisms, the correcting lenses being sufficient to relieve all symptoms.

Surgical Treatment of Heterophoria: Dr. G. C. SAVAGE, Nashville, said that no case of innervational heterophoria should be operated upon, neither should a case which can be cured by gymnastics, or which is produced by a small error of refraction, receive surgical treatment. Many cases do not receive benefit from lenses or gymnastic exercise and must be operated upon. To obtain a cure from surgical methods there must be an alteration of the tension of the muscle and a change of plane of action. The operation consists of dividing the central fibers of the muscle so as to allow the peripheral fibers to be of equal strength. Never cut the tendon completely in heterophoria. If too much is cut, modify by taking up Tenon's capsule.

Discussion: Dr. RISLEY commended both papers, but thought the truth lay in a median line. No mathematic rules can be put down for treatment of these cases. There are many modifying factors, probably the most important being the shape of the skull in different individuals and the cheek ligaments.

There was a great deal of discussion on these papers, the general consensus of opinion being that nonsurgical treatment was in the ascendency. Without exception conservatism was emphasized.

Table of Paralysis of Ocular Muscles: Dr. H. M. STARKEY (Chicago, Ill.) demonstrated a very complete and elaborate table to the members, using it to elucidate the points of the paper. Having detailed the anatomy of the ocular muscles, their primary and secondary action, the paralysis of individual muscles was taken up for consideration.

The Extraction of Hard Cataract without Iridectomy: Dr. S. D. RISLEY (Philadelphia) said that "ripe" or mature cataracts are selected for this method of operation. The patient to be operated upon should be in bed, so there is a little moving about as possible. With a carefully selected knife the puncture and counter puncture is made at the corneoscleral margin above the pupillary margin, but before completing section the knife is dipped slightly and a conjunctival flap made. The speculum is then removed, the upper lid retracted by the assistant, pressure is made above the wound with an instrument, and on the lower lid by the operator, as the lens tips and comes into the wound, it is followed by the lower lid so as to remove any lens matter that may remain. The eye is then closed by adhesive strips, pads and a bandage. In later years he had not washed out anterior chamber. He used a solution of eserine in eye just before operation, and later continues in use of atropin. When there is a tendency to prolapse of the iris it is usually detected at time of operation. The acuteness of vision was given in a large number of cases, the majority attaining a high standard.

[To be concluded.]

Section on Laryngology and Otology.

FIRST DAY.

JOHN N. MACKENZIE (Baltimore), chairman of the section, spoke of the lack of instruction in all the medical schools on the special subjects, particularly that of air passages in the head. He believes the use of special instruments should be insisted upon and that they should be demonstrated in connection with the diseased conditions. He cited the Johns Hopkins University as being the first to make such procedure obligatory on the students; it is there a part of the curriculum of the college course.

Dr. O. T. FREER (Chicago) gave a very interesting paper on the treatment of laryngitis. He believes local treatment is absolutely necessary in all cases. Many of the less advanced cases can be improved by the use of internal remedies, such as salicylates and iodids, and when these are used in conjunction

with astringent sprays, recovery will be speedy. He believes sprays of far greater value than powders or the applicator, the latter often causing damage to the diseased membrane. The local treatment demonstrates the infected mucous membrane and not a congested condition due to cold. The surface being covered with leukocytes, the most reliable astringent is the nitrate of silver 10% or 20% solution. In more severe cases when the submucous tissue becomes involved and an edematous condition arises, there is danger of strangulation, it then is necessary to use the knife. The chronic laryngitis will assume the epithelial character of the skin, often small nodules or long folds of the membrane will form, later atrophy, absorption of fat, erosions, fissures and small amount of secretions, forming crusts, then we have the condition of ozena. Here more radical and severe treatment is necessary, a solution of hydrogen dioxide followed by astringents in solution. He spoke of the latter use of ichthyol being very useful to contract the tissues, but he has not had much experience in its use.

Discussion.—Dr. INGALS believed the use of the spray to be most beneficial, and advises a deep inhalation after use so as to draw the fluid down below the vocal cords. Dr. FREER said the inhalation method was extremely irritating, and unless cocaine had been previously used it would be likely to cause spasm.

Edematous Laryngitis: JOSEPH S. GIBB (Philadelphia) describes this condition as inflammation of a mucous surface with serous transudation into the submucous tissues. Much confusion has arisen from the various names given, many attempts have been made to simplify by classification under certain types. All this confusion can be abolished by drawing a sharp line in the symptom edema without inflammation. Active, in which inflammation occurs; passive, in which no inflammatory action is present. To clearly demonstrate this feature the doctor cited 4 cases. Of these 4 cases 3 were due to some form of septic infection. A large number of cases taken from other men show about the same proportion. This leads to the belief that a classification based upon first, those in which there is no true inflammatory condition of the laryngeal mucous membrane; second, acute catarrhal accompanied by more or less thickening of the mucosa; third, secondary septic processes complicating zymotic diseases; and, fourth, the infectious cases. In all appears the one symptom, edema and accompanying aphonia.

Dr. G. F. COTT (Buffalo) reported a case of total extirpation of the thyroid gland. The patient, a man, had for 16 years difficulty in breathing, rapid heart and swollen thyroid. The immediate cause for treatment was a great exacerbation of symptoms. A 2% solution of eucain was used and tracheotomy performed. It was impossible to pass a canula. A small soft rubber catheter was introduced into the larynx, and 30 hours later operation was attempted under the use of eucain; the pain became intense, and chloroform was used. After a half hour it became necessary to stimulate and use intravenous injection of salt solution. After 3 hours the glands, weighing $5\frac{1}{2}$ ounces, were removed. He related the history of a girl of 5 years having a papilloma in the larynx. She would not submit to the use of instruments. The trachea was opened and tube inserted which she wore for 2 years. One week ago the larynx was split between the vocal cords and the papilloma removed. Larynx sewed together. Perfect recovery.

SECOND DAY.

The Relation of the Middle Turbinate Body to Chronic Nasal Disease: C. S. BAKER (Bay City, Mich.) said that the nasal chambers must be accepted as mere ducts to drain the upper air passages, any obstruction in the turbinate bodies acting as a dam, thereby causing infection of the ethmoid cells. In nasal operations we drain out the upper cavities by opening up the obstruction. In many cases the chronic condition was due to the pressure of the ethmoidal cells against the septum; the opening of the ethmoidal cells saved a secondary operation on the septum. In this operation it is possible to remove the whole of the turbinated bones.

Discussion.—Dr. CASSELBERRY believes we should not interfere with the middle turbinated unless some pathogenic condition exists and there is a decided interference with drainage. In most cases of empyema, drainage by operation cannot be entirely relied on alone. It is not devoid of danger, there being the greatest danger from infection and also from hemorrhage. It is frequently a bloodless operation, yet sometimes it is not and there is a great amount of blood lost. He has used adrenalin and cocaine, with which the tissues become shrunken, parchment-like tissue which can be cut off with scissors; this is frequently followed by persistent hemorrhage. Adrenalin is of great assistance, but is followed frequently by persistent hemorrhage. Packing by iodoform gauze after removal of middle turbinate will stop the hemorrhage and can be removed following day. It is unsafe to send patient home without this provision.

Discussion.—Dr. WARREN. Middle turbinate is the chief trouble in the nose. There are 14 cavities in the nose. You can drain the antrum through the removal of the middle turbinate. A deviation of the septum is not so important. The initial lesion of catarrhal disease is in the middle turbinate.

Dr. CARR: So far as I can discover there is no difference in chronic discharge in the nose and that of other parts of the body. The whole point is drainage by removal of middle turbinate.

Dr. COTT: There is a point not particularly mentioned and that is the disturbance of cerebration: the constant pressure interferes with breathing, causing morbidity and later mind affection. This operation relieves. I object to the use of gauze, it insinuates itself on the small spiculas of bone remaining and cannot be easily removed. I find cotton more readily removed.

Dr. PAYNE believes use of cotton to be best. By repeating the use of adrenalin do we get the secondary hemorrhage. It can be used every 2 or 3 hours for several days. There is an operation of removal of middle turbinate beneath the mucous membrane which is devoid of danger. The bleeding is less, and less apt to cause infection.

Dr. MAYER: After the use of adrenalin, the patient should not be allowed to go away without packing. Have in many cases used no packing, but have resorted to adrenalin every 2 or 3 hours, the effect has been satisfactory. But before the day of hemostatics, a patient after operation was put to bed and kept there for 2 or 3 days. No packing was used and no hemorrhage resulted.

Dr. BAKER said there was no marked difference in the kind of material used for packing. He did not find gauze to insinuate itself more than cotton. It is not always possible to put a patient to bed. Have been obliged to pack in some cases, but recognized another danger. After removal of polyps when pus was discharged, the packing was the cause of infection and loss of the patient.

[To be concluded.]

Section on Hygiene and Sanitary Science.

FIRST DAY.

Only 7 members were present at the opening of the session. The secretary, Dr. J. N. HURTZ, was unavoidably absent and the chairman appointed Dr. J. R. NEELY (Chicago) acting secretary for the meeting.

The chairman thanked the members for placing him in the responsible position as chairman. The first paper was read by Dr. W. H. HEATH (Buffalo, N. Y.), by invitation, on **State Supervision of Marriage, its Feasibility, Scope, Justification and Possibilities**. As the standard of everything is made higher, so too this problem should be elevated, while it is a difficult one to deal with; the steps toward reform were that official license should be obtained, and 3 certificates should be issued. (1) Regarding health and heredity; this certificate should be issued by the family physician, and should include a medical examination; (2) a certificate to be issued by the municipal Board of Health as to their freedom from any and all hereditary or constitutional disease as well as educational in many respects; (3) a certificate as to the evidence of capability or ability of support, both on the part of the male and female, and this should include their passing a civil service examination in case the former was rendered permanently disabled.

Discussion.—Dr. EGNERT (Philadelphia) thought we were not ready for this innovation. In large cities many of the people are ignorant of a preliminary education on this point, hence opposition would be great on the part of the people, and they are not yet ready for such legislation. A course of lectures might be expedient in large municipalities, and one course alone would not be sufficient. This might be done during the winter months, and the poor would grow tired of attending these lectures.

Dr. L. H. MONTGOMERY (Chicago) said most of the salient points embodied in the paper have from time to time appeared in the literature, particularly that which has emanated from the State boards of health of Illinois and New York. He doubted if the people would regard this interference otherwise than that of being unconstitutional, but as sanitarians, as he regarded it, each of us, individually, favored practically all which was outlined by the author of the paper. In localities where there were no municipal health boards or other health authorities, the rule could not be made effective.

Dr. L. B. TUCKERMAN (Cleveland) said the great trouble with these educational schemes is that they render cautious those who do not need to be made cautious and have no effect on those who need to be made cautious. The more intelligent among the working classes do not marry at all. An inquiry by Hon. Carroll D. Wright as to the status of over 17,000 influential wage workers in 22 cities, showed over 15,000 unmarried. They do not marry because their tenure of employment is uncertain—they do not know when they will lose their jobs. The marrying is done by the thoughtless, happy-go-lucky class, with whom such cautioning instruction has but little weight.

Dr. FERD. C. VALENTINE (New York) said to carry public good to a logical conclusion, we should prevent people from marrying who have had gonorrhoea and syphilis. Fewer blind and other helpless charges would then be placed upon us. The question is one under State control, but that it would be impossible to carry out the provisions at the present time.

Dr. WILLIAM T. ENGLISH (Pittsburg) read the next paper, entitled **Pulmonary Fearlessness**. This paper elicited no discussion, except that Dr. EGNERT rose to say that he was glad to see one professional advocate of the college yell.

The following Nominating Committee was appointed: J. R. Neely, A. W. Suiter, William T. English.

SECOND DAY.

The Limitation of the Venereal Diseases: DENSLAW LEWIS (Chicago) referred to the universal prevalence of the venereal diseases and their disastrous and far-reaching effects. He asserted that a maudlin sentimentality and a false modesty prevented their consideration and he maintained that their importance justified a straightforward study as is done when other infectious diseases are investigated. There is no higher duty nor a more sacred privilege than the opportunity to do something toward the prevention of these loathsome diseases. At puberty the child's attention is directed to the external genitals. Masturbation is likely to result. The removal of all sources of irritation is a prophylactic factor of importance. Circumcision in the male and liberation of the preputial hood in the female may be necessary. When older, the dominating influence of the awakened sexual instinct asserts itself. Howard Kelly says the child follows the immediate impulse and nothing should be told him. It is asserted that a father is false to his trust if he does not warn his children against the dangers that beset them. If the father is a medical man neglect here becomes criminal. Illustrations relative to botany and zoology are instanced to show method of teaching the child. The boy should know the dignity of virility. He should keep himself pure so that in adult life no premature or indiscreet act may interfere with his assumption of the parental function. Certain conditions of our society should be told him. He should know about the venereal diseases and prostitution. He should learn the control of the sexual appetite. He should appreciate his duty to woman-kind. He should understand that if all men knew, as he now knows, regarding his duty in honor toward the young girl, prostitution could not be. The young girl should study physiology. There is no immodesty in her knowing that the bowels should move daily. There is no impropriety in understanding that menstruation indicates the possibility of maternity. The State also has a duty. In Illinois it is now a crime for a man to seduce an unmarried female of previous chaste character, under 18 years of age. The truth should be told the young girl. She should also know about the venereal diseases and it is a lesson in humanity for her to know regarding the prostitute—her unfortunate sister. There is danger in married life unless the sexual relations are satisfactory. There is danger in case of the absence or pregnancy of the wife, for at such times the polygamous nature of the man may assert itself. The prostitute should be considered as a focus of infection, and venereal diseases in her should be restricted by instruction in prophylaxis and by knowledge of the antiseptic douche and how to use it. Means for the treatment of venereal diseases should be increased. A hospital should exist in every city. The funds of every community cannot be more advantageously expended than in an effort to restrict venereal diseases. Class legislation is unconstitutional in America. Our idea of justice prevents the incarceration of a prostitute, even if diseased. Educational methods and adequate provisions for consistent treatment are the only feasible and practical means for limiting venereal diseases.

Discussion.—Dr. FRED C. VALENTINE (New York) said, in extending the views of the author to a practical end, advocated (1) that the State should include in reportable disease all contagious genitourinary and venereal ailments; (2) that sufficient hospital and dispensary services be established to separately treat genitourinary and venereal diseases; (3) that following the indications of the prostitutes themselves, who congregate in certain districts, to segregate them in definite regions; (4) that those who can be reached by law be regularly examined; (5) that circulars of instruction in the dangers of venereal diseases and in the methods of their avoidance be distributed to the prostitutes themselves, and to every male who enters the prostitute's districts. If these mere outlines of ideas on the subject be carried out, the work of public-spirited men, as Dr. Lewis, will bear the fruits for which they labor, and if but a small proportion of the youth of our generation be saved from venereal disease, in consequence of this advocacy, the efforts will not have been in vain. Dr. HOWARD A. KELLY (Baltimore) discussed the paper at considerable length in a dignified and ethical manner and recited instances where women had been saved. Dr. KOBER (Washington, D. C.) advocated athletic training of the youth. Dr. R. HARVEY REED (Rock Springs, Wyo.) said: We are at a loss how to get at a practical way to suppress prostitution, or social evil. This problem to be handled successfully, and to regulate vice, and the limitation of the disease will follow if such course is pursued, is to educate the boys and girls on these matters in the congregations of our churches. To attack the disease, or those contaminated with the disease, we must make them antiseptic. The legal phases are better discussed in cities than in the country. It is our duty to do the whole moral thing—moral persuasion and the theologian should be called in—psychology from the stand of the theologian we should join hands with. Dr. S. EGNERT (Philadelphia) said public lectures may be advantageous to instruct the ignorant in this class of disease. Venereal clinics for a young man to visit are very well and good if the young man does not visit these

clinics too frequently, for then he becomes flippant about it. We must educate the women also in this direction and in similar manner, even at the risk that the poor people grow tired of attending clinics and lectures.

Dr. FULLER (Iowa) said legislation will not control this, but it will restrain it somewhat. Of this there is no doubt. Teaching the young will assist them to be moral and thus the disease will be lessened. Dr. J. C. SHRADER (Iowa City, Ia.), said we are making progress no doubt in this matter, and we can readily suppress this, first, by helping to restrain our boys from wrong-doing, school teachers must teach morality among children. A great deal of good can be done by them by teaching morality in a discreet and proper manner. Dr. L. H. MONTGOMERY referred to the International Medical Conference for the prevention of Syphilis and Venereal Diseases, which was held at Brussels in September, 1899, where this topic, which had special reference also to the social evil problem, was discussed for 5 days by leading men of our profession throughout Europe and other foreign countries, from the standpoints not only of legalizing the disease, but of segregation of the courtesan, municipal control of same, etc., and yet the problem was unsolved. He did not agree with the author of the paper regarding the ravages or virulence of syphilis as he outlined it, that nowadays the disease is not so prevalent nor its virulence so great. Perhaps because people are educated and also that a physician is early consulted. Neither did he think that the disease was as prevalent where ignorance and poverty prevailed as the author had described it, or that these were the chief causes of producing the courtesan. It is not alone in the factory girl, nor any class in particular, that the disease exists. In his experience he sees more of gonorrhoeal infection among the clandestine class of women than in a public woman. Seduction of a young woman in other classes, under the promise of marriage, whether it be among the educated as well as among the illiterate, does occur under the promise of marriage, and then when disappointment overcomes them, through shame, or otherwise, step by step the young woman descends lower in the social sphere, and while she may ultimately become a semi-public character, not infrequently exposes others to unclean contact, or is herself thus exposed.

[To be concluded.]

THE AMERICAN ACADEMY OF MEDICINE.

ANNUAL MEETING HELD AT ST. PAUL, MINN., JUNE 1 AND 2, 1901.

FIRST DAY.

The First Year Medical Curriculum: THOMAS D. DAVIS referred to the changes in the past few years in all medical courses. The change from a 3 years' to a 4 years' course is not necessarily an advance in medical education, and there is absolute necessity for higher admission requirements. The graduate in art and science should have some advantage over those whose preliminary education stops with the high school. The first year in the course in medicine should approach the last year in college. There are many of the college studies that are a great advantage to the medical man, especially logic, psychology, botany and rhetoric.

Symposium on Reciprocity in Medical Licensure.—

Is the Demand for Reciprocity Based Upon Fact or Fancy? CHARLES MCINTIRE read this paper, mainly an examination of the reports of various State boards of medical examiners to determine what percentage of physicians desire to remove from one State to another.

The Desirability of Reciprocity in Medical Licensure:

—J. N. HALL referred to the fact that many physicians of excellent reputation wish to locate in Colorado on account of their health or for personal reasons. These men are often men of experience and well fitted to practise medicine, but are rusty on the foundation studies, such as anatomy and physiology. Reciprocity would be of benefit to these men, but reciprocity should not be established except among States where requirements are essentially equivalent.

Reciprocity in Medical Licensure from the Standpoint of a Physician who Changes His Residence: EDWARD JACKSON said that about 1 in every 4 or 5 physicians changes his residence from one State to another sometime in his career. Some give up the practice of their profession on account of the difficulties involved in such a change. The difficulty is not with the practical branches, which they are constantly in the habit of using, but rather with the preliminary studies, such as chemistry, anatomy, etc., whose technicalities they do not feel able to pass a stringent examination upon. The physician who wishes to remove cannot be expected to keep better posted upon those branches than he who does not wish to remove. The acceptance of the certificate of another State board as evidence of a proper acquaintance with such studies, would remove the chief hardship. The fear of lowering the standard seems to be the greatest obstacle in the way. The standard in many States

is placed "so high" that evasion in the form of special legislation lets in all sorts of irregular practitioners and threatens the permanence of medical practice laws.

Away with Reciprocity. CHARLES MCINTIRE thinks reciprocity will perhaps lead the profession far astray. Physicians already possessing the legal qualifications to practise medicine in one State should have certain privileges granted them in removing to another State. These privileges should be both fair to the people of the State as well as the physician, and the physicians already practising in that State.

Symposium on Institutionalism.—

Institutionalism: What Is It? Dr. ELMER LEE said the church was the first to start refuges for the sick and the afflicted. It was followed by corporate system, State charities and private enterprises. The individual fits himself for dependence by vicious habits, and ignorance of knowing how to care for himself; also by misdirected energies and misfortunes. The author describes the classes that apply for institutional charities, and mentions some of the abuses connected therewith.

The Soul of Institutional Oversight. JOHN CURWEN thinks that under the present organization of society there is a necessity for institutions for the care of certain of the defectives. In order to protect society and to care for these defectives, it is necessary that the State give its aid to properly accomplish it.

SECOND DAY.

Abuses of Institutionalism. EUGENE C. CARPENTER claims that institutionalism is an outgrowth of organization. The result is routinism. Routinism begets perfunctorism, which leads to automatism. Automatism is not different from that which is mechanical. Mechanical action is in fixed lines and does not depend upon experience and reflection. Opposition to innovations follows such action, and is therefore opposed to progress. The result is that the institutionalist is dominated by the institution instead of dominating it, and so becomes its victim. The true institutionalist must always remain master of the institution and strive to keep out of too strict routinism. If he is narrow all the participants in the institution will follow his narrowness. His policy, therefore, should be one of broadness and liberality, so that the institution may be known for its progress and breadth of purpose.

Tendencies in Hospitals for the Insane, with Some Suggestions. J. E. ROBBINS points out that too much isolation and lack of competition tends to make an institution inefficient. The medical staff is liable to become ultraconservative and the employes of all grades degenerate. It is necessary to keep in touch with the outside world and prevent the caste spirit of estimating men and women by themselves, and not by their positions.

The Advantage of Civil Service Principles in the Conduct of the Insane Hospitals.—GERSON H. HILL read a paper with this title in which he describes the plan of the organization of the State institutions in Iowa, and treating of the benefits resulting from the system and the principles underlying it.

Evils in Some Hospitals and Nurses' Training Schools that Might be Avoided by Proper Requirements, Regulations and Inspections by the Board of Health of each State.—ALBERT GOLDSPOHN said that it is important that the administrative body of hospitals, asylums, etc., should be composed of both laymen and medical men. Competition is one of the greatest evils of the hospital system. The author also enters into the question of how can the abuse of medical charitable service in hospitals be reduced and regulated.

The Need of National Cooperation in the Establishment of Sanatoriums for Tuberculosis.—A. MANSFIELD HOLMES pointed out that sanatoriums increase the chances for recovery, and afford an opportunity for the carrying out of rigid sanitary regulations which they do not have at home. They also educate the friends of those infected against the source of the infection, and thus prevent the spread of the disease. Sanatoriums should be graded so as to suit those for whom they are instituted. They may be conducted entirely for profit, or on the cooperative plan, or purely for charity alone. They may be located in climates known to possess beneficial influences, or near large centers of population. The State could not direct its energies in a more useful channel than in the establishment and maintenance of sanatoriums for tuberculosis.

Hospitals and Sanatoriums Founded, Owned, and Controlled by the Medical Profession: A Case in Hand.—H. BERT ELLIS divides hospitals into 3 classes, charitable, private, and mixed, and describes these classes, and another owned and controlled by physicians alone. For the latter plan he claims many advantages, and commends its adoption to physicians.

Institutional Life for Epileptics and for Feeble Minded: A. C. ROGERS.—The family is unable to cope with certain abnormal conditions found in the life of epileptics. These can only be properly managed in institutions. The organization, equipment and management of these institutions should have in view the necessities and requirements of the particular class of people for whom it is intended. All institutions are remedial, custodial, or a combination of the two. The community life is necessary for the feeble-minded and the epileptics, in order to supply the variety of physical, mental, moral, and religious opportunities suited to their needs.

The Care of Epileptics in Massachusetts: EVERETT FLOOD read this paper, which is a history of institutional care of epileptics in Massachusetts, dealing more especially with statistics and the administration of the institutions.

A Suppressed Educational Problem: JAMES A. TAYLOR urges an "enlightened" natural selection in lieu of the ignorant haphazard methods of selection practised by the majority of people, which result so generally in physical as well as intellectual deterioration.

Necessity for Revising Medical Fees: P. MAXWELL FOSHAY said that medical services are not adequately remunerated, and a plea is made for changing the method of computing the value of professional services. The custom of charging a fixed sum is a relic of antiquity and is illogical. Charges should be made according to the importance of the services rendered, as is done in other callings. The greatest advantage would be the removal of all conditions that at present serve as an excuse to justify the offering of commissions by the surgeon and the specialist.

The Relation of the Clinical Laboratory to its Hospital: HENRY W. CATTELL discusses this paper from a personal experience of 12 years, and an intimate connection with hospitals during that time, in various capacities.

DR. S. D. RISLEY (Philadelphia) gave the **President's Annual Address** to the Academy to a large audience composed of the Fellows of the Academy, and invited guests of the Aberdeen Hotel, Saturday evening. His topic was **Some of the Ethical and Sociologic Relations of the Physician to the Community**. In closing the address he emphasized it in the following language: "I have striven to show that a most striking characteristic of the medical man is a sense of obligation to the community; that this ethical attitude finds expression not only in the laborious routine of his daily professional service, but in a pronounced educational influence on all those lines which pertain to the healthfulness of the people and their medicsociologic welfare, this attitude being maintained notwithstanding frequent lapses from reciprocity upon the part of the laity; that this educational influence is originally exerted in the investigation and control of the relations which our defective classes of the population sustain to the social body. The student of social evolution realizes that through altruistic civilization, a rapidly increasing percentage of degenerates has grown up, presenting a serious and complex problem for solution by the twentieth century. Two suggestions are made for its arrest. First, the legalization of means to prevent the propagation of defectives; and second, by a wider education of the community regarding the importance of selection for the marriage contract, and its possible control by the State.

AMERICAN CLIMATOLOGIC ASSOCIATION.

EIGHTEENTH ANNUAL MEETING, HELD AT NIAGARA FALLS, N. Y., JUNE 1, 2 AND 3.

[Specially reported for AMERICAN MEDICINE.]

When the Climatologists were assembling the falls were enveloped in a dense fog, and the weather conditions for some time previous had been such that the natives were not so much disposed as they might otherwise have been to put forward the claims of the place to be regarded as an ideal holiday or health resort, at all events in the spring or early summer. On the other hand, it was noticeable that though the members of the association had come from all parts of the country they were singularly reticent about the kinds of weather they had been having recently in their respective homes, the inference being that on no quarter of the continent has there lately been much to boast about in this respect. A tacit understanding seemed in short to have been arrived at to ignore the concrete actualities and to deal only in generalities with regard to the elements.

Of course, the battle royal of the congress was waged, as it has been on many previous occasions, over the vexed question or questions as to what and where is the **best climate for the treatment of tuberculous patients**; but before it was entered on there were a number of affairs of outpost, which had the double effect of putting the combatants in good training and of warming them to their work. The president, Dr. ROBERT H. BARCOCK (Chicago) directed the exercises with decided skill and with an evident appreciation, not to say relish, of the different phases of the conflict. At the outset he cleared the way by delivering a **presidential address** which defined clearly and accurately the ground on which they were met, at the same time that he hinted at some of the points on which there was a difference of opinion. Taking as his particular theme the **limitations of medicinal therapeutics**, he showed that, while all good drugs were useful in their particular spheres, and some like quinin and mercury had claims to be regarded as specifics and at all events could not be done without, he pointed out that there was more and more tendency on the part of the most enlightened members of the medical profession to pay attention to the general health of their patients and, with a view to this, to call in the aid of natural agencies as far as possible. The influence of climate, life in the open air, the use of water in various ways, exercise, diet, and other things now receive more attention than they had done, and it was well that they should do so, if

only, but not principally, for the reason that the general public had revolted against the excessive use of drugs and called for a greater reliance on the resources of nature's laboratory—exaggerated manifestations of which were found in the growth of bodies like the Christian Scientists, Faith Curists, Kneippists, etc. Simultaneously with this outbreak of therapeutic nihilism, it was true that a new era was being opened up by the discoveries of what could be done by means of antitoxins, and serotherapy, and organotherapy generally, but this was no reason why skilled physicians should neglect natural agencies and leave the rich field to ignorant empiricists. Proceeding to speak in more detail of hydrotherapy, he reminded his hearers of the belief that the Romans had in baths, and after remarking that though their utility had been lost sight of with many other good things in the Dark Ages, the therapeutic value of water again commenced to be recognized in the seventeenth and eighteenth centuries, and now they could say in regard to it that it not only was the only remedial agency that had stood the test of time but that it stood higher now than it did 2,000 years ago. The activity of the last 30 years in the study of bacteriology had given rise to the belief that every disease was due to some sort of microbe, but they now knew that there must be some additional factor besides bacteria. In other words, there must be a condition of the body that afforded a good culture medium, otherwise the bacteria would not thrive. They might speak of it as susceptibility to particular diseases, or say that the power of resistance was slight, or that a person's vitality had become low, but it all meant the same thing, and showed the importance of observing the general laws of health. The physician was behind the times who depended entirely on medicines; they must make intelligent dual use of medicinal and natural agencies.

The reading of papers was then proceeded with, the first being one on the **Climate and Diseases of Puerto Rico**, by Dr. CHARLES H. ALDEN, formerly Assistant Surgeon-General, U. S. A. Having showed that the diseases most prevalent in the island were largely due to bad sanitary arrangements, he recounted the good that had been accomplished since it came under the jurisdiction of the United States, particularly in respect to smallpox, which previously had been very much neglected and was consequently very common, but which through the agency of vaccination had rapidly diminished and almost entirely disappeared.

The Fevers of Florida were then reported on by Dr. FRANK FREMONT-SMITH, Palm Beach, who, admitting that his experience had been confined to 1 or 2 of the larger cities on the coast, adduced figures to show that there was nothing to be particularly alarmed at as regarded either the number of patients who suffered from fever or the severity of their attacks, but quite the reverse, there having been only a small number of cases and some of these having evidently been imported. Casual references he made to "mountain fever" caused several speakers to protest against the use of that term, and the reader of the paper said he only used it with the understanding that it meant typhoid contracted in the mountains. Dr. JOHN L. HEEFRON, Syracuse, N. Y., said he had heard that it was impossible to get the words "typhoid fever" out of Florida by telegram, and an attempt that he had made to get them into the State had certainly failed, a telegram he sent when one of his patients was attacked with fever there having failed to get delivered. Dr. FREMONT-SMITH assured the doctor that this must have been due to accident, as there was no such conspiracy as was suggested to prevent the use of the words in reference to Florida.

The Climatology of Augusta, Ga., was next discussed in a paper by Dr. THOMAS D. COLEMAN, of that city. He drew a distinction, however, between the city proper and the elevated suburb of Summerville, on the site of which he admitted that it would have been well if the whole of Augusta had been built. Summerville, he added, was built on a hill of sand, had excellent drainage, enjoyed a pleasant climate free from sudden changes, and was altogether a very suitable place for tuberculous and other patients. Apologizing for the want of some statistics, he said he understood that it was not considered necessary to keep mortuary records in Summerville.

Remarks on the Climatic Influences of Newport, R. I. Dr. W. C. RIVES (Washington), and a paper on **Nantucket and the Ocean Climate**, Dr. HAROLD WILLIAMS (Boston), gave rise to an exchange of courtesies between these gentlemen. Among the principal advantages claimed for the climate of Newport by Dr. Rives were its coolness in summer and mildness in winter. These he attributed to the prevailing winds and the gulf stream. He admitted that the winter was not good for consumptives, but said he would prefer it to other parts of the New England coast. Dr. Williams inquired the authority for the statement regarding the effect of the gulf stream, his impression was that that stream did not come within 300 miles of Newport. Dr. Rives said the temperature of the water was undoubtedly warmer than at Cape Cod, and it seemed reasonable to attribute this to the gulf stream, as was done in a paper by Dr. Storer. Dealing with Nantucket Dr. Williams said its climate resembled that of the ocean more nearly than that of all other Atlantic resorts, with the possible exception of Atlantic City, and for the reason principally that it was further out to sea than any of the rest. Dr. Rives asked whether a few years ago the deathrate from tuberculosis in Nantucket was not

the highest in the State. Dr. Williams explained that fact by saying that the population was very much reduced some time ago by the abandonment of certain industries causing a great number of people to go elsewhere. Many of these, however, came back to Nantucket to die.

Notes on the Climate of New York and New England were given in a paper by Dr. GUY HINSDALE (Philadelphia). He said the peculiar changeableness of the climate of this region was due to the fact that it was the meeting ground of 2 storm tracks. The cyclones from the Great Lakes and the storms that moved along the coast from the South met in New England. Cyclones were not to be confounded with tornadoes, the element of extreme violence not being involved in them. It had been said that New England was the exercise ground of the weather, and that as a consequence a New Englander was a person who was always about to be warm and comfortable. Still, that, as Charles Dudley Warner said, was the sort of stuff of which martyrs and heroes were made. The speaker proceeded to give interesting details of records he had kept of the climatic conditions with particular reference to the coast of Maine, which was free from some of the disadvantages alluded to, and mentioned that when his paper was published it would be found to contain some notes in regard to the great blizzard. A remark he made to the effect that it was a mistake to suppose that the prevailing wind in Boston was from the East was confirmed by other speakers, and Dr. W. F. R. PHILLIPS, of the Weather Bureau at Washington, made the official statement that Boston has in reality 2 prevailing winds—southeasterly in summer and northwesterly in winter. The reason for the popular error, it was suggested, was that when the wind did blow from the east it produced such an effect that its impression was not easily forgotten.

In a paper entitled **Some Observations on Southern California**, Dr. SAMUEL A. FISK, in spite of the fact that he hails from Denver, Col., gave a glowing account of the pleasure and benefit he had derived from a trip to the lower part of the Pacific Slope. Contrasting the climates of the 2 regions he said that Colorado was stimulating while Southern California was soothing; both were good for invalids, though at different stages and under different conditions. Dr. NORMAN BRIDGE (Los Angeles) read a paper on the same subject. He remarked that Southern California was the paradise of the old and of children, and that tuberculous patients usually did well there. It was a question whether intense dryness of atmosphere was as important as had generally been assumed. The quality of climate they required for tuberculous patients was one that enabled them to live largely in the open air, and that was the kind of climate they had in a marked degree in Southern California. Several of the Colorado doctors present referred to patients who were in the habit of coming from Southern California to Colorado for tonic effects, and one said that if patients were going to try both climates he would advise them to try Colorado first. In replying on the *discussion*, Dr. FISK said he went to Southern California a consumptive and he came back cured. He was loyal to Colorado, but as some cases did better there than elsewhere, so other cases did better elsewhere than there.

The Proper Definitions of the Terms Usually Applied to Tuberculosis to indicate stages of advancement of the disease and results of treatment, were discussed in a paper by Dr. J. EDWARD STUBBERT (Liberty, N. Y.), who gave illustrations of the different meanings that were attached to the following: (1) Pretuberculous or prebacillary stage; (2) incipient stage; (3) moderately advanced stage; (4) far advanced stage; (5) improved condition; (6) arrested condition; and (7) cured or apparently cured condition. He pointed out among other things that the pretuberculous stage was not recognized by many authorities, that the other terms were all used with different meanings, and that there was a complete absence of agreement as to the conditions under which and after what lapse of time a patient could be pronounced cured. After discussion it was agreed to appoint a committee of 5 to draw up definitions of what the members of the association should agree to understand by the terms in question or others that might be decided on. The selection of the committee was left to the president, and he subsequently announced the appointment of the following: Dr. Charles E. Quimby (New York), Dr. F. I. Knight (Boston), Dr. James C. Wilson (Philadelphia), Dr. Edward R. Baldwin (Saranac Lake, N. Y.), and Dr. J. E. Stubbert (Liberty, N. Y.).

Tuberculin Tests was the next subject brought to the notice of the association, Dr. EDWARD O. OTIS (Boston) reporting the results of further tests he had made, and Dr. W. E. CASSELLBERRY (Chicago) reading a paper in which he described the cases in which he thought the test seemed justified and decisive. The discussion which followed showed the general opinion to be favorable to further experimentation with tuberculin and also with other substances which were reported as giving similar reactions. The fact that syphilis sometimes responded in the same way as tuberculosis was considered only an additional reason for pursuing the investigation further.

Dr. R. G. CURRIE (Philadelphia) reported 2 cases of **Aneurysm of the Heart and 1 of Spontaneous Rupture of the Heart**, and the proceedings of the first day were brought to a close by Dr. SHERMAN G. BONNEY (Denver) reading a paper on the influence of the Colorado Climate upon **Pulmonary Hemorrhages**.

SECOND DAY.

The second day's proceedings were devoted almost exclusively to the consideration of questions connected with the **treatment of tuberculosis**. Before this subject was reached, however, there was an interesting discussion on the question raised by Dr. F. I. KNIGHT (Boston), **The Association of Tuberculosis and Syphilis—Is it always injurious, or does one disease exert an inhibitory action upon the other?** Dr. KNIGHT mentioned that, having had his attention directed to the subject he looked into the literature, and came across very conflicting opinions, one being that syphilis predisposed a person to tuberculosis and aggravated the disease, and another that it might in the course of time be found desirable to make use of a vaccine of syphilis in order to save the people from tuberculosis. The matter was of great importance, on account among other things of the difficulty in some cases of diagnosing between the 2 diseases and the impression which prevailed that antisyphilitic treatment was apt to complicate tuberculosis. He had never himself found antisyphilitic treatment have this effect, and indeed had had cases where its effect or that of the syphilis was to make the tuberculosis symptoms disappear. Rheumatism and some other diseases were recognized as being antagonistic to tuberculosis. Might not this also be true of syphilis? All the speakers who took part in the discussion agreed that the subject was deserving of further investigation. A case of **Mechanical Obstruction of a Bronchus Simulating Rapid Tuberculosis** was then described by Dr. J. B. WALKER (Philadelphia); and Dr. THOMAS W. HARVEY (Orange, N. J.), gave an account of a case in which a **Case of a Piece of Meat in the Bronchus Disappeared by Apparent Absorption**, followed by the recovery of the patient.

The symposium on tuberculosis was introduced by a paper on the **Selection of Favorable Cases of Pulmonary Tuberculosis for Sanatorium Treatment**, by Dr. E. R. BALDWIN (Saranac Lake, N. Y.). In no other disease, he said, was it so difficult to make a prognosis, many cases that were regarded as incipient being really incurable, while others that were apparently far advanced might be cured. This showed the necessity of coming to a better understanding than now existed as to how cases should be classified, and he submitted a scheme (which he explained in some detail) not with the belief that it was perfect, but in order that the members might have something to work upon. Under the present system or want of system a great deal of harm was done—on the one hand by patients who were thought to be only in an incipient stage being given extravagant promises of speedy improvement or recovery, and on the other hand by the stamp of "incurable" being put on those who, in spite of the fact that the disease appeared to have reached an advanced stage, might be cured, or at all events much improved. Apart from such considerations, the success of State and municipal or semicharitable sanatoriums required discrimination in favor of curable cases. Economic reasons, indeed, compelled it at present, the interests of the curable necessitating the exclusion of very ill patients. Separate provision, he contended, should be made for the latter because of the impossibility of which he had spoken of determining prognosis. Probably many years would elapse before adequate provision was made for all classes, and until such a time had arrived encouragement should not be given for obviously unfavorable cases to apply for admission, as refusal meant incurability in the eyes of the patient and his or her friends. The factors that might be considered as favorable, doubtful or unfavorable in prognosis were tabulated in his scheme, which he admitted could not apply to every case, though he thought it might aid in the selection of cases.

The next paper was by Dr. CHARLES L. MINOR (Asheville, N. C.) and dealt with the **carrying out of the hygienic treatment of tuberculosis outside of sanatoriums**. He had no wish, he said, to belittle the work that was being done in sanatoriums but much could also be done at the residences of patients in health resorts like Asheville. Many patients did not care to go to sanatoriums, and in selecting a place to send such patients to, the doctor could not be too careful in studying the local conditions and also the circumstances of the patient. Pure air and pleasant natural surroundings were of the utmost importance, but these would not atone for bad cooking and a cheerless house. The character and habits of the patient had also to be studied, as had likewise his family and business relations, the object being to place him as far as possible in a position where he would be free from anxiety and worry. For much of this it was necessary to depend on the family physician. When the patient came to a resort it was incumbent on the doctor having charge of his case to impress on him how largely his progress towards recovery or otherwise was in his own hands. It was well to be candid with the patient up to a certain point, the revelation of the whole truth, though not always desirable, being almost always better than concealment. Then they should proceed to build up the system by means of food and exercise, light and air, the patient being requested to keep a record of his symptoms and daily life, but at the same time instructed not to speak to any one but the doctor of his ailment.

Dr. IRWIN H. HANCE, Lakewood, N. J., who had the next place on the program, dealt with practically the same phase of the question, the title of his contribution being **The Home Treatment of Tuberculosis**. He said that what was most desirable was the means of extending to the masses the advant-

ages that the few got in sanatoriums, and this was found in localities where the patients could have plenty of fresh air, good food, and rest. He also attached much importance to baths, rubbing, etc.; medicines played only a secondary part in the treatment of such patients. It was a question in his mind whether the prevailing idea that climatic change was necessary in the treatment of tuberculosis had not had a retarding effect. At all events, for the great majority of people, what they ought to aim at discovering was how they could be best treated at a distance not too far from their homes. Dr. CHARLES FOX GARDNER (Colorado Springs) who read the next paper on the list, insisted on the other hand on the **Importance of Early and Radical Climatic Change in the Cure of Pulmonary Tuberculosis**. He dwelt also on the advantages of high altitudes, and expressed the belief that more patients were cured in boarding houses in Colorado than in sanatoriums in damp climates. No doubt the best of all results were those that could be obtained by the advantages of climate and sanatoriums combined.

Dr. ARNOLD C. KLENS, (Chicago) speaking on the **selection of a proper locality for the treatment of tuberculous patients**, reminded the meeting how first warm temperatures and then cold temperatures, dry climates and ocean voyages, in fact, every variety of atmospheric elements have been recommended for this disease. The conclusion at which he had arrived was that there was no climate, any more than there was any drug, that suited all cases. In spite of the discovery of the bacillus of tuberculosis, they still knew little of the disease, and he was not sure but the discovery of the bacillus had delayed, rather than advanced cures, all the attention being directed to the bacillus and the body itself being neglected. In other words, the bacillus occupied a prominent position among bacteria to the detriment of suffering humanity. Among the objections to climatic change were the expense and the worry it was likely to give a patient if he could not well afford it, homesickness, the fact that the physicians who recommended a change did not know much about the conditions and climates of different places that were supposed to be good for such patients, and above all, the fact that so small a proportion of patients who went to other climates were ever able to return home without having a recurrence of the disease. Condemnation of the climatic treatment might seem radical, but he was looking at the matter from the point of view of the masses, and he did not hesitate to say that what they required was some place not too far from their homes where they could get fresh air and sunshine, comfort and good food.

Dr. VINCENT Y. BOWDITCH (Boston), in discussing the papers, referred to the **vagueness of terms** that were used and the absence of proper data for making accurate comparisons. The results, however, obtained in New England had justified them in changing their views to the extent of believing in the curability of a large number of cases in local sanatoriums. At the same time it must be acknowledged that each case must be treated individually, and that the treatment must be regarded as experimental. Merely **sending patients away haphazard to climates** that were supposed to be beneficial to such cases was not satisfactory. He believed that better results could be obtained in the West than in the East. Nevertheless they required sanatoriums in every locality where tuberculosis prevailed.

Dr. E. O. ORIS (Boston), while admitting the **advantages of climatic change**, said it was sometimes a question whether they were not too dearly bought, especially when a patient had to be acclimated twice over, first say in Colorado and then on his return home to New England or elsewhere. It was no longer recognized that climate was the whole or primary consideration in the treatment of the disease. A revelation had been made within the last few years of what could be done at home, by means of sanatoriums and otherwise. Comparing the treatment in sanatoriums at home with the treatment without sanatoriums in more favorable regions, he questioned whether the advantages of climate in the latter counterbalanced the advantages that were derived from the sanatoriums. Patients cured at home were more likely in his opinion to remain cured.

Dr. FISK (Denver) said that after all it could not be gained that a strong line of demarcation was drawn by the pocket-book of the patient. What was most desirable was to get the best climate and the best home at the same time. There was little use in a man going to a good climate and starving himself or living in a damp room.

Dr. S. G. BONNEY (Denver) regretted the tendency that existed in some quarters to **minimize the importance of climate**. At the same time he fully agreed to the proposition that the best results could not be got without a combination of climate and an appropriate system of daily life. Local hospitals were required everywhere for the hopelessly ill, who were a source of great danger to the rest of the community.

Dr. S. E. SOLLY (Colorado Springs) remarked that if he had his way he would have every patient go into a **sanatorium first**, not necessarily to remain there long, but for observation. The way that home doctors sent patients to Colorado and elsewhere for treatment showed that they did not know enough about them. A short residence in sanatoriums would enable the patients to be classified and an intelligent idea formed of the climate and treatment that would benefit them. He still believed in the value of climate, and said that if a patient were cured in a good climate the good effects would remain to the same extent as if he had been cured elsewhere.

Dr. JAMES A. HART (Colorado Springs) agreed with the statement that **no drug or climate was a specific**. The ideal treatment was one combining climatic benefit with hygienic conditions. Removing patients 15 miles or so from their homes and putting them on regular diet and giving them fresh air, exercise and other things was a step in the direction of giving tuberculous patients what they would get if they went to the Rocky Mountains.

THE CHAIRMAN remarked that he was glad to see so much general agreement in favor of open air, with proper exercise and good food, regimen and rest. Doctors had too long relied in such cases on tonics and cough mixtures. It was not medicinal therapy that was needed; it was the proper regulation of the patient's daily life.

Dr. C. F. MCGAHAN (Aiken, S. C.) said it was undoubtedly better that patients should have **fresh air and good food at home** than that they should be sent to a health resort and put in a cheap boarding house. There were many people, however, who could not endure the discipline of a sanatorium, and who, if they could afford to go to a health resort, might be educated to the point of following a regular course of home treatment.

Dr. ALBERT C. GETCHELL (Worcester, Mass.) observed that an incidental advantage gained from the sanatorium was that the patients who spent some time there assisted on their return home in educating the public. In this way they were assisting in a work that ought to be much more systematically entered on, having for its end the **stamping out of tuberculosis**.

In the course of further discussion, Dr. R. G. CURTIN (Philadelphia) said there could be no doubt that, while there was a great deal in climate, a great deal could likewise be done at home. The difficulty was to get patients to carry out the instructions given them.

Dr. JAMES C. WILSON (Philadelphia) was disappointed that he had not heard more about the **treatment of patients in their actual homes**. Most of what has been said had related either to treatment in sanatoriums in the locality of their homes or treatment out of sanatoriums in other places where the climate was more favorable. It should not be overlooked that in many places, Philadelphia among them, good results had been obtained by getting the patients to carry out regular regimens in their own houses. He thought that municipalities ought to be urged to do more in the way of providing local hospitals.

The readers of papers having replied, the discussion was brought to a close. On the motion of Dr. H. L. ELSNER (Syracuse, N. Y.) a motion was adopted in support of the principle of the **State care of the tuberculous poor**.

THIRD DAY.

Business Meeting.—The election of office-bearers resulted as follows: President, Dr. Samuel A. Fisk, Denver, Colo; vice-presidents, Dr. Norman Bridge, Los Angeles, Cal., and Dr. W. F. R. Phillips, Washington, D. C.; secretary and treasurer, Dr. Guy Hinsdale, Philadelphia, Pa., reelected; member of council, Dr. Robert H. Babcock, Chicago, Ill.; representative to Congress of Physicians, Dr. F. A. Knight, Boston; alternate, Dr. R. G. Curtin, Philadelphia. It was decided to hold the next meeting at Coronado Beach, San Diego, Cal., on or about the first of June and the following days. After discussion it was agreed to limit the membership of the association to 150. Eleven new names were added to the roll.

A paper was read by Dr. C. C. RANSOM (New York) on **Clinical Aspects of Spa Treatment**, and a communication on the same subject was received from Dr. BEVERLY ROBINSON (New York) and ordered to be included in the transactions. Dr. BOARDMAN REED (Philadelphia) contributed a paper on **The Hygienic and Mechanical Treatment of Heart Disease**, and Dr. GUY HINSDALE (Philadelphia) followed with one on **Analogous European and American Mineral Springs**. These papers were all discussed together, and the importance of the work of investigation started by Dr. HINSDALE being recognized, a committee, consisting of that gentleman and Dr. ALBERT C. PEALE (Washington) and Dr. RANSOM (New York), was appointed to carry it on.

Among the other papers on the program several of which were read by title in consequence of the absence of the authors, were: **Devitalized Air Toxemia a Prime Cause of Tuberculosis**, Dr. Charles Denison (Denver); **The Relation of Sunshine to the Prevalence of Influenza**, Dr. Howard S. Anders (Philadelphia); **A Case of Pulmonary Osteoarthropathy**, Dr. R. C. Newton (Montclair, N. J.); **The Physiologic Influence of Climate on Nervous Diseases**, Dr. F. Savary Pearce (Philadelphia); **The Use of Strychnin in Diseases of the Heart**, Dr. Abraham Jacobi, (New York); **The Cause of Death in Aneurysms of the Thoracic Aorta Which do not Rupture—Report of 2 Cases**, Dr. H. D. Arnold, (Boston); **The Etiology, Pathology and Clinical Aspects of the Bovine Heart**, Dr. Leonard Weber (New York); **A Case of Chronic Endocarditis**, Dr. Judson Daland and Dr. W. D. Robinson (Philadelphia); **The Increased Corpuscular Count of the Blood at High Altitudes, especially in Rapid Ascent**, Dr. W. A. Campbell (Colorado Springs); **The Use of Guaiacum in the Treatment of Pulmonary Tuberculosis**, Dr. W. W. Bulette, (Pueblo, Col.); and **Note Upon the Shifting of Apparent Gastric Pain into True Angina Pectoris**, Dr. Glentworth R. Butler (Brooklyn).

PULSATION OF THE UVULA IN AORTIC INSUFFICIENCY.¹

BY

DAVID RIESMAN, M.D.,
of Philadelphia.

Professor of Clinical Medicine, Philadelphia Polyclinic; Instructor in Clinical Medicine, University of Pennsylvania; Visiting Physician to the Philadelphia Hospital.

The occurrence of pharyngeal pulsation in aortic insufficiency was, it seems, first brought to the attention of clinicians by F. Müller in 1889. Since then but few references have been made to the subject, and the majority of textbooks are silent upon it. A recent paper by Schlesinger,² of Vienna, has served to stimulate a renewed interest in the phenomenon.

Schlesinger examined 40 cases of aortic regurgitation, but found unmistakable pharyngeal pulsation in only a small number. Much caution is necessary in the examination, as muscular movements produced by attempts at retching or swallowing may simulate pulsatile phenomena. The patient should be instructed to hold the mouth open steadily and to breathe quietly. The employment of a tongue-depressor did not, in my limited experience, seem to interfere with the interpretation of the pharyngeal movements; but it is well to make the examination both with and without the use of this instrument.

Two types of pulsation of the soft parts are distinguishable: a communicated movement, connected with the throbbing of the carotids, and usually affecting the tonsils and faucial arches; and an independent movement, brought about by a systolic increase in the volume of the tissues. This manifests itself in a rhythmic turgescence of the soft parts. Schlesinger has observed the pulsation in the tongue, both by inspection and by palpation. It may likewise be discernible in the half-arches and in the uvula. At times the posterior wall of the pharynx is pushed forward with each systole of the heart; in some cases the swelling is so marked as to produce a distinct rhythmic narrowing of the oral and pharyngeal cavities. I have looked for the phenomenon in 3 cases of aortic regurgitation that have recently come under my observation, and found pulsation of the uvula in 2 of them.

CASE 1.—The first patient was seen in the dispensary of the University of Pennsylvania Hospital. He was a man of 37 years, who had a double aortic murmur and dilated hypertrophy of the heart. The murmur was of the see-saw quality, and could be heard over the greater part of the chest. The capillary and water-hammer pulses were both well marked. On inspection of the pharynx, the uvula was seen to quiver synchronously with the pulsations of the heart; at every systole, its tip was tilted forward and brought nearer to the base of the tongue. The movements were rendered more noticeable by the fact that with every change of position the reflection from the glistening, mucus-covered surface of the uvula was modified. I was not able to convince myself that there was pulsation of the half-arches or of the posterior pharyngeal wall; there was no rhythmic swelling of the tongue.

CASE 2.—The second patient was a girl of 16, who came to the University Hospital Dispensary from Chester, Pa. She had aortic regurgitation and hypertrophy of the heart. There was only a single, diastolic murmur at the base. The capillary and Corrigan pulses were present. In this patient there was also a distinct pulsation of the uvula, synchronous with the heart's action. Other pulsatile phenomena in the pharynx or mouth were not present.

Both patients were exhibited to the students in my ward classes, who witnessed the phenomenon.

CASE 3.—The third case, seen in private practice, was a typical one of aortic disease, with double murmur, in a boy of 10 years. He had a capillary and a water-hammer pulse, but I was unable to find any rhythmic pulsation of the uvula or other parts of the pharynx. Why it was absent in his case, I am unable to say.

The phenomenon is, of course, of the same nature as the capillary pulse, although it is possible that in such soft parts as the tonsils, the half arches, the uvula, and the tongue the vibration of the small arterioles may participate in the production of the pulsation. As a physical sign, pharyngeal pulsation has no special diagnostic value and possesses no greater significance than the capillary pulse. The knowledge of its existence merely adds one more point to be looked for in the critical study of a case, and thus helps to stimulate and to sharpen the powers of minute observation.

PREVENTION AND CURE OF POSTOPERATIVE
HERNIA.

BY

JAMES E. MOORE, M.D.,
of Minneapolis, Minn.

A paper upon this subject must necessarily be short because the subject is a small one at the present time, but we can all remember when it was very large and important. Modern surgeons very rarely see hernia following their own operations, except after operations for acute appendicitis in which they have been obliged to drain. In the controversy between the advocates of abdominal and vaginal hysterectomy, the fear of a ventral hernia should no longer be an argument against the abdominal route, because any operator competent to perform hysterectomies will not have a hernia follow his operations. All the ventral hernias I have seen during the past 3 years, with one single exception, have either followed operations for acute appendicitis in which it was necessary to drain, or operations performed by "occasional operators." The one exception was in a hemophiliac, who had had her wound packed to save her life.

The causes of ventral hernia are sepsis, improper closing of the wound, and drainage. It follows that hernia may be avoided by asepsis, proper closing of the wound, and by avoiding drainage. Upon the question of asepsis we all practically agree, but concerning the closure of the wound, there are still differences of opinion. This was very manifest in the discussion of Dr. Richardson's paper last year. At one time it was believed that a hernia was more frequently the result of an improperly made or located wound, than of an improperly closed one, but at the time when we were all having some cases of ventral hernia, we were more particu-

¹ Paper read before the University of Pennsylvania Medical Society, April 19, 1901.

² Wiener klin. Wochenschrift, October 4, 1900.

lar as to the location of the wound than we are now. While we always prefer to make the wound parallel with the fibers of the tissues, we do not hesitate to cut crosswise when a cross incision will better expose the field of operation, for we know that by a careful closing of the wound, we need not fear hernia. When we first began to perform appendicitis operations, it was believed that our hernias were due to cutting the muscles crosswise, but we can make a short cross incision now when operating for chronic appendicitis, and by closing the wound accurately and aseptically, can avoid a hernia.

When we cut across muscular fibers in other parts of the body we expect them to unite when properly approximated, why not expect the same of the abdominal muscles?

The fact that every experienced surgeon believes his particular method of closing the abdominal wound the best, proves that when certain rational principles are adhered to, the particular method of carrying them out is of less importance than we are apt to believe. The nearer we approach nature's methods the more rational we are. We are certainly following nature's method when we close a wound by uniting fascia to fascia, muscle to muscle, and peritoneum to peritoneum—and we certainly are not following nature's method when we bury unabsorbable material in the wound. Dr. Coley stated in his discussion of Dr. Richardson's paper last year that he had seen 30 cases of sinus due to buried unabsorbable sutures. We rarely meet with sinuses in the Northwest because of the universal use of absorbable ligatures and sutures.

I will describe briefly the method I have employed for several years in closing the abdominal wound and give my reasons for preferring it. This is also the method employed by all of the surgeons who operate in the same hospitals with me, except my collegue, Dr. A. W. Abbott, who uses the crossed suture of Dr. Fowler with some slight modifications.

The peritoneum is first closed by a running stitch of medium weight catgut. Silkwormgut sutures are next passed through all of the tissues except the peritoneum by means of a full curved needle of a size suited to the thickness of the abdominal wall. The needle passes from without inward through the integument, fascia, muscle and deep fascia, coming out next to the peritoneum. It then passes from within out through the inner fascia, muscle, outer fascia and integument. In a very thin abdominal wall the needle can be passed through both edges of the wound at one sweep but in most cases it is better to take them separately. These stitches are placed about a half inch apart. The fascia of the external oblique is next united by a running stitch of medium weight catgut. All the ends of the silkwormgut are now caught and pulled upon at once so that they are made taut, after which they are tied lightly. Extra skin sutures are applied when needed.

The advantages of this method are: first, the peritoneal cavity is closed without delay; second, there is no unabsorbable material left in the tissues to make future trouble; third, the suturing of the outer fascia gives such support that the silkworm sutures need not be tied so tight as to cause necrosis; fourth, it obliterates all

dead space, and last, it yields eminently satisfactory results. The catgut used is sterilized by the dry heat process of Boeckmann and is always sterile. The advantages claimed for passing the needle from within out is only theoretic, for I have not taken the time to do this and since I have worn rubber gloves stitch abscesses are practically unknown in my work.

Dr. Abbott's cross-stitch differs from Dr. Fowler's original suggestion in two points. He first closes the peritoneum with catgut and instead of tying over rubber tubes he ties the two ends together just as we do in the through and through stitch. After closing the peritoneum he takes a thread of silkwormgut with a medium sized carved needle on each end and passes one needle from within out, first through the deeper fascia then across through the muscle and outer fascia of the opposite side then across through the integument of the original side. He then takes the other needle and passes it from within outward just as he did the first needle but beginning on the opposite side. This is an excellent stitch, for it brings the tissues together layer by layer and leaves no dead space. There are, however, objections to it: it requires much more time to apply it and it causes the patient more pain when it is removed.

In most cases of acute appendicitis drainage through the abdominal wound can not be avoided but the wound should be partly closed leaving just sufficient room for drainage. In the few cases in pelvic surgery requiring drainage it is safer and better in every way to drain through the vagina.

The same rules should govern the treatment of post-operative hernia that apply to other varieties of hernia.

When a patient applies to a surgeon for advice the rule should be to advise operative treatment. Mechanical treatment is unsatisfactory and is only palliative at best. The tendency is for the hernia to grow larger and for the surrounding tissues to undergo changes so that the chances for a successful operation diminish with time.

Until quite recently the tone of the literature upon the treatment of ventral hernia was quite pessimistic because written when ventral hernia was quite common. It follows that an operator who had hernia follow his operations frequently would often fail to cure the hernia.

At the present time the prognosis in the operative treatment of ventral hernia is good. My results since employing the technic described in this paper have been as good as those following operations for inguinal hernia. When we undertake to cure a ventral hernia we should endeavor to restore the tissues to their normal relations and hold them there by artificial means until nature has had time to unite them firmly. I believe that it is unwise to go beyond this and try to assist nature permanently by burying unabsorbable material in the tissues, and I know from experience that it is unnecessary.

It is just as important to enter the peritoneal cavity and remove the sac in this variety of hernia as in any other variety. The entrance should be made well away from the cicatricial tissue for fear of injuring an adherent intestine. All of the scar tissue should be dissected away and the various layers of the abdominal wall care-

fully isolated. When this has been accomplished the operation resolves itself into the closure of an abdominal wound. The wound should be closed by through and through sutures of silkwormgut and buried animal sutures, the method differing from the closing of an ordinary abdominal wound only in that the silkwormgut sutures should be much closer together and the buried sutures should be of kangaroo-tendon or chromicized catgut because the tension is greater and the tissues are not in so favorable a condition for healing.

It has recently been suggested that we use silver wire sutures wound around a piece of ivory, together with buried sutures of kangaroo-tendon. (See *Medical News*, September 1, 1900.)

The reported results are good and the method is doubtless a good one but a return to the old quill suture seems like a step backward and is unnecessary.

Next to asepsis the most important step in this operation is the separation of the various tissues by careful dissection. A simple cutting out of the scar and bringing the freshened edges together is very liable to lead to disappointment. It is of special importance to bring the muscular layer together because it is the best protection against a hernia. We do not often find this tissue in the covering of a hernia. In a median hernia it is often necessary to open the sheaths of the recti in order to bring the muscles together.

After the operation the patient should be kept in bed at least 3 weeks to give the tissues ample time to heal before weight is thrown upon them. When the patient is very fat it is often advisable to keep him in bed on a milk diet for 3 or 4 weeks before the operation just as we do in umbilical hernia in fat people. Patients with pendulous abdomens should wear an abdominal support after the operation but spare persons do not need it.

A FEW USEFUL POINTS IN THE SYMPTOMATOLOGY OF EYE DISEASES APPLIED TO GENERAL PRACTICE.

BY

HENRY BASSETT LEMERE,

of Omaha, Neb.

Oculist and Aurist to Douglas County Infirmary.

I purpose to speak of those eye-cases which may with advantage be treated by the general practitioner. The family doctor often complains that so-called specialism is invading his provinces, whereas the work of the specialist is naturally an aid to general medicine, treating of those conditions in which it fails, and often throwing light into dark corners of disease existing elsewhere.

In the diagnosis of eye diseases the following conditions are readily ascertained and their combined significance will generally lead to a correct diagnosis, even by one who is unfamiliar with the ophthalmoscope. I shall enumerate these symptoms, named in the order of their importance:

1. Diminution in the acuteness of vision.
2. Pain in its various degrees.
3. Redness, accompanying manifest inflammation.
4. Impaired mobility of pupil.

5. Changes in the tension of the globe.

6. Gross lesions visible without the aid of instruments or artificial illumination.

1. Diminution in the acuteness of vision is of paramount importance to the patient. Every physician should be provided with a Snellen test card, by means of which he may tell the gross changes or deficiencies in the acuteness of vision. Each eye should be tested separately, the other eye being covered. Any departure from normal acuteness will suggest 1 of the following 5 conditions:

1. Errors of refraction and accommodation.
2. Opacities of any of the refractive media.
3. Diseases of the fundus and optic nerve.
4. Functional disturbances.
5. Amblyopia.

In regard to errors of refraction the general physician will not as a rule be consulted, except in so far as they bear on the symptoms of pain and headache, which we discuss later.

Opacities of the cornea may be recent, such as those caused by interstitial keratitis, ulcers, lime-burns, etc.; or old, in which case they are generally the result of ulcers, traumatism or trachoma. Opacities on the anterior or posterior surfaces of the lens, or in its substance, can generally be recognized. It should be remembered in this connection that the reflex from that most deadly form of sarcoma found in children, the glioma, has been mistaken by the inexperienced for cataract, and thus delay fatal to the little patient has resulted.

In diseases of the fundus and optic nerve the acuteness of vision is a varying quantity. Pronounced cases of optic neuritis often have normal vision, large peripheral spots of choroiditis not showing functionally until the field of vision is carefully taken. On the other hand, the eye may be absolutely blind from retrobulbar lesion and the fundus at first show absolutely no signs of any disease. Functional loss of vision also requires that the field of vision shall be taken carefully.

In congenital amblyopia there will be a history of the condition dating back to infancy, and very often a squint which has been in evidence since childhood. The diminution of the acuteness of vision will, therefore, indicate, generally speaking, a disease deeply seated or a refractive error, and is thus of such a nature that it will be out of reach of the general practitioner, as the responsibility for the loss of vision is a very serious one.

2. Pain ranks probably as the next subjective symptom of importance, and in questioning the patient one should be sure he is understood correctly. Pain may be only relative, but I here allude to pain of a severe neuralgic variety and not the burning and smarting frequently complained of by the patient as "paining of the eyes." Like other head-neuralgias, this pain is referred to the distribution of the branches of the fifth nerve. These are in the eyeball itself, or in the forehead, temple and scalp.
