## ABSTRACT

The Water Quality Bureau of the Montana Department of Health and Environmental Sciences has completed a two-year biological-benthic inventory of streams draining the southern Fort Union coalfield area in southeastern Montana and a small part of northern Wyoming. This study was conducted with funding made available by the United States Geological Survey. Attention was directed primarily to the benthic macroinvertebrate associations and periphyton communities that are found in these waters, and a large number of streams and sampling stations within the study area were collected for such organisms, involving the analysis of numerous biological samples. In addition, water quality collections were made throughout the project, and appropriate physical measurements were taken to supplement the biotic information. This publication is one of the final requirements of the investigation, and it is designed as a data report that presents most of the data that has been collected. The sampling program of the inventory and the related field and laboratory methods are also discussed to set the stage for reviewing the many data tables. Two companion reports to this publication will more specifically consider the macroinvertebrate and the periphyton segments of the project.

## ACKNOWLEDGEMENTS

A large number of individuals besides the authors of this report became involved with the completion of the southern Fort Union region, hydrobiological-benthic inventory. Mr. Gordon Hills of the State Water Quality Bureau conducted the water quality analyses that were undertaken in the Billings branch office of the Bureau, and Mr. John Hawthorne and other staff members of the State Chemistry Laboratory Bureau in Helena conducted the remaining chemical work. Dr. George Roemhild, Mr. Dick Oswald, and other associates of the Department of Biology at Montana State University in Bozeman provided many of the taxonomic verifications and expert advice on aquatic macroinvertebrate taxonomy, sample analysis, and field collection. Mr. Erich Weber of the Water Quality Bureau assisted with the laboratory evaluations of the periphyton samples, and Mr. Rob Greene of this same agency and Mrs. Peggy Bahls helped with the statistical assessments of these collections. Mr. Greene also assisted in other phases of the project as did Mrs. Sue Cohen, Ms. Lani Morris, and Mr. Tom Costa. Mr. Don Willems provided the administrative expertise that was needed to originally initiate the study, and Mrs. Jerrine Litwin typed the different manuscripts and the many data tables.

This inventory was funded via Research Grant Number 14-08-0001-G-503 from the United States Geological Survey. Mr. Mike Whittington of the Bureau of Land Management, and Mr. Bob Averett, Mr. Joe Moreland, Mr. Roger Knapton, and Mr. Rodger Ferreira of the United States Geological Survey provided support in the developmental stages of the inventory, and these same individuals also offered valuable advice throughout the course of the study. The Alderson family of the Bones Brothers Ranch near Birney, Montana allowed the use of a field station which enhanced the feasibility for sampling an extensive project area, and the Aldersons and other ranchers and farmers in the Tongue River and adjacent drainages afforded access to many of the project's sampling stations. The Northern Cheyenne Tribe also permitted trespass to several of the study area streams. The authors greatly appreciate the assistance of all of these individuals and governmental entities.

## INTRODUCTION

During the first part of 1978, the Water Quality Bureau of the Montana Department of Health and Environmental Sciences (DHES) received a grant from the United States Geological Survey (USGS) and the Bureau of Land Management to conduct the first year of a proposed two-year biological-benthic inventory of streams draining the southern Fort Union coalfield area in southeastern Montana. This portion of Montana has an abundance of strippable coal deposits, and because of this feature, the southeastern segment of the State is expected to experience some degree of future water quality impacts from projected coal mining activities. The anticipation of these potential difficulties in view of the general paucity of biological information for many of the lotic waters in this region provided the main impetus for developing and undertaking such an inventory effort, and the basic objective of the project was to develop for future reference purposes a relatively extensive hydrobiological data base for the coalfield area that adequately characterizes and describes the benthic biota of its smaller streams.

As a second objective for the project, an attempt was to be made to ascertain the possible effects of salinity on the aquatic biota of the coalfield streams since enhanced salinity levels are forecast to have a relatively high likelihood of causing adverse instream impacts in conjunction with the expanded surface mining operations. In addition, salinity has an added and more general importance because water quality problems of this kind can also arise from other sources besides mining such as irrigation return flows and the development of saline seep locales, and both of the latter two manifestations are known to occur in the Fort Union region.

Upon notification of the receipt of funding for the inventory project, a preliminary field survey was first conducted of the study area preparatory to the establishment of appropriate sampling stations, and biological sampling at these stations was actually initiated in May of 1978 and continued through the fall of that year. Additional monies were subsequently given to the Water Quality Bureau (WQB) to extend the sampling through a second year, and with this extension, field work proceeded to a final termination date in early November of 1979. All of the laboratory analyses of the biological samples collected during the study were then completed in June of 1980 leading to the preparation of the final project reports.

The focus of the coalfield sampling program was directed to the benthic macroinvertebrate associations (aquatic "bugs") that inhabit the bottoms of the streams and to the streams' periphyton communities and their macroalgae components. Two standing waters were also sampled for some of these organisms as miscellaneous collections. The term periphyton refers to an assemblage of microscopic algae (primarily diatoms) and other small organisms that grow attached to submersed surfaces such as rocks and logs, and this community typically forms a brown and slippery covering over such objects. Both the periphyton and the larger benthic macroinvertebrates are important to aquatic systems as food chain elements, and they also serve as valuable indicators of water quality. In addition to the obtainment of these biological samples per se, different kinds of physical measurements, e.g., current velocity and stream depth at the sampling point, were also taken at

the time of the biological sampling, and a large data pool of this type is now available for the southern Fort Union streams. Such physical applications along with the collection of numerous water quality samples were initiated in order to supplement the study's biotic data for interpretive purposes.

The end result of this inventory work was the eventual collection and analysis of 321 water quality, 288 periphyton-macroalgae, and 269 macroinvertebrate samples. The main intent of this particular presentation, therefore, is to compile a data report that lists in tabular fashion all of the water quality, macroinvertebrate, periphyton community-macroalgae, and physical information that has been collected during the past few years as a part of this project. These data are included in the appendix of this publication. Furthermore, summaries of the sampling program and the methodologies that were used are also included to set the stage for assessing the biological data. Two companion reports to this writing will also be available, one dealing with the benthic macroinvertebrate associations and the other with the periphyton communities, and each of these reports will more specifically detail the results that were obtained from the macroinvertebrate and periphytic components of the overall study. Earlier writings associated with the project include the two research proposals that were developed prior to the receipt of each year's funding (USGS Grant Number 14-08-0001-6-503) and an interim report that was prepared in the late spring of 1979 (Klarich, 1977, 1978, and 1979).

#### DESCRIPTION OF THE STUDY AREA

A major portion of the project study area consists of that part of the Fort Union region that is found in southeastern Montana south of the Yellowstone River and between the Bighorn River and the O'Fallon Creek-Little Missouri River drainages. As indicated in Figure 1, a minor deviation to this general description is the small southwestern "hump" that is located in Wyoming along the Tongue River, although all of the study region is within the Yellowstone Basin. With the exclusion of this Wyoming "hump," the Montana-Wyoming state line represents the southern boundary of the study area while the Yellowstone River delineates its northern limit. Several sampling stations were established on small streams such as Sarpy Creek that drain directly to the Yellowstone, and four sampling locations on the Tongue and its tributaries were collected in the small Wyoming segment. In addition, three sites were sampled in the Powder River drainage so that the eastern divide of this river system defines the eastern boundary of the study region; the western Sarpy Creek divide, the southwestern Rosebud Creek divide, and the extreme southwestern Tongue River divide, in turn, denote its most western extension. However, the bulk of the sampling actually took place on streams within Montana's Rosebud Creek and Tongue River drainages, and these systems thereby represent the central core of the project region.

Figure 1 presents a map of the study area that shows the general locations of the many biotic sampling stations. These stations will be considered in more detail in the next section of this report, and this will include a referencing of the site numbers that are contained on the map.

## SUMMARY OF THE SAMPLING PROGRAM

### SAMPLING STATIONS

As illustrated in Figure 1, 43 stations on 34 rivers and creeks of varying sizes and two standing waters were sampled during the course of the project in five minor drainage basins as defined by the USGS (1968). Most of the rivers and creeks had only one sampling site, although five of the streams were sampled at two distinct stations while one of the creeks was collected at three separate sites. Many of these streams were either typically perennial in nature showing a distinct discharge on each of the project trips, (e.g., Otter and Hanging Woman Creeks), or they have a relatively extensive drainage system (e.g., Pumpkin and Mizpah Creeks), and such features formed one of the major criteria for choosing each of the selected sites. To a large degree, therefore, attention was directed primarily to the smaller perennial waters of the study area, but a few of the intermittent and "water-gap" creeks and a few of the larger streams were also collected. The term "water-gap" in this report refers to streams that are continuously flowing or intermittent but only through short sections of their total length; that is, ephemeral reaches can be found between the flowing segments.

The smaller creeks in the study area were stressed in this project because very little in the way of biological data are on hand for this type of water in the Fort Union region. In contrast, some information of this kind is now available for the larger lotic systems of the region because of the completion of earlier biotic studies, e.g., Rosebud Creek (Baril, et al, 1978) and the Tongue River (Newell, 1977). Nevertheless, these larger waters were still sampled to some extent during this more recent investigation as a means of providing a direct basis of data comparison for the smaller aquatic systems in relation to the biology of first order streams of the area.

Another major criteria for station selection in the study area was the ease of access to a potential sampling site and its availability on the major travel routes, and the negative nature of these factors accounts for the lower frequency of sampling at some of the stations. Also, an attempt was made to sample different specific stream locations on each visit to a station in order to avoid a biasing of the more recent collections. To accommodate such a sampling need, each of the stations was defined as containing a considerable expanse of stream both above and below the direct access point, and the utilization of this definition provided the opportunity to meet this particular field requirement throughout the study period. In some instances, the different sampling locations at a station were far enough apart to be found in separate quarter-sections and/or sections, or even in separate townships and/or ranges, and this feature will be illustrated later in this report.

Two classes of sampling sites were ultimately developed for the coal-field aquatic inventory. These were termed the "intensive" and the "accessory" stations, and the latter category might be further split into another subclass that has been labelled the "miscellaneous" stations of the study. The main objective of sampling at the intensive sites was to provide for in-depth, replicated, and seasonal biological data for a select set of

representative stream stations, while the point of the accessory sites was to provide for a broad overview of the biological characteristics of a wide variety of waters in the southern Fort Union region. As a result, the intensive stations were sampled much more frequently and for a wider spectrum of biological applications than the accessory sites, although a much larger assortment of accessory sites than intensive sites was collected during the project. For the most part, the intensive stations were established on the more important smaller creeks of the study area with these streams having perennial, relatively high flow, and/or comparatively large drainage area characteristics. However, two intensive stations were also located on two of the region's largest streams in order to afford the basis of data comparison for the smaller waters that was noted earlier. In the case of the accessory sites, a wide range of both small and large streams was sampled in order to gain the broad biological overview that was required for this phase of the inventory.

In contrast to the intensive and accessory stations, the miscellaneous stations were sampled only on a few occasions and only for an incomplete set of biological data relative to what was collected at the normal accessory sites. These miscellaneous stations generally represent the "curiosity collections" that were added to the main sampling program after the inventory got underway. But nevertheless, the data from these stations will also contribute to any complete biological descriptions of the study area waters.

The nine intensive, the 24 accessory, and the ten miscellaneous stations that were established in the study area are listed in Table 1. In addition, the township (T), range (R), section (two-digit number), and quarter-section (letter) geographic descriptions for the main sampling location of each station are also included along with a few other pertinent items. The geographic designations for a site in Table 1 correspond to a general length of stream that was sampled most frequently during the project. However, it should again be mentioned that different specific stream locations within this reach were collected on each visit to a station, although these specific locations were not appropriately spaced in this case to require different geographic descriptions. The more widely-spaced alternate locations that did warrant separate designations are noted in the water quality tables of the Appendix (Tables A01 to A33), and the relationships between a particular biotic-water quality collection at a station and the corresponding geographic description are also indicated in these same summaries.

A few other features with reference to Table 1 should also be noted. First, the "stream type" listings in the table were based only on the field observations that were made during the many trips through the study area and not on any extra-study information. Second, the "basin code" specifications were taken from a USGS (1968) drainage basin map. Third, each of the 43 station numbers presented in Figure 1 are referenced in this table to a particular stream site, and as a fourth item, the intensive, accessory, and miscellaneous classifications of the different stations are also included in this summary.

Table 1. List of intensive (I), accessory (A), and miscellaneous (M) stations established in the southern Fort Union study region along with their associated geographic descriptions and other pertinent items (the first page of two pages).

\*si--Small intermittent based on the drainage area; sp--small perennial; ?--intermittent near the mouth; wg--"water-gap"; li--large intermittent based on the drainage area; mjp--major perennial; (b)--near Ashland.

As a final comment, the Pumpkin and Mizpah Creek locations were classified as intensive stations during the first field season but sampled as accessory sites during the second year while the reverse was true for the Squirrel and East Fork Hanging Woman Creek sites. This change was initiated in light of the station definitions and criteria because of the intermittent nature and poor access of Pumpkin and Mizpah Creeks in contrast to the perenniality and easy access of the other two streams. That is, both Pumpkin and Mizpah Creeks were far removed from the central core of the study area. Furthermore, both Squirrel Creek and the East Fork of Hanging Woman Creek appeared to have a greater potential for being more immediately affected by future coal development than the two more northern streams, and extra biological data from the two perennial waters, thereby, seemed to better coincide with the main theme of the project.

#### SAMPLING FREQUENCY AND OTHER ASPECTS

One of the main differences between the intensive and the normal accessory stations of project was related to the frequency of collection at the two classes of sites where macroinvertebrate and periphyton sampling was much more intense at the first type of station. An attempt was made to collect the intensive stations for the macroinvertebrates on a monthly basis through a mid-spring to mid-fall period during each of the two field seasons so that data might be available for each of the months within this span with some duplicate monthly data also on hand for the nine intensive sites. Furthermore single winter collections were also taken from a select set of intensive locations. As a result, six to eight macroinvertebrate samples were obtained for analyses from each of these stations for each year of the study. Periphyton-macroalgae sampling at these intensive stations was also organized on a largely monthly basis, and between 13 and 20 samples of this kind were obtained from each of the intensive stations of the entire study period. Fewer macroinvertebrate and periphyton samples were obtained from the Pumpkin, Mizpah, Squirrel, and East Fork Hanging Woman Creek locations than from the other intensive sites because of the mid-project change in the intensive-accessory status of these four streams.

In contrast to the intensive stations, only one to three macroinvertebrate samples were typically collected from the accessory sites during any of the two field seasons. This then totals between one and seven collections of this kind for each of the secondary sites through the entire inventory rather than the 14 to 19 samples obtained from the major stations. In addition, only between two and eight periphyton-macroalgae samples were typically obtained from the accessory stream locations during the two-year period. Since a few of the accessory stations were only sampled during the second year of the study and not during the first field season, this factor further accounts for the lower sample numbers that were obtained in these particular cases. Similar to the intensive sites, an attempt was made to collect samples from each of the accessory stations during a different month, or at least during a different season of the year, in order to afford some level of seasonal data for these streams also. However, this requirement could not always be fulfilled because of scheduling conflicts with the more important field trips to the intensive sites.

As a subclass of the accessory station category, the ten miscellaneous stations of the project area were also collected on a low frequency basis, but these particular stations differ from the normal accessory sites in being typically sampled only for the periphytic component of the benthic biota and not for the macroinvertebrates. However, two miscellaneous collections for the benthic fauna were taken from the Powder River. Such miscellaneous sampling generally involved only one visit to a site, although a few extra periphyton samples were collected from two of these minor stations.

A major proportion of the inventory's macroinvertebrate samples were collected from the natural substrates of the study area streams through the use of Surber sampler methodologies, and this application was made at both the intensive and the accessory stations. In turn, the bulk of the periphyton community and macroalgae samples were also obtained from these natural substrates by scraping submerged rocks and other objects. As an alternative, some of the macroalgae were collected by simply "picking" the required specimens from the stream. These two sampling approaches for the algae were also utilized at both classes of stations. As a further manipulation, the use of artificial substrates were employed at some of the sites as a means of collecting additional macroinvertebrate (jumbo multiplate or Hester-Dendy samplers) and periphyton (plexiglass plates) samples. However, these artificial applications were restricted to the intensive stations and were not used at the accessory sites, and this feature then represents another major difference between the two classes of project sampling locations. Because of the use of artificial substrates at the intensive sites, a broader range of biological data is available for these major streams over the data that are on hand for the region's accessory waters. The data obtained from the artificial substrates afford a somewhat different interpretive tool to the study relative to what would have been available if the natural substrates were sampled alone.

Table 2 summarizes the numbers and types of biological samples that were collected during the two years of this recent inventory project. As indicated in the table, numerous sets of physical measurements (stream current velocity, depth, and width along with stream flow estimates and a substrate classification) and a number of water quality samples were also obtained from the coalfield area streams to supplement the biological information. That is, quality and physical data were obtained to help define the habitat characteristics of the related biotic collections and to provide the potential for evaluating the different environmental factors such as salinity that might have a significant effect on these benthic organisms. Since the USGS has a rather extensive water quality monitoring program in the southern Fort Union region (USGS, 1979a), the sampling program of this inventory was initially developed to take advantage of this feature, and many of the project's biological stations, and particularly its intensive sites, were placed in close proximity to the USGS monitoring locations (Table 3) so that this agency's water quality data would also be applicable to this inventory. The location of the project sampling sites in this fashion formed another major criteria for station siting within the study area.

Table 2. Numbers and types of biological samples and numbers of physical measurements and water quality samples taken from the different study area streams (the first page of two pages). The symbols of the column headings are defined on the following page.

WQ--Water quality samples. Surber--Macroinvertebrate samples collected from natural substrates with a Surber sampler: F--first field season, S--second field season, T--total, and UA--unanalyzed samples; Art.--macroinvertebrate samples collected from artificial substrates (jumbo multiplate, Hester-Dendy samplers). Physical--Sets of physical measurements (stream width, depth, and current velocity plus estimated flow) taken in association with the Surber (Sur.) natural substrate and the artificial (Art.) substrate macroinvertebrate collections; Sub.--natural substrate evaluations made in conjunction with the Surber samples. Periphyton--The following classes of algae samples were collected from the streams:

- A. Standard collections from natural substrates and standard analyses involving counts of the diatom species (generally between 300 and 400 frustules).
- B. Standard collections from natural substrates but the samples analyzed for the non-diatom algae only (diatom species not counted).
- C. Collections for the non-diatom algae only.
- D. Collections from natural substrates with the diatom species evaluated by a "long-count" approach (more than 8,000 frustules).
- T. Total of the natural substrate algae collections.
- E. Same as "A" but with algae samples obtained from artificial substrates (plexiglass plates).

\*An asterisk denotes a United States Geological Survey station that generally corresponds to a biological site established for this inventory.

The water quality sampling that was completed as a part of this inventory effort was largely designed to accommodate the USGS collections of this kind in the region. Only a few samples for the common ion and metals analyses were thereby collected from those project stations in close vicinity of a USGS site in anticipation of the availability of this type of data from this agency (USGS, 1979b). However, samples for these analyses were regularly collected from the project streams that were not included in the USGS program. Also, samples for a nitrogen and phosphorous nutrient assessment were routinely collected from all of the biological stations regardless of USGS activities in this regard in order to increase the data base of these biologically important parameters. Collections for the field parameters, i.e., for pH, specific conductance, turbidity, and suspended sediment, were also obtained on almost all of the site visitations along with a temperature evaluation, and dissolved oxygen was collected on most of the sampling trips. In addition, biochemical oxygen demand (BOD), total coliforms, and silica were monitored on a few occasions in this study to further describe the quality characteristics of the study area streams.

#### SUMMARY OF THE METHODOLOGIES

##### WATER QUALITY

Many of the 33 water quality parameters that were assessed during the inventory, including the common ions, the nitrogen and phosphorous nutrients, and the metals, were analyzed by the Chemistry Laboratory Bureau of the DHES in Helena, Montana. However, all of the field parameters (temperature, pH, specific conductance, turbidity, suspended sediment, dissolved oxygen, BOD, and total coliforms) were evaluated either in the field or in the WQB's branch office laboratory in Billings, Montana, and some of the common ion and other analyses were also completed at this same facility. Water samples for most of the quality assessments were obtained from the study area waters in plastic, liter bottles and appropriately preserved on site for transport to the laboratory and for temporary storage under refrigerated conditions following Environmental Protection Agency (1979) guidelines. Furthermore, the holding-time or pre-analysis storage requirements specified by this agency were also observed throughout the project.

Standard coliform bottles were utilized for the bacteriological collections, and total coliforms were run in this project instead of the more common fecal evaluations because of the less stringent holding-time for the total variety. Collections for the dissolved oxygen (DO) determinations were made in regular BOD bottles as were the actual BOD samples, and the DO's were fixed in the field for transport following procedures described by Karp and Klarich (1978). The final titrimetric step for the latter parameter was performed in the branch office laboratory. Temperature readings were made at the stream stations using a calibrated mercury thermometer, and suspended sediment was assessed from the same grab sample that was collected for some of the other field parameter analyses. The metals evaluated during the inventory are of the total recoverable variety with acidification performed in the field without the application of a filtration step. The analyses were then completed at the Helena laboratory without any further extraction procedures.

Table 4 presents a summary of the various methods that were used in the Billings and Helena laboratories for the analyses of the different water quality parameters.

#### MACROINVERTEBRATES--FIELD APPLICATIONS

Natural Substrates. A square-foot Surber stream-bottom sampler following the design presented in Slack, et al (1973) was utilized to collect a major portion of the benthic macroinvertebrate samples of the inventory (Table 2). The proper application of this sampling technique requires the presence of a fairly distinct current to sweep the aquatic organisms into the Surber net, and because of this requirement, the riffles and channels of the study area streams, by having the requisite water velocities, were stressed in this phase of the project over the more ponded stream segments. However, an ideal sampling spot of this kind could not be found at a few of the sampling locations, and in these cases, a less than ideal location had to be sampled with no other options available.

Following the selection of an appropriate sampling location at a station and the placement of the Surber into the stream, about the top six inches of the bottom material bounded by the square-foot sampling perimeter was removed after gentle agitation and placed into the net portion of the sampler; any benthic macroinvertebrates that were dislodged by this initial collection effort were then captured by the Surber net. The Surber apparatus with its collected substrates and netted organisms was subsequently moved to the shore, and the substrates were placed into a #30 mesh sieve positioned over a board base for a removal of the remaining organisms that were still attached to the bottom materials. The net and sieve were also cleaned before concluding the on-site work, and the collected macroinvertebrates were gradually transferred to a sample container through the entire picking process for eventual preservation. In addition, the smaller substrate materials that could not be easily surveyed in the field, such as the detritus, the macroalgae, and the finer rock particles, were also added to this same container for later picking under laboratory conditions.

After the field cleaning of the collection, the larger substrates were discarded, and the organisms and other materials contained in the sample bottle were preserved with ethanol for transport and storage until further analytical work could be directed to the collection. A small amount of rose bengal dye was added to the alcohol before its use in order to impart a color to the organisms so that they would be easier to recognize in the sample amongst the debris during the final cleaning activities undertaken in the laboratory. Through the use of this sampling approach, it is felt that fairly large percentages of the benthic macroinvertebrates that had occupied the square-foot by six inch deep layer of stream substrate were actually collected as a discrete quantitative sample that could be used for further evaluations. Those organisms slipping through the net might be defined as microinvertebrates, and as such, they could be beyond the scope of this investigation.

In terms of sampling replications for the Surber collections, the following general guideline was used for this inventory: For the relatively rich sites showing a larger number or high density of benthic macroinvertebrates, only one sample was typically collected on each of the site visits; for the less rich sites showing a comparatively small number or low density of these organisms, duplicate or triplicate samples were commonly taken from these locations and composited into a single container. For many of the creeks, the application of one Surber actually covered a fairly large proportion of the width of the stream. However, duplicate and triplicate samples were collected on occasion from all types of streams in the study area, and on some of the station visits, the subsamples were added to different sample bottles to afford the option for a separate laboratory analysis and the option for an eventual comparison of the two sets of data as illustrated in the interim report (Klarich, 1979). But for the final tabulation of the macroinvertebrate taxa numbers that were collected from any station and date, the data from the two subsamples were appropriately averaged in all instances, and this is the case for the tables in this data report.

Artificial Substrates. As noted, artificial substrates were used in conjunction with the Surber collections at each of the nine intensive stations in the study region. The use of the artificial substrates provided some flexibility to the sampling program since this methodology is not restricted by the lack of a stream current as is the case for the Surber technique. As a result, with the use of these substrates, some attention could also be directed to the macroinvertebrates that inhabit the pools of the streams as well as their flowing segments, and this aspect eventually became the main point of the artificial substrate application in the project. The data obtained from this sampling approach also acts to supplement the information that was obtained directly from the streams' natural bottom material in the riffle and channel reaches.

Jumbo multiplate (Hester-Dendy) were used as the artificial substrates in this inventory, and they were generally similar to the illustration for this type of apparatus presented in Slack, et al (1973). The jumbo multiplate variety consists of a stack of thirteen, three inch by three inch masonite plates  $1/8$  inch in depth that are separated by varying distances from each other through the placement of a different number of one inch by one inch,  $1/8$  inch deep spacers of the same material in between the main squares. The whole assembly is held together by an eight inch eyebolt placed through the center of the stack. If the eye of the bolt is visualized as the top of the sampler, the 13 plates were spaced from the top to the bottom as follows:  $1/8$  inch (one spacer) between the first eight plates,  $1/4$  inch (two spacers) between the last plate of the first set and the following plate, and  $3/8$  inch (three spacers) between the last five plates. The larger number of main plates and their variable spacing represents the main difference between the type of Hester-Dendy sampler described by Slack, et al, and the jumbo sampler of this kind that was used in this study.

The jumbo multiplate samplers were placed in duplicate into three different and defined stream locations, and they were held in place by a wire attached from the eyebolt of the assembly and to an instream or onshore anchor. The three types of stream locations that were examined

with these artificial substrates were chosen to reflect different aquatic habitats at a fairly general level, and these thereby involved (1) a relatively shallow riffle section having a fairly rapid current that was located in close proximity to the main Surber work, (2) a much deeper and ponded segment of the stream having a very slow current, and (3) a transition or riffle to pool, ecotonal type of reach having intermediate depth and current velocity characteristics relative to the other two locations. But regardless of these different habitat requirements, all of the samplers of a station set could be positioned in close vicinity of one another at all of the sites.

Two exposure periods and two subsequent collections of the multiplate samplers from each of the three stream locations were anticipated for five of the intensive sites during each of the two field seasons; this would equal a maximum of twelve macroinvertebrate samples of this kind in total from these particular stations. Because of the change in site classification, Mizpah and Pumpkin Creeks were sampled with artificial substrates only during the first year of the inventory, while Squirrel and East Fork Hanging Woman Creeks were sampled in this way only during the second year; therefore, a maximum of six samples could be obtained from each of these four streams. However, an in situ loss of some of the samples for various reasons such as washouts, beachings, and cattle trampling, lowered the number that could be recovered from some of the sites, and a 10% sample loss was recorded for the study.

The artificial substrates were first introduced into the streams during an early to mid-summer period of each inventory year. The samplers were then collected for the first time and reintroduced for a second exposure during the late summer or early fall, and they were collected for a final time and removed from the field to terminate a sampling cycle during the mid-fall season of the same year. One month or greater exposure periods before collection were planned for all of the samplers, but this requirement was not always possible to achieve because of the need for reintroducing those units that were found in a disturbed condition. However, 86% of the samplers were exposed for greater than one month, 47% were exposed for greater than one and one-half months, and 8% were exposed for more than two months. These exposure periods ranged from 18 days in a few instances to 63 days in a few other cases, and they averaged 42 days for all of the samplers through the entire study.

Following an exposure period, the collection of the duplicate samplers from the streams involved the underwater use of a #30 mesh sieve that was placed under the samplers with the artificial substrates then carried on the sieve as they were taken out of the water. The sieve, therefore, acted as a catch-basin, and this approach to artificial substrate collection was utilized to avoid a loss of the organisms that could be washed out of the samplers during their removal from the streams. The sieve and samplers were then moved to the shore where the sieve-confined artificial substrates were thoroughly picked, rinsed, sprayed, and scraped to dislodge the still attached macroinvertebrates. The organisms were ultimately transferred from the sieve and from the two samplers to a single container where the composite sample was preserved with an ethanol-rose bengal solution as described for the Surber

collections. The cleaned samplers were then either replaced in the stream or removed from the field depending upon the time of the year. The preserved and labelled samples, in turn, were transported to the laboratory and stored until further assessments could be made on the collections.

#### MACROINVERTEBRATES--LABORATORY MANIPULATIONS

Sample Sorting and Calculations. Both the artificial substrate and the natural substrate macroinvertebrate samples were analyzed in the laboratory following the same general procedures. The sample was first dumped into a #30 mesh sieve, and the initial step of the process involved a rinsing of the sample bottle and a removal and cleaning of the larger substrate materials (rocks and twigs). These substrates were eventually returned to the bottle. The sieve was then washed to remove the finer sediment particles, and the washate was checked for the occurrence of small organisms. As a second step, the remaining contents of the sieve (organisms and other materials) were transferred to a white porcelain pan where they were thoroughly mixed and randomized to an even coverage over the bottom of this container. The sample, at this stage of its preparation, was divided into quarters for a final picking and cleaning of the collected macroinvertebrates from the remaining debris. If the sample contained a low number of organisms, or if the sample was relatively clean with only small amounts detritus and macroalgae, then the entire sample (all four quarters) was picked; large quantities of macroalgae proved to be particularly bothersome to this final cleaning process. But if large numbers of macroinvertebrates were found in the sample, and/or if the sample proved to be particularly dirty, then only one or two quarters (subsamples) were picked as feasible following Environmental Protection Agency (1973) guidelines for the laboratory subsampling of macroinvertebrate collections.

The next two steps of the analytical process can be described as follows: First, the large and obvious macroinvertebrates of the collection were removed at this time from one to four of the subsample quarters as appropriate and transferred to other containers for temporary storage; second, small aliquots of the collection were sequentially taken from the porcelain pan and surveyed under a dissecting microscope with magnification so that the remaining and typically smaller organisms could be spotted and removed. Throughout the application of these two steps, each of the picked organisms was identified taxonomically and placed into a labelled, friction sealed petri dish containing a small amount of alcohol preservative until the entire set of subsamples for a collection had been cleaned of all of its organisms. The sample was thereby sorted taxonomically through this procedure with each of the dishes associated with a particular field sample containing the individuals of a particular taxa. The final counts of the taxa individuals were then taken from these dishes as a final analytical step, and the numbers were recorded on a station-date data sheet. Following the counting of the dishes, they were stored in sealed vats for an eventual biomass assessment of the macroinvertebrate taxa. Any of the subsamples in the porcelain pan that were not sorted and analyzed were returned to the original sample bottle along with the related debris for storage and future reference.

Ultimately, the numbers on the station-date data sheets enumerating the taxa individuals of a sample were refined for a tabular presentation in the final project reports. For the Surber collections, these data are presented as a quantitative density estimate for each sampling site and date, i.e., the numbers of individuals of a taxa per square foot of stream bottom. In these data refinements, an adjustment for the duplicate field collections was made if necessary through an appropriate division, and an adjustment for laboratory subsampling was also made as required through the further application of a multiplication step. For the artificial substrates, the data are presented as the numbers of taxa individuals collected from the duplicate samplers that were exposed at each of the station's stream locations for each of the exposure periods. Mathematical adjustments for laboratory subsampling were made as needed in this case also.

Reference Collection and Taxonomic Identifications. Through the entire process of sorting and identifying the different macroinvertebrate samples, a few individuals of the different taxa were selected from among the many inventory samples for placement into the project's macroinvertebrate reference collection. The taxonomic identifications of these reference specimens and the sample individuals were made using the macroinvertebrate keys that are available in the reference materials chosen for the study, e.g., Merritt and Cummins (1978) for the insect families, Edmunds, et al (1976) for the mayfly genera (Ephemeroptera), Wiggins (1977) for the caddisflies (Trichoptera), Roemhild (1975) for the damselflies (Zygoptera), Klemm (1972) for the leeches (Hirudinea), and so on. Specific reference specimens were selected from the many taxa individuals that were available to best illustrate the critical taxonomic features of the particular macroinvertebrate group. The taxonomic identifications of these organisms were taken to the lowest systematic level possible in relation to the information that is presented in the keys, in relation to the expertise of the project workers and their associates, and in relation to the time constraints that were imposed upon the inventory. As stated in the first research proposal (Klarich, 1977), it ". . . is not proposed . . . to spend a great deal of time with the identification of taxonomically difficult forms . . .," and this precept has been followed throughout the macroinvertebrate segment of the study. The reference collection that was developed during the project is being stored in a preserved condition in labelled (taxa and sample information), airtight vials, and it has been used to make the taxonomic verifications that were initiated during this study. In addition, this collection is also available for perusal by any interested parties, and it will be on hand for any future verifications if this need should happen to arise.

Biomass Assessments. As a final step in the laboratory analysis of these macroinvertebrate samples, the preserved individuals stored in each of the taxa petri dishes were used as the basis of a biomass assessment for the different samples collected during the project. The individuals stored in each of the dishes were recounted and then transferred to tared weighing boats where they were air-dried for a period of 24 to 48 hours depending upon their size and numbers. After the drying period, the organisms were weighed two times between three and four hours apart using a Mettler balance. If the second weighing equalled the first, then

this number minus the tare was taken as the dry weight or the biomass expression of that taxa for that site and date. However, if the weights happen to decrease from the first to the second weighing, then this application was continued at suitable intervals until a stability was achieved as the final observation.

All of the taxa of a collection showing relatively large numbers of individuals were directly weighed in this fashion. Thus, a major fraction of the macroinvertebrate biomass of a sample was directly measured in the study. However, many of the taxa had only a relatively few number of individuals, and accurate and direct weight determinations in these cases were found to be very time-consuming and quite difficult for some types of organisms. Therefore, total dry weights for most of the scarcer taxa in a sample were estimated from weight per individual data that were available from other samples which had a larger number of individuals for this same macroinvertebrate group. Such directly measured or estimated weight data were then eventually developed into a final biomass expression for each taxa of a sample and for the sample in total as follows: milligrams of air-dried weight per square foot of stream bottom for the Surber applications, and milligrams of air-dried weight per duplicate samplers for the artificial substrate collections.

#### PHYSICAL MEASUREMENTS

Appropriate physical measurements were taken at the various stream stations in conjunction with all of the Surber macroinvertebrate and artificial substrate work. Current velocity was measured in feet per second using a standard pygmy flow meter attached to a graduated, top-setting wading rod. This assembly was placed in the stream at the spot of the Surber collection or at the location of the jumbo multiplate samplers for the timed current evaluation, and depth in tenths of a foot was then obtained from the rod. Current speed was measured at six-tenths of the depth below the surface (Environmental Protection Agency, 1973). Stream width in feet was also measured in this same vicinity perpendicular to the main thread of current, and either the wading rod or a tape was used for this determination depending upon the breadth of the water. Such width measurements were made during the inventory primarily as a means of characterizing one aspect of stream size at the different sampling sites, although these same data were also utilized in developing the study's flow estimates.

If these first current velocity, depth, and width measurements at a station appeared to be fairly representative of the stream segment, then these data were used to obtain a rough estimate of flow in cubic feet per second. But if the initial physical measurements at the selected sampling location did not appear to afford a very good estimate of the average values that might be obtained for the reach, then a few supplemental measurements at more appropriate spots in the stream were taken to provide a better basis for making a guess at its flow. Because of field time restraints, it should be stressed that no attempts were made to formally and accurately gage the streams following USGS procedures, and flows were estimated by simply multiplying the average width, depth, and velocity numbers. Some of the discharge data available to the inventory, particularly for the larger streams, was obtained from

published USGS (1979b) records, but since this agency did not monitor many of the smaller creeks that were sampled during this inventory, a flow estimating procedure, as described above, was instituted for the project as a means of quickly securing this type of information for the non-USGS waters. It was then applied to most of study area streams, as feasible, for the purposes of data consistency. The main point of gathering flow information for the project was to provide another type of stream size characterization for the different waters of the southern Fort Union region, and in this light, an extreme gaging accuracy was not thought to be necessary for the objectives of the investigation.

In the case of the artificial substrate applications, the current velocity, depth, width, and flow evaluations were generally first taken when the duplicate samplers were initially introduced to a stream location, or shortly thereafter, and also at the time that the samplers were later removed from the water to terminate an exposure run. An average of the two measurements for each physical variable was then assumed to represent a fairly accurate picture of the overall influences of these factors on the organisms that were housed by the samplers through the exposure period.

#### STREAM SUBSTRATE EVALUATIONS

In addition to the current velocity and depth factors, the nature of the stream substrate or bottom materials represents another physical variable that can have an effect on the benthic biota of lotic systems. Therefore, an attempt was made in this inventory to develop some type of representation for the substrate aspect of the streams that could be used in relation to the Surber biotic data for interpretive purposes. Since the application of quantitative evaluations of this kind could not be made during the inventory because of time restrictions, a qualitative approach was used to obtain the requisite substrate information.

The substrate classification system that was adopted for this inventory is summarized in Table 5 as a slight modification of the system presented by the Environmental Protection Agency (1973) in their biological reference manual. The detritus category of the table consists of the plant debris and macroalgae that might be associated with a collection. As indicated in the table, reference numbers between one and eight were assigned to each of the eight substrate categories so that the increasing magnitude of this number corresponds to an increasing size of the substrate materials. However, the variable detritus class was somewhat arbitrarily assigned to the number four position for the sake of convenience.

In the actual application of this classification system to the substrate evaluations, the percent relative abundance of each substrate category associated with a Surber sample is first estimated qualitatively in the field and then in the laboratory. Through a subsequent weighting (multiplication) of the appropriate category reference number with this abundance percentage as a decimal, a single or summary reference number ranging between one and eight can be calculated for a sample by summing the weighted values of the different categories. This summary number, in turn, provides a general description of the overall substrate

Table 5. Stream substrate classification system used in conjunction with the Surber macroinvertebrate collections.

Reference Number	Type of Substrate	Median Substrate Diameter	Range of Substrate Size
1	Clay, muck, and silt	0.03mm	<.05mm
2	Fine sand	0.15mm	0.05mm to 0.3mm
3	Coarse sand	1mm	0.3mm to 2mm
4	Detritus	variable	variable
5	Fine gravel	0.6cm	0.2cm to 1cm
6	Medium gravel	2cm	1cm to 3cm
7	Coarse gravel	5cm	3cm to 6cm
8	Rocks, rubble, and boulders	16cm	<6cm

characteristics of an analyzed stream segment such as a Surber sampling location. Summary numbers closer to eight are suggestive of a high proportion of the larger substrate materials like the boulders and the coarse gravels, and these higher numbers are probably most commonly obtained from the riffle sections of a stream. In contrast, the smaller summary numbers closer to one point to a high proportion of the finer substrate particles such as the silts and clays, and these numbers are probably most typically associated with the ponded segments having low current velocities. In response, different types of benthic macroinvertebrate associations might be anticipated for these two situations.

In addition to the use of the summary substrate reference numbers for the biotic correlations, the percentage values of the individual substrate categories per se might also have some interpretive applications. For example, a collection high in detritus might contain a different assortment of aquatic organisms than a sample with a similar summary number that is comparatively low in this same category. In any event, these kinds of data along with the summary numbers are also available for use in the assessment phase of the project.

Two steps were involved in obtaining the requisite category abundance percentages. First, the percentages of the broader substrate classes such as the sands and gravels were estimated and noted in the field as a component of the on-site habitat descriptions that were completed as a part of the inventory. Afterward, the smaller substrate materials that were transported to the laboratory as a portion of the Surber collections were again examined following the biological analyses for a further refinement of these percentage values. Although this type of qualitative substrate evaluation is probably not as valid as the application of a quantitative assessment, it is still felt that a fairly representative picture of the study area streams' substrate characteristics was obtained for the study in relation to the time expended through the use of the above described methodology.

## PERIPHYTON AND MACROALGAE

Field sampling for the periphyton and the macroalgae phases of the inventory was much more straightforward and simple than the effort that had to be applied to the macroinvertebrates. The essence of this work has been described previously in this report, and the scrapings that were taken from both the natural and artificial substrates were transferred to small vials and preserved with Lugols (IKI) solution for transport and storage. In the case of the natural substrates, a number of submerged objects from various nearby locations at a sampling site were scraped in order to afford a replicate, in miniature, of the entire periphyton community within that stream section. Furthermore, conspicuous macroalgae within the same stream vicinity were separately "picked" in proportion to their abundance and added to the same bottle. In a few instances, such collections involved only macroalgae to the exclusion of the diatoms that were attached to the bottom materials of the stream.

In the laboratory, sample evaluation first involved a vigorous agitation of the sample bottle to initiate a complete mixing of its contents. This action, in turn, resulted in a randomization of the collection, and it also dislodged any of the diatoms that might have been attached to the macroalgae in the sample. Other applications were then required, and the next seven steps of the analytical procedure will be earmarked with roman numerals in the below discussion for later reference purposes.

Following sample agitation, the subsequent three steps in the analysis of the algae collections were directed to the soft-bodied or the non-diatom forms as follows: I. The obvious soft-bodied algae were removed from the sample bottle, examined with a microscope, and identified to genus using the appropriate reference keys, e.g., Smith (1950). II. Subsequently, a small subsample was pipetted from the bottle onto a microscope slide and scanned under magnification until a majority of the smaller non-diatom algae had been located and identified. III. These soft-bodied algae at the generic level and the diatoms at the class level (Bacillariophyceae) were then ranked on the basis of their abundance in the sample with a rank of one being assigned to the most plentiful taxa. Furthermore, qualitative estimates of abundance on the basis of volume were also made in addition to the rankings by using "very abundant," "abundant," "very common," "common," and "rare" designations in relation to each of the algal taxa. These abundance descriptions then completed the assessment of the non-diatom groups, and further attention was directed entirely to the diatomaceous component of the sample.

The fourth step (IV) of the periphyton analysis required the preparation of permanent microscope slide mounts utilizing the remaining contents of the sample bottle. The techniques outlined in Standard Methods (APHA, et al, 1975) for slide preparation were followed in this inventory, and the resultant slides now comprise the diatom reference collection of the project. A subsequent phase of the algae assessment (V) involved a microscopic survey of these same slides with the diatom algae found on the mounts identified taxonomically to the varietal level. This was followed by the completion of proportional counts of the individuals of

each of the diatom species until between 300 to 400 total cells per slide-sample had been tabulated. Procedures described by the Environmental Protection Agency (1973) were utilized for making the counts. In the case of a few depaupered samples having a relatively low number of diatom individuals, only 100 to 200 cells were identified and tabulated because of the associated time restrictions involved in finding the remaining cells on the mount.

The major data output for the periphytic portion of the inventory resides in the percent relative abundance (PRA) values for the different diatom species that were counted on a slide-sample, and these PRA numbers were calculated as one of the final steps of the algae assessment (VI). A PRA is defined as the count obtained for a particular diatom taxa divided by the total number of diatom cells tabulated for the mount, and the total PRA of a collection should then be equal to 100%. As the last step of the analyses (VII), sample diversity and equitability as described by Lloyd, et al (1968) and by Lloyd and Ghelardi (1964), respectively, were eventually calculated from the PRA data for further interpretive and comparative purposes.

Five classes of periphyton community-macroalgae samples were collected from the study area streams as described in Table 2 (samples A to E). The A-type of sample, involving a complete analysis of the algae components through step VII, was obtained from all of the waters of the inventory; however, this A class was most consistently assessed from the intensive station collections as noted in the table. At least one A sample was evaluated for each of the accessory and miscellaneous sites, and these collections were most commonly obtained during a mid-summer period when algal diversity was at its highest in the streams. In the case of the B samples, the soft-bodied algae were analyzed through step III but with the analysis stopping after the completion of step IV. Thus, permanent mounts are available for all of the B samples as a part of the project's diatom reference collection. Most of the samples from the accessory stations are of the B class, and although slides for these collections are on hand, they were not processed for the diatoms because of study time restrictions related to a complete processing of the more important A samples from the intensive sites. The slides from the accessory B samples can also be analyzed to completion or to the A level at some time in the future if funding opportunities happen to arise, and these additional assessments will further enhance the periphytic data base for the study region waters.

In contrast to the A- and the B-types of algae samples, the C collections were obtained only for an evaluation of the macroalgae with no options for assessing the diatomaceous forms. Their analysis was thereby terminated after the completion of step III with no permanent mounts prepared for the collection. Samples of this kind were obtained from a variety of study area streams as new algal growths happened to appear through the field seasons, but the C class was most commonly collected from the intensive streams. The main point of the C effort was to enhance the inventory's taxonomic, distributional, and abundance information for the non-diatom algae.

Like the A samples, the D and E collections were also completely analyzed through step VII, and the major differences between the A and the D-E classes relate to the higher number of counts in the D case over

the A and to the use of artificial rather than natural substrates in the case of the E-type samples. The similarities between these three types of samples can be summarized as follows: Diatom counting intensity was generally the same for the A and E samples while natural substrates were scraped to obtain both the A and D collections. In addition, and with only one exception (Indian Creek near Kirby for the D series), the D and E samples were obtained only from the nine intensive stations and not from any of the accessory sites.

A single D-type sample was obtained from each of the intensive sites and from Indian Creek, and they were collected during the mid-summer in conjunction with the high algal diversities. In addition to increasing the algal data pool of the project, another purpose for obtaining the D samples and the high counting intensities was to provide an in-depth look at the structure of streams' periphyton communities in the hope that this will afford a future opportunity to complete rigorous statistical comparisons between time-different periphyton samples obtained from the same stream locations during the same season in order to spot any changes in water quality that might have occurred during the intervening years. Furthermore, such an in-depth look at the streams' algal communities is of scientific interest in its own right.

Several of the E-type samples were obtained from each of the intensive stations, and these were collected from the artificial substrates or plexiglass plates that had been exposed in the stream for a period greater than one month. These six inch by nine inch plates were suspended in the stream through the use of wooden stakes that were pounded into the stream bottom, and the plates were then attached to the stakes through the use of U-bolts that were passed through holes appropriately drilled in the plexiglass. With the use of this system, the plates were vertically positioned in the stream so that the top, 1/4 inch wide edge of the plate was located at or slightly below the surface of the water. The artificial substrates were placed in a fairly deep segment of the stream, and a spot was chosen that had a low to moderate current velocity. This stream location, therefore, is generally equivalent to the riffle to pool, transition zone described previously for the artificial substrate, macroinvertebrate work.

A major reason for making an artificial substrate application to the algal phase of the project was to compare the older periphyton communities obtained from the natural substrates to the younger communities that had recently colonized the plates. In addition, these artificial substrate collections act to supplement the taxa listings of the project, and they also enhance the rank, abundance and frequency data for the different algae that inhabit the study area streams. This includes the macroalgae as well as the diatoms since the soft-bodied forms can also grow on the plates. Furthermore, since the plexiglass plates afford a well-defined substrate for the algae, the data from this segment of the project should be quite conducive to making various physical-water quality and biological statistical correlations because of the somewhat controlled circumstances in this application with a smaller number of non-biotic factors affecting the communities. Statistical applications of this kind should thereby be somewhat more straightforward and easier to interpret through the use of artificial substrates than the case with the natural bottom materials.

## APPENDIX

### TABULAR CONSIDERATIONS

General Features. All of the water quality data collected as a part of this inventory are summarized in the appendix of this report. Similarly, most of the biological data are also tabulated with one major exception. This exception resides with the periphytic phase of the project where the PRA values that were obtained for a major portion of the diatom species of each collection have not been presented. With the obtainment of around 42 bacillariophycean taxa per sample, and with the obtainment of upwards to about 60 different taxa per sampling site for all of the station collections, the complete and formal tabulation of all of this algal information would have been an overwhelming and voluminous task. As a result, only the PRA's of the dominant diatom species of each sample are listed with dominance defined as a PRA value in excess of 9.9%. However, complete listings of the many PRA numbers for each of the analyzed periphyton samples collected from the study area streams are on file with the Water Quality Bureau office in Helena, Montana, and these data sheets are available for perusal.

A major part of the physical data obtained during the macroinvertebrate segment of the inventory is also presented in this appendix. As one exception in this regard, the physical measurements associated with the initial introduction of the jumbo samplers to the streams and with their subsequent removal have not been presented in favor of the tabulation of a mean value. This elimination was necessary because of space restrictions in the associated tables. In addition, only the single summary reference number that describes the substrate features of a Surber collection are listed in these same tables. The substrate category percentages relative to Table 5 have not been included because of the space requirement for a listing of 1528 members of this kind. But again, the substrate category percentages describing each Surber sample are on file with the Water Quality Bureau.

Except for the water quality tabulations, the Surber physical measurements, and the qualitative estimates of macroalgae and diatom abundance, and with the exception of some of the periphyton information (total diatom taxa and taxa counted and total diatom cells counted), the data that are presented in this appendix are best described as "semi-raw" in nature since some refinements have been applied to the "raw" numbers before their entry into the tables. Such data refinements can be summarized as follows: (1) Adjustments of the actual counts of the macroinvertebrate taxa individuals in a sample for the occurrence of duplicate-triplicate sampling on a station visit and/or for the occurrence of subsampling in the laboratory, and this then led to the density, taxa numbers, and biomass expressions that are presented for the Surber and jumbo multi-plate collections; the taxa means for a station and the sample totals are also listed. (2) Determinations of mean current velocity, stream width, and stream depth from the initial and final values that were measured in association with the macroinvertebrate artificial substrate work. (3) Calculations of single summary substrate reference numbers from the category percentage estimates that were made in conjunction with the Surber collections. (4) Calculations of PRA values from the cell counts of the diatom species that were identified in a periphyton sample, and (5) determinations of sample diversity and equitability from the PRA data

of a periphyton collection. These "raw" and "semi-raw" data will be additionally refined and reduced as appropriate for interpretive considerations in the other two final and companion reports of the project.

The "raw" and "semi-raw" physical, water quality, and biological data that are now on hand for the coalfield area streams as a result of this recent inventory effort are presented in this report as a series of tables generally organized on the basis of sampling station and collection date. These tabular series can be described as follows: Series A--water quality data tables; Series C--Surber macroinvertebrate density tables (numbers of taxa individuals, sample totals, and taxa means per square foot of stream bottom); Series D--artificial substrate macroinvertebrate tables (numbers of taxa individuals, sample totals, and taxa means per duplicate jumbo multiplate samplers); Series E--Surber macroinvertebrate biomass tables (milligrams of air dry weight for each taxa, sample totals and taxa means per square foot of stream bottom); Series F--artificial substrate, macroinvertebrate biomass tables (milligrams of air dry weight for each taxa, sample totals, and taxa means per duplicate jumbo multiplate samplers); Series G--physical measurements that were taken in conjunction with the macroinvertebrate work; Series I--macroalgae and bacillariophycean abundance rankings and estimates, PRA's of major diatom species, and periphytic community information that were obtained from natural stream substrates; Series J--macroalgae and bacillariophycean abundance rankings and estimates, PRA's of major diatom species, and periphytic community information that were garnered from artificial substrates exposed to the streams; and Series L--examples of a complete floristic periphyton sample analysis.

In addition to these series tabulations, Table B34 of the appendix presents a listing of the macroinvertebrate taxa collected from the study area waters during the inventory, plus some other descriptive information, and Tables H137 and K171 make a similar presentation for the periphytic and macroalgal segment of the project. Certain details of these three summary tables plus those within each of the above mentioned tabular series are discussed below.

Water Quality. The water quality data collected during the project are presented in Tables A01 to A33. The symbols used in these tables for the different water quality parameters are defined in Table 4 of the text. The data are presented in the units of milligrams per liter (mg/l) whenever appropriate--TSS, DO, BOD, common ions, nitrogen and phosphorous nutrients, metals, and silica, and the concentrations of the nutrients are given as mg/l of the nutrient element, i.e., as mg P/l or as mg N/l. Other concentrational units and related notes can be listed as follows: Temp in degrees centigrade (C), pH in standard units, SC in micromhos per centimeter at 25C, Turb in nephelometric turbidity units (NTU), TC as the number of colony counts per 100 ml, TH as mg CaCO<sub>3</sub>/l, and TA as mg CaCO<sub>3</sub>/l. The "N" in the TLN column of the tables denotes a "nearly equal to" or "about equal to" value in those cases where ammonia or nitrite-nitrate concentrations were below detectable limits.

These same water quality tables also contain the geographic descriptions of the sampling locations for each of the water quality (and biological) collections. The "a" designations denote the most frequently sampled segment, the "b" designations denote the next most frequently sampled segment, and so on. The symptomatic run notations point to the collection of water quality (and biological) samples at a number of sequential stations along the length of two selected streams within a short period of time.

Macroinvertebrates. The macroinvertebrate section of the appendix data tables is initiated with a summary taxa listing of all of the macroinvertebrates collected during the investigation (Table B34). The common names for these taxa are also listed as available. The taxa identifications presented in this table were taken to the lowest systematic level possible in relation to the objectives and theme of the study and in relation to the expertise that was immediately available to the project and its time restrictions. Thus, identifications to genera were feasible in many instances, and species identifications were possible for a few of the organisms. In all cases, only those taxonomic identifications that were felt to be fairly secure at a particular systematic level are listed, and the unreasonable "forcing" of these identifications to lower systematic categories in light of the information that was on hand was avoided throughout the inventory. Verifications of many of the organisms have been obtained from various non-project individuals that are also working in the aquatic macroinvertebrate field, and any identifications that are still felt to be somewhat tentative are noted as such in the data tables.

Some of the macroinvertebrates could only be identified to a higher taxa above the generic level because of the difficulty in keying certain of the ambiguous forms such as the chironomids, oligochaetes, flatworms, and nematodes, and because of the lack of suitable keys. Further identifications of these kinds of organisms would ultimately require the efforts of expert taxonomists in a particular macroinvertebrate group, or an excessive expenditure of project time, and both of these requirements were beyond the tenants of the study. In other cases, generic identifications could not be made because of the small size of the specimens or because of their inadvertent mutilation during field collection and sample processing, and both of these factors resulted in an obscuring of critical taxonomic characteristics. For whatever reason, the identifications that had to be stopped at a higher systematic level are noted in Table B34.

In addition to the taxa list per se, the systematic features of the organisms are also included in Table B34 along with a few accessory notes describing their significant habits and characteristics. This information was taken from a variety of reference sources as follows: Pennak (1978), Merrit and Cummins (1978), Burch (1972), Klemm (1972), and Edmondson (1958). These same sources also list various common macroinvertebrate taxa that are typically found in aquatic systems but for which no specimens were obtained from the study area streams under the sampling regime of the project. These uncollected taxa are also indicated in the table.

The macroinvertebrate data tables (Tables C35 to F134) are organized on the basis of higher taxa levels such as order, class, or phyla. They generally copy the sequence of taxa presented in Table B34, and the symbols that are used for the higher taxa markers in the data tables are defined in this initial summary. Some geographic descriptions are also included for those cases where more than one sample was collected from a broadly defined station in a single day. For the remaining collections, the sampling date can be used to find the appropriate geographic description in the water quality tables.

The "t" designations in Tables C35 to F134 denote a tentative taxonomic identification while the "p" notations indicate the presence of a particular taxa at a sampling station although intact individuals could not be found in the sample. That is, the presence of these taxa was

intimated by the occurrence of accessory evidence in the collection such as empty shells, cases, or exoskeletons, but these fragments were not counted as a part of the data tabulations. The "A," "L," and "P" symbols in the tables describe the collection of adult, larval, and pupal stages respectively. For the rest of the insect taxa that lack these designations, the larval forms were collected, and adults were generally obtained in the case of the non-insect taxa.

Physical Measurements and Substrate. Table G135 presents the physical data that were taken in association with the Surber macroinvertebrate samples, and this same table also contains the summary substrate reference numbers that were calculated for each of these collections. In addition, a few related notes describing the general stream habitat that was utilized for the collection and the condition of the stream at the time of sampling are also included. The riffle references in these notes refer to a relatively shallow section having a distinct gradient and a fairly rapid current velocity so that a distinct turbulent flow was evident over the stream's bottom materials. The channel segments, in contrast, although also possessing a marked current, did not demonstrate as pronounced a turbulent flow as the riffle reaches, and they therefore appeared to be much smoother in character. As a further item in Table G135, a listing of the extraneous visits to the different stations is presented with associated comments summarizing the reasons why Surber samples could not be collected on these particular dates.

As a sister tabulation, Table G136 presents the physical data obtained in conjunction with the jumbo multiplate samplers. Notes are also included in this table on the occurrence of sampler loss during the study period, and a listing of the various miscellaneous site visits that were made in conjunction with the artificial substrate work is also included to help elucidate the general sampling schedule for this phase of the inventory.

Periphyton and Macroalgae. The periphyton portion of the appendix tables is prefaced with a summary listing of the major algal taxa, both the diatoms and the soft-bodied forms, that were collected during the course of the study (Table H137). As indicated in this table, the diatoms were identified to species (and to variety as feasible) while the non-diatoms could only be taken to the generic level. Common names are also included as they happen to be available for the different taxa. In addition, the systematics of these algae are presented along with a few notes describing some of their major characteristics. Such descriptions represent an amalgamation of the information that is contained in the following reference sources: Robbins, et al (1965), Round (1965), Wiesz and Fuller (1962), and Smith (1950). In general, most of the descriptive features contained in the table for the algal taxa were specifically chosen from among a large number of such characteristics so that they might serve to distinguish only the algal forms that were collected as a part of this inventory. Therefore, the information in Table H137 should not be viewed as a key that would be helpful in identifying algal taxa outside of the study area, or useful in keying an unlisted and unidentified taxa that might still be collected from the project region.

Tables I138 to J170 contain the periphytic and macroalgae data that were collected during the project. The abundance rankings of the soft-bodied algae and the Bacillariophyceae are included as well as their class abundance estimates using the very abundant (VA), abundant (A),

very common (VC), common (C), and rare (R) designations described previously. The dominant diatom taxa and the associated PRA values are also listed along with various types of data describing the nature of the periphyton community in each collection. Summed PRA numbers for the Achnanthes spp. and Nitzschia spp. are presented because of the importance of these two genera as water quality indicators (Lowe, 1974).

Tables I138 to I165 contain the periphytic and macroalgae data that were collected from the natural substrates of the streams, and Tables J166 to J170 contain similar data that were obtained from the plexiglass plates. The sample codes listed in these tables are defined in Table 2 of the text, and the sample number of each collection pertains to a labelling system that is used by the Water Quality Bureau to provide easy access to the permanent mounts that form a part of the Bureau's diatom reference assemblage.

Table K171 in the appendix acts as an extension of the initial algal summary table where all of the diatom taxa identified in the analyzed project periphyton samples are listed. Authoritative, varietal, and form names associated with each diatom species are also included in the same table. This diatom species list is termed tentative at the present time since the opportunity for future taxonomic work on the collections will probably result in verifications or nomenclatural alterations of some of the questionable identifications, and this work could also eventually result in the identification of some of the currently unknown taxa. Furthermore, it is felt that new diatom species might be found in the coalfield area periphyton collections with the continuation of taxonomic work in this direction.

The final three tables in the appendix of this report (Tables L172 to L174) provide examples of the taxa listings and related PRA values that were obtained from a standard floristic evaluation of the study area algal samples. Data obtained from seven intensive sites collected on two different dates were chosen for this presentation. The listings are organized on the basis of "major," "sub-major," and "minor," species as defined in the tables, although this format was not meant to have any significant interpretive value; rather, it was formulated simply as a convenient way to arrange the species names and numbers. The trace amounts (tr) noted in these tables for some of the diatoms refer to those species in a sample that were spotted during the microscopic scans of the permanent mounts while never being actually counted during the tabulation process.

#### DATA TABLES

The many data tables that were developed as a result of the southern Fort Union region biological-benthic inventory are presented on the following pages of this data report. A complete listing of these tables is included in the "List of Tables and Figure" section located at the front of this publication.

Table B34. Taxa list, associated systematics, and major habits and characteristics of benthic macroinvertebrates collected from streams draining the southern Fort Union region of southeastern Montana (the first page of eight pages).

Phylum: Arthropoda--joint-footed animals

Subphylum: Mandibulata (Antennata)--antennae present

Class: Insecta (Hexapoda)--insects

Order: Coleoptera (COL)--beetles and weevils

Family: Carabidae (L)\*--predaceous ground beetles

Family: Chrysomelidae--leaf beetles

Donacia (L)--clinging beetles

Family: Curculionidae (L)\*--weevils

Hyperodes (L)--climbing and clinging weevils

Listronotus (L,A)--climbing and clinging weevils

Family: Dryopidae--riffle beetles

Helichus sp. (A)--clinging beetles

Helichus striatus (A)

Family: Dytiscidae (L)\*--predaceous diving beetles

Agabus (L,A)--swimming and diving beetles

Deronectes sp. (A)--swimming and climbing beetles

Deronectes liodessus (A)

Deronectes-Oredytes complex (A)

Oredytes (L)--swimming and climbing beetles

Hydroporus-Hygrotus complex (L)--diving beetles

Rhantus (L)--swimming and diving beetles

Family: Elmidae (L)\*--riffle beetles

Dubiraphia sp. (L,A)--clinging and climbing beetles

Dubiraphia vittata (A)

Microcylloepus sp. (L,A)--clinging, climbing beetles

Microcylloepus pusillus (A)

Optioservus sp. (L,A)--clinging beetles

Optioservus divergens (A)

Optioservus quadrimaculatus (A)

Stenelmis sp. (L,A)--clinging beetles

Stenelmis sinuata (A)

Stenelmis sinuata-humerosa complex (A)

Stenelmis vittipennis (A)

Zaitzevia parvula (A)--clinging beetles

Family: Haliplidae--crawling water beetles

Haliplus (L,A)--climbing and swimming beetles

Family: Heteroceridae (L)\*--subaquatic and littoral beetles

Family: Hydrophilidae (L)\*--water scavenger beetles

Berosus (L)--swimming and diving beetles

Enochrus (L)--burrowing and sprawling beetles

Helophorus (A)--climbing beetles

Hydrochus (L)--climbing beetles

Laccobius (L,A)--swimming and climbing beetles

\*An asterisk denotes the collection of a higher taxa representative that could not be identified to the generic level.

L,A: These designations denote the larval and adult forms respectively.

Table B34. Continued (the second page of eight pages).

Class: Insecta--(continued)

Order: Coleoptera (COL)--(continued)

Family: Hydraeinidae (Limnebiidae) (L)\*--crawling water beetles  
Ochthebius (L,A)--clinging beetles

Family: Gyrinidae--whirligig beetles  
Gyrinis-Gyretes complex (L)--surface swimming beetles

Family: Limnichidae (L)\*--riffle beetles

Family: Noteridae#--burrowing water beetles

Order: Diptera (DIP)--true flies

Suborder: Brachycera\*

Family: Dolichopodidae\*--burrowing aquatic flies

Family: Empididae\*--dance flies

Clinocera--clinging flies

Clinocera-Chelifera complex

Hemerodromia--sprawling and burrowing flies

Family: Stratiomyidae\*--soldier flies

Euparyphus--sprawling flies

Nemotelus--swimming and sprawling flies

Odontomyia (Eulalia)--sprawling flies

Stratiomys (Stratiomyia)--sprawling, burrowing flies

Family: Tabanidae\*--horse and deer flies

Chrysops--sprawling and burrowing flies

Tabanus--sprawling and burrowing flies

Suborder: Cyclorrhapha

Family: Ephydriidae--shore and brine flies

Hydrellia--burrowing and mining flies

Family: Muscidae (Anthomyiidae)\*--aquatic "houseflies"

Limnophora--burrowing flies

Family: Scatophagidae\*--dung flies

Suborder: Nematocera

Family: Blephariceridae#--net-winged midges

Family: Ceratopogonidae (Heleidae)\*--biting midges, "no-see-ums"

Bezzia--burrowing midges

Bezzia-Probezzia-Palpomyia complex

Palpomyia--burrowing midges

Culicoides--burrowing midges

Family: Chironomidae\*--true midges

Family: Culicidae#--mosquitoes

Family: Deuterophlebiidae#--mountain midges

Family: Dixidae--dixid or dixia midges

Dixa--swimming and climbing midges

\*An asterisk denotes the collection of a higher taxa representative that could not be identified to the generic level.

L,A: These designations denote the larval and adult forms respectively.

#This designation denotes a generally lotic and/or relatively common higher taxa for which no representatives were collected from the study area streams.

Table B34. Continued (the third page of eight pages).

Class: Insecta--(continued)

Order: Diptera (DIP)--(continued)

Suborder: Nematocera--(continued)

Family: Psychodidae\*--moth flies

Pericoma--burrowing flies

Family: Ptychopteridae#--phantom crane flies

Family: Simuliidae--black flies

Simulium (L,P)--clinging flies

Family: Tipulidae\*--Craneflies

Dicranota--sprawling and burrowing flies

Ormosia--semiaquatic, burrowing flies

Pseudolimnophila--burrowing flies

Tipula--burrowing flies

Order: Ephemeroptera (EPH)\*--mayflies

Family: Baetidae\*

Baetis--rapid water, free-ranging mayflies

Pseudocloeon--swimming and clinging mayflies

Family: Baetiscidae#--sprawling and clinging mayflies

Family: Caenidae

Caenis--quiet water, bottom sprawling mayflies

Family: Ephemerellidae\*

Ephemerella--variable mayflies

Family: Ephemeridae

Ephemera--quiet water, burrowing mayflies

Family: Heptageniidae\*

Heptagenia--running water, clinging mayflies

Rhithrogena--running water, clinging mayflies

Stenonema--running water, clinging mayflies

Family: Leptophlebiidae\*

Choroterpes--clinging and bottom sprawling mayflies

Choroterpes-Leptophlebia complex

Leptophlebia--clinging and swimming mayflies

Paraleptophlebia--rapid water, free-ranging mayflies

Family: Polymitarcyidae

Ephoron--quiet water, burrowing mayflies

Family: Siphonuridae

Ameletus--rapid water, free-ranging mayflies

Siphonurus--quiet water, climbing mayflies

Family: Tricorythidae

Tricorythodes--clinging and bottom sprawling mayflies

\*An asterisk denotes the collection of a higher taxa representative that could not be identified to the generic level.

L,P: These designations denote the larval and pupal forms respectively.

#This designation denotes a generally lotic and/or relatively common higher taxa for which no representatives were collected from the study area streams.

Table B34. Continued (the fourth page of eight pages).

Class: Insecta--(continued)

Order: Hemiptera (HEM)--true bugs

Suborder: Heteroptera (L,A)\*--aquatic bugs

Family: Corixidae\*--water boatmen

Hesperocorixa sp. --swimming and climbing bugs

Hesperocorixa laevigata

Hesperocorixa vulgaris

Sigara sp.--swimming and climbing bugs

Sigara comani

Sigara trilineata

Trichocorixa--swimming and climbing bugs

Family: Gerridae--water striders, pond skaters, wherry-men

Gerris sp.--skating bugs

Gerris remigis

Family: Naucoridae--creeping water bugs

Ambrysus mormon--clinging and swimming bugs

Family: Notonectidae#--back swimmers

Family: Saldidae\*--shore bugs

Family: Veliidae#--broad-shouldered water striders

Suborder: Homoptera\*--cicados, aphids, etc., semiaquatic bugs

Order: Lepidoptera (LEP)--butterflies and moths

Family: Pyralidae--aquatic caterpillars

Parargyractis--silk retreat makers

Order: Megaloptera (MEG)--alderflies, dobsonflies, and fishflies

Family: Sialidae\*--alderflies

Sialis--burrowing, climbing, and clinging alderflies

Family: Corydalidae

Subfamily: Corydalinae#--dobsonflies and hellgrammites

Subfamily: Chauliodinae--fishflies

Dysmicohermes--clinging and climbing fishflies

Order: Odonata (ODO)\*--dragonflies and damselflies

Suborder: Anisoptera (ANI)\*--true dragonflies

Family: Aeshnidae--darners

Aeshna--climbing dragonflies

Family: Gomphidae\*

Gomphus--burrowing dragonflies

Ophiogomphus--burrowing dragonflies

Family: Libellulidae\*

Leucorrhinia--climbing dragonflies

Family: Petaluridae#--mountain dragonflies

\*An asterisk denotes the collection of a higher taxa representative that could not be identified to the generic level.

L,A: These designations denote the larval and adult forms respectively.

#This designation denotes a generally lotic and/or relatively common higher taxa for which no representatives were collected from the study area streams.

Table B34. Continued (the fifth page of eight pages).

Class: Insecta--(continued)

Order: Odonata (ODO)\*--(continued)

Suborder: Zygoptera (ZYG)\*--damselflies

Family: Calopterygidae (Agriidae)

Hetaerina--climbing and clinging damselflies

Hetaerina americana

Family: Coenagrionidae (Coenagriidae)\*

Argia--clinging and climbing-sprawling damselflies

Argia (Hyponedra) vivida

Ischnura--climbing damselflies

Order: Plecoptera (PLE)--stoneflies

Family: Chloroperlidae\*--clinging stoneflies

Family: Nemouridae\*

Nemoura (a)--sprawling and clinging stoneflies

Family: Perlidae

Acroneuria (a)--clinging stoneflies

Family: Perlodidae\*

Isogenus (a)--clinging stoneflies

Isoperla--clinging and sprawling stoneflies

Family: Pteronarcyidae#--clinging and sprawling stoneflies

Pteronarcys#--salmon flies ("helgrammites")

Order: Trichoptera (TRI)--caddisflies

Family: Brachycentridae\*--tapered tube-case makers

Brachycentrus--clinging caddisflies

Family: Glossosomatidae\*--saddle-case, turtle shell-case makers

Culoptila--clinging caddisflies

Family: Helicopsychidae--snail shell-like, tube-case makers

Helicopsyche--clinging caddisflies

Family: Hydropsychidae\*--net spinning, fixed retreat makers

Cheumatopsyche--clinging caddisflies

Hydropsyche--clinging caddisflies

Potamyia--clinging caddisflies

Family: Hydroptilidae (L,P)\*--microcaddisflies, purse-case makers

Hydroptila (L,P)--silken case, clinging caddisflies

Ithytrichia (L,P)--silken case, clinging caddisflies

Ochrotrichia--silken case, clinging caddisflies

Family: Lepidostomatidae#--climbing, sprawling tube-case makers

\*An asterisk denotes the collection of a higher taxa representative that could not be identified to the generic level.

(a)These stonefly genera have numerous subgenera which are often given a generic rank by some "split-prone" authorities.

#This designation denotes a generally lotic and/or relatively common higher taxa for which no representatives were collected from the study area streams.

L,P: These designations denote the larval and pupal forms respectively.

Table 34B. Continued (the sixth page of eight pages).

Class: Insecta--(continued)

Order: Trichoptera (TRI)--(continued)

Family: Leptoceridae (L,P)\*--variable tube-case makers

Nectopsyche (Leptocella)--climbing, swimming caddisflies with long and slender tube-cases

Oecetis--clinging, sprawling caddisflies with curved and tapered tube-cases

Family: Limnephilidae\*--variable tube-case makers

Anabolia--climbing and sprawling caddisflies with rough tube-cases of plant pieces

Glyphopsyche--sprawling caddisflies with smooth tube-cases of plant pieces

Hesperophylax (Platyphylax) (L,P)--sprawling caddisflies with slightly curved and slightly coarse mineral tube-cases

Limnephilus--climbing and sprawling caddisflies with variable tube-cases of plant pieces and/or sand grain construction

Onocosmoecus--sprawling caddisflies with tube-cases of plant pieces or minerals

Psychoglypha--sprawling and clinging caddisflies with mixed tube-cases of plant pieces and minerals

Family: Odontoceridae#--sprawling tube-case makers

Family: Philopotamidae#--clinging sack-like, silk net spinners

Family: Phryganeidae--cylindrical tube-case makers

Ptilostomis--climbing caddisflies

Family: Polycentropodidae--net spinning retreat makers

Neureclipsis--clinging caddisflies with trumpet-shaped silk nets

Nyctiophylax--clinging caddisflies with silk tube retreats

Polycentropus--clinging caddisflies with silk tube retreats

Family: Rhyacophilidae#--free-living, free-ranging and clinging caddisflies having no cases

Phylum: Arthropoda--joint-footed animals

Subphylum: Mandibulata (Antennata)--antennae present

Class: Crustacea--crustaceans

Subclass: Ostracoda (OST)\*--seed shrimp

Order: Podocopa\*--fresh-water seed shrimp

\*An asterisk denotes the collection of a higher taxa representative that could not be identified to the generic level.

L,P: These designations denote the larval and pupal forms respectively.

#This designation denotes a generally lotic and/or relatively common higher taxa for which no representatives were collected from the study area streams.

Table B34. Continued (the seventh page of eight pages).

Class: Crustacea--(continued)

Subclass: Malacostraca--lobsters, crabs, sow bugs, scuds, crayfishes, etc.

Order: Isopoda#--aquatic sow bugs

Order: Amphipoda (AMP)--scuds, sideswimmers, "fresh-water shrimp"

Family: Gammaridae

Gammarus

Family: Talitridae--common sideswimmer

Hyalella azteca--only Talitridae in North America

Order: Decapoda#--lobsters, crabs, crayfishes, etc.

Family: Astacidae#--crayfishes, crawfishes, crawdads

Phylum: Arthropoda--joint-footed animals

Subphylum: Chelicerata--antennae absent

Class: Arachnida (Arachnoidea)--spiders, scorpions, mites, ticks, etc.

Order: Acari (Acarina) (ACA)\*--mites and ticks

Group: Hydracarina (Hydrachnellae)(b)\*--water mites

Phylum: Annelida--segmented worms

Class: Hirudinea (HIR)\*--leeches

Order: Gnathobdellida--no protrusible proboscis, five eye pairs

Family: Hirudinidae

Percymoorensis marmoratis

Order: Pharyngobdellida--no protrusible proboscis, three or four eye pairs

Family: Erpobdellidae\*

Dina anoculata

Erpobdella

Order: Rhynchobdellida--protrusible proboscis present

Family: Glossiphoniidae\*

Batracobdella

Glossiphonia sp.

Glossiphonia complanata

Helobdella sp.

Helobdella stagnalis

Placobdella sp.

Placobdella papillifera

Theromyzon#

Family: Piscicolidae#

Class: Oligochaeta (OLI)\*--aquatic earthworms

#This designation denotes a generally lotic and/or relatively common higher taxa for which no representatives were collected from the study area streams.

\*An asterisk denotes the collection of a higher taxa representative that could not be identified to the generic level.

(b)The Hydracarina is an artificial assemblage of several families in the acarian suborder Trombidiformes that are restricted to fresh-water habitats along with certain of the Sarcopotiformes and the Parasitiformes which also have an aquatic habit.

Table B34, Continued (the eighth page of eight pages).

Phylum: Mollusca--mollusks

Class: Gastropoda (GAS)\*--univalve mollusks; limpets, snails and periwinkles

Subclass: Prosobranchia#--possess a gill and an operculum

Order: Mesogastropoda#--mostly marine species

Subclass: Pulmonata--possess a pulmonary sac (lung) and lack an operculum

Order: Basommatophora--fresh-water snails

Family: Ancyliidae--cone snails

Ferrissia

Family: Lymnaeidae--pond snails

Lymnaea

Family: Planorbidae--orb snails

Gyraulus

Helisoma

Family: Physidae--pouch snails

Physa

Family: Pupillidae

Columnella

Class: Pelecypoda (PEL)\*--bivalve mollusks; clams and mussels

Order: Eulamellibranchia

Family: Unionidae\*--pearly mussels or naiads

Order: Heterodonta

Family: Sphaeriidae--pea, pill, and fingernail clams

Pisidium--anterior of shell longer than posterior

Sphaerium--posterior of shell longer than anterior

Phylum: Platyhelminthes--flatworms

Class: Turberbellaria (TUR)\*--free-living flatworms

Phylum: Aschelminthes--roundworms

Class: Nematoda (NEM)(c)\*--nematodes

Class: Nematomorpha (NMT)(c)\*--"hair snakes" or "horsehair worms"

Order: Gordiida (Gordioidea)\*--gordian worms

\*An asterisk denotes the collection of a higher taxa representative that could not be identified to the generic level.

#This designation denotes a generally lotic and/or relatively common higher taxa for which no representatives were collected from the study area streams.

(c)The Nematoda and Nematomorpha are given a phylum rather than a class ranking by some authorities.

(1) Riffle to pool samplers were found buried on 10/08/78 and not assessed.

Sampling Location: a--T06N, R51E, 25C.

This sheet is intended as a filler for a set of 33 appendix tables ("E" series) that will be prepared for inclusion into this data report once the requisite data are at hand. The availability of this data and the preparation of these tables is anticipated for the near future. These "E" tables will be similar in sequence, organization, and content to the "C" series of the appendix which lists the macroinvertebrate-Surber density numbers by sample, station, and taxa. But in the case of the "E" tables, a biomass as an air-dried weight in milligrams per square foot will be presented for each taxa and Surber sample collection rather than a density value. These extra tables will entail an additional 39 pages for the report.

#### Tables E85 to E117

Biomass (milligrams of air-dried weight per square foot) of benthic macroinvertebrates collected with a Surber sampler from various streams draining the southern Fort Union region in southeastern Montana.

This sheet is intended as a filler for a set of 17 appendix tables ("F" series) that will be prepared for inclusion into this data report once the requisite data are at hand. The availability of this data and the preparation of these tables is anticipated for the near future. These "F" tables will be similar in sequence, organization, and content to the "D" series of the appendix which lists by sample, station, and taxa the macroinvertebrate numbers collected with the duplicate jumbo multiplate samplers. But in the case of the "F" tables, a biomass as an air-dried weight in milligrams will be presented for each taxa and duplicate jumbo multiplate collection rather than the individual count tabulations. These extra tables will entail an additional 18 pages for the report.

#### Tables F118 to F134

Biomass (milligrams of air-dried weight) of benthic macroinvertebrates collected from duplicate jumbo multiplate samplers placed into different types of stream habitats at the various intensive stations of the coal-field study area.

Table E85. Biomass (milligrams dry weight per square foot) of benthic macroinvertebrates collected with a Surber sampler from upper Rosebud Creek near Kirby during the 1978 sampling season.

	Initial installation of samplers for the 1978 season.	07/31/78
	Samplers out of water and moved to new locations.	08/19/78
Mizpah Creek/Mizpah	Stream too high to install the 1978 samplers	07/21/78
	Initial installation of samplers for the 1978 season.	07/31/78
	Samplers out of water and moved to new locations.	08/19/78

d--The first installation of samplers at this station was delayed to some extent for the 1978 season because an inadequate number of samplers were initially available to the study.

Table H137. Taxa list, associated systematics, and major characteristics of algae collected from streams draining the southern Fort Union region in southwestern Montana (the first page of eight pages).

Systematic Features and Scientific: Common Names*	Morphological and Other Aspects
<u>PROKARYOTA</u> (Monera): fission plants.....	Prokaryotic cells lacking distinct organelles; includes the bacteria and the blue-green algae.
<u>D.</u> Cyanophyta (Schizophyta): blue-green algae....	Photosynthetic pigments, including chlorophyll a, present but not located in definite chloroplasts; color variable.
<u>C.</u> Cyanophyceae (Schizophyceae or Myxophyceae)	Cells solitary or in loose colonies; rarely filamentous.
<u>O.</u> <u>Chroococcales</u> .....	Thallus with a colonial organization.
<u>F.</u> <u>Chroococcaceae</u> .....	Colonies of a nondistinctive shape but with an obvious and colorless sheath.
<u>Chroococcus</u> .....	
<u>O.</u> <u>Oscillatoriales</u> .....	Thallus with a distinctly filamentous organization.
<u>SO-F.</u> <u>Oscillatorineae--Oscillatoriaceae</u> ....	Uniseriate unbranched trichomes lacking heterocysts.
<u>Oscillatoria</u> .....	Trichomes not regularly spiraled and lacking a sheath.
<u>Spirulina</u> .....	Trichomes regularly spiraled and lacking a sheath.
<u>Phormidium</u> .....	Sheaths present but watery with filaments interwoven.
<u>Trichodesmium</u> .....	Sheaths present but watery with filaments parallel.
<u>Lyngbya</u> .....	Sheaths present but firm, colorless to brown.
<u>SO.</u> <u>Nostochineae</u> .....	Variouly organized trichomes possessing heterocysts.
<u>F.</u> <u>Nostocaceae</u> .....	Unbranched trichomes lacking attenuation to the apices.
<u>Nostoc</u> .....	Thallus having a definite form.
<u>Aulosira</u> .....	Thallus amorphous with firm and thin sheaths.
<u>Anabaena</u> .....	Thallus amorphous with watery and broad sheaths.
<u>F.</u> <u>Scytonemataceae</u> .....	Falsey branched trichomes lacking a distinct attenuation.
<u>Tolypothrix</u> .....	False branching single and abundant.
<u>F.</u> <u>Rivulariaceae</u> .....	Variouly branched trichomes having a sharp attenuation.
<u>Rivularia</u> .....	Filaments united to form rounded colonies.
<u>Calothrix</u> .....	Filaments not forming rounded colonies.
<u>EUKARYOTA</u> : higher plants and animals.....	Eukaryotic cells possessing distinct organelles.
<u>Photosynthetic protista</u> : "true" algae.....	Photosynthetic pigments, including chlorophyll a, present and located in definite chloroplasts.

\*D--division (phyla), C--class, O--order, SO--suborder, and F--family; genera are also listed.

Table H137. Continued (the second page of eight pages).

Systematic Features and Scientific: Common Names*	Morphological and Other Aspects
Photosynthetic protista (continued)	
<u>D-C. Rhodophyta--Rhodophyceae: red algae.....</u>	Multicellular thallus tending to a red coloration because of the predominance of phycoerythrin pigments; fresh-water forms greyish-green; chlorophyll d also present. Relatively complex thallus growing from apical cells. Microscopic and freely branched filamentous thallus lacking a distinct central axis.
SC-0. <u>Florideae--Nemalionales.....</u>	
<u>F. Chanturiaceae.....</u>	
Audouinella: freshwater red algae	
<u>D-C. Euglenophyta--Euglenophyceae: euglenoids...</u>	Pigmented or unpigmented and typically unicellular motile flagellates lacking a cell wall; chlorophyll b also present with lipid and paramylum storage. Flagellated motile cell dominant phase of life cycle.
<u>O. Euglenales.....</u>	
<u>F. Euglenaceae.....</u>	
Euglena: euglena.....	
Trachelomonas.....	
<u>D. Chlorophyta: grass-green algae.....</u>	Cells plastic and lacking a lorica; grass-green in color. Protoplast surrounded by a lorica. Cellulose cell wall, starch storage, and green pigmentation; chlorophyll b also present.
<u>C-0. Charophyceae--Charales: stonewarts.....</u>	
<u>F. Characeae.....</u>	
Chara.....	
<u>C. Chlorophyceae.....</u>	Erect and branched thallus with nodes and internodes. Includes all present-day members; complex thallus. Rather pronounced musky odor. "Catch-all" group with highly variable morphologies but lacking unique reproductive modes; typically uninucleate. Flagellated motile vegetative cells dominate life cycle. Nonfilamentous, non-flagellated gelatinous colonies with cells that divide vegetatively.
<u>O. Volvocales: e.g., volvox #.....</u>	
<u>O. Tetrasporales.....</u>	
<u>F. Palmellaceae.....</u>	
Sphaerocystis.....	
<u>O. Chlorococcales.....</u>	
<u>F. Hydrodictyaceae.....</u>	
Pediastrum.....	

\*D--division (phyla), C--class, SC--subclass, O--order, and F--family; genera are also listed.

#Genera of this order were not identified in any of the macroalgae-periphyton samples.

Table H137. Continued (the third page of eight pages).

Systematic Features and Scientific: Common Names*	Morphological and Other Aspects
<u>D-C. Chlorophyta--Chlorophyceae (continued)</u>	
F. <u>Chlorococcales</u> (continued)	
F. <u>Coelastraceae</u> .....	Radially arranged cells in a somewhat globose coenobium.
F. <u>Coelastrum</u> .....	Coenobium a hollow sphere of four to 128 cells.
F. <u>Oocystaceae</u> .....	Variable morphologies; colonies lacking a cellular orientation; reproduction by autospores.
<u>Planktosphaeria</u> .....	Spherical cells embedded in a wide homogenous envelope.
<u>Ankistrodesmus</u> .....	Spindle-shaped and loosely aggregated cells.
F. <u>Scenedesmaceae</u> .....	Reproduction by autospores and colonies possessing a definite cellular orientation.
<u>Scenedesmus</u> .....	Colonies a flat plate of elongated and parallel cells.
O. <u>Ulotrichales</u> .....	Filamentous with a single laminate parietal chloroplast.
F. <u>Ulotrichaceae</u> .....	Unbranched filaments lacking H-pieces.
<u>Hormidium</u> .....	Filament without a basal cell.
<u>Ulothrix</u> .....	Filament with a basal cell.
F. <u>Microsporaceae</u> .....	Unbranched filaments possessing H-pieces.
<u>Microspora</u> .....	Only genus for this family.
F. <u>Chaetophoraceae</u> .....	Branched filaments lacking seta; relatively complex.
<u>Microthamnion</u> .....	Ends of branches not pointed.
<u>Chaetophora</u> .....	Ends of branches pointed; thallus having a definite shape.
<u>Stigeoclonium</u> .....	Ends of branches pointed; thallus lacking a definite shape. Cubical cells united laterally to form sheets, tubes, or cylinders; single laminate or cup-shaped chloroplast.
O. <u>Ulvales</u> .....	Thallus a sheet, ribbon, or hollow tube.
F. <u>Ulvaceae</u> .....	Mature thallus a hollow tube.
<u>Enteromorpha</u> .....	Mature thallus an expanded sheet.
<u>Monostroma</u> .....	Thallus a solid cylinder of brick-like cells.
F. <u>Schizomeridaceae</u> .....	Only genus for this family.
<u>Schizomeris</u> .....	

\*D--division (phyla), C--class, O--order, and F--family; genera are also listed.

Table H137. Continued (the fourth page of eight pages).

Systematic Features and Scientific: Common Names*	Morphological and Other Aspects
D. Chlorophyta (continued)	
<u>C.</u> Oedogoniophyceae.....	Filamentous with cells much longer than broad; a unique type of cell division; only one order in this class.
<u>O.</u> Oedogoniales	Only family for this order.
<u>F.</u> Oedogoniaceae.....	Unbranched filaments.
<u>Oedogonium</u> .....	
C. Bryopsidophyceae.....	Macroscopic with multinucleate siphons or cells.
<u>O.</u> Cladophorales: river "moss".....	Simple or branched filaments with multinucleate cells.
<u>F.</u> Cladophoraceae.....	Only family for this order.
<u>Cladophora</u> .....	Filaments freely branched and branches distinct.
<u>Rhizoclonium</u> .....	Filaments sparsely branched and branches short.
<u>O.</u> Siphonales #.....	Thallus a single but extensive multinucleate cell (siphon).
<u>C.</u> Conjugatophyceae.....	Complex chloroplasts; reproduces by conjugation.
<u>O-F.</u> Desmidiiales--Desmidiaceae; desmids.....	Cells formed into two hemicells joined by an isthmus.
<u>Pleurotaenium</u> .....	Cells united in unbranched filaments.
<u>Cosmarium</u> .....	Cells solitary with a median constriction.
<u>Closterium</u> .....	Cells solitary without a median constriction.
<u>O.</u> Zygnematales: pond scum.....	Filamentous and lacking hemicells.
<u>F.</u> Zygnemataceae.....	Cylindrical cells united in unbranched filaments.
<u>Zygnema</u> .....	Cells with two stellate chloroplasts.
<u>Mougeotia</u> .....	Cells with a single axial and laminate chloroplast.
<u>Spirogyra</u> .....	Cells with one or more spiral chloroplasts.
<u>D.</u> Pyrrophyta: golden-brown algae.....	Typically unicellular biflagellates (two flagella differ); chlorophyll c also present; lipid and starch storage.
<u>C.</u> Dinophyceae: dinoflagellates.....	Cells encircled by a transverse or spiral groove.
<u>O.</u> Peridinales.....	Cell walls composed of definitively arranged plates.
<u>F.</u> Peridiniaceae.....	Thick walls with two antapical plates; horns absent.
<u>Peridinium</u> .....	Country's only freshwater genus for this family.
<u>F.</u> Ceratiaceae.....	Thick walls with distinct horns evident.
<u>Ceratium</u> .....	Country's only freshwater genus for this family.

\*D--division (phyla), C--class, O--order, and F--family; genera are also listed.  
 #Genera of this order were not identified in any of the macroalgae-periphyton samples.

Table HL37. Continued (the fifth page of eight pages).

Systematic Features and Scientific: Common Names*	Morphological and Other Aspects
<u>Photosynthetic protista (continued)</u>	
<u>D. Chrysochyta: yellow-green algae</u> .....	Preponderance of carotenoid pigments; starch never a storage product; pectin cell membranes in two overlapping pieces and frequently impregnated with silica.
<u>C. Xanthophyceae</u> .....	Yellow-green coloration; chlorophyll e also present; leucosin and some oils are major storage products; two halves of cell wall and silica impregnation not obvious.
<u>O. Heterotrichales</u> .....	Cylindrical cells united end to end to form filaments.
<u>F. Tribonemataceae</u> .....	Unbranched filaments.
<u>Tribonema</u> .....	Thick cell walls with H-pieces clearly evident.
<u>O. Heterosiphonales</u> .....	Multinucleate and siphonaceous cells.
<u>F. Vaucheriaceae</u> .....	Filamentous.
<u>Vaucheria</u> .....	Only genus for this family.
<u>C. Chrysochyceae</u> .....	Golden-brown coloration; chlorophylls b-e missing; leucosin and oils are major storage products; two halves of cell wall not obvious but often containing silica.
<u>O. Chrysomonadales</u> .....	Motile during vegetative phase of life cycle.
<u>F. Ochromonadaceae</u> .....	Biflagellated forms with flagella of unequal length.
<u>Dinobryon</u> .....	Cells with a lorica in free-swimming dendroid colonies.
<u>C. Bacillariophyceae: diatoms</u> .....	Brown coloration; chlorophyll c also present; oils are the major storage product; sculptured silica cell wall (frustule) as two distinct halves (valves).
<u>O. Centrales: centric diatoms</u> .....	Non-motile cells with valves circular, polygonal, or irregular in outline; ornamentation radial or concentric about a central point; raphe-pseudoraphe missing.
<u>SO. Coscinodiscineae</u> .....	Discoid or cylindrical cells lacking horn-like processes.
<u>F. Coscinodiscaceae</u> .....	Discoid cells ornamental pattern not in distinct sectors.
<u>Melosira</u> spp.....	Cells united in long filaments.
<u>Melosira varians</u>	
<u>Stephanodiscus</u> spp.....	Cells solitary; valve surface with radiate hyaline areas.
<u>Stephanodiscus subtilis</u>	

\*D--division (phyla), C--class, O--order, SO--suborder, and F--family; genera and major diatom species are also listed.

Table HL37. Continued (the sixth page of eight pages).

Systematic Features and Scientific: Common Names*	Morphological and Other Aspects
D-C. Chrysophyta--Bacillariophyceae (continued)	
O-F. Centrales--Coccinodiscaceae (continued)	
<u>Cyclotella</u> spp.....	Cells solitary; two unlike concentric patterns evident.
<u>Cyclotella glomerata</u>	
<u>Cyclotella meneghiniana</u>	
S0. Biddulphiaceae.....	Generally zygomorphic cells possessing horn-like processes.
F. Chaetoceraceae.....	Frustules rounded; spine-like horns present.
<u>Chaetoceros</u> sp.....	Frustules without intercalary bonds.
F. Biddulphiaceae.....	Frustules angled; stout horns present.
<u>Biddulphia</u> sp.....	Country's only freshwater genus for this family.
O. Pennales: pennate diatoms.....	Cells often elongate; ornamentation bilaterally arranged to a sagittal line and never with reference to a central point; raphe-pseudoraphe present.
S0. Fragilarineae.....	Pseudoraphe or primitive raphe on both valves.
F. Meridionaceae.....	Internal septa typically present; valves cuneate to form fan-shaped or spiral colonies or filaments.
<u>Meridion</u> sp.....	Only freshwater genus for this family.
F. Diatomaceae.....	Internal septa present but valves bilaterally symmetrical.
<u>Oephora</u> sp.....	Girdle view cuneate.
<u>Diatoma</u> spp.....	Girdle view rectangular.
<u>Diatoma tenue</u>	
<u>Diatoma vulgare</u>	
F. Fragilariaceae.....	Valves typically symmetrical but lacking internal septa.
<u>Asterionella</u> sp.....	Ends of valves dissimilar in size.
<u>Fragilaria</u> spp.....	Valve ends similar; filamentous or stellate colonies.
<u>Fragilaria capucina</u>	
<u>Fragilaria crotonensis</u>	
<u>Fragilaria vaucheriae</u>	

\*D--division (phyla), C--class, O--order, S0--suborder, and F--family; genera and major diatom species are also listed.

Table H137. Continued (the seventh page of eight pages).

<u>Morphological and Other Aspects</u>	
<u>Systematic Features and Scientific: Common Names*</u>	
<u>D-C. Chrysophyta--Bacillariophyceae (continued)</u>	
<u>O-F. Centrales--Fragilariaceae (continued)</u>	
<u>Synedra</u> spp.....	Valve ends similar; cells solitary or in radiate colonies.
<u>Synedra famelica</u>	
<u>Synedra fasciculata</u>	
<u>Synedra ulna</u>	
<u>Eunotiaceae</u> .....	Arcuate (curved) valves lacking internal septa.
<u>Eunotia</u> sp.....	Valve ends similar; concave side not tumid in center.
<u>SO. Achnanthineae</u> .....	Pseudoraphe on one valve and true raphe on the other.
<u>F. Achnanthaceae</u> .....	Only family for this suborder.
<u>Rhoicosphenia curvata</u> .....	Frustules cuneate in girdle view.
<u>Achnanthes</u> spp.....	Frustules not cuneate; long axis curved.
<u>Achnanthes lanceolata</u>	
<u>Achnanthes minutissima</u>	
<u>Cocconeis</u> spp.....	Frustules not cuneate; transverse axis curved.
<u>Cocconeis pediculus</u>	
<u>Cocconeis placentula</u>	
<u>SO. Naviculineae</u> .....	Axial true raphe on both valves and not in keel.
<u>F. Naviculaceae</u> .....	Valves symmetrical and both valves alike.
<u>Mastogloia</u> spp.....	Frustules internally septate.
<u>Caloneis</u> spp.....	Remaining genera of this family not internally septate;
<u>Diploneis</u> spp.	these genera separated on the basis of various differ-
<u>Diploneis puella</u>	ences in frustule ornamentation and organization.
<u>Pleurosigma delicatulum</u>	
<u>Gyrosigma</u> spp.	<u>F. Naviculaceae (continued)</u> <u>F. Naviculaceae (continued)</u>
<u>Amphipleura pellucida</u>	<u>Navicula pavillardii</u>
<u>Frustulia</u> spp.	<u>Navicula radiosa</u>
<u>Stauroneis</u> spp.	<u>Navicula symmetrica</u>
<u>Pinnularia</u> spp.	<u>Navicula tripunctata</u>
<u>Anomoeoneis</u> spp.	<u>Navicula viridula</u>

\*D--division (Phyla), C--class, O--order, SO--suborder, and F--family; genera and major diatom species are also listed.

Table H137. Continued (the eighth page of eight pages).

Systematic Features and Scientific: Common Names*	Morphological and Other Aspects
C-S0. Bacillariophyceae--Naviculineae (continued)	
F. Gomphonemataceae.....	Valves transversely assymetrical.
Gomphoneis spp.....	Longitudinal lines adjoining valve margin.
Gomphonema spp.....	Longitudinal lines not adjoining valve margin.
Gomphonema angustatum	
Gomphonema olivaceum	
Gomphonema tenellum	
F. Cymbellaceae.....	Valves longitudinally assymetrical.
Epithemia spp.....	Valves with transverse costae; raphe acute-angled.
Epithemia sores	
Rhopalodia spp.....	Valves with transverse costae; raphe not acute-angled.
Cymbella spp.....	Valves flat and without transverse costae.
Cymbella affinis	
Cymbella cymbiformis	
Cymbella microcephala	
Cymbella pusilla	
Amphora spp.....	Valves convex and without transverse costae.
Amphora perpusilla	
Amphora veneta	
S0. Surirellineae.....	True raphe on both valves but concealed in a keel.
F. Surirellaceae.....	Raphe in a marginal position on both margins of a valve.
Cymatopleura spp.....	Face of valve transversely undulate.
Surirella spp.....	Face of valve not transversely undulate and flat or spiral.
Surirella ovata	
F. Nitzschaceae.....	Single excentric keel next to one lateral valve margin.
Denticula spp.....	Frustules with transverse septa.
Hantzschia sp.....	Frustules without transverse septa; raphes opposite.
Nitzschia spp.....	Frustules without transverse septa; raphes diagonally opposite.
Nitzschia acicularis, N. amphibia,	
Nitzschia communis, N. dissipata,	
Nitzschia filiformis, N. frustulum,	
Nitzschia microcephala, N. palea, N. valdestrata	

\*C--class, S0--suborder, and F--family; genera and major diatom species are also listed.
