“ The stomach is lodged partly in the breast and back, but the greatest portion of them is in the abdomen. When swollen with blood, it appears of a dark brown colour, which is visible through the skin, and is either a faint red, or a full or bright brown, as the contents of the stomach are more or less changed. Where the stomach joins the breast above, its figure resembles a fork with two teeth; these are two hidden appendages of the stomach, which go deep into the breast, and on either side near the gullet and spinal marrow, and reach to the first pair of legs. These are those two blackish, transparent and coloured parts, which I have mentioned in general in the history of the external parts.

“ The part of the stomach connected with the abdomen, deserves particular consideration; it is formed like an oblong bag, which is here and there continually contracted and again extended: When it is empty, it is colourless, and the stomach and its appendages are transparent. But as the stomach fills, the colour is seen plainly through the outward skin. It manifestly consists of two coats, the outward is thicker, the inner very thin, as it is in all insects. Nay, it is probable that it has three coats, and that the third is muscular.

“ The outward coat of the stomach is furnished with so great a number of pulmonary pipes as can hardly be expressed in words. The longer branches are very conspicuous in it, but the smallest cannot be discovered, except by the assistance of the best microscopes. On the contrary, the inward coat is very thin; the third, which I suppose to be situated between the two former, comprehends, without doubt, the muscular fibres of the stomach, by the help of which it performs its wonderful motions. The coats of the stomach, especially the outmost, appear to consist of very many globular little grains, which are very irregular in form; but whether these little grains properly belong to the texture of the stomach, or whether they are rather particles of the fat, which cover the stomach, whereby the pulmonary pipes are gently moved, I could not well discern; only this I know, that the greatest part of them, when often touched, retire from the stomach.

“ Underneath, in the abdomen, on a little rising, or prominence, nearly in the middle of the stomach, there is seen a certain little part, which Doctor Hook apprehends may be the liver; but I should rather take it to be the pancreas, or sweetbread,

though there want sufficient arguments to prove it. Its colour is not properly whitish, but somewhat inclining to yellow; and it is so strongly connected with the stomach, that it cannot be easily separated from it. If this be laid before the microscope, it may easily be divided into many little grains, like glands, but these are not very transparent. When it is accurately viewed by the microscope, the pulmonary pipes also appear in it. The substance of this little part is more firm than that of the rest, for when it is extracted from the body and dried, it is but little diminished. It is of a very irregular figure, and is formed divers ways in almost every Louse, being sometimes greater and sometimes less; but it is always finished in the same general manner, by reason of its bendings and situation over the stomach.

“ At the lower region of the stomach is seen the pylorus, and immediately from this, the intestinum tenue, or small gut, which is extended on each side, and formed like the stomach: this is also provided with a great many pulmonary pipes. At the end of this small gut, which is for the greatest part bent in a serpentine manner, or like the letter S, are discovered four small vessels, which the sagacious and excellent anatomist Marcellus Malpighius, has called the swollen vessels in silk-worms; but these are straighter and less inflected than the Louse; they are considerably long, and of the same texture with the intestines. These four little vessels are properly four intestina cœca, or blind guts, which I have found in all insects; wherefore, by inference, I call them here by this name, though I never have had the fortune to see their extremities. They open into the intestine, from whence they arise at the place just mentioned. After these appears the little intestine colon, and at the end of that, there is a manifest dilatation or extention, which is the cloaca, or place where the excrements acquire their figure; for they are very irregular, and not like those of other insects, which are usually formed in a singular and regular manner. Within this dilatation appears the intestinum rectum, which shews its aperture, as the anus situated upon the belly, between the division of the tail; and just under this the skin is very bristly.

“ As to the motion of the stomach, it is truly admirable; insomuch that one might suppose it an animal within an animal, by reason of the strong agitations, contractions, dilatations, corrugations, and expansions, all which belong to it, and strike one with amazement, the whole being plainly seen through the body. These appear plainly at the time when the stomach is full of food, but they are best of all seen, when the blood passes into it at the time of sucking; for then it is sometimes observed, that the remainder of the old aliment is mixed with the new, and is shaken and agitated up and down, and on every side, in the stomach. This may be seen the more distinctly, as the colour of the contents is more dark.

“ Hence one may easily conceive what strange changes and emotions the pulmonary pipes on the stomach undergo at that time, and after what various ways the air contained in them is pressed, moved, propelled, and so purified; changed from its first nature, and rarified within the creature. But who can discover, by the most diligent researches, the use of the air in that place? surely no one. Yet, very wonderful motions are observed on this occasion, particularly in that little part which I called the pancreas, or sweet-bread; for this being connected with the stomach, must obey all its motions. These motions are continually repeated by turns, and undergo an infinite number of variations.

“ As to the method whereby the Louse sucks the blood, and conveys that nourishment into the sto-

mach; it is performed thus, by the assistance of the proboscis, and its aculeus or point. First, if the Louse has abstained from food two or three days, it becomes very hungry, which is discoverable from the empty stomach, and because the creature is then wholly transparent; in this case, immediately as soon as he is placed on the hand, he seeks for food, which he will the sooner and more readily find, if the hand be first rubbed until it grows red. Then the Louse turns its head, which lies between the two fore legs; to the skin, and diligently searches for some pore of sweat: when he finds it, he fixes his aculeus or sucker therein; a little after this, the blood is observed, through the microscope, to ascend to the head, in a very rapid; and, as it were, frightful stream:

“ The Louse has at that time matter enough to feed on in any pasture; for if it finds any hairs on the hand, by which it does not desire to descend, it stays in that pasture, and sucks with its head down, and its tail elevated. I have likewise observed, that it sometimes sucked with its belly upward, that is, when the hair it took hold of was bent down; and then the motion of the stomach, and pancreas, or sweet-bread, might be seen most beautifully by the help of a microscope.

“ But I should think the principal use of the claws, which I have described to be situated at the end of the sheath or case of the aculeus or sucker, is to assist the creature in sucking, and that the aculeus serves for this purpose; for whilst these are strongly fixed in the superficies of the inner skin, and in the extremities of the pores, they enable the Louse to use its aculeus the more freely, and to move it at discretion, when the end of its sheath is placed firm and immoveable.

“ Sometimes, whilst the Louse was sucking, I have strongly pulled the skin of my hand aside, that by this means the sheath, or rather its claws, together with the aculeus or sucker, might be bound fast in the skin, and the Louse could not disengage itself. This affords, indeed, a very agreeable sight. This I did with a design, that if I could thrust the Louse out of its place, I might the more plainly see the aculeus: but I could never accomplish my desire in this particular, though I had then almost wished to have three hands, that I might the better find what I wanted. There are some speculations and researches in anatomy that will not bear writing, since they almost distract the mind.

“ When the Louse is employed in sucking, a very small rivulet of blood immediately appears behind the aculeus or sucker, which is seen through the transparent head. Between and before its eyes, on the middle of the head, there is observed also a considerable dilatation, for the jaws are there remarkably expanded, by the blood continually ascending. These parts are so swiftly contracted again, that there scarce remains the least sign of blood after a moment, and both are performed with such velocity, that the dilatation can hardly be distinguished from the contraction; wherefore I do not know how to explain this matter more properly, than by the sudden oscillation of the pendulum of a clock. Behind the eyes, a small rivulet of blood is likewise observed to run down within the head: this passage may be properly called the œsophagus or gullet, which lies behind the jaws, and grows wide again in the Louse's neck, as has been shewn before. I have chosen to exhibit all these as one continued canal, that my description may be the more clear.

“ After the blood has ascended to the jaws, and comes to the gullet, we observe that it is immediately conveyed to the stomach, and that the bifurcated appendages, as well as the stomach itself, are at once filled with it. The motions of the stomach are then remarkably increased, its muscular parts being

being distended; for as these muscular parts are then stretched, they have an opportunity of contracting themselves again. Wherefore it is immediately observed, that the excrements in the large guts begin likewise to move; nay, it usually happens, that the Louse discharges them during the sucking.

“The food being thus received into the stomach, is agitated about in a wonderful manner; it is moved up and down, and by contractions and dilatations, which are not to be described, then performed by the stomach, is, as it were, sifted. After this, it is seen, that the contents first begin to divide into parts in the back, or hinder portion of the stomach, and they then appear like raisins preserved in jars, and are thus distributed through the body. However, this is a false appearance; it arises from hence, that the skin being divided into many grooves, is not equally transparent every where, and that some difference is in this respect seen through it, because the grooves are not equally transparent with the intermediate parts. Nay, the particles of the internal fat not being uniformly visible through the skin, and obscuring the brightness of the skin, conduce likewise to deceive the sight, as if the retreating blood entered into many peculiar vessels. To this may be added, that the blood has not at that time a homogeneous or equal colour, for its parts separate from each other. From these appearances, before I had accurately examined things, I thought that the blood was distributed out of the stomach, through various vessels, into the other parts of the body; but I afterwards observed that the phenomenon arose, as well from the blood itself, as from the different colours of the parts through which it was seen, and which I then took to be vessels. Perhaps others, especially Dr. Hooke, who first prejudiced me in favour of this opinion, have split on the same rock. I have not as yet made this experiment on the smallest Lice, in which more peculiarities may probably be seen, than in the larger kind.

“I have likewise resolved to receive the blood, when changed in the stomach, into a glass tube, and then to view it in the open air, or in some dark place by candle-light; but this I have not hitherto done, being hindered from making this, as well as many other experiments which I had a mind to try. In some hours after feeding, the contents of the stomach are observed to become insensibly more brown or blackish, and to diminish slowly; wherefore the intestines are afterwards seen to be more and more distended with excrements, which sometimes lie in them regularly divided, as it were, into globules. The reason of this is, that the intestines do not, at one and the same time, contract themselves about the fœces, and therefore they cast or extrude them out of the body at different times. I have already treated of the muscles of the abdomen in this insect, I shall now proceed to the parts of the breast.

“In this part, and in the back, are seen several muscles, which move the legs and head; and herein are also visible the appendages of the stomach, and a great number of pulmonary pipes and particles of fat. In the same view is also seen the gullet and spinal marrow, together with the nerves arising from thence, of which I shall now speak distinctly.

“In the middle of the back is seen a certain tendinous point, under the small shield there situated, where the skin does not appear to be so transparent as in the rest of the body. This shield seems there to be hollow, being thrust down into a little pit. At this point almost all the muscular fibres are seen to concur, and their motion and contraction are here very visible. As to the appendages of the stomach, and other parts of the breast and back, we have before treated of them at large.

No. 31.

“The spinal marrow is properly situated in the breast, and therein reaches to the insertion of the last pair of legs. When this is discovered, it is easy to judge what that short whitish groove is, which appears through the breast, between the appendages of the stomach; for these appendages are placed on both sides of the spinal marrow. The structure of the spinal marrow itself, does not differ much from that found in the worm, from which the *Scarabæus Nasicornis*, or Horned Beetle, by the ancients consecrated to Mercury, is produced, as is manifest from the history and figures of the latter. It consists of three remarkable swellings, expansions, or dilatations, from which, on either side, we observe three nerves to arise, which reach to the muscles of the six legs; but underneath, or in the hinder part of it, I distinguished six nerves issuing, which doubtless are distributed through the rest of the viscera, to give them life, sense, and motion. The lowest of those little knots, whereof the spinal marrow is composed, is formed in a different manner from the upper ones, which are alike. The membrane which covers the marrow is interwoven with a great many pulmonary pipes, and seems to be composed of irregular and globular little parts, in the same manner as we have shewn in respect of the coat and stomach; and this texture, together with the great number of pulmonary pipes belonging to the part, afford a very agreeable sight in the living insect.

“I could discover no fibres in the nerves, which arise from the posterior part of the marrow, though I viewed them fresh with the microscope; they seemed indeed to be made up of a homogeneous, bright and transparent matter, and at their sides were hung a great many pulmonary pipes, with particles of fat. The origin of the marrow, where it is connected with the brain, is seen like a fine thread. But in all other insects this beginning of the marrow is perforated, and through its aperture or cavity the gullet passes.

“The brain of the Louse is shaped like a pear, and is divided into a right and left part. The dura mater, surrounding it, is formed like the membrane which covers the marrow, and is provided with pulmonary pipes and particles of fat. I can very easily at any time shew the marrow, but the demonstration of the brain must be obtained rather by chance, than with any premeditated design or art; it is clearly seen, when by any accident it happens to be stript of the parts wherewith it is covered.

“The optic nerves are short, and the eyes, which are connected to them, are so small, that I could not dissect them to my satisfaction; as well because this operation is but awkwardly performed under microscopes, which magnify objects so much, that all instruments are too coarse for this purpose. Thus much, however, I distinctly saw, that this black part in the eyes might be separated or lifted up from them; which part in other insects I call the tunica uvea, not being situated at the bottom, but on the superficies of the eye; after this appears the tunica cornea; this seemed divided, as it were, into hexagons, as it is in other insects, though the other was not; but that I would not affirm for certain, for we are not to suppose or imagine, but to pursue by our senses, and discover the actions and productions of nature. This opinion, however, does not please some anatomists, who therefore esteem all comments on the brain merely as ingenious fancies. The younger Bartholinus, who, speaking of the fiction that silk-worms had no brain, expresses himself thus: “Behold, how many are pleased with their own blindness! who, altho’ they are blind, and shall for ever remain so, yet cry aloud they can see, since these their contemptible works, which ought to be removed from their eyes, and buried in oblivion, are lasting monuments of their cloudy arrogance; for

by this means they might afterwards seek for the light of the truth."

"Whether Lice are distinguished by the parts of generation, into males and females, as other insects are, I could not discover. Heretofore, indeed, I had sometime remarked, that Lice get upon each other; but this I could not observe while employed in this dissection. I found an ovary in every one of forty, which I dissected; this almost inclined me to think, that these little animals are hermaphrodites; and perhaps they really have in each animal the generative parts in the same body, as I have found in snails. Whether, indeed, it be so, is still a secret to me; for though I saw the ovary very distinctly, I could discover that only, notwithstanding the great hopes I had of finding it, from having observed, that all kinds of insects have very large organs of generation.

"The ovary is extended through the whole cavity of the abdomen, so that with its appendages it reaches even to the breast. It has an opening distinct from the end of the intestines, for as the upper part of the fundament is placed in the division of the tail, in which the abdomen ends; so, on the contrary, the vagina or mouth of the ovary opens into the lower part of the abdomen, where the body is divided, as it were, into two parts. The ends or extreme appendages of the oviduct, or egg-passage, are like two tubes, naturally joined in one point. In the oviduct are seen at once perfect eggs, and their rudiments or principles; so that in one ovary I have counted ten larger and forty-four smaller eggs, together making fifty-four. In the uterus I saw one perfect egg, which was fallen down ready for birth: at that time these little eggs are called nits.

"The ovary is double in all Lice, and every part of it is subdivided into five oviducts, which on each side end in one common canal; next comes in sight the uterus, in which the egg acquires its full perfection. Where the uterus ends, is seen a sacculus or bag full of a glutinous matter, opening in that part into the uterus; this is designed for fastening the eggs, whilst they are laying; the same may be likewise observed in many other insects, and particularly in bees. I must acknowledge that I have not seen the glutinous matter contained in this bag; but I infer, from the situation and structure of the part, that the bag was designed for keeping such a substance. After this appears the neck of the uterus, and therein is a small dilatation or expansion; by means of which, the ovary immediately opens itself into the outward womb.

"The oviducts embrace the eggs so closely, that scarce any difference is observed between them, nor can we separate the oviducts from the eggs, without great labour; when we do this, a great many bags of fat issue from thence, which obstruct the sight. It therefore has appeared to me, that the structure of the oviduct is the same with that of the stomach and intestines; though the texture of this part is nevertheless more delicate, and that the globular particles proceed from thence with greater ease, than in the other viscera. The oviducts are provided with many pulmonary pipes, of which, as we have already observed, this little animal has a very large number, though no bigger than a point; its structure and viscera, which excel all human art, the greatest geniuses ought to be amazed at, as I have here, though briefly, yet clearly explained and demonstrated. I am persuaded that I might make many more discoveries in it, if I had more time for that purpose, since I have completed this dissection, and discovered these remarkable miracles in this microcosm, or little world, in the space of six days. If the learned Daniel Heinsius had searched for these things in nature herself, and not in his own fancy, and in books, he would not have written so poor an encomium on this insect.

"As to the structure of the external skin of the Louse, it affords many particulars worthy of observation, nor is there any thing that bears a greater likeness to it, than stiff and transparent parchment: it is in several places marked with small grooves or channels, in the same manner as the ends of our fingers; which, when viewed with the best microscopes, really seem to be so many divisions of pulmonary pipes. But the lens of the microscope must, for this purpose, be carefully managed; for as it is turned one way or another, different things are seen: one cannot bring the lens nearer, or remove it further, by the least distance, but something is immediately perceived by the sight, which was not observed before. Globular particles, sometimes appear in the place of channels, or oblong pipes, tho' the eye is always fixed on the same part; then between the grooves themselves, where the skin is simply membranaceous, globular particles are likewise observed. In other places, as in the extremities of the abdomen, the structure of the skin is different; for there it seems to be composed, as it were, of irregular squares; wherein circular grooves may be seen in one part; in another globules; in a third, both globules and grooves, nay, sometimes the plain transparent skin only is seen full of points; all which, as we have before observed of the oblong grooves, are represented according to the transparency of the parts, which have not been yet totally separated from the inner surface of the skin; or just as the microscope is moved, somewhat nearer to, or farther from the skin."

NATURAL HISTORY of the BUG.

THIS also is a nauseous insect, which intrudes upon the retreats of mankind. The night is usually the season when the wretched have rest from their labour; but this seems the only season when the Bug issues from its retreats to make its depredations. It cunningly avoids the light; but when darkness promises it security, it issues from every corner of the bed, and greedily attacks its prey. Happily, however, for Great-Britain, they multiply less in that island, than in any part of the continent: in France and Italy the beds swarm with them; and in those countries they grow larger, and bite with a more cruel appetite than they do with us.

This animal consists of three principal parts; the head, the corselet, and the belly. It has two feelers, with three joints; beneath these there is a crooked trunk, which is its instrument of torture, and which lies close upon the breast when it is in motion: the breast is a kind of ring, and the belly consists of nine rings. It has six legs: its body is smooth, except that it has a few short hairs near the vent, which may be seen by the microscope: its motion is slow and unwieldy. The smell of this insect, when killed, is insupportable.

Linnæus reckons up forty of the Bug kind; but the principal are the common Bug; the green and yellow Bug; the plant Bug; and the grass Bug.

NATURAL HISTORY of the WOOD-LOUSE.

THIS insect seldom exceeds half an inch in length, and a quarter of an inch in breadth. Those found about dunghills, and on the ground, are usually of a livid black; but those found under timber, tiles, and in drier places, are of a lighter colour. Of this insect Linnæus makes three species; that with seventy feet on each side; that with fifty; and that with twenty: it has two short feelers, and the body is of an oval shape. When touched, it rolls itself up into a kind of ball; and the sides, near the

the feet are dentated like a saw. Wood-Lice have great medicinal virtues, being impregnated with a saline quality, which is diuretic and stimulating.

The MONOCULUS, or WATER FLEA.

Water Fleas are of a blood colour, and are sometimes seen in such multitudes on the surface of standing water, that many people have taken it for blood. It is peculiar to the water, and has the legs before divided into branches, with which it either swims or leaps, and the body is covered with a crust or shell. It appears to have but one eye.

NATURAL HISTORY of the SCORPION.

THIS is one of the largest of the insect tribe, and is not less terrible from its size than its malignity. Its shape somewhat resembles that of a lobster, but is infinitely more hideous. Nine different kinds of this dangerous insect have been enumerated; but they are principally distinguished by their colour: some are yellow, others brown; some are of an iron grey; and others are black, red, and white. The head of the Scorpion seems to be joined to the breast; in the middle of which are seen two eyes, and two others are placed more forward in the fore part of the head: these eyes are so small as to be almost invisible. On each side of the head are two arms, each composed of four joints; the last of which is large and strong, and resembles a lobster's claw. Below the breast are eight articulated legs, each divided into six joints, the two hindmost of which are each provided with two crooked claws. The belly is divided into seven little rings; and the tail is composed of six joints, which are bristly, and appear like little globes; the last being armed with a crooked sting: this is that fatal instrument which renders this insect so truly mischievous and formidable. As it generally takes shelter in houses, it frequently stings those among whom it resides. In some of the towns of Italy, and in the province of Languedoc, in France, it is one of the greatest pests that torment mankind: but by the natives of Africa and the East, their malignity is woefully experienced. In Batavia, where they grow twelve inches long, a piece of furniture cannot be moved in the house without the utmost danger of being stung by them. We are assured by Bosman, that, along the Gold Coast, they are frequently seen larger than a lobster; and that their sting is inevitably fatal. In Europe, however, they are neither so plenty, so large, nor so venomous. There it seldom exceeds two or three inches in length, and its sting is not often fatal.

NATURAL HISTORY of the SCOLOPENDRA and GALLY WORM.

WE know little except the figure and the noxious qualities of these insects. We have some in this country that resemble them in form, but we are placed at a happy distance from such as are really formidable. With us they seldom exceed the length of an inch, but in the tropical climates they are sometimes found nine inches long. The Scolopendra, from the number of its feet, is also called the centipede. Those of the East Indies are about six inches long, of a ruddy colour, and as thick as a man's finger: they consist of many joints, and have a leg on each side of every joint: they are covered with hair, and seem to have no eyes: the head is round, and furnished with two small teeth, with which they inflict wounds that are painful and dangerous.

The Gally Worm differs from the Scolopendra in having double the number of feet: some of them are smooth and others hairy; some are black, others yellow, and others brown. When touched, they all roll themselves up in a ball. In Europe they are perfectly harmless. All these, as well as the scorpion, are produced perfect from the parent or the egg, and suffer no changes after exclusion.

NATURAL HISTORY of the LEACH.

THE common Leach is a water insect: it has the general figure of a worm, and is about as long as a man's middle finger. Its skin is composed of rings, by means of which it swims with some agility in the water. When out of the water it contracts itself in such a manner, that, when touched, it is not above an inch long. It has a small head, and a black skin, edged with a yellow line on each side: the belly is of a reddish colour, marked with whitish yellow spots. It is remarkable, that the mouth of this animal can assume whatever form it finds convenient. When at rest, however, the opening is usually triangular, and within it are placed three very sharp teeth. These animals are very useful in medicine, and when they are applied, they should be taken from the water, in which they are contained about an hour before, for they thus become more voracious, and fasten more readily. The most remarkable particular of this animal is, that tho' it takes a large quantity of food, it has no passage to eject it from the body when it has been digested: it is supposed to go off thro' the pores of the body.

The *horse-leach* is larger than the former, and grows to four inches in length. It has a smooth glossy skin, black on the back, spotted with grey. It is of no use, as it will not stick to the skin.

The *snail-leach* is about an inch in length, and of a very flat shape: its skin is smooth and glossy, and of a whitish colour. This leach will stick, tho' it is not large enough to extract a sufficient quantity of blood from the patient.

The *broad-tailed* Leach grows to an inch and an half in length, and has a smooth glossy skin, of a dusky brown colour. The back is raised into a kind of ridge. It will stick but on very few occasions. It is common on stones in shallow running waters.

NATURAL HISTORY of the LIBELLA, or DRAGON FLY.

THESE insects are called by different names in different parts of the kingdom: they are of all colours, blue, green, crimson, white, scarlet, or a union of the most agreeable tints. They are distinguished from all other flies, by the length of their bodies, the largeness of their eyes, and the beautiful transparency of their wings, which are four in number. Though there are three or four different kinds of Dragon Flies, they all agree in the most striking parts of their history. The largest are from two to three inches long; their tail is forked: their body divided into eleven rings; and their wings are of a beautiful glossy transparency. They have two teeth, covered with a beautiful lip; they bite fiercely when they are taken; but their bite is perfectly harmless. These animals are produced from eggs, deposited in the water; they afterwards become worms, and have six legs; they continue in their reptile state for a year; at length their wings expand, and they enter upon the flying state.

NATURAL HISTORY of the ANT-LION.

THIS insect in its reptile state, is of the size of a common wood-louse, but somewhat broader. It has a longish head, and a roundish body, which becomes a little narrower towards the tail. The colour is a dirty grey, speckled with black. The body is composed of several flat rings, which slip one upon another. It has six feet, four fixed to the breast, and two to the neck. It is generally produced in autumn, and in about a year afterwards it assumes a winged form, and becomes a large and beautiful fly of the libellular kind, with a long slender body of a brown colour; with large bright eyes, long slender legs, and four large transparent wings.

NATURAL HISTORY of the GRASS-HOPPER, and the LOCUST.

THERE are a tribe of little animals, which, though differing in size and colour, strongly resemble each other in figure, appetite, and nature. Of this variegated tribe, the common Grass-Hopper, that is found in such plenty in every meadow, and that continues chirping through the summer, is best known to us; and a history of that will contain a history of all the rest. The colour of this animal is green, with a line of brown which streaks the back, and two pale lines under the belly and behind the legs. The head is oblong, in some degree resembling that of a horse. The mouth is armed with teeth of a brown colour, hooked at the point. The corset is elevated, narrow, armed above and below by two ferrated spines. The back is armed with a strong buckler. The last pair of legs are longer and stronger than the first two pair, fortified by thick muscles, and admirably formed for leaping. It has four wings; the belly is composed of four rings, and terminated by a forked tail.

The Grass-Hopper, though seemingly without wings; is in reality possessed of them from the first, but it cannot break the bonds by which they are folded up, till it has been excluded above twenty days. When arrived at their winged state they are still vocal, and in the midst of summer, are heard much louder at sun-setting than during the heat of the day. Though slow in flight, they are sometimes seen to fly to considerable distances.

The larger kinds differ from this only in size, rapidity of flight, and the powers of injuring mankind, by swarming upon the productions of the earth. The grass which is destroyed by a few Grass-Hoppers which sport in our fields can be of no great consequence; but when a swarm of Locusts, two or three miles in length, and several yards in depth, settle upon a field, the consequences are frightful.

Europe is seldom visited by them in this manner. Those which were seen in several parts of England in the year 1748, were the great brown Locusts, and dreadful consequences were apprehended from their appearance. They were about three inches long.

Locusts are eaten by the natives in many kingdoms of the East. They certainly were a common food with the Jews, as Moses, in the book of Leviticus, permits them to eat four different kinds of this animal, which he particularly specifies.

The great West Indian Locust is the most noxious of this tribe of animals. It is armed with a sting, and those who touch it are sure to be stung by it: a little palm-oil, however, is a certain cure for it.

NATURAL HISTORY of the CRICKET.

THIS insect resembles the grass-hopper in its shape, its voice, and its leaping; but its colour is uniformly of a rusty brown. Its residence is most usually in the warmest chinks behind a country hearth. It is of a most chilly nature, seldom quitting the fire side. It is a voracious little animal, and will eat sugar, bread, meat, or flour. Except in the very coldest weather, they never cease their chirping.

There is a species of this insect that lives entirely in the woods and fields.

The Mole-Cricket is a very large insect, being two inches and an half in length, and three quarters of an inch in breadth. It chiefly resides under the surface in soft garden grounds, and is very injurious to gardeners.

NATURAL HISTORY of the EARWIG and the FROTH INSECT.

THE Earwig is so common as hardly to require a description: it is equally remarkable for its swiftness in the reptile state, and its velocity when it has arrived to its winged state. It is very prolific, and very harmless. The name, and the deformity of its figure, have subjected it to an imputation which has often procured its destruction. It is said that it often enters into the ears of people sleeping; thus causing madness from the intolerable pain, and soon after death itself; these reproaches, however, are entirely groundless: it were to be wished, that the accusations which gardeners bring against the Earwig were as slightly founded. At length the wings of this animal burst from their confinement, and when it becomes a winged insect it flies in pursuit of the female, ceasing to feed, and is wholly employed in the business of propagation. After having lived a few days in its winged state, and taken care for the continuance of posterity, it dries up and expires.

To this order of insects belong the Cuckow-Spit or Froth-Worm, that is often found in the frothy matter on the surface of plants. The Water Tipula, the common Water Fly may be classed in the same order. To these may be added the Water Scorpion, which is near an inch in length, and half an inch in breadth. The Water Scorpion lives in the water by day, out of which they rise into the air in the dusk of the evening, and often betake themselves to other waters in quest of food.

NATURAL HISTORY of the EPHEMERA.

THERE are several kinds of Ephemeræ, which are of various colours, as brown, yellow, and cream-coloured. It appears surprizing that there should be a tribe of flies whose duration extends but to a day; but some of this kind seem to be born and to die in a much shorter time: the reptile, however, from which they are bred, are sometimes known to live two or three years. They are produced from the egg in the form of worms, from whence they change into the form of aurelias; and from thence they take their last mutation, which is into a beautiful fly, of a shorter or longer duration, according to its kind. In its fly state, it is a beautiful winged insect, and strongly resembles the butterfly. But though the usual date of these flies is five or six hours, there are some kinds that live several days.

NATURAL HISTORY of the CATERPILLAR, BUTTERFLY, and MOTH.

CATERPILLARS are readily distinguished from worms or maggots by the number of their feet, and by their producing Butterflies or Moths:

WINGED INSECTS

BUTTERFLIES

MOTHS

BEE

Moths. All this class have from eight to sixteen feet; and the animal into which they are converted is always a Butterfly or a Moth. It is well known, that all these little animals are hatched from the eggs of Butterflies, and, during winter, the greatest number of Caterpillars are in an egg state. When it has strength to break its shell, it always finds its favourite aliments provided in abundance before it.

The body of a Caterpillar is composed of rings, which are generally twelve in number; by which they may be distinguished from any other insects that resemble them. The head is connected to the first ring by the neck: the jaws are placed rather vertically, and each jaw is armed with a large thick tooth. With these the animals devour their food in amazing quantities. A single Caterpillar will eat double its own weight of leaves in a day, without appearing to be disordered by the meal.

With regard to their external figure, Caterpillars are either smooth or hairy; they have in general six small black spots on the circumference of the fore ring; three of which are larger than the rest, which Reaumur supposes to be eyes. This insect has nine holes on each side of the body, through which it is supposed to breathe; they are called the stigmata.

The life of the Caterpillar seems to be one continued succession of changes, and, before the great metamorphosis, changes its skin eight or ten times. At length it becomes an aurelia; and one would imagine, that they were conscious of the precise time of their continuance in their aurelia state; their little sepulchres, with respect to their solidity, being proportioned to such duration. At length the Butterfly bursts from its aurelia skin, and decorates our fields with its symmetry and beauty.

The number of Butterflies is very great: Linnæus has reckoned up above seven hundred and sixty different kinds, and the catalogue is still very incomplete. Those of the warmer climates, however, are larger and more beautiful than such as are bred at home.

It is not by day alone that these animals are seen fluttering wantonly from flower to flower, as the greatest number of them fly by night, and expand the most beautiful colouring, at those hours when there is no spectator. They are therefore divided into diurnal and nocturnal flies; or Butterflies and Moths. They may be readily distinguished from each other by their horns or feelers: those of the Butterfly being clubbed or knobbed at the end: and those of the Moth tapering finer and finer to a point. The female Moth lays its eggs soon after it leaves the aurelia, but many of the Butterflies do not think of providing for posterity till the summer is far advanced.

NATURAL HISTORY of the SILKWORM.

THIS little animal, which only works for itself, has been of infinite service to the human race, and furnishes them with a more beautiful covering than can be supplied by any other animal. It is imagined, that Silkworms were not brought into Europe till the beginning of the twelfth century; when Roger of Sicily brought some manufacturers in silk from Asia Minor, on his return from his expedition to the Holy Land, and settled them in Sicily and Calabria. From these this manufacture was taught to the other kingdoms of Europe.

The Silkworm is a large caterpillar of a whitish colour, with twelve feet, and is afterwards transformed into a butterfly of the moth kind. The cone on which it spins, is formed for covering it while it remains in the aurelia state; and several of these, when properly wound off, and united together,

form those strong and beautiful threads, which are woven into silk: and, as our luxuries are increased, the silk manufacture is become one of the most lucrative of any in the southern provinces of Europe.

Previous to spinning its web, the Silkworm seeks for a convenient place to erect its cell, without any obstruction. Having found a leaf, or a chink fitted to its purpose, it begins to writhe its head in every direction; and fastens its thread on every side to the sides of its retreat.

In the course of a fortnight or three weeks the aurelia is changed into a moth: no sooner is the winged insect completely formed, than having divested itself of its aurelia skin, it prepares to burst through its cone, or outward prison, and by repeated efforts becomes emancipated. This animal, in its fly state, seems produced for no other purpose than to transmit a future brood. It neither flies nor eats; the male only seeking the female; their union continues for about four days without interruption; the male then dies, and the female survives him only till she has laid her eggs; which in the ensuing spring, are hatched into worms.

NATURAL HISTORY of the BEE.

THE Bee is a small and well known insect, famous for its industry.

This useful and laborious insect is divided by two ligaments into three parts or portions, the head, the breast, and the belly. The head is armed with two jaws and a trunk; the former of which play like two jaws opening and shutting to the right and left. The trunk is long and taper, and, at the same time, extremely pliant and flexible, being destined by nature for the insect to probe to the bottom of the flowers, through all the impediments of their chives and foliage; and drain them of their treasured sweets: but were this trunk to be always extended, it would prove incommodious, and be liable to be injured by a thousand accidents, it is therefore of such a structure, that, after the performance of its necessary functions; it may be contracted, or rather folded up; and besides this, it is fortified against all injuries by four strong scales, two of which closely sheathe it, and the two others, whose cavities and dimensions are larger, encompass the whole. From the middle part or breast of the Bee grow the legs, which are six in number: and at the extremity of the paws are two little hooks, discernible by the microscope, which appear like sickles, with their points opposite to each other. The wings are four, two greater and two smaller, which not only serve to transport them through the air, but, by the noise they make, to give notice of their departure and arrival, and to animate them mutually to their several labours. The hairs with which the whole body is covered, are of singular use in retaining the small dust that falls from the chives of the flowers, of which the wax is formed. The belly of the Bee consists of six rings, which slide over one another, and may be lengthened or contracted at pleasure; and the inside of this part of the body contains the intestines, the bag of honey, the bag of poison, and the sting. The office of the intestines is the same as in other animals. The bag of honey is transparent as crystal, containing the sweet juices extracted from flowers, which the Bee discharges into the cells of the magazine for the support of the community in winter. The bag of poison hangs at the root of the sting, through the cavity of which, as through a pipe, the Bee ejects some drops of this venomous liquor into the wound, and so renders the pain more excessive. The mechanism of the sting is admirable, being composed of two darts, enclosed within

within a sheath that tapers into a fine point, near which is an opening to let out the poison. The two darts are ejected through another aperture, which, being armed with several sharp beards like those of fish-hooks, are not easily drawn back again by the Bee; and indeed she never disengages them, if the wounded party happens to start and put her into confusion; but if one can have patience to continue calm and unmoved, she clinches those lateral points round the shaft of the dart, by which means she recovers her weapons, and gives less pain to the person stung. The liquor which at the same time she infuses into the wound, causes a fermentation, attended with a swelling, which continues several days; but that may be prevented by immediately pulling out the sting, and enlarging the puncture, to let the venomous matter have room to escape.

Let us now consider the generation, polity, and labours of these insects, the true knowledge of which is very much owing to the modern invention of glass hives, through which all the secrets of the community are laid open to a curious observer. Any person who carefully examines a hive at different seasons of the year will distinguish three sorts of Bees; of which the far greater number are the common working Bees, who do all the business of the hive, and seem to be neither male nor female. The working Bee. The second sort, called drones, are the males, and somewhat larger than the former; they have no sting, nor ever stir from the hive, but live upon the honey prepared by the others. The third sort is a much larger and longer bodied Bee, of which there are often but one in every swarm or colony of young Bees, who are from time to time detached from the hive in search of another habitation. This large Bee is what the ancients called the king, from the respect they always saw paid to it by the other Bees; but being the female, the moderns more properly give the title of queen, or mother of the swarm.

When these industrious insects begin their works, it is observed they are divided into four parties, one of which is destined to the fields to provide materials for the structure; the second works upon those materials, and forms them into a rough sketch of the dimensions and partitions of the cells; the third examines and adjusts the angles, removes the superfluous wax, polishes the work, and gives it its necessary perfection; and the fourth is employed in bringing provisions to the labourers that build them, because polishing is not so laborious. They begin their work at the top of the hive, continuing downwards to the bottom, and from one side to another; and to make it the more solid, they use a sort of tempered wax, resembling glue. The form of the cells of the honey-comb is hexagonal, which figure, besides what is common with a square and equilateral triangle, has the advantage of including a greater space within the same surface.

The expedition of the Bees in their labour, is almost incredible; for notwithstanding the elegance and just proportions of the work, they are so indefatigable, that they will, in one day, finish a honey-comb a foot long, and six inches broad, capable of receiving three thousand bees.

When the cells are completed, the queen takes possession of those she likes best to deposit her eggs in, and the rest are left to be filled with honey. She lays one egg in each cell, and sometimes more than an hundred of those eggs in a day; but what is still more remarkable, she lays those eggs which are to produce common Bees, in cells of the common shape and size; those that are to become drones or males, in the cells of a larger size; and deposits those which are to become females, like herself, in the spheroidal cells already described.

These eggs, after lying some time in the cells, are

hatched into maggots, and fed with honey ten or twelve days, after which, the other bees close up the cells with a thin piece of wax; and under this covering they become gradually transformed into Bees, in the manner as silk-worms are into butterflies. Having undergone this change, the young Bees pierce through their waxen doors, wipe off the humidity from their little wings, take their flight into the fields, rob the flowers of their sweets, and are perfectly acquainted with every necessary circumstance of their future conduct. As to the males or drones, which are destined only to propagate their species, they live very comfortably for about three months after they are hatched; but when that time is over, and the females are impregnated, the common Bees either kill them, or drive them from the hive, as burthensome to the community, and not a drone is to be found till the next season.

It is an excellent observation of a modern author, that the hive is a school to which numbers of people ought to be sent; prudence, industry, benevolence, public spiritedness, œconomy, neatness, and temperance, are all visible among the Bees. These little animals are actuated by a social spirit, which forms them into a body politic, intimately united, and perfectly happy. They all labour for the general advantage; they are all submissive to the laws and regulations of the community: having no particular interest, no distinction but those which nature or the necessities of their young have introduced amongst them. They are free, because they only depend on the laws; they are happy, because the concurrence of their several labours inevitably produces abundance, which contributes to the riches of each individual. Let us compare human societies with this, and they will appear altogether monstrous. Necessity, reason, and philosophy, have established them for the commendable purposes of mutual aid and benefits: but a spirit of selfishness destroys all; and one half of mankind, to load themselves with superfluities, leave the other destitute of common necessities.

When the hive is become too much crowded, by the addition of the young brood, a part of the Bees think of finding themselves a more commodious habitation, and with that view single out the most forward of the young queens. A new swarm is, therefore, constantly composed of one queen at least, and of several thousand working Bees, as well as of some hundreds of drones. The working Bees are some old, some young.

The usual method of uniting swarms is very easy. Spread a cloth at night upon the ground close to the hive in which the two casts or swarms are to be united; lay a stick across this cloth; then fetch the hive with the new swarm, set it over the stick, give a smart stroke on the top of the hive, and all the Bees will drop down upon the cloth in a cluster. This done, throw aside the empty hive, take the other from off the stool, and set this last over the Bees, who will soon ascend into it, mix with those already there, and become one and the same family. Others, instead of striking the Bees down upon the cloth, place with its bottom upmost the hive in which the united swarms are to live, and strike the Bees of the other hive down into it. The former of these hives is then restored to its natural situation, and the Bees of both hives soon unite. If some Bees still adhere to the other hive, they may be brushed off on the cloth, and they will soon join their brethren. Or one may take the following method, which gives less disturbance to the Bees. Set with its mouth upmost the hive into which the young swarm has been put, and set upon it the other hive. The Bees in the lower hive, finding themselves in an inverted situation, will soon ascend into the upper.

Columella directs, that the apiary, or Bee-garden, face the south, in a place neither too hot, nor too much exposed to the cold; that it be in a valley, in order that the loaded Bees may with the greater ease descend to their homes; that it be near the mansion-house, on account of the conveniency of watching them, but so situated as not to be exposed to noisome smells, or to the din of men or cattle; that it may be surrounded with a wall, which, however; should not rise above three feet high; that, if possible, a running stream be near them, or, if that cannot be, that water be brought near them in troughs, with pebbles or small stones in the water, for the Bees to rest on whilst they drink; or that the water be confined within gently declining banks, in order that the Bees may have safe access to it; they not being able to produce either combs, honey, or food for their maggots, without water. That the neighbourhood of rivers or basons of water with high banks be avoided, because winds may whirl the Bees into them, and they cannot easily get on shore from thence to dry themselves; and that the garden in which the apiary stands be well furnished with such plants as afford the Bees plenty of good pasture. The trees in this garden should be of the dwarf kind, and their heads bushy, in order that the swarms which settle on them may be the more easily hived.

We come now to explain the most inhuman method commonly practised of taking Bees, which consists in wantonly destroying the whole swarm, in order to enjoy the fruits of their labours.

Were we to kill the hen for her egg, the cow for her milk, or the sheep for the fleece it bears, every one would instantly see how much we should act contrary to our own interest: and yet this is practised every year in regard to Bees. Would it not argue more wisdom in us to be contented with taking away only a portion of their wax and honey, as is the practice of many countries? The common method here is, that when those which are doomed for slaughter have been marked out (which is generally done in September) a hole is dug near the hive, and a stick, at the end of which is a rag that has been dipped in melted brimstone, being stuck in that hole, the rag is set on fire, the hive is immediately set over it, and the earth is instantly thrown up all around, so that none of the smoke can escape. In a quarter of an hour, all the Bees are seemingly dead; and they will soon after be irrecoverably so, by being buried in the earth that is returned back into the hole: they will soon be absolutely killed by this last means; because it has been found, by experiment, that all the Bees which have been affected only by the fumes of the brimstone, recover again, excepting such as have been singed or hurt by the flame. Hence it is evident, that the fume of brimstone might be used for intoxicating the Bees, with some few precautions. The heaviest and the lightest hives are alike treated in this manner; the former, because they yield the most profit, with an immediate return; and the latter, because they would not be able to survive the winter. Those hives which weigh from fifteen to twenty pounds, are thought to be the fittest for keeping.

The practice of the ancients was, however, very different from this: they were content to share with these industrious insects the produce of their labours; and some very laudable attempts have been made in our own country, to attain the desirable end of getting the honey and wax, without destroying the Bees. John Geddy, Esq. published in the year 1665, his invention of boxes for preserving the lives of Bees. These were improved by Joseph Warder, physician, at Croydon, who at the same time embellished his account of the structure and use of

these boxes, with several other curious circumstances concerning Bees, in his work, intitled, *The True Amazons; or the Monarchy of Bees*. Two very worthy clergymen, the Rev. Mr. John Thorley, of Oxford, and the Rev. Mr. Stephen White, M. A. Rector of Holton, in Suffolk, have brought the method of preserving the lives of Bees to still greater perfection.

The indefatigable Mr. Wildman, so universally known for his curious experiments with Bees, has obliged the world with the following method of taking the wax and honey, without destroying the Bees:

Remove, says he, the hive from which you would take the wax and honey, into a room, into which admit but little light, that it may at first appear to the Bees as if it were late in the evening. Gently invert the hive, placing it between the frames of a chair, or other steady support, and cover it with an empty hive, keeping the side next the window of the empty hive raised a little, to give the Bees sufficient light to get into it. While you hold the empty hive steadily supported on the edge of the full hive, between your side and your left arm, keep striking with your other hand all round the full hive from top to bottom, in the manner of beating a drum, so that the Bees may be frightened by the continual noise from all quarters; and they will in consequence mount out of the full hive into the empty one. Repeat the strokes rather quick than strong round the hive, till all the Bees are got out of it, which will generally be in about five minutes. It is to be observed, that the fuller the hive is of Bees, the sooner they will have left it. As soon as a number of them have got into the empty hive, it should be raised a little from the full one, that the Bees may not continue to run from the one to the other. As soon as all the Bees are out of the full hive, the other, in which the Bees are, must be placed on the stand from which the former hive was taken, in order to receive the absent Bees as they return from the fields.

If this be done early in the season, the operator should examine the royal cells; for if any of them contain young Bees, they must, as well as all the combs that have young Bees in them, be saved in the hive. Take out the other combs with a long broad and pliable knife; cutting them from the sides and crown as clean as possible, to save the future labours of the Bees, who must lick up the honey spilt, and remove every grain of wax: the sides of the hive should then be scraped with a table-spoon, to clear away what was left by the knife.

Having thus finished taking the wax and honey, let a table covered with a clean cloth, be placed near the stand, and giving the hive in which the bees are a sudden shake, striking it at the same time pretty forcibly, the Bees will be shaken on the cloth. Put their own hive over them immediately, raised a little on one side, that the Bees may the more easily enter, and when all are entered, place it on the stand as before. If the hive in which the Bees are, be turned uppermost, and their own hive placed over it, the Bees will immediately ascend into it, especially if the lower sides be struck to alarm them: for the effects of fear impressed on the Bees, by the continual noise, renders them for a considerable time so mild and tractable, that they will bear any handling, which does not hurt them, without any shew of resentment.

NATURAL HISTORY of the WASP and HORNET.

THOUGH the bee and the Wasp resemble each other very strongly, yet they differ very widely in their manner and duration. The Wasp is well known to be a winged insect with a sting: it is longer

longer in proportion than the bee, and is marked with bright yellow circles round the body: it is the swiftest and most active insect of all the fly kind. It has a long tooth on each side of the mouth, with which it is enabled to cut almost any substance, and carry it to its nest.

Like bees, these insects live in community, and sometimes upwards of ten thousand are found inhabiting one nest. Among bees every community is composed of females, or queens, drones or males, and neutral or working bees. The occupations of Wasps are similar; the two first are for propagating the species, the last for defending and nursing the rising progeny. Bees, however, have seldom more than a queen or two in an hive; among Wasps there are two or three hundred. The nest of the Wasp is very curious, the construction of which is not very different from that of the bee; and each cell is hexagonal, like that of the bee.

The Wasps of Europe are very mischievous, but they are innocent when compared to those of the tropical climates, where all the insect tribes are not only numerous, but large, voracious, and formidable. In some of the islands, no precautions can prevent their attacks, and their sting is sometimes as terrible as that of a scorpion.

The Hornet is about twice as large as the Wasp, but strongly resembles it in shape. It has four wings, those above being double the size of those below. It makes a greater noise in flying than a Wasp, and is a very troublesome and dangerous insect.

NATURAL HISTORY of the ICHNUMON FLY.

THERE are many different kinds of this insect, but that which is the most formidable, is called the common Ichnumon. The body is long, slender, and black: the head, breast, feelers, and weapon at the tail, are of the same colour: it has four wings, like the bee, which are transparent, with a black spot near the edge of each. The weapon at the tail is longer than the body, and consists of three parts like hairs. Ray calls it the Wasp Ichnumon. This creature is a dreadful enemy to the insect tribe, but a particular friend to mankind. The millions it destroys in a summer are inconceivable; and without such a destroyer, the fruits of the earth would only furnish a banquet for the insect race.

NATURAL HISTORY of the ANT.

THESE insects are famous from all antiquity for their social and industrious habits: they are offered as a pattern of parsimony for the profuse, and of unremitting diligence to the sluggard. It is, however, surprising that all the writers of antiquity should describe this insect as labouring in the summer, and feasting upon the produce during the winter; it being well known that they require no supply of winter provisions, as they are actually in a state of torpidity during that season. But this may not, perhaps, be the case in some of the warmer climates, where the winter is mild.

The common Ants are of two or three different kinds; some are red, others black; some have stings, others have none. Such as have stings, inflict their wounds with them; such as have not, spirt from their hinder parts an acid pungent liquor. The body of an Ant is divided into the head, breast, and belly. The eyes are black, and under them are two small horns or feelers. The breast is covered with a fine silky hair, from which project six legs, the extremities of each have two small claws. The body is of a brown chestnut colour, somewhat reddish about the belly. Like bees, they are divided into

males, females, and the neutral or working tribe. The females are larger than the males, and the working Ants are the smallest of all. The former, in general, have wings, the latter never have any; and upon them are devolved all the labours that tend to the welfare of the community. The males and females mix with the working multitude, but seem no way to partake in the common drudgeries of the state.

The fond attachment which the working Ants shew to the rising progeny is amazing: in cold weather they convey them in their mouths to the very depths of their habitation, where they are less subject to the severity of the season. In a fine day they remove them nearer the surface, where their maturity may be assisted by the warm beams of the sun.

The Ants of Africa are of three kinds; the red, the green, and the black; the latter is a very formidable insect, and above an inch in length. Their sting produces great pain, and their depredations are sometimes extremely destructive. From their hills, which are from six to twelve feet high, they fall out in a body in quest of adventures, and sometimes sheep, fowls, and even rats, are killed and devoured by these merciless insects.

NATURAL HISTORY of the BEETLE.

THERE are various kinds of the Beetle, all concurring in one common formation of having cases to their wings. Such a covering is the more necessary to these insects, as they sometimes live under the surface of the earth, in holes which are made by their own industry. The May-bug or dorr-beetle is so well known as to require no description. The elephant Beetle is the largest of this kind hitherto known; it is found in South-America, particularly Surinam, and about the river Oroonoko. It is black, and the whole body is covered with a hard shell. Its length from the hinder part to the eyes, is about four inches. The cantharis is of the Beetle kind, from whence come cantharides, well known by the name of Spanish flies, and for their use in blisters. Some are of a pure azure colour, others of pure gold, and others of a mixture of both. They are chiefly natives of Spain, Italy, and Portugal. The cochineal is an insect of a scarlet colour within, and without of a blackish red; sometimes of a white reddish or ash-colour, which are accounted the best, and are brought us from Mexico. These insects are used both in dying and in medicine.

NATURAL HISTORY of the GNAT and the TIPULA.

THE Tipula, or long legs, and the larger kind of Gnat, have frequently been mistaken for each other; they are both mounted on long legs, both furnished with two wings and a slender body: the principal difference is, that the Tipula wants a trunk, and the Gnat has a large one, which it often exerts to very mischievous purposes; but the Tipula is peaceful and innocent. The Gnat of Europe, indeed, gives but little uneasiness; but it is very different in America, where the waters stagnate, and the climate is warm, and where they are produced in multitudes beyond expression. There they are found from six inches in length to a minuteness that requires even the microscope to perceive them. Tho' the suffering inhabitants destroy millions daily, still millions more succeed, and produce unceasing torment.

The native Indians, who anoint their bodies with oil, and who have from their infancy been used to their depredations, find them much less inconvenient than those who are newly arrived from Europe; they sleep in their cottages, covered all over with thousands of the Gnat kind upon their bodies, and yet do not seem to have their slumbers interrupted by their cruel devourers. If a candle happens to be lighted in one of those places, a cloud of insects at once light upon the flame, and extinguish it; they are therefore obliged to keep their candles in glass lanthorns; a miserable expedient to prevent an unceasing calamity!

The Gnat proceeds from a little worm, which is usually seen at the bottom of standing waters. The manner in which the insect lays its eggs, is particularly curious; after having laid the proper number on the surface of the water, it surrounds them with a kind of unctuous matter, which prevents them from sinking; but at the same time fastens them with a thread to the bottom, to prevent their floating away, at the mercy of every breeze, from a place the warmth of which is proper for their production, to any other, where the water may be too cold, or the animals its enemies too numerous. Thus the insects, in their egg state, resembles a buoy which is fixed by an anchor. As they come to maturity, they sink deeper, and at last, when they leave the egg as worms, they creep at the bottom. They now make themselves lodgments of cement, which they fasten to some solid body at the very bottom of the water, unless, by accident, they meet with a piece of chalk, which being of a soft and pliant nature, gives them an opportunity of sinking a retreat for themselves, where nothing but the claws of a cray-fish can possibly molest them. The worm afterwards changes its form. It appears with a large head, and a tail invested with hair, and moistened with an oleaginous liquor, which she makes use of as a cork, to sustain her head in the air, and her tail in the water, and to transport her from one place to another. When the oil with which her tail is moistened begins to grow dry, she discharges out of her mouth an unctuous humour, which she sheds all over her tail; by virtue whereof, she is enabled to transport herself where she pleases, without being either wet or any-ways incommoded by the water. The Gnat, in her second state, is, properly speaking, in her form of a nymph, which is an introduction, or entrance into a new life. In the first place, she divests herself of her second skin; in the next, she resigns her eyes, her antennæ, and her tail; in short, she actually seems to expire. However, from the spoils of the amphibious animal, a little winged insect cuts the air, whose every part is active to the last degree, and whose whole structure is the just object of our admiration. Its little head is adorned with a plume of feathers, and its whole body invested with scales and hair, to secure it from any wet or dust. She makes trial of the activity of her wings, by rubbing them either against her body, or her broad side-bags, which keep her in an equilibrium. The furbelow, or little border of fine feathers, which graces her wings, is very curious, and strikes the eye in a most agreeable manner. There is nothing, however, of greater importance to the Gnat, than her trunk, and that weak implement may justly be deemed one of nature's master-pieces. It is so very small, that the extremity of it can scarcely be discerned through the best microscope that can be procured. That part which is at first obvious to the eye, is nothing but a long scaly sheath under the throat. At near the distance of two-thirds of it, there is an aperture, through which the insect darts out four stings, and afterwards retracts them. One of which, however sharp and active it may be, is no more than the case in which the other

three lie concealed, and run in a long groove. The sides of these stings are sharpened like two edged swords; they are likewise barbed, and have a vast number of cutting teeth towards the point, which turns up like a hook, and is fine beyond expression. When all these darts are stuck into the flesh of animals, sometimes one after another, and sometimes all at once, the blood and humours of the adjacent parts must unavoidably be extravasated; upon which a tumour must consequently ensue, the little orifice whereof is closed up by the compression of the external air. When the Gnat, by the point of her case, which she makes use of as a tongue, has tasted any fruit, flesh, or juice, that she has found, if it be a fluid, she sucks it up, without playing her darts into it; but in case she finds the least obstruction by any flesh whatever, she exerts her strength, and pierces through it, if she possibly can. After this, she draws back her stings into their sheath, which she applies to the wound in order to extract, as through a reed, the juices which she finds enclosed. This is the implement with which the Gnat performs her work in the summer, for during the winter she has no manner of occasion for it. Then she ceases to eat, and spends all that tedious season either in quarries or in caverns, which she abandons at the return of summer, and flies about in search after some commodious ford, or standing water, where she may produce her progeny, which would be soon washed away and lost, by the too rapid motion of any running stream. The little brood are sometimes so numerous, that the very water is tinged according to the colour of the species, as green, if they be green, and of a sanguine hue, if they be red.

These are circumstances sufficiently extraordinary in the life of this little animal, but it offers something still more curious in the method of its propagation. However similar insects of the Gnat kind are in their appearance, yet they differ widely from each other in the manner in which they are brought forth, for some are oviparous, and are produced from eggs, some are viviparous, and come forth in their most perfect form; some are males, and unite with the female; some are females, requiring the impregnation of the male; some are of neither sex, yet still produce young, without any copulation whatsoever. This is one of the strangest discoveries in all natural history! A Gnat separated from the rest of its kind, and inclosed in a glass vessel, with air sufficient to keep it alive, shall produce young, which also, when separated from each other, shall be the parents of a numerous progeny. Thus, down for five or six generations, do these extraordinary animals propagate, without the use of copulation, without any congress between the male and female, but in the manner of vegetables, the young bursting from the body of their parents, without any previous impregnation. At the sixth generation, however, their propagation stops, the Gnat no longer produces its like, from itself alone, but it requires the access of the male, to give it another succession of fecundity.

NATURAL HISTORY of WORMS.

ANIMALS of the Worm kind are the first in the class of the zoophytes: being entirely destitute of feet, they trail themselves upon the ground, and find themselves a retreat under the earth or in the water. Like most other insects, Worms have breathing-holes along the back, adjoining each ring, but they are without bones, without eyes, and without ears. Some animals live without their limbs, but the earth-worm, and all the zoophyte tribe, continue to live in separate parts when cut

into pieces; and one animal, by the means of cutting, is divided into two distinct existencies, and sometimes into a thousand. This is the most astonishing phenomenon in all natural history, that man should have a kind of creative power, and out of one life make two, each completely formed, with all its apparatus and functions. This obtains also in the Sea-Worm, the Water-Worm, and in many other of the vermicular species.

When Des Cartes first started the opinion, that brutes were machines, the discovery of this surprising propagation was unknown, which might, in some measure, have strengthened his fanciful theory. What is life, in brutes, he might have said, or where does it reside? In some we find it so diffused, that every part seems to maintain a vivacious principle, and the same animal appears possessed of a thousand distinct irrational souls at the same time. But let us not, he would say, give so noble a name to such contemptible powers, but rank the vivifying principle in these with the sap that rises in vegetables, or the moisture that contracts a cord, or the heat that puts water into motion! Nothing, in fact, deserves the name of soul, but that which reasons, that which understands, and by knowing God, receives the mark of its currency, and is minted with the impression of its great Creator.

Such might have been the speculations of this philosopher; however, to leave theory, it will be sufficient to say, that we owe the first discovery of this power of reproduction in animals, to Mr. Trembley, who first observed it in the polypus; and after him, Spalanzani and others found it taking place in the Earth-Worm, the Sea-Worm, and several other ill-formed animals of a like kind, which were susceptible of this new mode of propagation. This last philosopher, has tried several experiments upon the Earth-Worm, many of which succeeded according to his expectation; every Earth-Worm, however, did not retain the vivacious principle with the same obstinacy; some, when cut in two, were entirely destroyed; others survived only in the nobler part; and while the head was living, the tail entirely perished, and a new one was seen to burgeon from the extremity. But what was most surprising of all, in some, particularly in the small red-headed Earth-Worm, both extremities survived the operation; the head produced a tail with the anus, the intestines, the annular muscle, and the prickly beards; the tail part, on the other hand, was seen to shoot forth the nobler organs, and, in less than the space of three months, sent forth a head, heart, with all the apparatus and instruments of generation. This part, as may easily be supposed, was produced much more slowly than the former, a new head taking above three or four months for its completion, a new tail being shot forth in less than as many weeks. Thus two animals, by dissection, were made out of one, each with their separate appetites, each endued with life and motion, and seemingly as perfect as that single animal from whence they derived their origin.

The Sea-Worm, the White Water-Worm, and many of those little Worms with feelers, found at the bottom of dirty ditches; in all these, the nobler organs are of such little use, that if taken away, the animal does not seem to feel the want of them; it lives in all its parts, and in every part, and by a strange paradox in nature, the most useless and contemptible life, is of all others the most difficult to destroy.

As Worms, like serpents, have a creeping motion, so both, in general, go under the common appellation of reptiles; a loathsome, noxious, malignant tribe, to which man by nature, as well as by religion, has the strongest antipathy. But though Worms, as well as serpents, are mostly without feet,

and have been doomed to creep along the earth on their bellies, yet their motions are very different. The serpent having a back-bone, which it is incapable of contracting, bends its body into the form of a bow, and then shoots forward from the tail; but it is very different with the Worm, which has a power of contracting or lengthening itself at will. There is a spiral muscle, that runs round its whole body, from the head to the tail, somewhat resembling a wire wound round a walking-cane, which, when slipped off, and one end extended and held fast, will bring the other nearer to it; in this manner the Earth-Worm, having shot out, or extended its body, takes hold by the slime of the fore part of its body, and so contracts and brings forward the hinder part; in this manner it moves onward, not without great effort, but the occasions for its progressive motion are few.

As it is designed for living under the earth, and leading a life of obscurity, so it seems tolerably adapted to its situation. Its body is armed with small stiff sharp burs or prickles, which it can erect or depress at pleasure; under the skin there lies a slimy juice, to be ejected as occasion requires, at certain perforations, between the rings of the muscles, to lubricate its body, and facilitate its passage into the earth. It has a mouth, and also an alimentary canal, which runs along to the very point of the tail. In some Worms, however, particularly such as are found in the bodies of animals, this canal opens towards the middle of the belly, at some distance from the tail. The intestines of the Earth-Worm, are always found filled with a very fine earth, which seems to be the only nourishment these animals are capable of receiving.

The animal is entirely without brain, but near the head is placed the heart, which is seen to beat with a very distinct motion, and round it are the spermatic vessels, forming a number of little globules, containing a milky fluid, which have an opening into the belly, not far from the head: they are also often found to contain a number of eggs, which are laid in the earth, and are hatched in twelve or fourteen days into life, by the genial warmth of their situation; like snails, all these animals unite in themselves both sexes at once, the reptile that impregnates, being impregnated in turn; few that walk out, but must have observed them, with their heads laid against each other, and so strongly attached, that they suffer themselves to be trod upon.

When the eggs are laid in the earth, which, in about fourteen days, as has been said, are hatched into maturity, the young ones come forth very small, but perfectly formed, and suffer no change during their existence: how long their life continues, is not well known, but it certainly holds for more than two or three seasons. During the winter, they bury themselves deeper in the earth, and seem, in some measure, to share the general torpidity of the insect tribe. In spring, they revive with the rest of nature, and on those occasions, a moist or dewy evening brings them forth from their retreats, for the universal purpose of continuing their kind. They chiefly live in a light rich and fertile soil, moistened by dews or accidental showers, but avoid those places where the water is apt to lie on the surface of the earth, or where the clay is too stiff for their easy progression under ground.

Helpless as they are formed, yet they seem very vigilant in avoiding those animals that chiefly make them their prey: in particular, the mole, who feeds entirely upon them beneath the surface, and who seldom ventures, from the dimness of its sight, into the open air; him they avoid, by darting up from the earth, the instant they feel the ground move; and fishermen, who are well acquainted with this, take

take them in what numbers they chuse, by stirring the earth where they expect to find them. They are also driven from their retreats under ground, by pouring bitter or acid water thereon, such as that water in which green walnuts have been steeped, or a lye made of pot-ashes.

Such is the general outline of the history of these reptiles, which, as it should seem, degrades them no way beneath the rank of other animals of the insect creation; we have mentioned a part of their history, which proves the imperfection of their organs, from the easiness with which these little machines may be damaged and repaired again. It is well known in mechanics, that the finest and most complicated instruments are the most easily put out of order, and the most difficultly set right; the same also obtains in the animal machine. Man, the most complicated machine of all others, whose nerves are more numerous, and powers of action more various, is most easily destroyed: he is seen to die under wounds which a quadruped or a bird could easily survive; and as we descend gradually to the lower ranks, the ruder the composition, the more difficult it is to disarrange it.

NATURAL HISTORY of the STAR-FISH, the POLYPUS, the CORAL PLANTS, and all the Varieties of the SEA-NETTLE.

NATURALISTS have given to the worm, and all these animals, the name of zoophytes. These are not produced by the ordinary forms of generation, but are propagated by dissection. Some of these, as already observed, though cut into an hundred parts, still retain life in each; and are endued with such a vivacious principle, that every part becomes a perfect animal in a very short time. They are a set of creatures placed between animals and vegetables, and form the shade that connects animal and insensible nature. Such are the Cuttle-fish, the Sea-Star, the Sea-Nettle, and Coral Plants. Numbers of what seem plants at sea, are not only the receptacles of insects, but also entirely of insect formation. Hence some philosophers have been led into opinion, that all nature was animated, and that the most inert mass of matter was endued with life and sensation, and only wanted organs to make those sensations perceptible to the beholder.

All of the Star-Fish kind are formed of a semi-transparent gelatinous substance, covered with a thin membrane; and, to an inattentive spectator, often appear like a lump of inanimate jelly, floating at random upon the surface of the sea, or thrown by chance on shore at the departure of the tide: but upon a more minute inspection, they will be found possessed of life and motion; they will be found to shoot forth their arms in every direction, in order to seize upon such insects as are near, and to devour them with great rapacity. Worms, the spawn of fish, and even muscles themselves, with their hard resisting shell, have been found in the stomachs of these voracious animals; and what is very extraordinary, though the substance of their own bodies be almost as soft as water, yet they are no way injured by swallowing these shells, which are almost of a stony hardness. They increase in size, as all other animals do. In summer, when the water of the sea is warmed by the heat of the sun, they float upon the surface, and, in the dark, they send forth a kind of shining light, resembling that of phosphorus. Some have given these animals the name of Sea-Nettles, because they burn the hands of those that touch them, as nettles are found to do. They are often seen fastened to the rocks, and to the largest sea-shells, as if to derive their nourishment from them. If they be taken and put into spirit of wine, they

will continue for many years entire, but if they be left to the influence of the air, they are, in less than twenty-four hours, melted down into limpid and offensive water.

In all of this species, none are found to possess a vent for their excrements, but the same passage by which they devour their food, serves for the ejection of their sœces. These animals take such a variety of figures, that it is impossible to describe them under one determinate shape; but, in general, their bodies resemble a truncated cone, whose base is applied to the rock to which they are found usually attached. Though generally transparent, yet they are found of different colours, some inclining to green, some to red, some to white, and some to brown. In some, their colours appear diffused over the whole surface; in some, they are often streaked, and in others, often spotted. They are possessed of a very slow progressive motion, and in fine weather, they are continually seen, stretching out and fishing for their prey. Many of them are possessed of a number of long slender filaments, in which they entangle any small animals they happen to approach, and thus draw them into their enormous stomachs, which fill the whole cavity of their bodies. The harder shells continue for some weeks indigested, but at length, they undergo a kind of maceration in the stomach, and become a part of the substance of the animal itself. The indigestible parts are returned by the same aperture by which they were swallowed, and then the Star-Fish begins to fish for more. These also may be cut in pieces, and every part will survive the operation; each becoming a perfect animal, endued with its natural rapacity. Of this tribe the number is various, and the description of each would be tedious and uninteresting; the manners and nature of all, are nearly as described.

Of all other animals, the Cuttle-fish, though in some respects superior to this tribe, possesses qualities the most extraordinary. It is about two feet long, covered with a very thin skin, and its flesh composed of a gelatinous substance, which, however, within-side, is strengthened by a strong bone, of which such great use is made by the goldsmith. It is possessed of eight arms, which it extends, and which are probably of service to it in fishing for its prey: while in life, it is capable of lengthening or contracting these at pleasure; but when dead, they contract and lose their rigidity. They feed upon small fish, which they seize with their arms; and they are bred from eggs, which are laid upon the weeds along the sea-shore.

The Cuttle-Fish is found along many of the coasts of Europe, but are not easily caught, from a contrivance with which they are furnished by nature; this is a black substance, of the colour of ink, which is contained in a bladder generally on the left side of the belly, and which is ejected in the manner of an excrement from the anus. Whenever, therefore, this fish is pursued, and when it finds a difficulty of escaping, it spirts forth a great quantity of this black liquor, by which the waters are totally darkened; and then it escapes, by lying close at the bottom. In this manner the creature finds its safety, and men find ample cause for admiration, from the great variety of stratagems with which creatures are endued for their peculiar preservation.

The Polypus lives in fresh water, and is found at the bottom of wet ditches, or attached to the under surface of the broad-leaved plants, that grow and swim on the waters. The same difference holds between these and the sea-water Polypus, as between all the productions of the sea, and of the land and the ocean. The marine vegetables and animals grow to a monstrous size. The eel, the pike, or the bream, of fresh waters, is but small; but in the sea they
grow

grow to an enormous magnitude. The herbs of the field, are at most but a few feet high; those of the sea, often shoot forth a stalk of a hundred. It is so between the Polypi of both elements. Those of the sea, are found from two feet in length, to three or four; and Pliny has even described one, the arms of which were no less than thirty feet long. Those in fresh waters, however, are comparatively minute; at their utmost size, seldom above three parts of an inch long, and when gathered up into their usual form, not above a third even of those dimensions.

It was upon these minute animals, that the power of dissection was first tried in multiplying their numbers. They had been long considered as little worthy the attention of observers, and were consigned to that neglect in which thousands of minute species of insects remain to this very day. It is true, indeed, that Reaumur observed, classed, and named them. By contemplating their motions, he was enabled distinctly to pronounce on their being of the animal, and not of the vegetable kingdom; and he called them Polypi, from their great resemblance to those larger ones that were found in the ocean. Still, however, their properties were neglected, and their history unknown.

Mr. Trembley was the person to whom we owe the first discovery of the amazing properties and powers of this little vivacious creature: he divided this class of animals into four different kinds; into those inclining to green, those of a brownish cast, those of flesh colour, those which he calls the polype de panache. The differences of structure in these, as also of colour, are observable enough; but the manner of their subsisting, of seizing their prey, and of their propagation, is pretty nearly the same in all.

Whoever has looked with care into the bottom of a wet ditch, when the water is stagnant, and the sun has been powerful, may remember to have seen many little transparent lumps of jelly, about the size of a pea, and flatted on one side; such also as have examined the under side of the broad-leaved weeds that grow on the surface of the water, must have observed them studded with a number of these little jelly-like substances, which were probably then disregarded, because their nature and history was unknown. These little substances, however, were no other than the living Polypi, gathered up into a quiescent state, and seemingly inanimate, because either undisturbed, or not excited by the calls of appetite to action. When they are seen exerting themselves, they put on a very different appearance from that when at rest: to conceive a just idea of their figure, we may suppose the finger of a glove cut off at the bottom; we may suppose also, several threads or horns planted round the edge like a fringe. The hollow of this finger will give us an idea of the stomach of the animal; the threads issuing forth from the edges, may be considered as the arms or feelers, with which it hunts for its prey. The animal, at its greatest extent, is seldom seen above an inch and a half long, but it is much shorter when it is contracted and at rest: it is furnished neither with muscles nor rings, and its manner of lengthening or contracting itself, more resembles that of the snail, than worms, or any other insect. The Polypus contracts itself more or less, in proportion as it is touched, or as the water is agitated in which they are seen. Warmth animates them, and cold benumbs them; but it requires a degree of cold approaching congelation before they are reduced to perfect inactivity; those of an inch have generally their arms double, often thrice as long as their bodies. The arms, where the animal is not disturbed, and the season not unfavourable, are thrown about in various directions, in order to seize and entangle its little prey; sometimes three or four

of the arms are thus employed, while the rest are contracted like the horns of a snail, within the animal's body. It seems capable of giving what length it pleases to these arms; it contracts and extends them at pleasure, and stretches them only in proportion to the remoteness of the object it would seize.

These animals have a progressive motion, which is performed by that power they have of lengthening and contracting themselves at pleasure; they go from one part of the bottom to another; they mount along the margin of the water, and climb up the side of aquatic plants. They are often seen to come to the surface of the water, where they suspend themselves by their lower-end. As they advance but very slowly, they employ a great deal of time in every action, and bind themselves very strongly to whatever body they chance to move upon as they proceed; their adhesion is voluntary, and is probably performed in the manner of a cupping-glass applied to the body.

All animals of this kind, have a remarkable attachment to turn towards the light, and this naturally might induce an enquirer to look for their eyes; but however carefully this search has been pursued, and however excellent the microscope with which every part was examined, yet nothing of the appearance of this organ was found over the whole body; and it is most probable, that, like several other insects which hunt their prey by their feeling, these creatures are unfurnished with advantages which would be totally useless for their support.

In the centre of the arms, as was said before, the mouth is placed, which the animal can open and shut at pleasure, and this serves at once as a passage for food, and an opening for it after digestion. The inward part of the animal's body seems to be one great stomach, which is open at both ends; but the purposes which the opening at the bottom serves, are hitherto unknown, but certainly not for excluding their excrements, for those are ejected at the aperture by which they are taken in. If the surface of the body of this little creature be examined with a microscope, it will be found studded with a number of warts, as also the arms, especially when they are contracted; and these tubercles, as we shall presently see, answer a very important purpose.

If we examine their way of living, we shall find these insects chiefly subsisting upon others, much less than themselves; particularly a kind of millepedes, that live in the water, and a very small red worm, which they seize with great avidity. In short, no insect whatsoever, less than themselves, seems to come amiss to them: their arms, as was observed before, serve them as a net would a fisherman, or perhaps, more exactly speaking, as a limetwig does a fowler. Wherever their prey is perceived, which the animal effects by its feeling, it is sufficient to touch the object it would seize upon, and it is fastened without a power of escaping. The instant one of this insect's long arms is laid upon a millepede, the little insect sticks, without a possibility of retreating. The greater the distance at which it is touched, the greater is the ease with which the Polypus brings the prey to its mouth. If the little object be near, tho' irretrievably caught, it is not without great difficulty that it can be brought to the mouth and swallowed. When the Polypus is unsupplied with prey, it testifies its hunger by opening its mouth; the aperture, however, is so small, that it cannot be easily perceived; but when, with any of its long arms, it has seized upon its prey, it then opens the mouth distinctly enough, and this opening is always in proportion to the size of the animal which it would swallow; the lips dilate insensibly by small degrees, and adjust themselves

elves precisely to the figure of their prey. Mr. Trembley, who took a pleasure in feeding this useful brood, found that they could devour aliments of every kind, fish and flesh, as well as insects; but he owns they did not thrive so well upon beef and veal, as upon the little worms of their own providing. When he gave one of these famished reptiles any substance which was improper to serve for aliment, at first it seized the prey with avidity, but after keeping it some time entangled near the mouth, it let it drop again with distinguishing nicety.

When several Polypi happen to fall upon the same worm, they dispute their common prey with each other. Two of them are often seen seizing the same worm at different ends, and dragging it at opposite directions with great force. It often happens, that while one is swallowing its respective end, the other is also employed in the same manner, and thus they continue swallowing each his part, until their mouths meet together; they then rest, each for some time in this situation, till the worm breaks between them, and each goes off with his share; but it often happens, that a seemingly more dangerous combat ensues; when the mouths of both are thus joined upon one common prey together; the largest Polypus then gapes and swallows his antagonist; but what is very wonderful, the animal thus swallowed seems to be rather a gainer by the misfortune. After it has lain in the conqueror's body for about an hour, it issues unhurt, and often in possession of the prey which had been the original cause of contention: how happy would it be for men, if they had as little to fear from each other!

These reptiles continue eating the whole year, except when the cold approaches to congelation; and then, like most others of the insect tribe, they feel the general torpor of nature, and all their faculties are for two or three months suspended; but if they abstain at one time, they are equally voracious at another, and like snakes, ants, and other animals that are torpid in winter, the meal of one day suffices them for several months together. In general, however, they devour more largely in proportion to their size, and their growth is quick exactly as they are fed; such as are best supplied, soonest acquire their largest size; but they diminish also in their growth, with the same facility, if their food be taken away.

Such are the more obvious properties of these little animals, but the most wonderful still remain behind: Their manner of propagation, or rather multiplication, has for some years been the astonishment of all the learned of Europe. They are produced in as great a variety of manners as every species of vegetable. Some Polypi are propagated from eggs, as plants are from their seed; some are produced by buds issuing from their bodies, as plants are produced by inoculation, while all may be multiplied by cuttings, and this to a degree of minuteness, that exceeds even philosophical perseverance.

With respect to such of this kind as are hatched from the egg, little curious can be added, as it is a method of propagation so common to all the tribes of insect nature; but with regard to such as are produced like buds from their parent stem, or like cuttings from an original root, their history requires a more detailed explanation. If a Polypus be carefully observed in summer, when these animals are chiefly active, and more particularly prepared for propagation, it will be found to burgeon forth from different parts of its body, several tubercles or little knobs, which grow larger and larger every day; after two or three days inspection, what at first appeared but a small excrescence, takes the figure of a small animal, entirely resembling its parent, furnished with feelers, a mouth, and all the apparatus for seizing and

digesting its prey. This little creature every day becomes larger, like the parent, to which it continues attached; it spreads its arms, to seize upon whatever insect is proper for aliment, and devours it for its own particular benefit; thus it is possessed of two sources of nourishment, that which it receives from the parent by the tail, and that which it receives from its own industry by the mouth. The food which these animals receive, often tinctures the whole body, and upon this occasion the parent is often seen communicating a part of its own fluids to that of its progeny that grows upon it; while, on the contrary, it never receives any tincture from any substance that is caught and swallowed by its young. If the parent swallows a red worm, which gives a tincture to all its fluids, the young one partakes of the parental colour; but if the latter should seize upon the same prey, the parent Polypus is no way benefited by the capture, but all the advantage remains with the young one.

But we are not to suppose that the parent is capable of producing only one at a time, several young ones are thus seen at once, of different sizes, growing from its body, some just budding forth, others acquiring their perfect form, and others come to sufficient maturity, and just ready to drop from the original stem, to which they had been attached for several days. But what is more extraordinary still, these young ones themselves, that continue attached to their parent, are seen to burgeon, and propagate their own young ones also, each holding the same dependence upon its respective parents, and possessed of the same advantages that have been already described in the first connection. Thus we see a surprising chain of existence continued, and numbers of animals naturally produced without any union of the sexes, or other previous disposition of nature.

This seems to be the most natural way by which these insects are multiplied; their production from the egg being not so common; and though some of this kind are found with a little bladder attached to their bodies, which is supposed to be filled with eggs, which afterwards come to maturity, yet the artificial method of propagating these animals, is much more expeditious, and equally certain: it is indifferent whether one of them be cut into ten, or ten hundred parts, each becomes as perfect an animal, as that which was originally divided: but it must be observed, that the smaller the part which is thus separated from the rest, the longer it will be in coming to maturity, or in assuming its perfect form. It would be endless to recount the many experiments that have been tried upon this philosophical prodigy; the animal has been twisted and turned into all manner of shapes; it has been turned inside out; it has been cut in every division, yet still it continued to move; its parts adapted themselves again to each other, and in a short time, it became as voracious and industrious as before.

Besides these kinds mentioned by Mr. Trembley, there are various others which have been lately discovered by the vigilance of succeeding observers, and some of these so strongly resemble a flowering vegetable in their forms, that they have been mistaken by many naturalists for such. Mr. Hughes, the author of the Natural History of Barbadoes, has described a species of this animal, but has mistaken its nature, and called it a sensitive flowering plant; he observed it to take refuge in the holes of rocks, and when undisturbed, to spread forth a number of ramifications, each terminated by a flowery petal, which shrunk at the approach of the hand, and withdrew into the hole from whence before it had been seen to issue. This plant, however, was no other than an animal of the Polypus kind, which is not only to be found in Barbadoes, but also on many parts

parts of the coast of Cornwall, and along the shores of the Continent.

NATURAL HISTORY of LITHOPHYTES and SPONGES.

IT is very probable that the animals we see, and are acquainted with, bear no manner of proportion to those that are concealed from us. Although every leaf and vegetable swarms with animals upon land, yet at sea, they are still more abundant; for the greatest part of what would seem vegetables growing there, are in fact nothing but the artificial formation of insects, palaces which they have built for their own habitation.

If we examine the bottom of the sea along some shores, and particularly at the mouths of several rivers, we shall find it has the appearance of a forest of trees under water, millions of plants growing in various directions, with their branches entangled in each other, and sometimes standing so thick as to obstruct navigation. The shores of the Persian gulph, the whole extent of the Red Sea, and the western coasts of America, are so choaked up in many places with these coraline substances, that though ships force a passage through them, boats and swimmers find it impossible to make their way. These aquatic groves are formed of different substances, and assume various appearances. The coral plants, as they are called, sometimes shoot out like trees without leaves in winter; they often spread out a broad surface like a fan, and, not uncommonly, a large bundling head, like a faggot; sometimes they are found to resemble a plant with leaves and flowers; and often the antlers of a stag, with great exactness and regularity. In other parts of the sea are seen Sponges of various magnitude, and extraordinary appearances, assuming a variety of fantastic forms, like large mushrooms, mitres, fonts, and flower-pots. To an attentive spectator, these various productions seem entirely of the vegetable kind; they seem to have their leaves and their flowers, and have been experimentally known to shoot out branches in the compass of a year. Philosophers, therefore, till of late, thought themselves pretty secure in ascribing these productions to the vegetable kingdom; and count Marfigli, who has written very laboriously and learnedly upon the subject of corals and Sponges, has not hesitated to declare his opinion, that they were plants of the aquatic kind, furnished with flowers and seed, and endued with a vegetation entirely resembling that which is found upon land. This opinion, however, some time after, began to be shaken by Rumphius and Jussieu, and at last by the ingenious Mr. Ellis, who by a more sagacious and diligent enquiry into nature, put it past doubt, that corals and Sponges were entirely the work of animals; and that, like the honey-comb, which was formed by the bee, the coral was the work of an infinite number of reptiles of the polypus kind, whose united labours were thus capable of filling whole tracts of the ocean with those embarrassing tokens of their industry.

If, in our researches after the nature of these plants, we should be induced to break off a branch of the coraline substance, and observe it carefully, we shall perceive its whole surface, which is very rugged and irregular, covered with a mucous fluid, and almost in every part studded with little jelly-like drops, which when closely examined, will be found to be no other than reptiles of the Polypus kind. These have their motions, their arms, and their appetites, but they soon expire when taken out of the sea, and our curiosity is at once stopped in its career, by the animals ceasing to give any make of their industry; recourse therefore has been had to

other expedients, in order to determine the nature of the inhabitant, as well as the habitation.

If a coraline plant be strictly observed, while still growing in the sea, and the animals upon its surface be not disturbed, either by the agitation of the waters, or the touch of the observer, the little Polypi will then be seen in infinite numbers, each issuing from its cell, and, in some kinds, the head covered with a little shell, resembling an umbrella, the arms spread abroad, in order to seize its prey, while the hinder part still remains attached to its habitation, from whence it never wholly removes. By this time it is perceived that the number of inhabitants is infinitely greater than was at first suspected; that they are all assiduously employed in the same pursuits, and that they issue from their respective cells, and retire into them at pleasure. Still, however, there are no proofs that those large branches which they inhabit, are entirely the construction of such feeble and minute animals. But chemistry will be found to lend a clue to extricate us from our doubts in this particular. Like the shells which are formed by snails, muscles and oysters, these coraline substances effervesce with acids, and may therefore well be supposed to partake of the same animal nature. But Mr. Ellis went still farther, and examined their operations, just as they were beginning. Observing an oyster-bed, which had been for some time neglected, he there perceived the first rudiments of a coraline plantation, and tufts of various kinds shooting from different parts of this favourable soil. It was upon these he tried his principal experiment. He took out the oysters, which were thus furnished with coralines, and placed them in a large wooden vessel, covering them with sea-water. In about an hour, he perceived the animals, which before had been contracted by handling, and had shewn no signs of life, expanding themselves in every direction, and appearing employed in their own natural manner. Perceiving them therefore in this state, his next aim was to preserve them thus expanded, so as to be permanent objects of curiosity. For this purpose he poured, by slow degrees, an equal quantity of boiling water into the vessel of sea-water in which they were immersed. He then separated each Polypus with pincers from its shell, and plunged each separately into small crystal vases, filled with spirit of wine mixed with water. By this means, the animal was preserved entire, without having time to contract itself, and he thus perceived a variety of kinds, almost equal to that variety of productions which these little animals are seen to form. He has been thus able to perceive and describe fifty different kinds, each of which is seen to possess its own peculiar mode of construction, and to form a coraline that none of the rest can imitate. It is true, indeed, that on every coraline substance there are a number of Polypi found, no way resembling those which are the erectors of the building; these may be called a vagabond race of reptiles, that are only intruders upon the labours of others, and that take possession of habitations, which they have neither art nor power to build for themselves. But in general, the same difference that subsists between the honey-comb and the bee, and the paper-like cells of the wasp, subsists between the different habitations of the coral-making Polypi.

With regard to the various forms of these substances, they have obtained different names from the nature of the animal that produced them, or the likeness they bear to some well-known object, such as coralines, fungimadrepores, sponges, astroites, and keratophytes. Though these differ extremely in their outward appearances, yet they are all formed in the same manner by reptiles of various kinds and nature. When examined chemically, they

V E S I C U L A T E D

T U B U L A R

C E L L I F E R O U S

they all discover the marks of animal formation; the corals, as was said, dissolve in acids, the sponges burn with an odour strongly resembling that of burnt horn. We are left somewhat at a loss with regard to the precise manner in which this multitude of cells, which at last assume the appearance of a plant or flower, are formed. If we may be led in this subject by analogy, it is most probable, that the substance of coral is produced in the same manner that the shell of the snail grows round it; these little reptiles are each possessed of a slimy matter, which covers its body, and this hardening, as in the snail, becomes an habitation exactly fitted to the body of the animal that is to reside in it; several of these habitations being joined together, form at length a considerable mass, and as most animals are productive, in proportion to their minuteness, so these multiplying in a surprising degree, at length form those extensive forests that cover the bottom of the deep.

Thus all nature seems replete with life; almost every plant on land has its surface covered with

millions of these minute creatures, of whose existence we are certain, but of whose uses we are entirely ignorant; while numbers of what seem plants at sea, are not only the receptacles of insects, but also entirely of insect formation. This might have led some late philosophers into an opinion, that all nature was animated, that every, even the most inert mass of matter, was endued with life and sensation, but wanted organs to make those sensations perceptible to the observer: those opinions, taken up at random, are difficultly maintained, and as difficultly refuted; like combatants that meet in the dark, each party may deal a thousand blows without ever reaching the adversary. Those perhaps are wiser who view nature as she offers; who without searching too deeply into the recesses in which she ultimately hides, are contented to take her as she presents herself, and storing their minds with effects rather than with causes, instead of the embarrassment of systems, about which few agree, are contented with the history of appearances, concerning which, all mankind have but one opinion.

C H A P. III.

DIRECTIONS FOR ANGLING:

CONTAINING

The whole ART of FLOAT and FLY-FISHING,

The best RULES for the CHOICE of TACKLE,

And a Description of NATURAL and ARTIFICIAL BAITs.

Collected from PRACTICE and OBSERVATION, as well as from the WRITINGS of the most Experienced Authors on the Subject.

OF ANGLING in GENERAL.

THOUGH much has been said by many writers, concerning the antiquity of Angling, and in which they have introduced a great deal of fable, we shall content ourselves with mentioning only two authorities, such as cannot be disputed. It is certain, that angling is much more ancient than the incarnation of our Saviour; for, in the prophet *Amos*, mention is made of fish-hooks; and in the Book of *Job*, which was long before the days of *Amos*, mention is also made of fish-hooks, which must imply anglers in those times.

No diversion is perhaps better calculated to raise the mind, to calm and compose the troubled passions of the soul, to inspire health, content, and ease, than that of Angling. While the great lawyer is swallowed up in business, and the statesman is preventing or contriving plots, the angler is perhaps sitting on a bank enamelled with cowslips, listening to the enchanting voices of the little feathered songsters, while the silver stream at his feet with pleasing murmurs glides gently along. Hunting, as well as many other dangerous diversions, may have its charms to allure some people to the pursuit of it; but it cannot be so natural as that of angling: the one is all noise and tumult, the other peace and serenity. The angler leisurely surveys the wonderful works of the creation, and adores that Being, from whom he receives all his pleasures. His retirement and solitude

are physic for his soul, and delivers it from the hurry and various passions, in which other pursuits are too much involved. As exercise is its necessary companion, and a pure and clear air one of its constant attendants, health always follows in its train. In short, the various objects which continually offer themselves, as subjects for the angler's contemplation, inspire the mind with that innocent cheerfulness, ease and tranquillity, that is hardly to be expected from any other diversion, and never to be found amidst noise and tumult.

With respect to the qualifications of an angler, Mr. *Markham*, in his book entitled *Country Contentments*, says, that he should be a good scholar, and master of the liberal sciences; as a grammarian, to know how to talk or write of his art in correct language; he should have sweetness of speech, to entice others to delight in an exercise so laudable; and should have strength of argument to defend and maintain his profession against ridicule and slander: he must be bold and resolute, neither to be afraid of storms, nor affrighted at thunder. If he is not possessed of that excellent virtue, patience, and cannot endure a little fasting, he loses all the delight which contributes to make this pastime pleasing.

Of the ANGLER'S RODS and LINES.

THE choice of the Angler's ROD is a matter of no small importance. For fishing at the bottom,

tom, whether with a running line or float, the reed or cane rod is, on account of its lightness and elasticity, to be preferred to the hazel, especially if you angle for those fish, which bite but tenderly, as the Roach and Dace: of these, some are put up in the form of a walking stick. There are others, which are composed of many joints, and put up all together in a bag, and are therefore called bag-rods. These last are very useful to travel with, as they take up but little room.

Next to these is the hazel rod; but that is more apt to warp than the cane. These, as well as excellent fly-rods, are to be had at every fishing-tackle shop, and therefore need no particular description. Be careful, however, when you bespeak a rod of reed or cane, that the workman does not rasp down into the bark, which grows round the joints. This is a fault, of which rod-makers are too often guilty, and thereby make the rod weaker at the joints than in any other part; for, there being no bark to repel the wet, it soon rots, by which fault you may lose a good fish, and break your rod.

It may not, however, be improper to give some directions for making rods, as many anglers live in those parts of the country, where they are not always to be bought.

When the sap is gone down into the roots of trees, which is generally between the latter end of November and Christmas, gather the straightest hazels you can find, in order to use them for stocks: these, at the larger end, must be about an inch, or more, in diameter. At the same time, gather shoots of a less size for middle pieces and tops. Tie them together in a bundle, and let them lie on a dry floor.

At the end of fifteen months match them together; and to the slender ends of the tops, after cutting off about eight or ten inches, whip a fine taper piece of whalebone of that length. Then cut the ends of the other pieces with a long slant, so that they may join exactly to each other, and spread some shoemaker's wax very thin over the slants: after this, bind them neatly with strong waxed thread. Lastly, fix a strong loop of horse-hair to the whalebone, and let the rod, so made, lie a week to settle before you use it. In this manner also you may make a fly rod; but observe, that the latter must be much more slender from the end of the stock than the former.

To make a very neat fly-rod, you must proceed in the following manner. Get a yellow whole deal board, which is free from knots; cut off about seven feet from the best end, and saw it into square breadths: let a joiner plain off the angles, and make it perfectly round, a little tapering: this will serve for the stock. Then piece it to a fine straight hazel, of about six feet long, and then a delicate piece of fine-grained yew, plained round like an arrow, and tapering, with whalebone, as before, of about two feet in length. There is no absolutely fixing the length of a fly-rod; but one of fourteen feet is as long as can well be managed. To colour the stock, dip a feather in aqua fortis, and chafe it into the deal, which will then become of a cinnamon colour.

Rods for Barbel, Carp, and other large fish, should be of hazel, and proportionably stronger than those for Roach and Dace. However, the following portable rod is so neat and useful, that no angler, who has once tried it, will be without it.

Let there be four joints, made of hickory, or some such very tough wood, and two feet four inches in length. The top must be bamboo shaved; and the stock of ash, full in the grasp, of an equal length with the other joints, and with a strong ferrel at the smaller end, made to receive the large joint, which must be well shouldered, and fitted to it with the

utmost exactness. This rod will go into a bag, and lie very well concealed in a pocket, in the lining of your coat on the left side, made on purpose to receive it.

The angler's LINE, whether it be a running-line, or for float-fishing, had best be of hair, unless you fish for Barbel, and then it must be of strong silk; but remember, that the single hair is to be preferred for Roach or Dace fishing. The fly line must be very strong; and, for the greater facility in throwing, should be eighteen or twenty hairs at the top, diminishing gradually to the hook. Lines are sold at the fishing shops, which have no joints, but are wove in one piece. But, notwithstanding this and other improvements, as some may perhaps still chuse to make their own lines, we shall endeavour to give some directions for that work.

Your hair must be round and clear, and free from galls or frets; for a well chosen, even, clear, round hair, of a kind of glass colour, will prove as strong as three that want those perfections. You will seldom find a black hair which is not round; but many white ones are flat and uneven; for which reason, if you get a lock of round, clear, glass coloured hair, you ought to make much of it.

In making your lines observe this rule: first let your hair be well washed before you set about twisting it; and then chuse not only the clearest hair for it, but such as are of an equal size; for then they generally stretch and break all together, which hairs of an unequal size never do, but break singly, and thereby deceive the angler in the strength of his line. When you have twisted your links, lay them in water for a quarter of an hour at least, and then twist them over again before you tie them into a line.

Though many prefer twisting hairs with the fingers, yet we would rather recommend a little engine for that purpose, which is sold at all the fishing tackle shops in London, with proper directions for using it.

When you use the fly, you will find it necessary to continue your line to a greater degree of fineness: in order to which, supposing your line to be ten yards in length, let your upper link consist of nine or twelve hairs, diminishing the number in the succeeding links, till you come to the size of a fine grass, and to the end of this fix your hook-link, which should be either of very fine grass, or silkworm gut. A week's practice will enable a learner to throw out one of these lines; and he may lengthen it, by a yard at a time, at the greater end, till he can throw fifteen yards neatly; till when, he is to reckon himself but a novice.

As to the colour of your line, you must be determined by that of the river in which you fish; but we have generally found, that a line of the colour of pepper and salt (which is made by mixing a black hair among the white ones in twisting) will suit any water.

Indian or sea grass makes excellent hook-links; and, though some object to it, as being apt to grow brittle and snap in using, yet with proper management, it is the best material for the purpose yet known, especially if ordered in the following manner.

Take as many as you please of the finest you can get, put them into any vessel, and pour therein the scummed fat of a pot, wherein fresh (but by no means salt) meat has been boiled. When they have lain three or four hours, take them out one by one, and stripping the grease off with your finger and thumb, stretch each grass as long as it will yield, coil them up in rings, and lay them by. You will then find them become nearly as small, full as round, and much stronger, than the best single hairs you can get. To preserve them moist, keep them in a piece

of bladder well oiled, and, before you use them, let them soak about half an hour in water, or in your walk to the river side, put a length of it into your mouth. If your grass is coarse, it will fall heavily on the water, and scare away the fish; on which account gut has the advantage. After all, if your grass is fine and round, it is the best thing you can use.

Silk must never be mixed with hair lines; and, though silk lines are very apt to rot and break, yet they may serve in some places, where good hair is not easily to be come at. In this case a good angler will always make the lowest part of such lines of the smallest lute or viol strings.

The next thing to be considered is the FLOAT, which, for river fishing, should be of cork; but, for ponds and standing waters, quills will do very well, as also in slow rivers, when you angle near the top with tender baits or pastes. Let your cork be the finest, and free from flaws; bore it through with a small hot iron, and thrust it on to a sizeable quill, after having shaped the former with a penknife to the likeness of a pyramid, egg, or pear, of a proportionable bigness, and finely smoothed on a pumice stone. Run your line through the quill, and wedge it in with the uppermost hard part of the quill, the smaller end of the cork being towards the hook, and the bigger towards the rod. Let the cork be so poised with lead on the line, that the quill standing directly upright, the least bite or nibble may sink the cork.

A cork float, for one hair, must be no bigger than a pea; for three, as big as a bean; for six, as a small walnut; and for twelve hairs, as big as a French walnut.

Quill floats may be bought every where; and, if it chance to be bruised or split, save the plug, and it will serve another. If the water gets in at the top, cover it with sealing-wax; or if your plug be loose, take bees-wax bruised small, chalk scraped fine, and powdered black rosin, of each an equal quantity. Melt them in a spoon, and mix them well as they melt, which will be a proper cement to fasten it, by dipping the plug in, and immediately putting it into the float; for it cools as soon as sealing wax.

In choosing HOOKS, mind that they are sharp at the point, the beards not broken, of proper length, and the wire well tempered and firm: a short-shanked hook is esteemed best.

Those hooks, which are now known by the name of Kerby's hooks, for shape and temper, exceed all others. The size of your hook must be regulated by the fish for which you intend to angle. Barbel and Chub require large hooks; Carp, Eels, Tench, Pearch, and Bream, a moderate sized hook; Smelts, Roach, Dace, and Gudgeons, require a small one. To sharpen a dull hook, you should carry a whetstone about two inches long, and a quarter square, that being much better than a file, which rather leaves it rough than sharp.

Of the other Sorts of TACKLE necessary in ANGLING.

THE angler who pursues his sport at any distance from home, must be supplied with many articles, such as a rod with a spare top; lines coiled up, and neatly laid in round flat boxes; spare links, single hairs, and waxed thread and silk; plummets of various sizes, floats of all kinds, and spare caps; worm bags, and a gentle-box; hooks of all sizes, and some whipped to single hairs; shot, shoemaker's wax, in a very small gallipot covered with a bit of leather; a clearing ring, a landing net, a sharp knife, and a pair of scissers. All these things, however, may be contained in a wicker panier of about twelve

inches wide, and eight high. But let us proceed to examine some of the angler's materials more particularly.

The PLUMMET, which is used in order to try the depth of the water, in which you intend to angle, should be made of sheet lead, that, by opening it, you may at any time the more easily fix it on the hook without any fear of losing it.

The LANDING NET must be deep, with a round iron rim at top, made to fasten to the end of a long stick, in order to land such fish, as are too heavy for your tackling. At the other end of the stick should be a large hook, which you may thrust into the mouths of Salmon, and such other fish as are too bulky for your net, and by that means bring them safe to shore.

The CLEARING RING is used to disengage your hook, when it has caught hold of a weed, &c. It must be thick and heavy, but not wider than the round part of your hook, and is thus to be used. Take off the thick joints of your rod, and slip the ring over the remaining small ones, and holding a cord fastened to the ring, let it fall gently. This, as soon as it reaches the hook, will disengage it, by the assistance of your gently pulling the cord.

The GORGER is a small piece of cane, of five inches long, and a quarter of an inch wide, with a notch at each end. With this, when a fish has gorged your hook, you may, by putting it down his throat till you feel the hook, and holding the line tight while you press it down, easily disengage it.

It would be needless to give any description of the use of knives, scissers, wax, thread, &c. as these materials of themselves explain the various purposes they are intended to serve.

Of FLOAT FISHING, and of LIVE and DEAD BAITS.

WITH respect to FLOAT FISHING, there are some rules, with which the young angler ought to be acquainted. Let the rod be light and stiff, and yet so smart in the spring, as to strike at the tip of the whalebone: from fourteen to fifteen feet is a good length for the rod.

In places where you sometimes meet with Barbel, the line should be six or seven hairs at top: then diminishing gradually for two yards, let the rest be strong Indian grass, to within about half a yard of the hook, which may be whipped to a fine grass, or silk-worm gut. This line will kill a fish of six pounds weight.

For mere Roach and Dace fishing accustom yourself to a single hair, with which an artist may kill a fish of a pound and a half weight.

For your float, in slow streams, a neat round goose quill is proper; but for deep or rapid rivers, or in an eddy, the cork, shaped like a pear, is indisputably the best, which should not, in general, exceed the size of a nutmeg. Let not the quill, which you put through it, be more than half an inch above and below the cork; and this float, though some prefer a swan's quill, has great advantage over a bare quill; for the quill, being defended from the water by the cork, does not soften; and the cork enables you to lead your line so heavily, that the hook sinks almost as soon as you put it into the water; whereas, when you lead but lightly, it does not get to the bottom till it is near the end of your swim. In leading your lines, be careful to balance them so nicely, that a very small touch will sink them. Some use, for this purpose, lead shaped like a barley-corn; but there is nothing better to lead with than shot, which you must have ready cleft always with you, remembering, that when you fish fine, it is better to have on

your line a great number of small than a few large shot.

Whip the end of the quill round the plug with fine silk, well waxed, which will keep the water out of your float, and preserve it greatly.

In fishing with a float, your line should be about a foot shorter than your rod; for, if it is longer, you cannot so well command your hook when you come to disengage the fish.

Pearch and Chub are caught with a float, and also Gudgeons, and sometimes Barbel and Grayling. For Carp and Tench, which are seldom caught but in ponds, use a very small goose or duck quill float; and for ground bait, you may every now and then throw in a bit of chewed bread. For Barbel, you may bait the place, the night before you fish, with graves, which are the sediments of melted tallow, and may be had at the tallow-chandlers: use the same ground bait, while you are fishing, as for Roach and Dace. In fishing with a float for Chub, in warm weather, fish at mid-water; in cool weather, lower; and, when it is very cold, at the bottom.

Having thus given some necessary rules for float fishing, we shall proceed to a particular description of baits in general for that purpose.

The **ASH GRUB** is a soft, white insect, found, bent head to tail, under the bark of any decayed ash, oak, or alder, that has been some time felled. It is to be preserved in bran.

Of **BEES**, the black ones that breed in clay walls, at the top of the water, and the humble bees, which breed in long grass, at the bottom, are good baits for the Chub.

BOBS are of two colours, yellow and red. The former are gathered in the furrows of fresh-ploughed lands; the latter under cow dung. They are summer baits only, and must be scoured in bran, dry moss, or meal.

BRANDLINGS are worms usually found in old dung-hills, or places near them, as also in tanners bark, when thrown up in heaps after use. They must not be put in water above an hour before use, and then into fennel for immediate use. If you intend them for long keeping, put them into an earthen pot with plenty of moss, fresh shifted every three or four days in summer, and every week in winter; or, at least, the moss must be clean washed and squeezed. The point of the hook must be put in at the end of his tail, and run up to the belly, and very near the head, which must be left hanging down. Some call this worm by the name of the Gilt-tail.

CADEWS, CADIS, or CASE WORMS, are of various sorts, and in their maggot state thus house themselves: one sort in straws, called from thence **Straw-Worms**; others in two or more sticks, laid parallel to one another, creeping at the bottom of brooks; others, with a small bundle of pieces of rushes, duck-weed, sticks, &c. glued together, with which they float on the top, and can row themselves therein about the water, with the help of their feet: both these are called **Cad-Baits**.

All these animals have a wonderful faculty in gathering such bodies as are fittest for their purpose, and then glueing them together, some being heavier than water, that the animal may remain at the bottom, where its food is, (for which purpose they use stones, with sticks, rushes, &c.) and some being lighter than water, to float on the top, and gather its food from thence. These little houses look coarse, and outwardly shew no great artifice; but are well secured, and made within of a hard tough paste, into which the hinder part of the maggot is so fixed, that it can draw its shell after it any where, without danger of leaving it behind, as also to thrust out its body to reach what it wants, or to draw it into its cell, to guard it against injuries.

The **PIPER** is a Cadis, whose husk or case is a

piece of reed, about an inch long, and nearly as big round as a silver two-pence. These worms, being kept three or four days in a woollen bag, with sand at the bottom of it, and the bag wet once a day, will in three or four days turn yellow, when they are an excellent bait for the Chub, or indeed for any great fish, being a large bait.

There is also a smaller Cadis worm, called a **COCK-SPUR**, being in shape like the spur of a Cock, sharp at one end, and the case or house, in which it dwells, is made of small husks, gravel, and slime, in a most curious manner, so as not to be imitated by the art of man.

There is another Cadis, called by some a **ROUGH-COAT**, whose house or case is made of little pieces of rushes, straws, and water-weeds, which are so knit together with condensed slime, that they stick about the husk or case not unlike the bristles of a hedge-hog.

These three Cadis are commonly taken in the beginning of summer, and are good for any kind of float fishing. These at particular times of the year turn into flies; but to pursue this subject further, would be leading the young angler into a very difficult pursuit, highly improper upon this occasion.

DOCK-WORMS are found by plucking up the plants of that name, and washing their roots from the earth. In their fibres are little cases of a red or yellow colour, which upon being opened with a pin, will discover the worm; they are kept in bran, like the gentle.

EARTH BOBS, or GRUBS, are the brood of a beetle found in the furrows of fresh ploughed land. Gather a number of them, and put them, with a peck or two of their own earth, into a tub, and cover them from frost or cold. Thus you may keep them all winter, and kill fish with them at all times. Put them into earth and honey a day before used, and they will be an excellent bait for Bream or Carp.

GENTLES, or MAGGOTS, are easy to be got or bred by putrefaction, and scoured well with wheat bran. They are sometimes added to a worm on the hook, often to a dub-fly; but oftener by themselves, two or three on a hook. You may breed and keep them thus. Take a piece of the liver of any beast, and, with a cross stick, hang it in some corner, over a pot or barrel half full of dry clay; and as they grow big, they will fall into the barrel, where they will scour themselves, and be ready for use whenever you want them. In this manner they may be produced till after Michaelmas. If you desire to fish with them all the year, get a dead cat or kite, let it be fly blown, and when the gentles begin to stir, bury it and them in moist earth, but as free from frost as you can, and you may dig them up whenever you want to use them. They will last till March, when they will turn to flies.

LOB WORMS are found in gardens or in meadow grounds, after rain, by the help of a lanthorn at night. The best are those, which have a red head, a streak down the back, and a broad tail. They may be scoured in fennel or moss washed clean, wetted, squeezed dry, and often changed: but the best way is to take a piece of very coarse cloth, washed clean and dried, and then soaked in fresh beef liquor, in which there has been no salt; wring it, but not too dry; lay it in a broad, deep, glazed earthen pan, and your worms in it, to creep through and scour themselves in. Rinse it out in the same sort of liquor every two days, and your worms will keep a month, if set in a cool place, and be in excellent order. Put what you want for present use in wetted moss squeezed.

RED WORMS are found in rotten earth, or dung-hills, chiefly of cow or hog's dung; but the best are found among tanners bark.

WATER FROGS, which, about February or March,

March, breed in ditches, are not venomous; and are a good bait for some fish, Pike in particular. Put the hook through his mouth, and out of one of his gills. Then sew the upper part of his leg, with only one stitch, to the arming wire of your hook, and he will live a long time.

Of SNAILS, the little white one is a bait for the Roach, and the black one slit for a Chub.

WASPS, when dried in an oven, or boiled, are good baits.

PASTES are of various sorts; and, though some of them have been mentioned before, it may not be improper to bring them into one general view.

Old cheese and turpentine, and a bit of fat rusty bacon, compose an excellent bait for the Chub in winter.

Take some of the finest flour, drop a little milk or water upon it, and work it well in the palm of your hand, till almost dry. Then temper it with a small quantity of the finest honey, make it into a round ball, and keep it in a moist linen cloth; or it will grow dry and hard. If you would have it yellow, mix turmeric with it; if of a flesh colour, vermilion, and knead it well.

Take some old Cheshire cheese, the crumb of a French roll, and some sheep's kidney-suet, beat them in a mortar into a paste, adding as much clarified honey as will soften it. This is excellent for a Chub.

Take Shrimps and Prawns, pull off the shells, and skins; and beat the clear meat in a mortar, with a little honey, till it comes to a paste: with this cover the point of the hook.

Grate fine bread in a little clear water, in which gum ivy has been soaked, and you will find it a good bait for Roach and Dace.

For Carp or Tench, you may mix crumbs of bread with honey, and you will often find it answer your wish.

With respect to the use of pastes, observe these general rules: Proportion the quantity of paste you put upon your hook to the size of the fish, for which you angle. Pastes must not be angled with in rapid streams; but on small hooks, in pits, ponds, lakes, or slow running rivers.

WHEAT. A handful or two of the best wheat, boiled in a little milk till soft, and fried leisurely with honey, and a little beaten saffron dissolved in milk, is a good bait for Roach, Dace, Chub, or Grayling.

OF FLY FISHING.

FLY FISHING, or fishing at the top of the water, is of two sorts; with a natural and living fly, or with an artificial and made fly.

Of the natural flies, those mostly in use are the Green-Drake and the Stone-Fly, and these in the two months of May and June only; but there are others, of which, as well as of these, we shall give a short history at the end of this account of Fly-Fishing.

These are to be used with a short line, not more than half the length of your rod, if the wind is still; but, if you have a wind that will carry it from you, it may then be longer. This way of fishing is called Dapping, Dabbling, or Dibbling, wherein you are always to have your line flying before you up or down the river, as the wind serves, and to angle as near as you can to the bank of the same side on which you stand; though, when you see a fish rise near you, you may guide your fly over him, whether in the middle, or on the contrary side, and if you are pretty well out of sight, either by kneeling, or the interposition of a bank or bush, you will be always sure to take him, provided you are quick in your motions: your fish may otherwise remove to some other place,

if it be in the still deeps, where he is always in motion, and roving up and down for prey; but in a stream you may generally, especially if there is a large stone near, find him in the same place. Your line, in this case, ought to be of three good hairs next your hook; because in this kind of angling you are to expect the largest fish, and that, wanting length to give him line after he is struck, you must be forced to tug for it. However, not an inch of your line being suffered to touch the water in dibbling, it may be allowed to be stronger on that account.

We come now to the second way of angling at the top of the water, which is with an artificial fly. In this kind of sport, you are to angle with a line longer by a yard and a half, and sometimes two yards, than your rod; and with both this and the other, in a calm day in the streams, in a breeze that curls the water in the still deeps, you are likely to strike the best fish.

For the length of your rod, you are always to be determined by the breadth of the river in which you intend to angle. For a Trout river, one of five or six yards is long enough. If it is longer, be it ever so neatly and artificially made, it will soon become tiresome, and change your sport into toil and labour.

The length of the line, to a man that knows how to handle his rod, and cast it properly, is no manner of incumbrance, excepting in woody places, and in landing of a fish, which every one, who can afford to angle for pleasure, has somebody to do for him; and the length of line is a great advantage in fishing at a distance: to fish fine, and far off, is a principal matter in Trout angling.

Your line in this case should never be less, nor ever exceed two hairs next the hook; for one, whatever some may pretend, is not sufficient, as the least accident, even with the finest hand, may break it. However, he that cannot kill a Trout of twenty inches long with two hairs, in a river clear of wood and weeds, deserves not the name of an angler.

To have your whole line as it ought to be, two of the first lengths, nearest the hook, should be of two hairs each, the next three lengths above them of three, the next three above them of four, and so of five, six and seven, to the very top; by which means your rod and tackle will, in a manner, be taper from your very hand to your hook, your line will fall much better and straighter, and cast the fly to any certain place, to which the hand and eye shall direct it, with less weight and violence, which would otherwise circle the water, and fright away the fish.

In casting your line, do it always before you, and in such a manner, that your fly may first fall upon the water, and as little of your line with it as possible; though, if the wind be very brisk, you will then of necessity be obliged to sink part of your line to keep your fly in the water. In casting your fly you must aim at the further, or nearer bank, as the wind serves your purpose, which will be with and against you several times, on the same side, in an hour, as the river winds in its course, and you will be forced to angle up and down by turns accordingly; but you must endeavour, as much as you can, to have the wind on your back, and always be sure to stand as far off the bank as your length of line will give you leave, when you throw to the contrary side. When the wind will not permit you so to do, and that you are forced to angle on the same side on which you stand, you must then go to the very brink of the river, and cast your fly, at the utmost length of your rod and line, up or down the river as the gale serves.

Having now done with both ways of fishing at the top of the water, and the length of your rod and line for those purposes, we shall proceed to mention what materials the angler should be supplied with, in order

order to make artificial flies. As to the making them, many writers on angling have attempted to give directions for that purpose; but it is certain, if the angler is supplied with proper materials, and has the opportunity of seeing expert artists make flies, he will learn more from one week's practice and observation, than he possibly can in a twelve-month from the perusal of any book that was ever wrote on that subject.

First, you must be provided with bear's hair of different colours, as grey, dun, light, and dark-coloured, bright brown, and that which shines. Also camel's hair, dark, light, and of a colour between both. Badger's hair, or fur. Spaniel's hair from behind the ear, light and dark brown, blackish and black. Hog's down, which may be had about Christmas of butchers, or rather of those that make brawn: it should be plucked from under the throat, and other soft places of the hog. These should be either black, red, whitish, or sandy. If you want them of any other colour, you may send them to the dyer's.

Seal's fur is to be had at the trunk-maker's. This you may get dyed of the colour of calves and cows hair, in all the different shades, from the lightest to the darkest brown. You will then never need cows or calves hair, both which are harsh, and will never work kindly, nor lay handsomely.

Get also mohairs, black, blue, purple, white, and violet; camlets, both hair and worsted, blue, yellow, dun, light and dark brown, red, violet, purple, black, pink, and orange colours.

A piece of an old Turkey carpet will furnish excellent dubbing: untwist the yarn, and pick out the wool, carefully separating the different colours, and lay it by.

Get also furs of the following animals, viz. the squirrel, particularly from his tail, fox cub, from the tail where it is downy, and of an ash colour: an old fox, an old otter, a hare, from the neck, where it is of the colour of withered fern; and above all, the yellow fur of the martern, from off the gills or spots under the jaws. All these, and almost every other kind of fur, are easily got at the furriers.

Hackles are a very important article in fly making. These are the long slender feathers, which hang from the head of a cock down his neck. Fine ones may be also taken from near his tail; but be careful that they are not too rank, which they always are when the fibres are more than half an inch long. Be provided with these of the following colours, red, dun, yellowish, white, orange and perfect black; and whenever you meet, alive or dead, with a cock of the game breed, whose hackle is of a strong brown red, never fail to buy him. Observe, however, that the feathers of a cock chicken, be they ever so fine for shape and colour, are good for little; for they are too downy and weak to stand erect after they are once wet; and so are those of the bantam cock.

Feathers are absolutely necessary for the wings, and other parts of flies: get therefore feathers from the back and other parts of the wild mallard, or drake; the feathers of a partridge, especially those red ones that are in the tail; feathers from a cock pheasant's breast and tail; the wings of a blackbird, a starling, a jay, a fieldfare, and a water coot; feathers from the crown of the pewit, plover, or lapwing, and feathers from a heron's neck and wings.

Be provided with marking silk of all colours, fine, but very strong; gold and silver flatted wire or twist, a sharp knife, hooks of all sizes, hog's bristles for loops to your flies, shoemaker's wax, &c.

Remember, with all your dubbing, to mix bear's hairs, and hog's wool, which are stiff, and not apt to imbibe the water, as the fine furs, and most other kinds of dubbings do; and remember also, that martern's fur is the best yellow you can use.

The angler, who possesses these materials, and observes the manner in which skilful fly makers use them, will soon be enabled to form any fly whatever; for this art, like every other, is to be acquired only by practice. We might form an entire volume of nothing but lists of artificial flies for the use of every month in the year, which, instead of improving the young angler, would only contribute to dishearten and perplex him; we shall therefore content ourselves with mentioning only the twelve following:

1. The **DUN FLY**, in March: the body is made of dun wool, and the wings of the partridge's feathers.

2. Another **DUN FLY**, the body of which is made of black wool, and the wings of the black drake's feathers, particularly those under his tail.

3. The **STONE FLY**, in April, whose body is made of black wool, coloured with yellow under the wings and tail. For this fly you must use the wings of the drake.

4. The **RUDDY FLY**, in the beginning of May. Make his body of red wool, wrapt about with black silk. The feathers to be used are the wings of the drake, and the feathers of a red capon, which hang down on his sides next to the tail.

5. The **YELLOW or GREENISH FLY**, in May. Make the body of yellow wool, and the wings of the red cock's hackle or tail.

6. The **BLACK FLY**, in May, whose body may be made of black wool: the wings are made of those of a brown capon.

7. The **YELLOW FLY**, in June. His body is made of black wool, with a yellow list on each side. The wings should be formed of feathers taken from the wings of a buzzard, bound with black hemp.

8. The **MOORISH FLY**, whose body is made with darkish wool, and the wings of the same coloured mail of the drake.

9. The **TAWNY FLY**, which is good till the middle of June. The body is made of tawny wool, and the wings of the whitish mail of the wild drake.

10. The **WASP FLY**, in July. Make his body of black wool wrapped about with yellow silk: the wings must be made of the feathers of the drake or buzzard.

11. The **SHELL FLY**, which is useful in the middle of July. The body is made of greenish wool, wrapped about with the hurle of a peacock's tail, and the wings with feathers from those of a buzzard.

12. The **DARK DRAKE FLY**, which is good in August. The body is made with black wool, wrapped about with black silk. His wings are made with the mail of the black drake, with a black head.

Having said thus much of artificial fly-making, it may not be improper to give the young angler a short account of a few of the most material natural flies, in imitating which he may employ himself at home, when the weather will not permit him to pursue his sport abroad; and he may be assured, that, in collecting and arranging the materials, and imitating the various shapes and colours of these admirable creatures, he will soon find little less pleasure than even in catching fish.

The **GREEN DRAKE FLY** comes in about the middle of May; but are never properly fit for use till the end of that month, or the beginning of June, though they are sooner or later, according to the season of the year.

The **STONE FLY** comes much sooner, so early as the middle of April, but is not properly in season till the middle of May. He continues to kill much longer

longer than the green drake remains with us, even so long as almost to the end of June.

Both these flies, and perhaps many others, are certainly bred in the very rivers where they are taken. Our cadis, which lie under stones, in the bottom of the water, turn into these two flies; and, being taken in their husk near the time of their maturity, are very easily known and distinguished, being the largest of all others.

The green drake never discloses from his husk till he is there first grown to full maturity, body, wings, and all; and then he creeps out of his cell, but with his wings so cramped and ruffled, by being pressed together in so narrow a compass, that they are for some hours totally useless to him. Hence he is compelled either to creep upon the flags, sedges, and blades of grass, if his first rising from the bottom of the water be near the banks of the river, till the air and sun stiffen and smooth them. If his first appearance above water happens to be in the middle of it, he then lies upon the surface of the water; for his feet are totally useless to him there, as he cannot, like the stone-fly, creep upon the water, until his wings have acquired the necessary stiffness. In the mean time, it is a chance, if he does not fall a prey to some trout or grayling. If he escapes these fish, his wings soon get strength, which stand on his back like those of a butterfly, and his motion in flying is the same.

The body of this fly is, in some, of a paler, in others, of a darker yellow; for they are not in all exactly of a colour. They are ribbed with rows of green, long, slender, and growing sharp towards the tail, at the end of which they have three small whisks of a very dark colour, almost black, and their tails turn up towards their back like a mallard, from whence undoubtedly they have the name of Green Drake.

With these the angler must dabble; and, having gathered a sufficient quantity of them into a draw-box, with holes in the cover to give them air, where they will continue vigorous and fresh a night or two, he may take them out thence by the wings, and bait them upon the hook in the following manner:

First take out one, (for you must fish with two of them at a time) and, putting the point of the hook into the thickest part of his body under one of his wings, run it directly through, and out at the other side, leaving him spitted cross upon the hook. Then, taking the other, put him on after the same manner; but with his head the contrary way. In this posture they will live upon the hook, and play with their wings for more than a quarter of an hour. You must take care to keep their wings dry in playing them on the water, and that your fingers are not wet when you take them out to bait them; for then your bait will be spoiled.

With respect to this fly, it remains only to acquaint the angler, that it is taken at any time of the day.

We must now be a little more particular concerning the stone-fly, which has not the patience to continue in his crust or husk till his wings are full grown; but as soon as they begin to put themselves out, he feels himself strong, squeezes himself out of his prison, and crawls to the top of some stone, where, if he can find a chink that will receive him, or can creep between two stones, the one lying hollow upon the other, he there lurks till his wings are full grown: that is your only place to find him, and from thence he undoubtedly derives his name. For want of such a convenience, he will make shift with the hollow of a bank, or any other place, where the wind cannot come at him to force him away.

His body is long, and pretty thick, and almost as broad at the tail as in the middle. His colours

No. 32.

are a very fine brown, ribbed with yellow, and much yellower on the belly than the back. He has also two or three whisks at the tag of his tail, and two little horns upon his head. His wings, when full grown, are double, and flat down his back, of the same colour, though rather darker than his body, and also longer. He makes but little use of his wings; for he is seldom seen flying, though often swimming and paddling in the water with the several feet he has under his belly, without stirring a wing: whereas the drake will mount steeple high into the air, though he is to be found every where high and low near the river.

The stone-fly is to be used much in the same manner as before directed for the drake; but the trout is found to take the latter more greedily than the former.

The **LITTLE YELLOW MAY FLY** is in shape exactly as the green drake; but is very little, and of as bright a yellow as can be seen.

The **CAMLET FLY** is in shape like a moth, with fine watered wings, and is an excellent bait for the grayling. This fly, though it comes in May, continues all the month of June.

The **PALMER FLY** is a caterpillar, or worm, which never continues long in one state, though their colours are very elegant and beautiful. The following is a description of one of them in their most brilliant dress. His lips and mouth are a little yellow, his eyes black as jet, his forehead purple, his feet and hinder parts green, his tail two-forked and black, the whole body stained with a kind of red spots, which run along the neck and shoulder blade, not unlike the form of a St. Andrew's cross, and a white line drawn down his back to his tail. At a fixed age, this caterpillar ceases to eat, and towards winter is covered over with a strange shell or crust, called an Aurelia, and in that manner remains in a state of total inaction during the whole winter; but in the spring following, he commences a painted butterfly. To pursue this curious insect through all its various changes, would be useless here, as it is sufficiently described in other parts of this work.

The **OAK FLY** is also known by the name of the **ASH FLY** and the **WOODCOCK FLY**. Bowkler, in his Art of Angling, says, "This fly, as I have lately been informed by a gentleman of veracity, is bred in those little balls, which grow on the boughs of large oaks, commonly called oak apples, which he accidentally discovered by opening several of these balls, which had been gathered in the winter, and brought into the house. In each of them he found a fly, some of which, being enlivened by the warmth of the room, immediately took flight, and fixed in the window, with the head downwards, the position they observe on the trees."

This fly is found on the body of an oak or ash, from the beginning of May to the end of August. It is of a brown colour, and is easily taken.

The **ANT FLY** is often found in June, though it is in its highest perfection in July, and lasts till August and September. They must be taken from their hills, with a handful of their earth, and roots of the grass about them, and put all together in a large glass bottle. If they are not bruised in taking, nor their wings hurt, they will live above a month. If you would keep them longer, put them into a barrel, first washing it with honey and water. They are very good baits for roach, dace, or chub, fishing near the ground.

Of **ROCK ANGLING, NIGHT ANGLING, &c.**

ROCK-FISHING is practised chiefly in the South and South-West parts of England, and in some parts of Ireland. When you fish from rocks,

4 E

your

your line must be very strong, and consist at least of five or six hairs in a link. A float is necessary, and two hooks, one to reach the bottom, and the other to keep in mid-water. The best time for this sport is, when the tide is half spent; and till within two hours of high water. Morning and evening are the most preferable times, if the tide answers. The cockle, lob, and marsh-worms are the general baits used, and a hairy worm found on the sea shore. The prizes of this fishing are only Sea Bream, Flounders, Whiting-Pollock, and Rock-Whittings.

With respect to NIGHT ANGLING, few other fish are taken at that time but Trout and Eels. In the night, the best Trout come out of their holes, when they are taken on the top of the water with a great lob or garden worm, or rather two, which you are to fish with in a place, where the water runs quietly; for in a stream the bait will not be so well discerned.

In a dead place, near a current, draw your bait over the top of the water, backwards and forwards, and, if there is a Trout in the hole, he will take it, especially if the night is dark; for then he is bold, and lies near the top of the water, watching the motion of every frog, or any thing else, that swims between him and the sky. He hunts after his prey, if he sees the water but wrinkle, or move in one of these dead holes, where the large old Trouts usually lie, near to their holds; for he is both subtle and fearful, and does not usually stir out of his hole, but lies in it as close in the day, as the timorous hare does in her form. The chief feeding of either is seldom in the day, but usually in the night, and then the large Trout feed very boldly.

You must fish for him with a strong line and a large hook, and let him have time to bite; for he does not usually forsake the hook at night, though he does frequently in the day. If the night is not dark, you must in that case fish with an artificial fly of a light colour, and at the snap; indeed, in the night, he will rise at almost any thing.

Night angling is not, however, to be recommended, as it is in some measure dangerous, and very unwholesome.

The safest method of catching fish by night, particularly Eels, is by lines left in the water from the evening till the next morning. For this purpose, your line must be fifteen or twenty yards long, according to the width of the place in which you intend to throw it. To this, at equal distances, tie five or six hempen lines, of a moderate thickness. To each of these whip a hook, and bait with a Minnow, or any small fish; but, if they are not to be had, you may make use of a large lob-worm, or even a piece of beef. If you bait with a fish, put the point of the hook in at the tail, and out at the mouth, and cover the point of the hook with a small worm. At the hook end of the cord, fasten a weight about two pounds, and throw it across the river into some still deep, or at the tail or side of a deep current, first taking care, however, to fasten the other end of the line round a tree, or to some other secure place. When you go in the morning, it will be a chance if you do not find fish ensnared on the hooks.

There are other methods of catching fish, such as bobbing, dabbling, snigging, snapping, trolling, and fishing at hand. Of the three first, we have already made mention; we shall now proceed to describe the three last.

SNAPPING is a method of catching Pike with a rod sixteen or seventeen feet long, a stout whalebone top, as thick as the upper part of your little finger, and a strong line not quite so long as your rod. The snap-hook may be thus made. When it is to be placed at the end of your line, take twelve inches of gimp, and two large Salmon hooks, and turn them back to back. In the middle place the

gimp, and whip them together with silk well waxed: then place a Pearch hook between the other two, and fasten it towards the upper part of the shanks with waxed silk. At about eighteen inches from the bottom of your line, put on a large float of cork, and under it as much lead as will poise it. Fix your bait to the small hook, by running it under the back fin, (the best are Gudgeons, Dace, and small Roach) and let it swim down the current. When your float is drawn under water, give a strong jerk, and when you find you have hooked your fish, play him properly, and use the landing net.

TROLLING differs from snapping, in this, that the head of the bait fish must be at the bent of the hook, and that you must give the fish time to pouch or swallow the bait. Trolling hooks, which differ much from those for the snap, are to be bought ready made at the tackle shops, and therefore need no description.

ANGLING BY HAND is of three sorts, which we shall proceed to describe separately.

The first, with a line about half the length of the rod, a good weighty plumb, and three hairs next the hook, which is called a Running Line, and with one large brandling, or a dew worm of a moderate size, indeed, with almost any worm whatever; for, if a Trout is in the humour to bite, there is hardly any worm he will refuse. If you fish with two worms, you are then thus to bait your hook. First run the point of your hook in at the very head of your first worm, and so down through his body till it be past the knot, and then let it out. Slip the worm above the arming, that you may not bruise it with your finger till you have put on the other, by running the point of the hook in below the knot, and upwards through his body towards his head, till it be just covered with the head, which being done, you are then to slip the first worm down over the arming again, till the knots of both worms meet together.

The second way of angling by hand, and with a running line, is with a line something longer than the former, and with tackle made in this manner. At the extremity of your line, where the hook is always placed in all other methods of angling, you are to have a large musket bullet, into which the end of your line is to be fastened with a peg or pin even and close with the bullet. About half a foot above that, must be a branch of line, of about half a yard long for a swift stream, with a hook at the end, baited with worms; and, at about half a foot above that, another branch of line, armed and baited after the same manner, but with another sort of worm. Both these ways of angling at the bottom are most proper for a dark and muddy water, because in such a condition of the stream, a man may stand as near as he will, and neither his own shadow, or that of his tackle, will hinder his sport.

The third way of angling by hand, with a ground bait, and by much the best of all others, is with a line full as long, or a yard and a half longer than your rod, with no more than one hair next your hook, and for two or three lengths above it. There must be no more than one small pellet for your plumb, your hook little, your worms of the smaller brandlings well scoured, and only one upon your hook at a time, which is thus to be baited. The point of your hook is to be put in at the tag of his tail, and run up his body quite over all the arming, and still stripped on an inch at least upon the hair, the head and remaining part hanging downwards. With this line and hook thus baited, you are to angle in the streams, always in a clear rather than a troubled water, always up the river, throwing out your worm before you, with a light one-handed rod, like an artificial fly, where it will be taken sometimes at the top, or within a very little of the surface of the water,

water, and almost always before the light plumb can sink it to the bottom. Provided the rod is light and pliant, and true and finely made, a skilful hand will do wonders; and in a clear stream, it is undoubtedly the best method of angling for a Trout or Grayling.

Some PARTICULARS not generally known by
YOUNG ANGLERS.

THERE are particular methods of making baits more agreeable to fish than what are commonly practised; and, though the use of oils, ointments, &c. are by many anglers treated with contempt, it is nevertheless certain, from repeated experiments, that the following have been known to contribute greatly to the sport; at the very time, and on the same spot, when others, who despised the use of them, could catch nothing.

Anoint a little box with two or three drops of the oil of ivy berries, made by expression or infusion. Put your worms into this box about an hour or two before you use them, and they will acquire a smell, which is irresistibly attractive, and will force any fish within the smell of them to bite.

Some have dissolved gum of ivy in oil of spike, and therewith anointed a dead bait for a Pike, when the fish has followed it with more than common eagerness. And others affirm that any bait anointed with the marrow of the thigh bone of a herne is a great temptation to any fish.

Camphire put with moss into your worm bag with your worms, makes them, if many anglers are not very much mistaken, a tempting bait.

The roe of a Salmon or Trout is said to be an excellent bait. You may preserve it, by sprinkling it with a little salt, and laying it upon wool in a pot, one layer of wool, and another of spawn.

To know at any time what bait fish are apt to take, open the belly of the first you catch, and take out his stomach very tenderly: open it with a sharp pen-knife and you will discover what he fed on.

RULES and CAUTIONS to be observed by
YOUNG ANGLERS.

WHEN you have hooked a fish, never suffer him to run out with the line; but keep your rod bent, and as nearly perpendicular as you can. By this method, the top will ply to every pull he

shall make, and you will prevent the straining of your line.

For the same reason, never raise a large fish out of the water, by taking the hair to which your hook is fastened, or indeed any part of the line into your hand; but either put a landing net under him, or, for want of that, your hat. You may, indeed, in fly-fishing, lay hold of your line to draw a fish to you; but that must be done with great caution.

Your silk, for whipping hooks, and other fine work, must be very small. Use it double, and wax it, and indeed any other kind of binding will do with shoe-makers wax, which of all wax is the toughest and holds best. If your wax is too stiff, temper it with tallow.

Inclose the knots and joints of your lines in a small pill of wax, pressed very close, and the superfluties pinched off. This will soon harden, and prevent the knots from drawing.

If for strong fishing you use grass, which, when you can get it fine, is to be preferred to gut, remember always to soak it about an hour in water before you use it: this will make it tough, and prevent its breaking.

When you begin fishing, wet the ends of the joints of your rods, which, as it makes them swell, will prevent their loosening.

If you happen, with rain or otherwise, to wet your rod, so that you cannot pull the joints asunder, turn the ferrel a few times round in the flame of a candle, and they will easily separate.

Before you fix the loop or bristle to your hook, in order to make a fly, to prevent its drawing, be sure to singe the end of it in the flame of a candle. Do the same by a hair, to which at any time you whip a hook.

Make flies in warm weather only; for in cold your waxed silk will not draw.

In rainy weather, or when the season for fishing is over, repair whatever damage your tackle has sustained.

Never regard what bunglers and slovens tell you; but believe that neatness in your tackle, and a nice and curious hand in all your works, especially in fly-making, are absolutely necessary.

Never fish in any water, that is not common, without leave of the owner, which is seldom denied to any but those who do not deserve it.

If at any time you happen to be overheated with walking, or other exercise, avoid small liquors, especially water, as you would poison; but rather take a glass of rum or brandy, the instantaneous effects whereof, in cooling the body, and quenching drought, are amazing.

OBSERVATIONS on HOT-BEDS, and WATERING of PLANTS.

I N T R O D U C T I O N.

THE science of Vegetables may, with propriety, be divided into three classes: the first consists of the order of their arrangement in the botanical nomenclature; the second, of their culture; and the third of their properties. The two first, while they serve to amuse and delight us, enable us more readily to comprehend the last, which is the only one of real importance, and which claims our most serious attention.

However necessary the proper arrangement of the various species of Vegetables may appear, it is very certain, that the immense labours, which some late botanists have undergone, to give us a list of the names of plants, can contribute very little to the discovery of their properties. We should be led to suppose, from the repeated endeavours to systematise this science, that the whole of the student's pursuit was directed to acquire the names of plants. More time has been consumed in making catalogues of this nature, than, if properly applied, would have been sufficient to acquire a tolerable knowledge of the science, and perhaps have enabled the botanist to discover several new properties in the vegetable world, as yet unknown.

Numberless efforts have been made to impress distinct ideas of each plant, without fully describing

them; but every botanical system has hitherto failed in this particular, since nothing but a perfect description of each can give an adequate idea. For this reason, leaving such systems to the speculative, we shall, in the following work, pursue the common method, and give a perfect account of every Vegetable in use, its roots, leaves, stalk, height, flower, and seeds. Such complete distinctions are absolutely necessary to distinguish one object from another, throughout every department of Natural History, but particularly in this, where the objects are so numerous. The deviations of Nature are not to be reduced into systems: almost every plant, even of the same species, has its variations, this year differing, in some respects, from what it was the last.

Let us then, without paying any regard to systematical arrangement, treat this subject in the manner of the ancients, such as Pliny and Aristotle. Those, that have been already useful to mankind, we shall take particular care minutely to describe, and leave posterity and chance to find out the uses of others now unnoticed. But, before we proceed in this undertaking, it may not be improper to take a survey of Vegetables in general.

In every vegetable production, we may consider either the seed, the root, the leaf, the bark, the stalk, the

the pith, and the flower: all which are necessary in carrying on the business of vegetation, and transmitting the species, from season to season, without interruption. Though the principles of vegetation reside in every part of the plant, yet we generally find greater proportions of oil in the more elaborate and exalted parts of Vegetables, that is, in the seed. As this contains the rudiments of the future Vegetables, it was necessary that it should be well stored with principles, that would preserve the seed from putrefaction, and tend to promote vegetation. When the seed is sown, in a few days, it imbibes so much moisture as to swell, and thus it produces the radicle, or incipient root, with some force, which, when shot into the ground, imbibes nourishment from thence, and what it receives becomes, in a short time, the chief supply of future growth. When the root is thus far grown, it supplies the plume with nourishment, till this, by expanding and growing thinner, turns to green leaves, which are of such importance to the incipient plant, that it perishes, and will not thrive, if they are pulled off; but when the plant is so far come to maturity, as to have branches and expanded leaves to draw up nourishment, the feminal leaves, being no longer useful, soon perish, their perspiration being immediately impeded by the newly produced leaves that overshadow them, and their sap being drawn away by the larger channels of the upper foliage.

As the plant advances in stature, the first, second, third, and fourth order of lateral branches shoot out, each lower order being larger than those immediately above them, not only on account of their having a longer time to grow, but because, being inserted in larger parts of the trunk, and nearer the root, which is the grand supply, they are provided with greater plenty of sap: hence we frequently see trees beautifully tapering to the top.

As soon as the circulation of the blood in animals was discovered, botanists began to think, from the analogy there was between all the works of Nature, that the same circulation must also prevail in Vegetables; and some have actually undertaken to prove, that the sap first rises to the tops of trees by means of the pith, and then descends to the root by the bark, with the swiftest motion. That great naturalist, Dr. Hales, undertook by experiments, to confute this opinion; but, without entering into a detail of that gentleman's opinion, or that of Mr. Du Hamel, thus far we may venture to conclude, as a certain fact, that there is a constant flow of juices through every plant, the root furnishing it with great quantities, while the leaves, spreading an extended surface to the sun, have their moisture attracted in very large quantities; and, when the influence of his beams no longer continue, they at night act as sponges, and imbibe the humidity of the air. Thus we see, that the leaves are absolutely necessary in the works of vegetation: they, like young animals, are furnished with instruments to suck it from thence, and, besides this, they separate and carry off the redundant watery fluid, which, by being long detained, would turn rancid, and become fatal to the plant.

As the leaves are found to exhale moisture, so they are known to imbibe nourishment from the air. The acid and sulphureous spirit, with which the air abounds, is thence extracted by the leaves of plants: so that it is probable, the most exalted and aromatic principles of Vegetables are derived from this source, rather than from the grosser watery fluid of the sap. Leaves are found to perform, in some measure, the same office for the support of vegetable life, that the lungs of animals do for the support of animal life; but, as plants have not the power of contracting or dilating the chest, their inspirations will depend wholly on the alternate changes of the air. The

vine is known, from repeated experiments, to draw but little watery nutriment from the earth by its roots, and therefore it imbibes greater quantities of dew, impregnated with air by night, from whence it derives its richness of flavour. It is probable, that this may be the reason, why plants in hot countries abound more with fine aromatic principles, than northern Vegetables: the former chiefly extract their juices from the air by the leaf, the latter theirs from the earth by the root.

Nothing can exceed the regularity, with which leaves are placed on every plant; but the care which Nature seems to take of the young shoots when budding, still deserves greater admiration; for the most tender shoots are ever nourished by those, which have acquired a greater degree of strength. Besides this, the leaf, as every one knows, has two different surfaces: the upper, which seems more smooth and polished; the lower, in which the ribs are more prominent, and of the colour of a paler green. The cause of this difference has not a little puzzled the botanists of every age: perhaps, the upper polished surface, from its position, being more exposed to the external injuries of the air and rain, is thus formed rather to defend the lower part, in which, probably, the attractive powers may reside. In this manner, the leaves of trees contribute to improve the flavour of the fruits, and regulate the vegetation.

The assiduity of Nature in the production of growing plants, is not greater than her care to preserve the seeds, which are to propagate the future Vegetables. The curious expansion of blossoms and flowers seem to be appointed by Nature, not only to protect, but also to convey nourishment to the embryo seed, and the fruits in general serve to supply the seeds with moisture.

When trees stand thick together in woods or groves, the lower branches, being shaded by those of the neighbouring trees, can perspire little, and imbibe less, on which account they perish; but the top branches, being exposed to a free air, perspire plentifully, and by this means drawing the sap to the top, advance in height rather than extent. Dr. Hales compares a tree to a complicated engine, which has as many different powers of attraction, as it has arms or branches, each drawing from their common fountain of life, the root. The younger the plant, the greater is its power of attraction; but, as it grows older, the vessels of circulation become more rigid, it ceases to push out its tender branches, and the whole plant, from the rigidity of age, acquires its greatest degree of hardness, when it ceases to vegetate.

Though fruits in general are the most inconsiderate agents in promoting the work of vegetation, being, as is commonly supposed, only destined to supply the seed with proper moisture and nourishment; yet, with respect to man, they make the most useful and pleasing part of vegetable productions. Their general properties, as constituting a part of our food, may be considered as arising from their different degrees of maturity. In general, while unripe, they may be considered as astringent, and in some measure partaking of the qualities of the bark of their respective trees: when come to a sufficient degree of maturity, they cool and attenuate; but, from too great a power in these respects, they often bring on disorders that are fatal in warm climates, where their juices are possessed of those qualities much more than with us. In our climates, however, this seldom happens, and they probably do not make a sufficient part of our diet.

As to the increase of plants, some proceed from seeds only, others from seeds and suckers; as tulips, for instance, which have seeds in their pistils, and a large quantity of small suckers, which rise, in a numerous progeny, round the parent plant. Some

are propagated and brought to perfection by grafts, which are no more than small branches of the finest sort artfully inserted in an aperture, made in the wood or bark of some wild or ordinary plant; while others are multiplied by slips. The strawberry plant throws out two long fibres on each side, the knots whereof take root in the earth, and become so many new stems. The branch of a vine bowed down, and thrust into the earth, shoots out fibres through the knots that lie buried and concealed; cut the branch off where it joins with the stock, and the other end, which rises out of the ground, becomes a new vine. In short, there are plants, which proceed from little slips or twigs of trees, when set in the ground, without any other manual operation.

There is no difficulty in accounting for the two first; because a seed, or a seed and a sucker, contain in them a shoot, or a minute plant complete. The graft, likewise, containing its buds for leaves, as well as fruits, the sap, when it flows into it, not only gives, but discovers what the graft contains. Let us now proceed to what at first sight seems more difficult to be accounted for, the increase from slips of trees. When we set a slip into the ground, the sap, which overflows it, puts some of those shoots in motion, which are to produce new branches. The little suckers, which expand themselves on each side, are, by the pressure of the earth upon them, prevented from rising with ease into the air. The juice, which ascends into the stem, coming afterwards to flow back, and descend upon the same suckers in the earth, take their course downwards instead of upwards, and become roots instead of branches. From whence we may conclude, that the stem gives only a passage to the sap and the air, and that the sap and air give nutriment and motion to all the shoots; that these shoots are produced before-hand, and are perhaps wrapped up in one another, as they were from the beginning of the world, for the benefit and advantage of mankind, through the succession of all ages.

We must not quit our considerations on Vegetables, without paying particular respect to flowers, which are formed to please us, and for our delight have received their amiable appearances: no eye but ours can enjoy their beauties: common animals never seem to be affected with pleasure when they behold them, nor do they ever stop to contemplate their wonders. They confound them with the common herbage of the field, they trample on the most beautiful of the tribe, and are perfectly insensible of this ornament of the earth. Whereas man, amidst a crowd of objects and riches that surround him, distinguishes and pursues the flowers with a peculiar complaisance.

Flowers have likewise an agreeable correspondence with our eyes, and a set of powerful attractions that invite us to approach them. Whenever we gather them, they present us with new perfections, in proportion to our regarding them with nearer attention. The greatest part of them not only regale our view with the beauty and arrangement of their colours, but gently delight our smell with an exquisite perfume; and, when they have gratified our senses with an innocent satisfaction, the mind still discloses wonders in them, which ravish its faculties.

When we carefully survey the structure of a flower, in order to discover its relation with the seed, we always find one or more inclosures appointed for the reception of the semen. Around that inclosure is a set of chives sustaining several packets of powder, which they scatter on all parts. The whole is encompassed with an empalement, or soft robe, that unfolds and closes, with a kind of precaution, according to the disposition of the air.

All these things convince us, that these parts, which are disposed with so much art and regularity, and wither round the inclosure, when the seed is formed, are instrumental in the generation of that seed.

It is difficult to conceive, how far the design, to delight man with the beauty and profusion of flowers, has been extended. Their multitude is a real prodigy, and we are led to imagine, that they had been commanded to spring beneath every step we take. They rear their heads on the lofty tops of trees, and are diffused through the herbage that creeps along the earth; they embellish the valleys and the mountains, and the meadows are enamelled with their colours; they are gathered from the skirts of woods, make their appearance even in deserts, and the earth is a garden entirely covered with their bloom. The prospect they afford us is so pleasing, that the generality of those arts, which are ambitious to please, seem most successful when they borrow the assistance of flowers: sculpture imitates them in its softest ornaments, architecture courts the embellishments of leaves and festoons on those columns and fronts, which would otherwise be too naked: the richest embroideries are little more than foliage and flowers; the most magnificent silks are almost covered with these charming forms, and are thought beautiful in proportion as they resemble the lively tinge of natural flowers.

Flowers are not only intended to beautify the earth with their shining colours, but the greatest part of them, in order to render the entertainment more exquisite, diffuse a fragrance that perfumes all the air around us; and it should seem as if they were solicitous to reserve their odours for the morn and evening, when walking is most agreeable; but their sweets are very faint during the heat of the day, when we visit them the least. Let us endeavour to account for this.

The sap is perpetually transpiring through the flowers, in proportion to the sun's warmth. These fine spirits, which are the essence and aromatic parts of the flowers, are easily dispersed through an air rarified by heat, and affect the smell but faintly at that time; but their dissipation is much abated, when the air is condensed by the return of night. The action of the sun, by which they are diffused, is too weak, in the morning and evening, to scatter them to any considerable distance, and it is then that the reunion of these spirits affect us with the strongest impressions. The evaporation of these minute particles forms an atmosphere around the flower, which is dissipated or condensed, as the action of the sun is more or less intense.

This is a demonstration, that the spirit of flowers are dispersed in proportion to the sun's action upon them; but we will not confine ourselves to this particular: in the study of natural things, true philosophy is never limited to the contemplation of their mechanism, but extends its curiosity to the benefits they produce. We are easily sensible of the intercourse that appears between the flowers, the air, and the sun beams; and can we possibly be unacquainted with that goodness, which is so attentive to make this correspondence advantageous to man? Providence has not only enamelled his way with flowers, for the entertainment of his view, but has taken care to embalm and purify the air he breathes, by shedding the noblest perfumes in his passage.

Their services, however, are not limited to the sight and smell, for other senses may derive advantages from them. They supply us with pastes to enrich our deserts, and present us with powders to perfume our wardrobes; they afford us delicate syrups, and even remedies to relieve us, when we are indisposed; violets, jonquils, and peach-blossoms,
roses,

roses, jessamines, carnations, and especially orange-flowers, accommodate us with conserves, and a variety of confections, together with essences and distilled waters, that continue to us the enjoyment of the odours, and other useful qualities of flowers, when they have long ceased to be in season.

Upon the whole, we may undoubtedly draw this conclusion, that every Vegetable and flower, how-

ever lightly and insignificantly custom and taste may have taught us to behold it, affords us an ample field of admiration, and cannot fail to inspire us with the highest esteem and veneration for the great Author of Nature, who has created and formed so many things for our use and amusement.

C H A P. I.

Containing the NATURAL HISTORY of FOREIGN VEGETABLES, and their ROOTS, BARKS, WOODS, LEAVES, FLOWERS, FRUITS, SEEDS, RESINS, GUMS, and CONCRETED JUICES.

NATURAL HISTORY of ROOTS.

THE CALAMUS AROMATICUS or *Acorus Verus*, is a sweet smelling flag. It has a long, oblique, knotty root, about as thick as a man's finger, and a little compressed; when fresh, it is of a whitish green colour; but afterwards turns of a reddish yellow. It is white and spongy within; has a sharp bitterish aromatic taste, with a distant relish of that of garlick, and a fragrant aromatic smell.

From the root that lies near the surface of the earth, there arise leaves, some of which are a cubit in length, others half as much, and its peculiar characteristic is a simple elegant iulus, with leaves like the aromatic flower de luce. They are sharp at the point, of a pleasant green, smooth, and above a quarter of an inch broad. They have six petals, which are blunt, hollow, loose, thick above, and truncated below. There are six thickish filaments, a little longer than the corolla. The antheræ are thickish, and join to the dedymæ. The germen is gibbous, longish, and there is no style; but the stigma is a prominent point. The capsula is short, triangular, and consists of three cells. The seeds are of an oblong oval.

The INDIAN ACORUS, by some called the true *Asian Calamus Aromaticus*, has a root not unlike the former, but more tender and of a pleasanter smell; the taste is bitterish, but not disagreeable. It is found both in the East and West Indies, and is in shape much like the former. It is recommended for inciding cold gross humours, and some pretend it is good against poisons.

ANGELICA is placed by Ray among the umbelliferous herbs with a shorter seed. The flower, according to Linnæus, is a large convex umbella, and the universal corolla is uniform; but the proper consist of five oval concave petals, that are nearly equal to each other. There are five simple filaments, and roundish antheræ. The germen is beneath the receptacle; there are two simple erect styles of the length of the corolla, and the stigmata are capitated. The fruit is oval, oblong, streaked, and may be separated into two parts. There are two oval, oblong seeds, convex and streaked on the one side, and the other plain. The root is three digits thick, with many fibres, black and wrinkled on the outside, but within, white, soft, juicy, sharpish and bitterish. The stalk grows to two cubits and upwards in height, and is hollow, full of branches, with large leaves like those of meadow smallage, but much sharper. The dried root is brought to us from Bohemia, the Alps, and the Pyrenees. The best is thick, of a dusky colour without, whitish within, and with a most fragrant smell, a little in-

clining to musk, and of an acrid aromatic taste. The roots brought from Spain, are now very seldom prescribed upon any occasion. Our own candied Angelica roots are well known to every one as a sweetmeat.

ANTHORA, in English, *Monk's-blood*; or *wholesome Wolf's Bane*, is the *Aconitum* of Tournefort. The flower has five unequal petals set opposite to each other in pairs, the uppermost of which is galeated with its back turned upward, the point sharp, and reflected towards the base. The two on the sides are broad, roundish, and connivent; but the lowermost two are oblong, and turned downwards. The colour is of a palish yellow, and the pistil turns to a fruit, in which are collected, as into a head, corniculated membranaceous sheaths, full of angular wrinkled blackish seeds. The plant is generally about nine inches high, and sometimes it is above a cubit, with a singular stiff angular hairy stalk, on which the leaves are set alternately, are whitish below, and have a bitterish taste. The virtues of this plant are uncertain, and some think the use of it is dangerous.

ARISTOLOCHIA is of several kinds, as the round, the long, the clematitis, and the slender. *Aristolochia Rotunda*, or *Round Birthwort*, according to Linnæus, has a single unequal petal, with a ventricous base, and consists of an oblong tube of a hexagon cylindrick shape, and a broad edge, extended downwards like a long tongue. There are six antheræ joined to the lower part of the stigmata, and the germen is oblong, angular, and under the receptacle. There is scarce any style, and the stigma is roundish, concave, and divided into six parts. The capsula is large, hexangular, and consisting of six cells. There are many flat seeds, and the fruit is round. It consists of a great number of stalks proceeding from a single root, which are a cubit high, and the leaves are placed alternately on the stalks, almost without any pedicle. They are roundish, of a dusky green colour, and, as it were, embrace the stalks. The flowers proceed from the wings, the root is tuberose, solid, three inches thick, roundish, wrinkled, with a few fibres dusky on the outside, of a palish yellow within, and covered with a thick bark: the taste is acrid, aromatic, and bitterish.

ARISTOLOCHIA LONGA, *Long Birthwort*, has the same sort of flower as the former, only it is of a whitish green colour within, and outwardly of an herbaceous colour. The fruit is terminated like a top, and when it is ripe it gapes, shewing a broad reddish seed, which at length turns to a dusky colour. The root is oblong, and about an inch thick, though sometimes it grows to the thickness of a man's arm; it is wrinkled, and of a dusky colour without,

without, but within it is yellowish, and the taste is somewhat more faint than the former.

ARISTOLOCHIA CLEMATITIS has a long creeping root, divided into several fibres; it is seldom thicker than a goose quill, is dusky without, and yellowish within; and has a bitter taste, with a smell stronger than the former. The stalks are a cubit in length, and are rounder, harder, and stronger than those of the former; likewise the leaves are larger, full of veins, and of a pale green colour, with longer pedicles than the rest. The flowers are pale, shaped like those of *round Birthwort*, but less, and the fruit is like that of *long Birthwort*, but bigger, they being of the size of small apples; likewise the seeds are larger.

ARISTOLOCHIA TENUIS, *slender Birthwort*, otherwise called *Pistilochia*, has a root which consists of long slender filaments, meeting in one head of a yellowish colour, with an aromatic smell, and an acrid bitter taste. The stalks are about nine inches high, and slender. They are angular and streaked, and full of branches, with the leaves more pointed than the *round Birthwort*, but less wrinkled, and a little sinuous on the edges. The flowers are like those of the *round Birthwort*, but less, and sometimes black; but at others they are of an herbaceous yellowish colour, with fruit like those of the round. When they are ripe, they gape at the part next the pedicle, and the seeds are like those of the *round Birthwort*.

All the kinds are reckoned to be opening and a little cleansing, and some esteem the round sort as best. They are said to be good against catarrhs and disorders of the breast from gross humours; as also against wind, pains of the cholic, and obstructions of the viscera.

BEHEN ALBUM, *white Behen*, is a root which is brought to us in pieces about as thick as a man's finger; of an ash colour without, with a contracted wrinkled surface, but pale and pulpy within, and of an acrid taste.

BEHEN RUBRUM, *red Behen*, is a root brought to us in pieces like jalap, and is dry, thick, and of a blackish red colour, with a taste and smell like the former, but more faintish. They are both brought from Syria and other places. It has a long geniculated root without hairy fibres, and is creeping like Liquorice, which it resembles both in shape and thickness; but it is whiter on the inside.

BUTUA, or *Pareira brava*, is a Brazilian plant, and the root is woody, hard, contorted, dusky, and wrinkled without, as well lengthways as circularly; within it is of a dusky yellow, and seems to be interwoven with various fibres; so that when it is cut transversely, they appear like so many concentric circles, with several rays or fibres reaching from the center to the circumference. It is without smell, but of a bitterish taste, with a sweetness not unlike liquorice. It is as thick as a man's finger, and sometimes as a child's arm.

It is good in ulcers of the bladder and kidneys, and, when mixed with a little balsam of capivi, it will certainly cure them. Some say it is an excellent remedy in a moist asthma, and the yellow jaundice. The dose is from twelve grains to thirty in substance; and from two drachms to three in decoction.

CARLINA, or *Chamaelion albus* of the shops, is a root a palm or two in length, and of the thickness of a man's thumb; it is red without, and has a surface which seems to have been corroded; it is white within, with an acrid aromatic taste, and a fragrant smell. It is brought from the Alps and Pyrenees, and should be chosen fresh, dry, and not carious.

CASUMUNAR is an East Indian root, and is tuberose. It is thicker than a man's thumb, and is cut into transverse pieces; it is marked on the sur-

face with circles like galangal, and is a little geniculated. It is ash coloured without, yellowish within, with a subacid, bitterish, aromatic taste. What plant this belongs to is uncertain; however it is said to strengthen the nerves, refresh the spirits, corroborate the stomach, and repel wind. It is given in substance from ten grains to thirty, and the tincture from twenty drops to thirty. The extract is also given from six grains to fifteen; but the chief use made of it is to help digestion and dispel wind.

CHINA is a long root, and is so called from the place it is brought from. However, there are now two sorts, one of which is brought from the East, and the other from the West Indies. It is a thick arundinaceous, geniculated, heavy, woody root, beset with unequal tubercles, and the colour without is of a dusky red, but within of a reddish white. The taste while fresh is a little acrid, but when dry it has a small degree of an earthly astringent taste, and without smell; if it is good, it seems to be fat and unctuous when chewed. The plant to which it belongs is called the rough Chinese smilax; or bind weed. The medicinal use of this root is now but little regarded. The American China differs from the former, only it being of a darker colour without, and redder within.

CONTRAYERVA is a root an inch or two in length, and about half an inch thick, and is knotty on the outside; it is hard, thick, reddish or blackish without, wrinkled, and the protuberances are, as it were, covered with scales; it has also many slender filaments, or threads, but within it is pale, and has a somewhat astringent bitterish taste, with a sweet sort of acrimony when it has been held long in the mouth. The tuberose part is only to be chosen; for the filaments are of no value. It grows in several parts of the West Indies, and is brought to us from Spain. It is a mild alexipharmic, and has been counted excellent against all sorts of coagulating poisons. It strengthens the stomach, helps digestion, and discusses wind; it is also used by some in malignant fevers. The dose is generally a scruple; but it may be given to a drachm and upwards. It is certainly very good to promote a diaphoresis.

COSTUS is by authors said to be of various kinds; but that in use with us is the sweet Costus of the shops, and is brought from the East Indies. It is cut into oblong pieces, which are about the thickness of a man's thumb; which are light and porous, but hard and brittle, and a little resinous. Sometimes it is whitish, and sometimes of a yellowish ash colour; with an acrid aromatic bitterish taste; but the smell is fragrant, and not unlike that of violets. It is said to attenuate viscid humours, to promote expectoration, and is by some reckoned a cephalic, as well as to be good for promoting a diaphoresis and urine; but it is very seldom used.

CURCUMA, *Turmeric*, is a root brought from the East Indies, and is oblong, slender, tuberose, knotty, and of a yellow or saffron colour; the taste is subacid and bitterish, with a smell like that of ginger, but weaker. It is a very useful root to the dyers; and, as it is very much in request, there is scarce a garden in the East Indies where it is not cultivated: they use it with their victuals as a sort of spice. It is recommended against obstructions of the lungs, liver, spleen, mesentery, and womb; but its principal virtue is against the jaundice, in which it is looked upon as a specific. It is given in substance from a scruple to a drachm, and in infusion to two drachms.

CYPERUS LONGA, *long Cyperus*, is a long slender knotty contorted root, not easily broken; it is blackish without, and whitish within; and of a sweet subacid aromatic taste, with a fragrant smell like that of nard. It is generally brought to us from Italy, and care should be taken that it has a lively smell, and is not carious. There is another root called

round *Cyperus*, which has been brought from the Levant, and is a roundish and turbinated root, of the size and shape of an olive. It is rough, streaked, reddish without, and sometimes black; but it is white within, and there are several fibres depending from a single head. The smell and taste are the same as the former. Many virtues have been attributed to it; but in the present practice it is seldom used.

DICTAMNUS CRETICUS, *Dittany of Crete*, is a kind of Origany, and is now only used in Venice treacle; it is brought to us from Candy, and is said to grow on mount Ida. There is another sort called *white Dittany*, which is a sort of *Fraxinella*, now of some use in many parts of Europe. The root, or rather bark of the root, is thickish, white, and is generally brought to us wrapped up in the same manner as cinnamon; it is of a bitterish taste with a little acidity, and has a fragrant, and pretty strong smell when fresh. It is said to be an alexipharmic, to promote sweat and urine, to kill worms, and to resist putrefaction. The dose is from half a drachm to two drachms in substance, and in infusion to an ounce.

DORONICUM ROMANUM, *Roman Wolfsbane*, is a tuberose root full of knots and tubercles, which are hardly so big as small hazel nuts; it is yellowish without, and whitish within, and the taste is sweetish, clammy, and a little styptic. It is brought to us from the Alps. As the qualities of this root are not perfectly known, it is not adviseable to admit it into practice.

GALANGA MINOR, *the lesser Galangal*, is a tuberose, knotty, geniculated root, and is divided into branches, as well as encompassed with circular rings; is uneven, hard, solid, and about as thick as the little finger; of a dusky colour without, and reddish within; with an acrid, aromatic, bitter, pungent taste, burning the mouth like pepper or ginger, and has an aromatic or fragrant smell while it is fresh: it is used in the East Indies as a spice. It is a warm stomachic bitter, and is given to promote digestion. It is good to discuss wind, and in all disorders that proceed from a weak stomach. The dose is from fifteen grains to thirty in substance, and from half a drachm to two drachms in infusion.

GENTIANA, *Gentian*, is a root sometimes a foot in length, and near an inch in diameter, but sometimes more; it is dusky on the outside, but of a yellowish red within, and a taste intensely bitter; likewise the substance is a little spongy. It grows among the Alps, Pyrenees, and other mountains, and is brought to us from Germany. Not many years ago there was a poisonous root sold instead of Gentian; but it may be readily distinguished from it, it being of a whitish colour within, and without its bitter taste. Gentian is usually prescribed as a bitter to strengthen the stomach, and to help digestion. The dose is from half a drachm to two drachms.

GLYCYRRHIZA, *Liquorice*, is a root extremely well known almost to every body. The stalks rise to three or four cubits in height, and are divided into several branches, with roundish leaves of a faint green colour. They stand upon the stalks by pairs, that is, one on each side, but at the end there is one that is single. The flowers are papilionaceous, small, blueish, and at the top disposed as it were into a spike. The pistil that rises from the calyx turns into a reddish pod, half an inch long, which has two valves and a single cell containing the seeds, which are small, hard, flat, and in the shape of kidneys.

Liquorice grows spontaneously in Spain, Italy, France, and Germany, and is also common with us in England. The root temperates salt acrid humours, and is good in diseases of the breast. It is often prescribed in decoctions, as well to appease the heats of the fluids as to abate their acrimony. As

for the dose, it is not easily determined; for it is usually chewed by children in large quantities without any bad consequence. The inspissated juice, which is brought from Spain, is of a blackish colour, and is commonly called Spanish liquorice: it has the same virtue as the root, but stronger.

HELLEBORUS ALBUS, *white Hellebore*, is an oblong tuberose root, sometimes as thick as the thumb, dusky without, and white within, with a great number of whitish fibres; the taste is acrid, a little bitterish, subastringent, disagreeable and nauseous. The inward use is not very safe; nor indeed the outward; for when the powder is applied to an issue it will occasion violent purging. When taken inwardly, it is a strong emetic, and has been observed sometimes to occasion convulsions and other terrible disorders. However, in desperate cases, it may be sometimes ventured upon, particularly against madness; and the dose in this disease is a scruple: it ought always to be used with the utmost caution.

HELLEBORUS NIGER, *black Hellebore*, is a tuberose, knotty root, from which as a head many fibres hang, which are thick and black without, but white within, and of an acrid bitterish taste; the smell while fresh is exceeding strong. The inward use of this is much safer than the former, and is accounted a proper purge against melancholic and atrabilarious disorders. It acts particularly on the strait gut, for which reason it promotes the piles.

HERMODACTILUS, *Hermodactyl*, is a hard tuberose triangular root, or rather in the shape of half a heart, it being flat on one side, and tuberose on the other, terminating as it were in a point; it is reddish without, white within, and is easily reduced into a meal by pounding; it is of a clammy sweetish taste, with a slight acrimony. Hermodactyls are always dried when they are brought to us, and have been thought to purge gross humours, particularly of the joints, whence they have been esteemed as excellent in the gout; however, their purgative quality is but weak. It is given in substance from half a drachm to two, and in decoction to an ounce; but it is seldom or never used alone.

JALAPA, *Jalap*, is an oblong turbinated thick dense root, cut into transverse pieces, and is heavy and blackish without, but within dusky or ash coloured. It is resinous, hard to be broken, and has a taste that is something acrid and nauseous. It is the root of an American convolvulus, and is called by some Mexican night-shade with a large flower. It is in great use as a purge, and is of the stronger sort, though it seldom or never produces any bad consequences. It is best given in substance, because then it operates best; for the resin is apt to occasion gripes, and the watery extract is too weak. It is very useful in a cold phlegmatic habit of body; but is not at all proper in feverish disorders, nor in hot and dry constitutions, nor yet in melancholic, or scorbutic disorders. A scruple is the usual dose to grown persons.

IMPERATORIA, *Master-wort*, is not the same plant called by that name with us, for it is brought from the Alps and Pyrenean mountains; and is an oblong root as thick as a man's thumb, and wrinkled: it is somewhat geniculated, is dusky without, and white within, with a very acrid aromatic taste, violently vellicating the tongue, and heating the mouth; it has a most fragrant smell, but inclinable to what is commonly called physicky. It has been reckoned an alexipharmic, and has been recommended by Casper Hoffinan as a divine remedy in the cholic and windy disorders; but it is not now much in use with us.

IPECACUANHA is brought from America, and is of two kinds, the Peruvian and the Brasilian. The Peruvian is not a quarter of an inch thick, is

crooked, and as it were rough with circular rings; it is of a light brown or ash colour, and is dense, hard, brittle, resinous, with a small nerve which runs thro' its heart the whole length of the root; the taste subacrid, bitterish, and with little smell. The Brazilian *Ipecacuanha* is of a brownish colour, and is crooked and rough, with rings like the former, but more rugged, and is little more than the twelfth of an inch in thickness; it is brown or blackish without, but white within, and of a slightly bitterish taste. The *white Ipecacuanha* is a bastard sort, and is slender, woody, without wrinkles or bitterness. It is sometimes imported by the merchants for the true *Ipecacuanha*, but may be readily distinguished from it; for, besides the marks already mentioned, it is of a whitish yellow colour, neither will it work upwards or downwards like the two former. These last are now of great use in the beginning of dysenteries and other fluxes of the belly; but the Peruvian is accounted the best. Eight ounces of the root will yield ten drachms of resin, when the extract is made with spirits of wine. It has formerly been given to the quantity of a drachm; but now from six to ten grains are judged to be sufficient. In a confirmed dysentery, if the doses are so small as not to be strong enough to purge, and given several times a day, it will cure the ulcers of the intestines. It is now more generally used as an emetic than for any other purpose.

IRIS FLORENTINA, *Florentine orris*, is a root which is brought to us in oblong pieces, and it is geniculated, a little flat, white, with a yellow reddish bark, which being taken off, the root has a bitter acrid taste, with a fragrant violet smell. It is sometimes twice as thick as a man's thumb. The *Iris nostras purpurea*, the *common purple flower de luce*, is of the same kind as the former; for the roots, leaves and flowers, are of the same shape, though the colour is different. Florentine orris attenuates and incises the thick lymph lodged in the breast, and promotes its expectoration; whence it is good in the asthma, shortness of breath, and coughs; but it is chiefly used as a perfume, and is often mixed with snuffs. The dose is from a scruple to a drachm. When the juice is snuffed up the nose, it brings away a great quantity of serum; and, mixed with bean meal, it is said to take away freckles.

MECHOACANNA, *Mechoacan*, is a root brought from South America in white pieces, and is covered with a wrinkled bark. The substance is softish with scarce any fibres, and the taste is sweetish, with a little acidity, which sometimes causes a nausea. It has rings somewhat like briony; but differs from it in being compact, and in having no bitter taste, nor a strong disagreeable smell. It was looked upon at first as a most excellent purge, but is not so much cried up now since jalap became in use.

MEUM ATHAMANTICUM, *Spignel*, is an oblong root about as thick as the little finger and branched; it is covered with a bark of a ferruginous colour; but it is pale within, a little gummous, and contains a whitish pith. It smells almost like parsnips, though more aromatic, and the taste is not disagreeable, though it is acrid and a little bitter. It grows among the Alps and the Pyrenean mountains. It is said to attenuate thick gross humours, and is recommended in the humoral asthma; but it is now but seldom used.

NARDUS-CELTICA, *Celtick-Nard*, is a fibrous, capillary, reddish root, covered with small scales, of a yellowish green colour; with an acrid bitterish aromatic taste, and a fragrant strongish smell. It is said to be a carminative, to strengthen a weak stomach, and to help digestion; but it is now chiefly used in venice treacle and mithridate. The dose is from half a drachm to two drachms.

NARDUS INDICA, *Indian Spikenard*, is a hairy

root, or rather a congeries of slender capillaments adhering to a head, which is about as thick as the finger, and as long, and of the colour of rusty iron; the taste is bitter, acrid, aromatic; and the smell agreeable. It is said to strengthen the stomach, and to disperse wind; but its principal use now is in venice treacle and mithridate.

NINZIN, and **GIN-ING**, are generally taken for the same roots, but they are distinct from each other; however, their outer appearance and virtues are much the same, though Gins-ing bears the much greater price. The root of Ninzin is in the shape of a parsnip, is three inches in length, and about as thick as the little finger, with a few fibres proceeding from it. It is pulpy, whitish, and has some faintish cracks on the outside; but below it is divided into two branches. It has the smell of the yellow parsnip, and the taste of skirrets; but it is not quite so sweet, and there seems to be a little bitterish taste. It grows in Korea, from whence it is brought to Japan, and is in high esteem in those parts; for they pretend it is endowed with extraordinary virtues. However, it is of no use with us. Gins-ing is a root of an inch long, and about as thick as the little finger; it is slightly wrinkled, and generally divided into two branches, but sometimes into more, and at the small ends there are slender fibres. It is a little reddish without, but yellowish within, and the taste is subacrid, a little bitterish and aromatic, with an aromatic smell. On the top there are a row of knots placed in an irregular order, which seem to tell the years of its growth. It was thought only to grow in China and Tartary, between thirty-nine and forty-seven degrees of north latitude; but it is now found in Maryland and other parts near it, from whence it is brought to London, and sent to the East Indies, where it bears a great price; for it is confidently affirmed, that in China they will give three pounds of silver for a pound of this root. It is looked upon by the inhabitants as a panacea, and is their last refuge in all kinds of disorders.

PYRETHRUM, *Pellitory of Spain*, is about the length and thickness of a man's finger, and without it is of a blackish red, but it is white within, and has a most acrid burning taste, though it is without smell. This is brought from the kingdom of Tunis; but there is another kind which is more slender, and not so acrid. This root is remarkable for opening the salival ducts, and for procuring plenty of spittle; hence it is by some looked upon as a specific in the tooth-ach, from obstructions and catarrhs. It is likewise good in sleepy diseases, and the palsy of the tongue, when chewed and held in the mouth. It is seldom or never given inwardly except in clysters against sleepy diseases.

RHABBARBARUM VERUM, *true Rhubarb*, is a root brought to us in thick unequal pieces, from four inches to five or six in length, and three or four thick. It is a little heavy, and of a dusky yellow on the outside, but within it is of a saffron colour, and variegated with yellow in the same manner as a nutmeg; it is a little fungous, of a subacrid bitterish and somewhat astringent taste, with an aromatic smell, but somewhat strong. It grows in China, and though we have had several figures of the plant, it is not certain that any of them are like it, which is somewhat strange, since it grows in all parts of that country, though principally near the great wall; it was formerly brought from China through Tartary to Aleppo, and from thence to Alexandria, and at length to Venice; but we have it now from the East Indies and Russia. There is a sort that was sent to Jussieu, and called *Rhubarb with an oblong curled undulated leaf*. It was said to be the true China rhubarb, and is now growing in the physick garden at Paris; there is also some of it in the physick garden at Chelsea. It was brought to Mr. Rand, the then gardener,

gardener, and was called by him the Rhubarb, with an undulated smooth leaf, like burdock. These were generally thought to be the right sort; but Mr. Miller, the late gardener, affirms, that it was nothing else than the *Rhaponticum*. The faculties of Rhubarb are well known for both its purging quality, and for its general astringency of the stomach and intestines. It is supposed to open obstructions of the liver, and it is excellent in loosenesses. It is so mild, that it may be given to all ages and sexes at all times. However, it is not proper when the intestines are very hot, and there is a feverish heat. It is good in the jaundice, that proceeds from a clammy thick bile, which stops up the biliary ducts. Some chew it in a morning, before breakfast or dinner, to help digestion. It is given in substance from half a scruple to a drachm, and in infusion to two drachms.

The true RHAPONTIC is the *Rhubarb* of *Dioscorides*, and of the ancients, and is by some called the *English Rhubarb*. The impalement of the flower is composed of three small leaves, which are turned back; and the flower itself has three leaves, which are larger than those of the impalement, and are coloured. In the center of the flower is seated the three cornered pointal, supporting three small styles, and attended by six stamina; the pointal afterwards becomes a triangular seed, inclosed by the petals of the flower. It is frequently cultivated in gardens, and of late years the first stalks of the leaves have been used for making of tarts in the spring of the year; but they must have their outward skin peeled off, otherwise they will be very stringy: they have an agreeable acid flavour. When they are propagated for use, they should be planted three feet asunder, and in rich ground.

SARSAPARILLA root is made like a rod of several ells in length, whose twigs are of the thickness of a goose-quill, and are tough, flexible, and streaked lengthways. The bark is thin, and the colour without is reddish, but ash-coloured within; under this there is a white mealy substance, which is so soft, that it may be reduced to powder between the fingers; the taste is bitterish and clammy, but not disagreeable. Under this, in the middle, there is a woody bright tough substance, which is not easily broken. All these twigs or strings proceed from a single head as thick as a man's thumb, and scaly. It is brought from New Spain, Peru, and Brasil. It is sudorific, and attenuates gross humours. It has been reckoned a specific against a well known disease, the gout, the palsy, and other chronic disorders; but its virtues are now most approved against the first. The method of using it is this; to three ounces of the strings, which are good and not spoiled with age or other accidents, three quarts of river-water must be added, and it must be made to boil as soon as possible, in an open vessel, till two pints of the strained liquor remain. This quantity is enough for twenty-four hours, and may be given at two or three times, either warm or cold. It must be made fresh every other day, and the patient's diet should be slender while he takes it. Some have given it from half a drachm to two drachms in substance, and to half an ounce in decoction; but the former method is best. After all, it is not to be wholly depended on for the before-mentioned purpose, unless it receives the assistance of mercury, and that properly prepared by a very skilful hand.

SENEKA is the root of a plant called *Polygala Virginiana*, with oblong leaves and white flowers; but it is known to us by the name of the Rattle Snake root. It is usually about the thickness of the little finger, and is variously bent or contorted; it is divided into many branches with lateral fibres, and has a prominent membranaceous margin, running length-

ways; it is yellowish without, but white within, and has an acrid bitterish taste, but somewhat aromatic. It is thought to be good in all other disorders proceeding from a thick blood, particularly in the pleurisy and inflammation of the lungs, first letting the patient bleed. It has likewise been prescribed in nervous disorders, and slow fevers, with success. The usual dose of the powder is about thirty grains. It will sometimes vomit and purge; but if the patient cannot bear it, it may be prevented by mixing a testaceous powder with the tincture, or by giving twelve grains of salt of tartar in weak cinnamon water.

SERPENTARIA VIRGINIANA, *Virginian Snake-root*, is slender, fibrous, light, brown without, and yellowish within, with a subacid bitterish taste, and a fragrant aromatic smell, not unlike that of zedoary. It is now reckoned a species of the *Arifolochia*, and is brought from Virginia and Carolina. It consists of a great number of strings or fibres matted together, that proceed from a single head. It is accounted a great alexipharmic, and is frequently given in malignant fevers, and epidemical diseases. It may be given in substance from ten to thirty grains, and in infusion to two drachms.

TURPETHUM, *Turbeth*, is a root, or rather the bark of a root, cut into oblong pieces about as thick as the finger, and is brown or ash coloured without, but whitish within, with a subacid nauseous taste. It is best when it is fresh, resinous, not wrinkled, and easily broken. It belongs to an Indian *Convolvulus*. It has been thought a proper remedy to purge off thick and gross humours from the remote parts of the body, and has been commended in cold chronic diseases, especially in the gout, palsy, and dropsy. The dose is from fifteen grains to a drachm; but an extract made of spirits of wine is best, of which a scruple is a dose: it is now not much in use.

ZEDOARY is a tuberose root that is dense, solid, from three to six inches in length, and about as thick as a man's finger, terminating both ways in a blunt point. It is ash coloured without, and white within, with an acrid, bitterish, aromatic taste, and fragrant smell, which is most remarkable when it is chewed or pounded, and is somewhat like camphire. There is another sort, called round Zedoary, that is in substance, weight, solidity, smell, and taste, like the former; for it only differs in the shape, which is roundish, and only an inch in diameter. They are both brought from China; but the latter is seldom found in the shops. It has been greatly celebrated for its virtues: it promotes sweat, incides gross phlegm in the lungs, as well as in the stomach and intestines; it discusses wind, and cures the cholic proceeding from thence; it raises the spirits, and has been given in several chronic disorders. The dose in substance is from six grains to thirty, and two drachms will serve as an infusion to be drank in the manner of tea.

ZERUMBETH is a tuberose geniculated root, with an unequal surface, and is from the thickness of a man's thumb to that of his arm; it is a little flattish, and of a whitish yellow colour, with an acrid taste, not unlike ginger, and a fragrant smell: it is seldom or never kept in the shops.

ZINGIBER, *Ginger*, is a well known tuberose root, knotty, branched, and flattish, the substance is a little fibrous, of a pale or yellowish colour, and covered with a brownish skin, which is commonly taken off before it is brought to us. The taste is very acrid, hot, and aromatic, with a very fragrant smell. It is brought both from the East and West Indies, where it is looked upon, while fresh, as an excellent remedy against the cholic, loosenesses of the belly, and windy disorders. It strengthens the stomach, helps digestion, and is said to strengthen the

the memory. It is often added to purges, to correct them; but it should not be given in hot constitutions, for then it will do more harm than good. It may be taken in substance from five to fifteen grains, but it is oftener taken in infusion or decoction from half a drachm to half an ounce. The dose of that which is brought over candied, is from a drachm to an ounce.

NATURAL HISTORY of BARKS.

CINNAMOMUM, *Cinnamon*, is a well known spice, it being a bark that is sometimes exceeding thin, and sometimes pretty thick, and rolled up into a sort of tubes or pipes of different lengths. The substance is leginous and fibrous, but brittle; the colour is of a yellowish red, with an acrid, pungent, pleasant, agreeable taste, and a most delightful smell. It is the second and inward bark of a tree called *Canella Zeylanica*. It is commonly taken from trees that are three years old, in the spring or autumn; the ash coloured outside is taken off, and then it is cut into pieces, and exposed to the sun, and, when it is drying, it rolls itself up in the manner it is brought to us. When the tree is stripped of its bark, it continues naked for two or three years, and then another grows again, which serves for the same purpose. When it is distilled fresh, it yields plenty of oil, but when old and dry, very little; however, it is of two sorts, one of which sinks to the bottom of the water, and the other swims on the surface. This last is pale, but the former is of a reddish yellow colour, though they are both limpid, and of a most fragrant smell; but when they are tasted, they are exceedingly pungent. When the bark of the root is distilled, it yields an oil, with a volatile salt, or camphire, which is lighter than water, limpid, yellowish, and soon flies away. It has a strong smell between camphire and cinnamon, and has a very pungent taste. The camphire got from it is exceedingly white, and has a much finer smell than the common sort, but it is extremely volatile, and takes fire immediately, whose flame leaves nothing behind it. The fruit of this tree is an oblong roundish berry, somewhat above a third of an inch long, and is smooth, green at first, but afterwards turns to a dusky blue, sprinkled with whitish specks. Under the green pulp there is a thin brittle shell, containing a roundish kernel. It is common in the island of Ceylon, where it is in as great plenty as hazel trees with us. Cinnamon is heating, drying, aperient, discutient, and alexipharmatic; it strengthens the viscera, recreates the spirits, helps digestion, and discusses wind. It is given in substance from a scruple to a drachm, and in infusion from one drachm to two. The oil is so hot and burning, that it is never prescribed alone; but it may be mixed with sugar, and then given with any fluid. The dose is from one drop to three. A single drop on a lump of sugar, is an excellent remedy against hiccoughing. Likewise, if a drop of it be put with cotton into a hollow tooth, it cures the tooth-ach by drying and burning the nerve. Cinnamon, though commonly used as a spice, should be avoided when the stomach is inclinable to an inflammation, for then it does more harm than good; nor is it proper for hot and dry constitutions.

CASSIA LIGNEA, *Woody Cassia*, is a bark brought to us in rolls like cinnamon, and has somewhat of the smell and taste, but weaker, for which reason it may be easily distinguished from it, besides which it is clammy when tasted; however, the best is that which approaches nearest to cinnamon. It has much the same virtues as cinnamon, though in a smaller degree; and when given as an astringent, it is preferred to it, on account of its glutinous qua-

lity; it is good in loofenesses, and to strengthen the viscera. The dose in substance is two scruples, and, when infused in half a pint of white wine, an ounce.

CASSIA CARYOPHYLLATA is the bark of a tree called the *Clove-berry-tree*, and is found in the island of Cuba, and other parts of the West Indies. It is as thin as cinnamon, and of a dusky yellow. It is brought in rolls like cinnamon, and has a taste between cloves and that bark; but that of cloves is the most predominant. It grows stronger by length of time, and at length becomes so acrimonious, that the tongue is affected as though it was burnt with a slight caustic. It has the same virtues as cloves, but fainter.

CANELLA ALBA, by some called *Winter's-bark*, and by others *wild Cinnamon*, is rolled up in oblong tubes, in the same manner as cinnamon, but larger. It is thicker than cinnamon, and has an acrid, pungent, aromatic taste, as if it had been mixed with cinnamon, ginger, and cloves. It is accounted a good remedy against the scurvy; it discusses wind, and is sometimes used in disorders proceeding from catarrhs. The dose is from half a scruple to a drachm in substance, and to two drachms in infusion.

CORTEX WINTERANUS VERUS, *true Winter's-bark*, is brought over in tubes like the former, and has a covering of an ash colour, that is soft, fungous, unequal, and full of chinks; but within it is solid, dense, and of the colour of rusty iron, with an acrid, aromatic, pungent, burning taste, but the smell is extremely fragrant. It was brought from the Straits of Magellan, by William Winter, in 1567. It has been accounted excellent against the scurvy, for which some reckon it a specific. However, it is seldom or never to be met with in the shops, the *Canella Alba* being now used instead of it.

CORTEX PERUVIANUS, *Peruvian or Jesuits bark*, is generally from the sixth part of an inch to the fourth of an inch thick, and is rough on the outside, it being of a brownish colour; but sometimes is covered with a hoary moss: it is smooth within, a little resinous, and of a reddish rusty colour, with an intensely bitterish taste, and somewhat of astringency. Sometimes it is brought in large pieces, three or four inches in length or upwards, and an inch broad, and not rolled up, because it is taken from the trunk of the tree; sometimes inclining to tubes like cinnamon, though but slightly, and is marked with shallow circular chaps or fissures: this is taken from the slender branches. There is likewise a lesser sort, which is yellowish within, and hoary without, which is said to be obtained from the roots, and is in high esteem in Spain. It grows in South America, and particularly in Peru. It was at first greatly celebrated for its febrifuge qualities, and is still in the highest esteem upon that account. However, it has many other virtues, which have been discovered one after another; but that which was first remarked was its power in stopping mortifications. It is given, in various forms, for agues of every kind, and its tincture with saffron and snake-root is excellent in nervous as well as in spotted fevers. It is good in the measles, and cures the strumous ophthalmia and hectic fever, and has been found excellent in the epilepsy, as well as the whooping cough, and spitting of blood. It is of great use in a consumption, and in the intermitting putrid fevers of that disease, as also in the hysteric passion. It is good in the king's evil, cures a pimpled face, and malignant ulcers. It is excellent for hemorrhages in general, and for hysteric convulsions. It is useful in tremblings, in languors, against the worms, as well as in a diabetes, and colliquative sweats, in which last case it performs wonders: in short, there is no single remedy yet found out that is endowed with so many

many excellent qualities. However, there is one not yet mentioned, which must not be forgotten, and that is its being an excellent preservative in sickly aguish countries, in all parts of the world, and in sickly seasons. The dose of the bark in powder is half a drachm, though some have given it to two drachms; and if an ounce is infused in a pint of generous red wine, six ounces is a dose; however, it is certain, that when it is given in substance; it is much more efficacious than either in infusion or decoction; but when patients refuse to take it in substance, the infusion in wine is undoubtedly the best. In whatever form this medicine is given, it must always be repeated every third or fourth hour, and in agues must be repeated again in eight days time from the cure. It will be still better to give it a second or a third time, that is, a few doses of it every eight days, and this process is generally necessary for autumnal agues; besides, it must be observed, that no evacuations of any kind must be made after taking the bark for some weeks, or even months after a cure is performed.

CORTEX ELUTHERIÆ is known abroad by the name of *Cascarilla*, has been sold for the Jesuits bark, and it is still called by some the grey Peruvian bark. It is rolled up in tubes of the thickness of the finger, and from two to four inches in length. It is thinner than the Peruvian bark, and is of a white ash colour without, but within of the colour of rusty iron, with a bitter aromatic taste, and a fragrant smell when burnt. It is thought to be good in diseases of the breast, particularly the pleurisy and inflammation of the lungs, as also in loosenesses attending acute fevers. By its sedative quality, it is useful in inflammations, though it is bad in the quinsy. It has produced good effects in internal hemorrhages, and in enormous vomiting, as well as in all fluxes of the belly. The dose is from six grains to a scruple, though it has been given to a drachm three or four times a day.

NATURAL HISTORY of WOODS.

A GALLOCHUM, or LIGNUM ALOES, *Aloes Wood*, is of three kinds, and the first, which is best, is called Calambac by the East Indians. It is light, resinous, and as soft as mastick, for it will stick to the teeth and nails, and will melt over the fire with a very sweet smell; but the taste is bitterish and aromatic. The *Agallochum* of the shops is brought to us in fragments of various sizes, which are heavy, dense, and of a bay colour, variegated with blackish and resinous streaks: sometimes there are holes in it, as if it was rotten; but they are filled with a sort of reddish resin, and then the colour of the wood is of a purplish black. The taste of this is subacid, bitter, and aromatic, and the smell is very agreeable. It grows in the island of Sumatra, in Cambaya, and more especially in Cochin China. It is oftener met with in the shops than the former, because the price of that is exceeding great.

AGALLOCHUM, or LIGNUM ALOES OF MEXICO, is more light, porous, and not so resinous as that of the shops; the colour is of a brownish green, and the smell is sweet and fragrant, not unlike that of the true lignum aloes, but the taste is bitter. It is not only met with in Mexico, but in the islands of Solor and Timor in the East Indies. It is seldom or never taken notice of as a medicine, but is used in making boxes, chests of drawers, and other things of that kind.

LIGNUM RHODIUM, *Rhodium Wood*, is a name given to woods of several kinds. It had its name from the island from whence it was brought, and was also called Cyprinum, because it was had from the

island of Cyprus. This wood is of a pale yellow at first, but in time grows reddish; it is thick, hard, and solid, and marked with fat resinous knots, smelling like a rose. There is another sort of *Rhodium* brought from the island of Jamaica, and, though it smells like the true, it appears to be different on a careful examination.

GUAIAACUM, otherwise called *Lignum Sanctum* and *Lignum Vitæ*, the wood of *Guaiaac*, is solid, dense, heavy, and resinous, whose middle part or heart is of a blackish green, and variegated with pale green, and black colours; but the external part is of a palish yellow like box; it is of a bitterish and somewhat aromatic taste, with a mild acrimony, and the smell, when burnt, is somewhat fragrant, and not disagreeable. The bark is woody, thin, dense, smooth, and somewhat resinous, and consists as it were of several thin plates laid one upon another; the outside is of an ash coloured green, or blackish, variegated more or less with green spots, intermixed with a livid or lead colour; it is pale within, of an acrid taste, and disagreeably bitter. It grows in the West Indies, and particularly Mexico and New Spain: This wood is full of resin, inasmuch that a pint of rectified spirit of wine will extract at least two ounces thereof. When it is boiled in water for a considerable time, and afterwards gently evaporated, it will leave a mass that looks something like resin, which is balsamic, of an agreeable smell, and a somewhat acrid taste; when it is quite dry, reduced into powder, and taken as snuff, it will bring a large quantity of serum from the nose; besides which it is very friendly to the nervous parts of the head. *Guaiaac* incises and attenuates gross humours, opens obstructions, promotes sweat and urine, strengthens the stomach, as well as all the rest of the viscera, cures inveterate obstructions of the liver and spleen, and is prevalent against the jaundice, dropsy, and other disorders thence arising. It is also good in the gout, rheumatism, and all sorts of pains in the joints. It is a great friend to the nerves, brings all cold hard swellings to suppuration, and yet it is never attended with the least bad consequence. The bark has the same virtues as the wood. Twelve ounces of the wood, macerated in three quarts of water for a day, and then boiled over a gentle fire till half or more is evaporated, and strained off, is called the cream of *guaiaac*. We might here enlarge on its uses in venereal cases, and give the proper method of using it; but as this work is undoubtedly read by the young and inexperienced, such directions might lead the unguarded part of them into experiments destructive of their health and constitutions, since the best medicines, when improperly applied, may tend to hasten death rather than a cure; and, as the learned know where to look for informations of this kind, they will readily excuse an omission, which properly does not belong to Natural History.

LIGNUM TINCTILE CAMPECHENSE, *Logwood*, is well known as a dye; and is commonly brought from Campeachy in the Bay of Honduras. It is but lately used as a medicine, and that in loosenesses, in which it is very efficacious; for if two ounces of the chips are boiled in a quart of milk, and a quart of water to one quart, and a tea-cup full of this decoction be given every three hours, it seldom fails to cure a common diarrhoea.

LIGNUM NEPHRITICUM, *Nephritic wood*, is whitish or of a palish yellow colour, and is solid and heavy, with a subacid and a little bitterish taste; the bark is blackish, and the heart reddish or brownish. The wood has been recommended against disorders of the kidneys, and difficulty of urine.

SANTALUM RUBRUM, *red Sanders*, is a solid, dense, heavy wood; brought over from the East Indies, sometimes in strait and sometimes in crooked pieces.

pieces. It is the heart of the tree, and has no remarkable smell, but it has a slight astringent, and austere taste. The virtues of these woods is not agreed upon by authors: however, they generally agree, that they are inciding, attenuating, astringent, and strengthening. But the yellow is the most powerful incider, and is more astringent than the red.

SASSAFRAS is the root of a large American tree, and is brought to us in long strait pieces, which are very light and of a spongy taste. It is of a whitish red colour, and the bark is spongy, ash coloured without, but within of the colour of rust of iron. The taste of the wood is acrid, sweetish, and aromatic, with a fragrant smell, not unlike that of fennel. Its virtues are sudorific and inciding, and it is good in the cachexy, green sickness, and dropsy. The oil of Sassafras is good in disorders of the breast, and particularly in coughs, pains, and spasms. It may be taken alone or dropped upon sugar, or a drop or two may be mixed with a powder good for the same purposes. It is a medicine not very commonly known, but exceedingly useful: *Sassafras* is also made use of like tea.

NATURAL HISTORY of LEAVES and FLOWERS.

CORALLINA, *Sea moss*, is a small marine plant, divided into a great number of sprigs, which are slender, brittle, and consist of several joints. Without it seems to be covered with a sort of a whitish stony substance, and the colour is various; for it is either white, reddish, yellowish, ash coloured or black, and sometimes of the colour of grass. It has a nauseous fishy smell, with a saltish disagreeable taste, and crackles between the teeth; it may readily be reduced to powder by rubbing it between the fingers. It is seldom above an inch and a half, or two inches long, and is found growing on rocks in the sea, as well as on stones, shells, coral, and the like. It has no root, and is very plentiful on the shore of the Mediterranean sea. That is esteemed the best, which is whitish or ash coloured. It is greatly cried up for its virtue in killing worms, and is given in powder from half a drachm to a drachm.

SCHOENANTHUS, *Camels Hay*, is brought in sprigs with the leaves, and sometimes with the flowers from Arabia; they are dry, stiff, round, shining, geniculated, and about a foot in length; it is full of a spongy pith, and is of a pale yellowish colour at the root, but near the top it is green or purplish; the taste is hot, subacid, bitterish, aromatic, and not disagreeable. It is now out of use, except as an ingredient in venice treacle and mithridate.

MALABATHRUM, *the Indian leaf*, is like that of the cinnamon tree, and differs nothing from it except in smell and taste. The tree, to which this leaf belongs, is called the white cinnamon tree of Malabar. It is now only made use of in venice treacle and mithridate.

SENNA, or SENA, consists of small dry, flattish, firm, and sharp leaves of a yellowish green. The smell is not very strong, but the taste is subacid, bitterish, and nauseous. It is of two sorts, the Alexandrine and that of Tripoly; which last is the worst, and the leaves are green and large, with a blunt point and rough to the touch. This medicine is in great use as a purge, being seldom or never attended with the bad consequences of drastic purges. It is apt to gripe; for which reason physicians have endeavoured to correct it in various manners; some with ginger, others with cinnamon, and others again with spikenard. Some mix it with prunes, jujubs, raisins, violets, marsh mallows, and polypody of the oak; others with things that discuss wind, and in-

clude gross glutinous humours, such as fennel-seeds, anniseeds, coriander-seeds, and salt of tartar. Senna is not good in those disorders, in which the fluids are hot, and the solids tend to an inflammation, particularly in hemorrhages, all inflammations whatever, and diseases of the breast. In an infusion, or gentle decoction, it is prescribed from a drachm to half an ounce, either alone or with other purging medicines. Some have endeavoured to correct its disagreeable taste by various additions, which however have not succeeded extremely well; particularly, they have recommended the greater water fig-wort for that purpose; but as it has a strong smell, and a nauseous bitter taste, it can do little good this way; while others have recommended bohea tea with as little success.

DICTAMNUM CRETICUM, or DICTAMNUS CRETICA, *Dittany of Crete*, is a leaf, of a roundish shape, about an inch long, and of a greenish colour, and covered with a thick white down. It is generally brought over with the stalks, from whose tops a sort of spike of scaly leaves depend, of a purplish colour. The smell is fragrant and not disagreeable, and the taste is acrid, aromatic, and hot. The dose in powder is from half a drachm to a drachm, and in infusion from a drachm to half an ounce; but it is only used with us in venice treacle and mithridate.

THEA, *Tea*, is a small dried curled leaf, with a taste bitterish in a small degree, and slightly astringent; the smell is very agreeable, and by some is likened to that of new hay, or violets. It is brought from China, and has variety of names; but it may principally be divided into three kinds, namely, the green, the imperial, and the bohea. The green is of several sorts, and is of various degrees of goodness, from the common coarse green tea to the hyson, which is now the dearest and accounted the best of all. The imperial tea is so called, because it is chiefly used by the emperor and great men in China and Japan. The leaf is large, and not so much rolled up as in the other kinds: the colour is greenish, lively, and of a fine smell, with an agreeable taste. This, not many years ago, was in great request with us; but now we either have it not at all, or it is sold under a different name. The bohea is of a reddish brown colour, and the leaf is small, rolled up, and tinges the water of a brownish colour; but the difference of taste of these teas are so well known they need not be insisted on. Some authors assure us there is no difference between the green and bohea teas, but what arises from the manner of curing them; for the bohea is said to be higher dried, or rather burned, from which it receives its different taste and colour. The natives throw the bohea into a brass vessel full of water, and boil it over a slow fire, where they keep it the whole day, and it serves for their usual drink; but these are the common sort, for others are much more nice and careful in preparing it. The Japanese grind their tea into a small powder, and then put a spoonful of it into one of their cups, pouring hot water thereon, and then they beat them together with a sort of a brush composed of long bristles, till a foam arises thereon; but the Chinese make use of it in the same manner as we do. Tea is certainly of some use in abating the acrimony of the humours, and in keeping people awake, but more especially in those who drink it but seldom; however, when others take it late at night, it very often prevents their sleeping sound. It is gently astringent; for which reason it hinders the water from weakening the stomach, and in those that take it but seldom it will prevent the operation of a purge. It has indeed some power in preventing the gravel, but then it does not arise from the tea, for hot water alone will do the same. In general it may be observed, that tea has different effects on different people,

people, and therefore, though it may be good for some, it is hurtful to others.

STOECHAS ARABICA, *French Lavender*, consists of the florid tops of the plant, which, when dried, are called *Stoechas*; they are oblong, scaly, and of a purplish colour, with a subacid bitterish taste, and a fragrant pleasant smell. Though it is called the Arabian *Stoechas* it is brought from the southern parts of France, where it grows spontaneously. It is now cultivated with us by sowing the seeds upon a bed of light dry soil in March. When the plants are come up they should be carefully cleared from weeds, till they are two inches high, at which time they should be removed into a light dry level ground prepared for that purpose, and set at about five or six inches distant from each other, observing to water and shade them well till they have taken root. It has a labiated flower, consisting of one leaf, whose upper lip is upright and cut into two; but the under lip, or beard, is cut into three parts; and both are so divided as at first to appear like a flower cut into five segments, out of whose flower cup rises the pointal, attended by four embryoes, which afterwards become so many roundish seeds inclosed in the flower cup. The flowers are ranged in various rows with scaly heads, out of the top of which peep some small leaves which look very beautifully. The *Stoechas* used in the shops is still brought from the south parts of France; but as it is apt to contract a mouldiness in its passage, it is not near so good as that gathered fresh in England. It is recommended in cold disorders of the head and nerves; however, it is rarely met with in prescription, but is used in venice treacle and mithridate.

CROCUS, *Saffron*, grows in various parts of the world, but it is no where better, if so good, as in England. At present it grows plentifully in Cambridge-shire, and in all that large tract of ground between Saffron-Walden and Cambridge. They begin to plough the ground in the beginning of April, and about five weeks after they lay between twenty and thirty loads of dung upon each acre of ground, but the shortest rotten dung is best; and this they plough into the ground. Soon after Midsummer they plough it again, and the time of planting is the latter end of July; the method of which is this: one man with a shovel raises between three and four inches of earth, and throws it before him about six inches; two women follow him with the heads of saffron, and place them in the farthest edges of the trench, which is made at three inches distance from each other. As soon as the digger has gone once the breadth of a ridge, he begins again at the other side, and digging before covers the root last set, and makes room for the setters to place a new row; and thus they go on till a whole ridge is planted. The quantity of roots planted in one acre is generally about a hundred and twenty-eight bushels. When the leaves are ready to show themselves above ground, they pare the ground with a short hoe, and take off the weeds. Some time afterwards the saffron flowers appear, which are gathered before, as well as after, they are full blown, and the most proper time is early in the morning. They carry them home in baskets, spread them on a large table, and pick out the chives with a pretty large part of the style itself; but the rest of the flower they throw away as useless. They then dry them on a kiln, which is built on a thick plank, supported by four short legs, that it may be removed from place to place. It is set in the lightest part of the house, and they begin by laying five or six sheets of white paper on a hair cloth, upon which they spread the wet saffron between two and three inches thick; this they cover with other sheets of paper, and over all they lay a coarse blanket five or six times doubled. At first they give the kiln a pretty strong heat to make the chives sweat. When it has been

dried about an hour, they turn the papers and saffron upside down, covering them as before. The same heat is continued for an hour longer, and then they take off the papers, cover the saffron as before, and lay on a weight. Then they have nothing more to do than to keep a gentle fire, and turn the cakes every half hour till thoroughly dried, which is generally performed in twenty-four hours.

Saffron has a flower consisting of one leaf, which is shaped like a lily, and fistulous underneath, the tube widening into six segments, and resting on a foot stalk; the pointal rises out of the bottom of the flower, and is divided into three headed and crested capillaments; but the impalement afterwards turns to an oblong triangular fruit, divided into three cells, and is full of roundish seeds. It has a tuberose root, and long grassy leaves, with a longitudinal white furrow thro' the middle of each. The parts of the flower used in medicine are the long stamina or chives, of a reddish flame colour. Saffron is endowed with great virtues, for it refreshes the spirits, and is good against fainting fits and the palpitation of the heart; it strengthens the stomach, helps digestion, cleanses the lungs, and is good in coughs. It is said to open obstructions of the viscera, and is good in hysteric disorders. However, the use of it ought to be moderate and seasonable; for when the dose is too large it produces a heaviness of the head and a sleepiness; some have fallen into an immoderate convulsive laughter, which ended in death. A few grains of this is commonly a dose, though some have prescribed it from half a scruple to a scruple and a half.

NATURAL HISTORY of FRUITS and SEEDS.

DACTYLI, *Dates*, are oblong fruit of a roundish shape, of the thickness of a thumb and the length of a finger. They are in the form of acorns, and composed of a thin dusky yellow skin, with a fat, firm, sweet pulp, and a thick, oblong, hard stone, furrowed longways. Those are best that are large, soft, yellowish, with few or no wrinkles, and full of pulp. Dates are distinguished according to their degrees of ripeness: the first is when the end begins to grow ripe; the second when it is ripe to the middle, and the third when it is ripe in every part. With regard to the virtues of Dates, they are said to strengthen the stomach, stop loosenesses, and corroborate the intestines; they are also good in diseases of the breast, and promote the expectoration of gross humours. The tree that produces them grows in several parts of the world, particularly in Arabia, Syria, Persia, Africa, as well as in Greece, Italy, and the southern parts of France; but they do not thrive so well in these last places, and the fruit seldom comes to perfection.

SEBESTEN is a fruit not unlike small plumbs, which are blackish, turbinated, pointed at the top, and wrinkled. They consist of a dusky clammy pulp of a sweetish taste, which adheres firmly to the stone. It is in common use in some parts of Europe to abate the acrimony of the humours, and to appease coughs proceeding from a soft phlegm, as well as in hoarsenesses and heat of urine. They are out of use with us, and consequently are not kept in the shops.

UVÆ PASSÆ, *Raisins*, are the ripe fruit of the vine dried in the heat of the sun, and are universally known. There are several sorts, though not all known to us, as the raisins of Damascus, which are the largest; the raisins of Provence, which are of a middle size; and the raisins of Corinth, with us commonly called currants. Those of Damascus are most in use with us, and are named raisins of the sun. There is also another sort brought from Spain,

Spain, which are pretty much in use, called *Malaga* raisins. The vine that produces the larger raisins is like other vines, only the leaves are bigger, and not divided so much on the edges. The common use and taste is known to every one, and as to their physical use, they are said to attenuate gross humours, and to abate their acrimony. Those called *jar* raisins, being stoned and eaten frequently, are excellent in obstinate hoarsenesses. They are sometimes used in decoctions, to abate the disagreeable taste of other medicines.

CARICÆ, dried Figs, are so well known that they need no description. The flowers, which are always inclosed in the middle of the fruit, consist of a single leaf, and are male and female in the same fruit; the male flowers are seated towards the crown of the fruit, and the female, which grow nearer the stalk, are succeeded by small hard seeds. The entire fruit is for the most part turbinated and globular, or of an oval shape, and is fleshy, and of a sweet taste. Fresh figs, as well as those which are dried, serve among other things for food in some distant countries; and when they are ripe, they are easy of digestion, and perhaps more so than any common fruit whatever. They are moderately nourishing, soften the belly, and are good in disorders of the lungs, kidneys, and bladder; however, the too frequent use of them is hurtful, because they generate wind. When they are dried they have the same qualities, but are better for medical purposes. They are sometimes used in pectoral decoctions, and six figs are enough for every pint of liquor. Externally they are sometimes applied in the form of a cataplasm, to discuss or ripen swellings. Some roast them, and apply them to swellings of the gums, and others to ease the pains of the piles.

MYROBALANI, *Myrobalans*, are of several sorts; but the yellow are principally used in medicine, and are a dried fruit, of an oblong roundish turbinated shape, an inch and a quarter in length, and three quarters of an inch in breadth; they are blunt at both ends, and of a yellowish or citrine colour. They are marked generally with five larger streaks, and as many that are small between them; under the glutinous and as it were gummous bark, or rind, half a quarter of an inch thick, which is bitter, austere, and subacid, there is a stone of a lighter colour, that is angular and oblong, with several pits or cavities; the kernel is whitish, and covered with an exceeding thin dark yellow membrane. The rind or pulp, for they are both together, is the only part in use. They proceed from a tree like that of wild plumbs, whose leaves are set by pairs, like those of the ash tree.

The *CHEBULE MYROBALANS* are the largest, and are oblong, angular, and said to purge phlegm. They are like the former, but bigger, and more turbinated, and have likewise five high ribs made by the streaks or furrows; but they are of a darker colour, and more inclinable to brown; within they are of a blackish red, but taste as the former, though the pulp is thicker, and the kernel is fat, oblong, and of the same taste. They grow on a tree not unlike a peach tree.

Indian, or black MYROBALANS, are less than the yellow, and are marked with nine oblong lines: they are rather wrinkled than streaked, and are blunt at both ends. They are black on the outside, and within are of a shining black, like pitch. The taste is subacid, bitterish, and a little acrid; they adhere to the teeth, and provoke spittle. The tree grows to the size of a wild plumb-tree, which has leaves like those of willows.

The *BELLIRIC MYROBALANS* are a roundish fruit, of the colour and shape of a nutmeg, but a little more yellow, and almost an inch in length; the rind is bitter, austere, and astringent; under which

lies a stone of a lighter colour, containing a kernel like that of a hazel nut.

EMBLIC MYROBALANS are a dried fruit, of a round shape, but marked with six angles, and of a blackish ash colour. They are half an inch in diameter, and under the rind, which when ripe opens in six places, there is a white lightish stone of the size of a hazel nut divided into three cells. Generally speaking, there is nothing but the dried segments of the pulp or rind brought over, which are of a blackish colour, and of a tartish austere taste. They grow on a tree higher than any of the former, but we have no accurate description thereof, nor indeed of any of the former. They have been looked upon to have a purgative faculty, without producing the least weaknesses, and by their astringency they strengthen the bowels. The dose is from an ounce to an ounce and a half, but the present practice has laid them aside.

COLOCYNTHIS, *Coloquintida, or the bitter apple*, is about the size of an orange, of a roundish shape; the pulp when dried is spongy, and, as it were, full of cells; it consists of small membranaceous leaves, which are dry, white, and exceeding light when brought to us. It is of a very bitter, acrid, nauseous taste, and it has small, flat, hard, white or reddish seeds, of the size of those of a cucumber, but rounder and harder; it is brought from Aleppo.

It is now in use as a medicine, and is a most strong violent purge; therefore only proper to be used in desperate cases, and in obstinate inveterate diseases. It has sometimes very dangerous effects, for it greatly injures the stomach, viscera, nerves, and even the whole body. It is often mixed with other purgatives, to render the operation more quick, and particularly with aloes and scammony. The dose of it, when given alone, is from five grains to twenty, when reduced to a fine powder. It has such a purging faculty, that when laid to the navel with oxes gall, it not only purges but kills worms.

CASSIA FISTULARIS, *the pudding pipe tree*, is an exotic fruit contained in pods, sometimes half a yard long, and about an inch in diameter; it consists of a woody shell, of a dark brown colour, but though it is hard it is thin. It is divided into several cells with partitions transversely placed, and parallel to each other; the pulp is soft, black, sweetish, and of the consistence of honey, containing oblong, roundish, flattish seeds, that are hard, shining, and of a dusky yellow. Those pods are best that are fresh, full, and will not rattle when shaken. The pulp only is in use, which is taken from the pods, and is passed through a sieve. It is looked upon as a mild, gentle, harmless purge, agreeing with all sexes and ages. The tree from whence it proceeds, has been planted in the West-Indies, but as it does not grow naturally there, it does not succeed very well; for it has a thicker shell, and the pulp is acrid and nauseous. As a cathartic it must be given in a large dose, but a small one is sufficient to keep the body open. Some have complained of its bad effects, and say it produces wind in the stomach and intestines; but by mixing it with cream of tartar, or boiling it with tamarinds, this may be prevented.

TAMARINDI, *Tamarinds*, are a fruit with a thick clammy pulp, brought to us in masses of a blackish colour, with an acrid taste, and mixed with the rinds of the pods, as well as membranes, nerves, and filaments; as also with the hard seeds or stones. That pulp is best that is clammy, of a blackish red, acrid and moist. It is to be cleansed from the membranes, filaments, and seeds, before it is used. It is brought from Egypt, and the East and West-Indies.

The flower consists of several leaves, which are so placed as to resemble, in some sense, one that

is papilionaceous; but they expand circularly, and from the many leaved flower cup there arises a pointal, which afterwards becomes a flat pod, containing many flat angular seeds, surrounded with an acrid blackish pulp. The pods of the tamarind-tree in the East-Indies, contain six or seven seeds in each; whereas those of the West-Indies have seldom more than three or four. They may be propagated in England, by sowing the seeds on a hot bed in the spring, and when the plants are come up, they should each be set in a separate small pot, filled with light rich earth, and plunged into a hot bed of tanner's bark to bring them forward, observing to water and shade them till they have taken root. They must be constantly kept in the bark stove both winter and summer. When rightly managed, they will grow to the height of three feet in one summer from the seed. Tamarinds, besides their purging quality, temperate the acrimony of the humours, abate the heat of the bile and blood, quench thirst, and are good in acute burning fevers. They serve to correct the faults of violent purgatives, and to quicken those that are sluggish. The dose is from one drachm to an ounce, and in decoction from one drachm to three ounces.

CARDEMOMUM, *Cardomum*, is of several kinds, of all which some account will be given. The seeds of the greater Cardomum are contained in a dried oblong fruit, about the size of a fig, and much of the same shape, with a broad circular navel at the top, divided in the middle into three parts, and including in a thin, membranaceous, tough, fibrous, wrinkled, brown or reddish colour, a great number of seeds in three cells, which are uneven, shining, reddish, and lodged in a sort of membranes that lie between them.

The *middle-sized* **CARDOMUM** of *Matthiolum*, or the greater *Cardomum* of *Bontius*, is an oblong fruit, of the length of an inch or an inch and a half, but slender, triangular, streaked and blunt at the top; it is of an ash colour, not easily broken, and divided into three cells that contain a great number of seeds, wrapped up in thin white membranes. It is oblong, angular, thin, and on one side divided by a sort of small pipe, and there are several transverse lines run across it. It is of a reddish white colour, with an acrid aromatic taste. This sort is very common.

The *lesser* **CARDOMUM** of *Matthiolum* is the *Cardomum* of the ancient Greeks, and is a dried fruit with a short membranaceous pod, not half an inch in length, of a triangular shape, but sharpest at the pedicle, and blunt at the extremity; it is of a reddish colour, streaked, and has a much thinner shell than the middle-sized Cardomum. When it is fully ripe the three corners gape, and discover three cells, containing a double row of angular, wrinkled, reddish yellow seeds, but white within, and of an acrid, bitterish, aromatic taste, somewhat like camphire. It is brought from the East-Indies. In the places where they all grow they are used as spices, and are said to help digestion, to strengthen the stomach and brain; and to promote urine. The dose is from ten grains to a scruple in substance, and in decoction to half an ounce. They are much used in the present practice, that is the greater sort, and are a very warm grateful spice.

AMOMUM VERUM, the true *Amomum*, brought from the East Indies, is a dried fruit growing in small bunches, consisting of ten or twelve berries or membranaceous bladders, which are fibrous, and brittle, lying close to each other without pedicles. The bunch is supported by a woody sprig, which is fibrous, round, and the length of a man's thumb. It is adorned with leaves, as well as a row of small scales, where there are no berries, and there are six long leaves surrounding each berry or grape like a

flower cup. Three of the longest leaves are half an inch in length, but the other three are smaller, and scarce shew themselves above the grapes. The thickness and shape of the berries are like that of a middle sized grape; each contains three rows of seeds, separated from each other by a thin membrane, and each row consists of several angular seeds, wrapped up in the same thin membrane, and lying so closely together, that they appear to be only three long seeds. The whole bunches are of a wood colour, but paler in some than others. The seeds are solid but brittle, and the smell is fragrant, not much unlike that of lavender, but sweeter; however, when they are taken out of their shells, the smell is more acrimonious, and they have an acrid taste. They are said to contain many virtues, but at present are only used in venice treacle.

CUBEBÆ, *Cubebæ*, of the *shops*, are a fruit, or round dried grains like pepper, and sometimes bigger, with a long slender pedicle, and a wrinkled, darkish ash-coloured shell, containing a single seed of a roundish shape, blackish without, and white within, with a sweet, acrid, aromatic taste, but not so hot as pepper. They are said to be good in diseases of the head, to create an appetite, to strengthen the stomach, and to disperse wind. The dose is from three grains to a scruple, and infused in wine, from a drachm to two drachms.

PIPER, *Pepper*, is of several kinds, as *black pepper*, *white pepper*, *long pepper*, and *Jamaica pepper*.

PIPER NIGRUM, *black pepper*, is a dried fruit or grain, of the size of a small pea, with a wrinkled, brown or black rind, which taken off, a hardish compact substance appears of a yellowish green colour, but white within; the taste is acrid and hot, and seems, as it were, to bite the tongue. It grows on a shrub, with a small, fibrous, tough, blackish root, which sends out many shoots that are tough, flexible, green, and woody, which lie on the ground like hops, unless they are propped up; there are several knees, or knots, which when they lie upon the ground will send out shoots; and at each knot there are leaves alternately disposed, and opposite to each other, that are roundish, two or three inches broad, and four long, terminating in points; the texture is thick and firm, and on the upper part they are of a shining dusky green; but beneath of a light green, and have short, thick, green pedicles. The flowers grow in bunches, and are monopetalous, but divided into three parts at the edges, to which succeed the grains, which are ten, twenty, or thirty in number upon one pedicle, and are green at first, but red when ripe; but in drying they grow black and wrinkled. When the rind of black pepper is taken off, it becomes white, and is the only sort brought to us by the name of white pepper. Black pepper is met with in Java, Sumatra, and on all the coasts of Malabar.

Long **PEPPER** is an unripe dried fruit, about an inch or an inch and a half long. It is oblong, round, cylindraceous, and, as it were, streaked with spiral lines, with tubercles placed in the form of a net; within it is divided into several small cells, containing each a small round seed, scarcely the twelfth of an inch in breadth, blackish without, but whitish within, with an acrid, hot, bitterish taste.

Long pepper is commonly pickled, and is in high esteem among some. It is very good in cold phlegmatic constitutions. They have all much the same virtues; for they heat, dry, attenuate, resolve, open and strengthen relaxed fibres of the viscera; and by exciting an oscillation therein, refresh the spirits, divide gross humours, and increase the circulation of the blood.

PIMENTA, *Jamaica pepper*, by some called all-spice, because it has somewhat of the taste of every one, is a dried unripe fruit, of a roundish shape, and

generally somewhat larger than black pepper; the skin is brown and wrinkled, with a navel on the top, which is divided into four parts, and contains two black kernels covered with a greenish black membrane. The taste is a little acrid, aromatic, and somewhat like that of cloves. It grows in several parts of the West-Indies, is gathered while green, and dried in the sun for many days; but they are taken in night and morning, to avoid the dew. It is used as a spice, strengthens the stomach, helps digestion, and refreshes the spirits.

CARYOPHYLLI AROMATICI, *Cloves*, are a dried unripe fruit, somewhat in the shape of a nail, and a little quadrangular, wrinkled, and of a blackish red. On the top there is a head, much about the bigness of a very small pea, which is composed of scales wrapped one into another, and round about it there are four small leaves, not unlike a flower cup, and disposed like a star, between which, in a cavity, there is a small quadrangular style of the same colour. The taste is acrid, bitterish, and agreeable, with a most fragrant smell. Cloves are the flower cups and embryos of the fruit before the flowers are expanded, and are gathered from the month of October to February. When fresh, they are of a dark red, for they come blackish by being dried in the sun and by smoke. They grow in several islands of the East-Indies, which are all now in the hands of the Dutch. Its principal use is as a spice, though it is said to be good against all cold disorders of the brain, swimming of the head, and weakness of sight; it is also good for a cold stomach, and hysterical disorders. The dose in substance, is from three grains to a scruple; but in infusion, from thirty grains to two drachms.

ACAJOUS, or CAJOUS, by some called the occidental anacardium, and by the French the *nut of Acagous*, but by the English the *cashew-nut*, is a fruit, or rather a nut, of the shape of a kidney, and of the size of a chestnut; it is covered with an ash-coloured, or brown skin, about a twelfth part of an inch thick, hard and tough; it seems to consist of a double membrane with a fungous substance, which in its cells contains a sort of oily fluid of the consistence of honey; it is of a reddish colour, extremely acrid, bitter, and biting; for if a drop of it falls on the skin, it seems to burn it like a caustic; and if any one through ignorance should bite the nut, the lips and tongue are immediately affected with a very sharp pain. Under this is the kernel, which is covered with another brown skin of the thickness of paper, whose substance is extremely white, compact, oily, and of a more agreeable taste than almonds. The tree that produces this nut is one of the best fruit trees in all America, some of which are of the size of standard apricot-trees; and sometimes are pretty regular, but generally the branches are crooked, knotty, and are strangely contorted among each other. The wood is greyish, pretty strong, tough, and heavy; the bark is thin, smooth, and of a dirty white, a little variegated with brown specks and lines. The leaf is large, firm, well fed, pretty thick, and more round at the top than at the bottom. The flowers are small and grow in tufts, and when they are opened they are divided into five leaves, which form a flower cup of small stamina of a yellow golden colour, that surround a pistil of the same colour but longer; the leaves that compose the flower are whitish at first, and afterwards turn to a purple mixed with white lines; but they are of small duration, for the pistil soon changes to a fruit. The tree, either spontaneously or cut, yields plenty of gum, that is reddish, transparent, and solid; it will dissolve in water like gum-arabic, and supplies the place of glue; when the juice is expressed from the fruit and fermented, it becomes a sort of heady wine, which greatly promotes urine, and the spirit dis-

tilled from it is very good. The thick fluid above-mentioned tinges linen of a rusty iron colour, which can hardly be got out. Some get an oil out of it, which will stain linen with a black colour that can never be got out, and if any wood be smeared with it, it preserves it from rotting. The oily fluid first taken notice of is used for taking off warts and corns, when mixed with the black wax of Gaudaloupe, or warm water. The ladies make use of it to take off freckles, for it soon destroys the cuticle, which is succeeded by one that is fair and of a good colour. When the kernels are put into water, the skin will readily come off, and then they are fit to eat; but when they are dry, they open it a little with a knife, and then lay them over the fire, by which means the skin may be easily taken off. They are in very high esteem among the inhabitants of the West Indies, not only to eat by themselves, but to make mackaroons and marchpains; besides which, they give to rosa solis and other liquors a very fine flavour. They may be transported to any distant country, and will continue good for many years.

BEN, is the *Balanus Myrepica of the shops*, and is a nut of the size of a hazel-nut, but of different shapes, for it is sometimes oblong, roundish, or triangular; it is covered with a whitish shell, which is pretty thick and brittle, and contains a kernel covered with a fungous skin as white as snow, and of the same consistence as an almond; it is fat and of a bitterish taste. Eight pounds of the kernels will yield thirty ounces of a yellow limpid oil by expression. This nut is of great use among the perfumers for extracting the fine smell out of flowers, because it will never grow rancid, and has no smell of its own.

CACAO, or COCAO, the chocolate-nut, are oblong, roundish, and of the size of olives; and are covered with a thin, hard, brittle, blackish shell, which being taken off there remains a firm, dense, dry, flattish kernel, of a dusky yellow on the outside, and reddish, or of a bay colour within. They consist of several pieces closely united together, and have a little bitterish and slightly acerb, but not a disagreeable taste. Some take notice of four sorts of the trees, which grow spontaneously and without any cultivation, in many parts of America between the tropics; particularly near the river of the Amazons there are whole forests of them. The wild cocoa-tree is very large, and thick of branches; but those that are planted are cultivated in such a manner, that they never exceed twelve or fifteen feet in height, not only that the fruit may be gathered more easily, but that they may not be too much exposed to the wind. The leaf is generally eight or nine inches long, and sometimes more, but seldom less; and the breadth is one third of the length. It is pointed at both ends, and has a strong stalk two or three inches long. It is of a lively green above, but deeper beneath, and the edges, from the place where it is broadest to the point, is of a very fine flesh colour. The fibres or nerves are like those of the cherry tree. This tree is an evergreen. It bears fruit twice a year, as well as most of the trees in these parts of America; but more properly speaking, it is never without flowers or fruit; however, the produce is most plentiful near both the solstices, but that near Christmas is always the best. The flower is small, and has six leaves when opened, which form a small cup, in the center of which is a longish button, surrounded with five filaments and five stamina. The leaves of the flower are of a pale flesh colour variegated with red spots and specks; the filaments are of a reddish purple, and the stamina are of a fine silver colour; but the button is of a duller white, and it is this that produces the fruit. The flowers do not proceed from the branches, as in the European trees, but from the root up to
one

one third part of the five large branches. The fruit that succeed these flowers resemble cucumbers, and are pointed at the end; but on the sides there are furrows like those on melons, among which are small unequal tubercles, and these contain the nuts before described; besides which they contain a substance or pulp, of a palish colour, which is very light and delicate, and of the same taste as pomegranates. Within this pulp are the nuts, of which there are twenty-five in number in each pod. The trees are in greatest perfection when they are ten or twelve years old, not because they bear more, but the largest fruit. The chief use of these nuts is for making chocolate, which is every where very well known, and is said to have restorative qualities; for which reason it is good in consumptions, prepared with milk, for then it abates the acrimony of the humours.

- **PISTACHIA**, *Pistachio nuts*, are of the size and shape of hazle-nuts, only they are a little angular, and higher on one side than the other. They are covered with a double shell, the outermost of which is membranaceous, dry, thin, brittle, and reddish when ripe; but the other is woody, brittle, smooth, and white, under which is a kernel of a pale greenish colour, and of an oily, bitterish, sweetish taste, and agreeable to the palate; it is covered with a red skin. It grows in Persia, Arabia, Syria, and the East Indies; and is cultivated in Italy, Sicily, and the southern parts of France. They yield good nourishment, and are said to be restorative, causing those that are fallen away to regain their flesh very soon. They have been used to make emulsions in the same manner as almonds.

PINEI NUCLEI, *Pine-apple nuts*, are oblong, round, white, fat, sweet, covered with a reddish coat, and are included in a thick hard shell. These nuts are contained in the pine-apple, or cones, between their hard and woody scales. They contain a great deal of oil, which may be gained by expression; and are said to be very nourishing, but they are not easily digested. Some account them good for consumptive patients, because they destroy the acrimony of the humours; they are also good in heat of urine, and in ulcers of the kidneys and bladder.

COFFEE is a hard seed in an oval form, and somewhat above a third of an inch long, and a quarter of an inch broad; one side is convex and the other flat, marked with a remarkable furrow. It is yellowish or of an ash coloured palish green; it has a farinaceous taste, and before it is roasted has not much smell. The cup of the flower consists of one leaf, which is divided at the top into five segments, and the flower likewise consists of one leaf in the shape of a funnel, and divided into five segments; the flowers are succeeded by berries, which split in the middle. The coffee-tree is propagated by seeds, which should be sown soon after they are gathered, otherwise they will not grow, which is the reason that all other countries, except Arabia, have been so long without it. It was necessary to get trees that were growing, which has been at length done, and there are now many of them as well in Europe as in America; but they succeed best in the Caribbee islands; however, the coffee is not accounted so good as the Arabian. The berries are commonly ripe with us in April, at which time they should be sown in pots of fresh light earth, covering them about half an inch thick with the same; and then the pots should be plunged into a moderate hot bed of tanner's bark, observing to refresh them often with water; as also to raise the glasses in the heat of the day to admit fresh air; and in very hot weather it will be proper to shade the glasses with mats.

The blossoms, or flowers are white, and shoot out just where the stalks of the leaves join the branches; when the blossoms fall off there remains a small fruit,

which is green at first, but as it ripens becomes as red as a cherry, and not unlike one; and it is very good to eat, being strengthening and refreshing; under the flesh of the fruit, instead of a stone, there is the berry, covered with a fine thin skin. When the fruit has been dried by the sun, the pulp becomes a shell of a deep brown colour, under which there is a thick brown liquor extremely bitter. Some direct the taking off the pulp of the berries before they are sowed, but this is a mistake; for they will come up sooner when it is left on, and produce stronger plants. There are two seeds in each berry, which seldom fail to grow; but, when the plants are young, they may be easily parted and set in different pots, and about an inch and a half high. In the winter season they should be placed in a bark stove, and kept up to the heat proper for pine-apples. In Arabia they bear ripe fruit twice or thrice in a year. The use of coffee is now well known every where, and the liquor made with it is generally supposed to be good in weaknesses of the stomach, in want of appetite, and in the flatulent cholic. It prevents sleepiness, and is good in sleepy diseases, for which reason it refreshes the brain and the animal spirits. It is good for those that are fat; and abound with thick gross humours; but with those that are lean, and have hot constitutions, it does not so well agree, nor yet with those of melancholy dispositions.

- **NUX MOSCHATA**, or **NUX MYRISTICA**, the *Nutmeg*, is very firm and compact, and yet is very easily pounded in a mortar. It is wrinkled without, and somewhat of an ash colour; but within it is variegated with a whitish yellow, and a bay colour, running in veins without any regularity. The trees that bear nutmegs are now entirely in the possession of the Dutch, as are all the spice islands; they are like pear trees, and have an ash coloured bark, with a spongy wood. The flowers, or blossoms, are yellowish, with five leaves, not unlike those of cherries; to these succeed the fruit, hanging to a long pedicle. It is somewhat like a walnut, and the kernel, or nutmeg, is covered with three coats, the first of which is fleshy, soft and juicy; about as thick as a man's finger, but villous and red, and variegated with yellow, gold colour, and purple spots, like a peach. When it is ripe it gapes spontaneously, and is of an austere taste. Under this there is another reticular covering, or rather divided into several parts, which is of an oily clammy consistence, and as it were cartilaginous, but thin, of an agreeable aromatic smell, and of an acrid aromatic taste, with a sort of bitterness. It is of a saffron colour, and is what we call **MACE**. Between the clefts of this there is a third covering, which is a hard, woody, thin shell, of a dusky reddish colour, and brittle, and in this the nutmeg is contained. It is soft at first, but grows dry and hard in time. The taste and smell is too well known to need a description. The principal use of nutmegs is as a spice, and they are good to promote digestion, to stop vomiting, to discuss wind, and to ease pains of the cholic. However, the immoderate use is bad, for it will affect the head, and produce sleepy diseases, as they have found by experience in the East Indies. When roasted they have a binding quality, and are good in fluxes of the belly, and are given to the quantity of a drachm.

NUX VOMICA, the *Vomit nut*, is round, flat, depressed, about an inch broad, and a quarter of an inch thick; it is of a hard horny substance, of an ash colour, and a little downy without, with a navel on the middle of each side; but one side is flatter than the other, and the taste is bitter; it is brought from the East Indies with snake-wood. It is of no use in medicine.

CARTHAMUS, *Baslard Saffron*, produces seeds that

that are sometimes used in medicine, but the flowers very seldom, for they are chiefly used as a dye. It agrees with thistles in most of its characters, only the seeds are always without down. It is greatly cultivated in Germany, and is brought into England from thence; for the use of the dyers. It is sown in the open fields in the spring of the year, and when come up they hoe it out thin, as we do turnips, leaving the plants about eight or ten inches distant every way. These plants divide into a great many branches, each of which bears a flower at the top of the shoot, which when fully blown they pull off, and is the part the dyers make use of.

SANTONICUM SEMEN, *Worm seed*, is a gross powder, consisting of oblong, scaly, yellowish, green grains, of a disagreeable bitter taste, with somewhat of an aromatic acrimony; the smell is a little aromatic; but nauseous, and there seem to be diminutive leaves and exceeding small streaked stalks among it. Its chief virtue is against worms, besides which it is said to strengthen the stomach, discuss wind, and excite an appetite; the dose is from a scruple to a drachm.

ANISUM INDICUM STELLATUM is a fruit in the form of a star, which consists of six, seven, or more capsulæ, meeting like rays in the center; it is of a triangular shape, and from near half an inch to an inch in length, and from a quarter to near half an inch broad. It is a little flat and united at the base, being composed of a double rind, the outermost of which is hard, rough, wrinkled, and of a bay or rusty colour; but the inside is hard, smooth, and shining, and has two valves, which gape on the upper part in those that are dry and old. There is in every one a kernel, which is smooth, shining, oblong, flat, and near a quarter of an inch long, and a twelfth broad, of the colour of linseed, which in a slender brittle shell contains a whitish, fat, sweet flesh, or pulp, agreeable to the palate, and of a taste between aniseed and fennel-seed, but stronger. The capsula has the taste of fennel mixed with somewhat of an acidity, and the smell is like it, but more fragrant. It is brought from China, Tartary, and the Philippine islands, and has the same virtues as aniseeds and fennel-seeds; but stronger. They strengthen the stomach, discuss wind, and promote urine.

NATURAL HISTORY of LIQUID RESINS.

THE fluids that flow spontaneously from any plant or tree, or from the wounded bark, either concrete into a resin, or gum, or are somewhat of a middle nature between a gum and a resin, which ought carefully to be distinguished from each other.

A resin is a fat, oleaginous, inflammable substance, that will not dissolve in water, but will in oil or spirit of wine. It is of two sorts, for one is clammy, liquid, and tenacious; and the other dry and brittle, which however will grow soft with heat.

A gum is a concremented juice that readily dissolves in water, but will neither melt nor take fire. A gum resin is that which will dissolve equally in water or oil, or at least for the greatest part, and is composed of resinous and gummous particles.

OPOBALSAMUM, *Balm of Gilead*, is a liquid resin, of a very light yellowish colour, and of a fragrant smell, not unlike that of citrons, but the taste is acrid and aromatic. Authors have long disputed where this balsam is produced; but it is certain, that it is now only to be met with in Arabia Felix, and has different virtues according to its age, for when fresh it has a much greater efficacy than when old. It is given inwardly against putrefaction of the viscera, and abscesses of the lungs, liver, and kidneys. The dose is from two scruples to a drachm.

It also cleanses foul ulcers, and heals them in a short time; but it is hard to be met with genuine, and very little that is so is brought over to us.

BALSAMUM PERUVIANUM, of which there are two or three sorts, as the *Balsamum Peruvianum album*, the *white Balsam of Peru*, that is fluid, and thinner than turpentine, but of a clammy consistence, and is resinous, inflammable, limpid, and of a yellowish white colour. The taste is a little acrid and bitterish, but the smell is sweet and fragrant, approaching to that of storax. It is brought from Spanish America.

BALSAMUM PERUVIANUM FUSCUM, *brown Balsam of Peru*, is fluid, resinous, clammy, and nearly of the consistence of turpentine; the colour is brown or of a reddish black, with a most fragrant smell like that of benjamin; but the taste is subacid, and a little pungent on the tongue. It will readily take fire and flame, the smoke of which smells extremely agreeable. That which is quite black is bad. They both are the juice of the same tree, and the one proceeds from the wounded bark of the tree; but the other is obtained by boiling. They cut the wood, bark, and branches, into very small bits, and then boil them in water for a considerable time; when the water is cold, the balsam will swim on the top, which they put in shells, and keep for use. The dose is from four drops to twelve in an asthma, consumption of the lungs, and fits of the gravel. Outwardly they ease pains proceeding from cold humours, and are excellent in healing wounds.

BALSAMUM TOLUTATUM, *Balsam of Tolu*, is a resinous clammy juice, of a middle consistence between a fluid and a solid; the colour is bay, inclining to that of gold; it has a most fragrant smell, and the taste is sweet and agreeable, for it does not create a nausea like other balsams. It is brought in small gourd shells from South America, and particularly from Tolu. In length of time it becomes dry, hard, and brittle. It has the same virtues as balsam of Peru, and is of great use in consumptions of the lungs, and internal ulcers. It is very efficacious in curing wounds; and serves to make what is called the ladies black sticking plaster now so much in vogue.

BALSAMUM COPAIBA, *Balsam of Capivi*, is a resinous liquid juice, and while fresh is of the consistence of oil, but in time it grows thick and glutinous. It is of a yellowish white colour, with an acrid, bitter, aromatic taste, and of a fragrant smell. It is brought by the Portuguese from Brasil into Europe. It is often adulterated with turpentine, but may readily be known from it when taken; for it does not give the violet smell to urine as that does. It abates the acrimony of the humours, enriches poor blood, and it both inwardly and outwardly heals all manner of wounds. It is also good in disorders of the lungs, and is excellent in appeasing coughs. It is given in a bolus with sugar and powder of liquorice, from five to twenty drops.

LIQUIDUM AMBARUM, *liquid Amber*, is a resinous, liquid, fat juice, of the consistence of turpentine, and of a yellowish red colour; it is of an acrid aromatic taste, with a fragrant smell, not unlike storax. It is brought from New Spain, Virginia, and other parts of America. It was formerly of great use among perfumers, but is now laid aside, and is seldom met with in the shops.

STYRAX LIQUIDUS, *liquid Storax* is a resinous juice, of which there are two sorts in the shops, the one pure, and the other impure or thick. The best is of the consistence of turpentine, and semi-transparent; the colour is brown, or of a reddish brown, and sometimes of an ash coloured brown, with a strong smell like storax; but it being so violent it is disagreeable, and the taste is a little acrid, aromatic,

and oleous. The impure storax is a resinous juice, full of dregs, and of a brownish or ash colour; it is also opaque, fat, and has not so strong a smell. It is the produce of a particular tree, growing near Suez in Arabia, whose bark they strip off every year and boil in sea water to the consistence of bird-lime, and then they take off the resinous substance swimming at the top. It is in like esteem among the eastern people; it is said to have the same virtues as the former balsams, and is given from three drops to twelve to heal internal ulcers; but it is more commonly used outwardly for wounds, bruises, and ulcers.

TEREBENTHINA, *Turpentine*, is of several kinds, and there are four kept in the shops.

TEREBENTHINA CHIA VEL CYPRIA, *Chio Turpentine*, is a resinous liquid juice, of a whitish yellow colour, inclining a little to blue; it is sometimes transparent, and sometimes of a pretty firm consistence, and sometimes soft, thick, and glutinous. The taste is a little bitterish and acrid, and the smell is also acrid but not disagreeable. The best is brought from the islands of Chio and Cyprus. The use of this, as well as of the other turpentines, is both external and internal; externally it is emollient, discutient, resolvent, cleanses ulcers, and heals recent wounds. But it is generally prescribed inwardly, and is remarkable for healing ulcers of the stomach, intestines, liver, kidneys and bladder. It is good in an old cough, for purulent spitting, and the beginning of a consumption. It promotes urine, gives it a violet smell, and is good in heat of urine. The common dose is from half a drachm to a drachm and a half, in the form of a bolus, or dissolved in the yolk of an egg.

TEREBENTHINA VENETA, *Venice Turpentine*, is a resinous, liquid, limpid, clammy substance, thicker than oil, but more liquid than honey; it is a little transparent like glass, and of a yellowish colour; the smell is resinous, fragrant, and acrid, but not disagreeable: the taste is acrid and bitterish. It is called Venice turpentine, because it was formerly brought from Venice; but now from Savoy, and the southern parts of France.

TEREBENTHINA ARGENTORATENSIS, *Strasburg Turpentine*, while fresh is more liquid than the former, and is more transparent, not so clammy, and has a finer smell, something resembling that of citrons; but the taste is more bitter, pretty much resembling that of citron peel; in time it grows yellowish and thick. It flows from the tree called *abies taxifolio*, that is, the fir with the leaf of the yew tree; not only from its trunk and boughs, but also from certain tubercles within the bark. That which proceeds from the trunk is the worst, and when dry it resembles frankincense in colour and smell, but that which proceeds from the incision of the tubercles is best. It has the same virtues as Venice turpentine, though some think it is more efficacious, and it is given in the same manner.

TEREBENTHINA COMMUNIS, *common Turpentine*, is more thick and tenacious than any of the former, and is not so transparent; it has a resinous strong smell, with an acrid, bitterish, nauseous taste. It proceeds from the pine-tree, either spontaneously or from incisions. The white resin, called by the French galipot, is commonly mixed with wax for the making of flambeaux. When the white resin is melted with common turpentine, and oil of turpentine, the composition is called Burgundy pitch. In some places, the trunks of the old pine-trees that are still standing, have a ditch made round them and set on fire, which forces out a fluid well known by the name of tar, of which tar-water is made, lately so much in vogue, for the curing almost all sorts of distempers. All sorts of resins being set on fire, produce soot, which preserved, is known by the

name of lamp black. All sorts of resins, as well liquid as solid, are emollient, digestive, resolvent, and serve to make plasters and ointments for the curing of wounds and ulcers.

NATURAL HISTORY of SOLID RESINS.

ANIME *vel* ANIMUM, *Gum Anime*, is improperly called a gum, for it is nothing but a resin, and is either oriental, or occidental. It is a transparent resin, and is brought in fragments of various colours, for some are white, others reddish, and others brown. When kindled, it has a pleasant smell, and is brought from Arabia to us. We know nothing of the tree that it proceeds from, nor are we certain that this is its proper name.

AMINE OCCIDENTALIS SEU AMERICANA, *American Anime*, is a white resin, a little inclining to the colour of frankincense. It is more transparent than copal, but more oleaginous. It is of a most grateful and sweet smell, and when thrown upon live coals soon burns away. It is brought from New Spain, Brasil, and the American islands. Some apply this outwardly, when dissolved in oil or spirits of wine, to strengthen the nerves.

BENZOINUM, *Benjamin*, is a dry, hard, brittle, inflammable resin, consisting of various bits, some of which are yellowish, others whitish, in the same mass; it has a resinous taste, with a sweet fragrant smell, especially when it is set on fire. There are two sorts, one of which is pale, or of a reddish yellow, containing white grains like almonds; the other is blackish, with few or no spots. It is brought from the kingdom of Siam, and the islands of Java and Sumatra; that of the lightest colour is best. Its principal use is as a perfume, though it is good in disorders of the breast, promotes expectoration, and appeases coughs. The flowers of *Benjamin* promote sweat, and are good in the asthma. The resin is used externally to strengthen the head, stomach, and nervous parts, when made up into a plaster; the tincture is of great use in taking off tubercles and redness of the face.

CAMPHORA, *Camphire*, is a resinous fattish substance, white, light, and transparent, and is brought to us in a sort of loaves or masses, six inches long and one or two thick; it has an acrid, bitterish, aromatic taste, and yet with a sense of coldness: the smell is fragrant, somewhat like rosemary, but much stronger. It is so volatile, that when exposed to the air it will diminish by degrees, and at length fly quite away. It easily takes fire, leaving no earth, or any thing else behind it, when it has done flaming. It is brought from Japan into Holland, and from thence dispersed all over Europe. In the East Indies it is distinguished into two sorts, namely, that which is brought from Japan or China, and that which is produced in the islands of Borneo and Sumatra; but this is very dear and uncommon, and is seldom or never brought to us. It is produced from a tree like a laurel, but of a very large size, for it grows to the bigness of an oak tree. Camphire may be got from any part of it, for it flows through incisions like other resins, but in some places the country people cut the root and wood into small bits, pouring water upon them, and boiling them in an iron vessel, with a head fixed thereto made of straw, to which when it is sublimed it sticks like soot. However, it is coarse when first brought over to Europe, and is cleansed by the Dutch. The virtues of camphire are very great, especially in the hands of a skilful physician: for it is an alexipharmic, and is both anodyne and diaphoretic, without heating the body or disturbing the circulation of the blood; neither does it occasion thirst, nor render the urine of a higher colour, as hot medicines will. It

has also an anodyne and soporiferous quality, and is good in pains, madnefs, and spasms, often producing wonders. The dose is from three grains to a scruple, given in the form of a bolus, or dissolved in oil of sweet almonds. It is used externally, when dissolved in spirits of wine, in rheumatic pains and inflammations; it is also good against burns and scalds.

CARANNA, *Caranna*, is a resinous substance, as ductile as pitch when it is fresh, but when old it is hard and brittle, of a blackish ash colour without, and brown within; it has a resinous bitterish taste, somewhat like myrrh, and when kindled has a fragrant smell. It is brought from America in masses wrapped up in a sort of leaves. It is only of outward use, and is said to resolve tumours, ease pains, and strengthen the nerves. It is made into a plaster and laid to the temples for the tooth-ach, and on the top of the head for the head-ach.

ELEMI, *Gum Elemi*, is a yellowish resin, or of a greenish white, pretty hard on the outside, but within soft and clammy, and is brought to us in masses of a cylindrick form; when set on fire it has a strong but not disagreeable smell, somewhat like fennel. This is the *true elemi* that was brought from Ethiopia, and is now seldom to be met with in the shops.

ELEMI AMERICANUM, *American Elemi*, is sometimes whitish, sometimes yellowish, and sometimes greenish. It is somewhat transparent like resin, and has a strong smell like that; this is very common in the shops, and is only used outwardly for resolving tumours, dissolving ulcers, and easing pains. It is particularly recommended against diseases of the head and tendons, especially the ointment prepared with it, which is called the balsam of Arcæus.

RESINA HEDERÆ, the gum of the ivy tree, is a resinous, dry, hard, compact, brown or rusty coloured substance, somewhat transparent; it is broken into small fragments, among which some are of a reddish colour; the taste is subacid, a little astringent and aromatic, but it has no smell. It is brought from Persia, and other oriental countries.

LADANUM *vel* LABDANUM, *Labdanum*, is a resinous substance, of which two kinds are met with in the shops, one of which is brought in large compact masses, and is of an agreeable smell, with a reddish black colour. It is wrapped up in bladders or skins; but the other sort is without any, and is of a contorted shape, somewhat like a screw, and is dry and brittle; but when heated by the fire is a little soft, and is mixed with a kind of black sand. It is of a black colour, and weaker than the former, but is most commonly met with amongst us. Outwardly, labdanum is emollient, and is used to strengthen the stomach and promote digestion; but it is very seldom used.

MASTICHE, *Mastich*, is a dry resin, of a pale yellowish colour and transparent; it is brought in tears of the size of small peas, and is brittle at first between the teeth, but when warm it sticks thereto; and when thrown upon live coals it takes fire, emits a pretty good smell, and the taste is slightly aromatic, resinous, and subastringent. That is best that is pale, yellowish, transparent, dry, brittle, and has a pretty strong smell; but the black, green, livid, or impure, is good for nothing. Some physicians have commended mastich for strengthening the fibres of the viscera, and abating the acrimony of the humours. Some give from a scruple to half a drachm, in spitting of blood and inveterate coughs. Externally laid to the temples, it is said to cure the tooth-ach.

OLIBANUM, *Olibanum*, is of a resinous substance, of a pale yellowish colour, and transparent, it is brought in tears like mastich, but bigger, and is of

a bitterish taste, and pretty acrid, but not disagreeable, and of a fragrant smell. It readily takes fire, and flames a long while. That is best that is whitish, transparent, pure, shining, and dry. Some have accounted it a specific against a pleurisy, and commend it in disorders of the head and breast, especially coughs and spitting of blood. The dose is from a scruple to two drachms. A drachm of it, put into an apple, roasted under the ashes, and given to the patient, has been observed to cure those who have been given over in a pleurisy; but then they must be well covered in bed in order to sweat. If the first dose does not succeed, another must be given in six hours time. It is accounted a good vulnerary, and therefore is mixed in various plasters.

SANDARACHA, *Gum Sandarach*, is a dry, inflammable, transparent, resinous substance, of a pale yellow colour, and brought in tears like mastich. The taste is resinous, but the smell when it is kindled is fragrant and sweet. That is best that is yellowish, transparent, and shining. It is brought from the coast of Africa, and has much the same virtues as mastich, but is seldom given inwardly; nor is it very often applied outwardly. When powdered it is well known by the name of pounce, which is rubbed over paper to prevent the sinking in of the ink, and to render the writing more fair; it is also an ingredient in some sorts of varnish.

SANGUIS DRACONIS, *Dragons-blood*, is a dry, brittle, resinous substance, melting easily, and as readily taking fire. It is of a dark red, but when powdered is of an elegant crimson; when drawn into thin plates it is transparent, but is without taste or smell, unless when kindled; for then the fumes smell somewhat like storax. There are two sorts in the shops, one of which is hard and in masses, about an inch long, and half an inch thick, and is wrapped up in long narrow leaves. Dragons-blood in tears and drops is generally mixed with bark, wood, earth, or other heterogeneous substances, and then made into masses, or loaves, as some call them. There is another counterfeit sort, that may be readily distinguished from the true, for the masses are of a dusky red colour, and made up of several sorts of gums, tinged with Brasil wood. It will not flame, but when placed over the fire rises in bubbles, and being put into water dissolves therein. That is best that is shining, of a darkish red, wrapped in leaves, and when powdered is of a fine red shining colour. It is brought from the East Indies, and is produced by four different trees; however, that which is genuine will dissolve only in spirits of wine and in oils. It is of an astringent quality, and is excellent in all sorts of hæmorrhages whatever; the dose is from half a drachm to a drachm, and when applied outwardly dries up ulcers, heals wounds, and fastens loose teeth; it is also of use to painters, in making a red sort of varnish.

STYRAX SOLIDUS, *Storax*, is a resinous substance, of which there are two kinds, *Storax Calamite*, and *Common Storax*.

STYRAX CALAMITA, *Storax Calamite*, is a resinous, shining, solid, somewhat fattish substance, which is composed of reddish and whitish grumes or grains, of a resinous, acrid, but not disagreeable taste, and a most fragrant smell, especially when thrown on live coals; it takes fire readily, and emits a very bright flame.

STYRAX VULGARIS, *Common Storax*, is of a yellowish red, or brownish colour, which is shining, fat, and a little clammy, and is brought in masses mixed with whitish grains; it has the same smell and taste as the former. There is also another sort of storax which is mixed with saw-dust, and this is now commonly sold in the shops, and is oftener met with than the true. It is good in diseases of the

breast, and is said to strengthen the brain, refresh the spirits, and restrain their inordinate motions; it has also an anodyne faculty, and is good in pains of the head, and inveterate coughs, by abating the acrimony of the humours. The dose is from half a scruple to half a drachm.

TACAMAHACA, *Tacamabac*, is a resinous, dry, fragrant substance, of which there are two kinds in the shops, but that in shells is the best. It is a little soft, sometimes pale, sometimes yellowish, and at other times greenish. It is brought in shells, which seem to be of the gourd kind, and covered with leaves. It has a most fragrant aromatic and very sweet smell; but it is seldom met with in the shops. The common sort consists of whitish grains, or gleses, but they are sometimes yellowish, reddish, greenish, or variegated with all those colours, and semi-transparent. The smell is much like the former, but not so disagreeable, and it is brought from New Spain. It is seldom or never given inwardly, but is applied outwardly for easing of pains arising from cold flatulent humours; it resolves and ripens swellings, and restrains defluxions on the eyes, and other parts of the face. When laid to the temples, it is much praised by some for curing the tooth-ach, and on being applied to the stomach, it strengthens it, and assists digestion.

NATURAL HISTORY of GUMS.

GUMMI ARABICUM, *Gum Arabick*, is brought over to us in tears, or drops, of different colours, some of which are pale, others yellow, and others red, with a wrinkled surface, and brittle, and which shines like glass when broken. When held in the mouth it sticks to the teeth, and dissolves readily in water, but has no taste. It is produced by a tree called the *Acacia-Vera*, or the *Egyptian Thorn*, and is brought over from Arabia, Egypt, and other parts of Africa. The best is whitish, or of a palish yellow, shining, dry, transparent, and free from filth. When it is brought over in large reddish dirty masses, it is only fit for mechanical uses. It will not dissolve in spirits of wine, or oil, and in the fire it burns to ashes without flaming, whence it appears to consist of a mucilage and earth; whence it is good in hoarsenesses, coughs, salt catarrhs, spitting of blood, the stranguary, and heat of urine. The dose is from a scruple to two drachms. When a powder of this gum is wanted, it must be beaten in a red hot mortar, and then the powder of it may be exhibited for internal use.

GUMMI SENECA, *vel SENICA*, *Gum Seneca*, is not unlike gum arabick, and is called Senega, because it is brought from a province of Negroeland, bordering upon the river Senegal. We now have it in great plenty, and at present the whole trade is in our own hands, but from what tree it is obtained we are uncertain, though perhaps it may be a kind of an acacia. The white and smaller tears of this gum are often sold for the true gum arabick; and there is no great cheat in the matter; for their qualities and properties are much the same.

TRAGACANTHA, **TRAGACANTHUM**, and **DRAGACANTHUM**, *Gum Tragacanth*, is a gummy juice, sometimes brought over in long strings variously contorted and bent, and sometimes in small grumes, or bits; it is white, semi-transparent, and sometimes yellowish, reddish, or blackish. It is dry, but not very hard, and without either smell or taste. It is brought from Cyprus, Asia, and Greece. That in strings like worms or isinglass is best, when it is white and free from filth. It serves for the same purposes as gum arabic; and it is observable that a drachm of it will thicken a pint of water, full as much as an ounce of gum arabick, it being altogether a mucilage without any earthy parts. It is

good in dry sharp coughs, hoarsenesses, and other disorders of the breast, arising from an acrid lymph; as also in the stranguary, and ulcers of the kidneys; it is also of use to abate the heat of the mouth, and tongue, and to heal the painful chaps of the nipples. It is best taken dissolved in some convenient water, and the dose is from half a scruple to two drachms. It is never used externally, but serves the apothecaries for making troches.

MANNA, *Manna*, is a sort of gum, which flows spontaneously from several sorts of trees, and afterwards congeals into grumes in the form of an essential oleous salt; it not only proceeds from the ash and quicken-tree, but also from the larix, pine, fir, oak, juniper, maple, olive, fig-tree, and other plants; for which reason it differs in form and consistence, according to the place and tree from whence it was gathered; for some is liquid, and of the consistence of honey, and another sort is concreted into grains like mastich, and another again into grumes or small masses. *Manna* is also divided into the Oriental and European, the first of which is brought from India, Persia, and Arabia.

MANNA CALABRA, *Calabrian Manna*, is sometimes in grains, sometimes in tears, and sometimes in grumes or small masses; it is brittle and whitish while fresh, and somewhat transparent; but in time grows reddish, and in moist weather turns to the consistence of honey; it is as sweet as sugar, with a kind of an acidity. That is best which is white or yellowish, light and concreted into grains or grumes in the shape of icicles; but that which is fat, like honey, or blackish and dirty, is not good; for sometimes this is counterfeited with coarse sugar, honey, and a little scammony; likewise that which is white, opaque, solid, heavy, and not in the shape of icicles, is bad, because it is nothing but sugar and manna boiled together. This counterfeit sort may easily be distinguished from the true by its density, weight, opacity, and taste. This manna in Calabria and Sicily flows spontaneously from two sorts of ash-trees, and is found on the boughs and leaves in the summer months, unless prevented by rain. When the weather is dry, it flows from the trunk and large boughs of these trees, from the twentieth of June to the end of July, and from noon till evening, in the form of a limpid fluid, which concretes into various grumes, and grows white and dry. They gather it the next day, scraping it off with wooden knives, if the weather is fair; but if it should chance to rain, the manna is lost. When July is past, they make incisions into the bark of the ash and quicken-trees, and from noon till evening a liquid flows out, which concretes into thicker grumes, which are sometimes very large, and require a day or two to bring it to a proper consistence; this is redder than the former, and is sometimes blackish, on account of the earth and other filth mixed therewith.

MANNA DI FRONDE flows spontaneously in July and August, from about the nervous fibres of the leaves, which being dried in the air concrete into whitish grains of the size of wheat; inasmuch that in August the greater leaves of the ash-tree look white, as if they were covered with snow; however, this is very scarce, on account of the difficulty of gathering it. The virtue of manna is well known, it being a mild laxative purge, and is thought to dissolve gross humours, and to abate their acrimony; whence it is good in catarrhs and coughs, proceeding from an acrid phlegm. It is also good in disorders of the breast and lungs, when stuffed with clammy humours. It is also useful in the pleurisy, inflammation of the lungs, and tension of the belly, from a thick hot bile. The dose is from one ounce to three, and Hoffman, in some particular cases, has given to four.

NATURAL HISTORY of GUM RESINS.

AMMONIACUM, *Gum Ammoniac*, is a concreted juice, of a middle nature between a gum and a resin; it is composed of little lumps, or masses, shining here and there with bits that are milk white, or reddish; but the substance itself is a little brownish, and not unlike benjamin; but it is sometimes in tears. It is sometimes yellowish on the outside, and of a yellowish white within; the taste is sweetish at first, but afterwards bitterish, and the smell is fragrant, not unlike that of galbanum, but stronger. When chewed, it grows whiter and whiter by degrees, and when thrown upon burning coals, it will flame; it will dissolve in vinegar or hot water, and is brought from Alexandria in Egypt. The tears are best for internal use, especially when pure, dry, and without mixture. Ammoniac incises gross humours, and is good in the asthma, in crude tubercles of the lungs, and is in general a great aperient. The dose is from half a scruple to a drachm, in the form of an emulsion, electuary, bolus, or pills. Outwardly it is discutient, and is of great use in ripening tumours.

ASSA-FŒTIDA is a kind of gum resin, and is of the consistence of wax; it is frequently bought in large masses, full of shining, whitish, yellowish, reddish, flesh-coloured, or violet spots. It has a very strong smell, somewhat like garlick, and has a bitter, biting, acrid taste. It is brought from Persia, and the East-Indies, and that is best which has the strongest smell, and seems to be composed of tears reduced into masses. It proceeds from the wounded root of a tree, but never from any other part, and at first it is as fluid as cream, and of the same colour; but being exposed to the air and sun, it becomes brownish and thick. It is prescribed in the flatulent cholic, hysterical disorders, and for promoting secretions. It is diaphoretic, and promotes sweat; it is good in disorders of the nerves, and is of some use in a palsy. The dose is from twelve grains to a drachm, and even to two drachms.

BDELLIUM, *Bdellium*, is a gum resin, which is brought to us in masses of several shapes and sizes, and has somewhat of the appearance of myrrh, it being of a rusty reddish colour; but in the inside it is a little transparent. It is brittle, of a bitterish taste, and has no disagreeable smell when kindled; it will flame for a considerable time, with a sort of a crackling noise. It is a good emollient, and is effectual in dispersing tumours of the glands.

EUPHORBIIUM, *Euphorbium*, is a resinous gum, and is brought to us in drops, or tears, of a pale yellowish, or gold colour; are bright, and of different shapes and sizes, with a most acrid, burning, nauseous taste; but without smell. It is brought from the inland parts of Africa to Sallee, from whence it is transported into Europe. It is a most violent and dangerous purge, and often produces fainting and cold sweats; for which reason various methods have been used to correct it, which are not worth mentioning, because in whatever manner it is given it is never safe.

GALBANUM, *Galbanum*, is a fat substance, as ductile as wax, and is shining and semi-transparent, it being of a middle nature between a gum and a resin. It is of a whitish colour while fresh, but afterwards grows yellowish or reddish. It has a bitter acrid taste, with a strong smell. That is best which is fresh, fat, pure, and moderately viscous. When taken inwardly, its virtues are not unlike gum ammoniac, but weaker; however, it dissolves thick phlegm, for which reason it is good in an asthma, and old cough; it discusses wind, is good in the cholic, and opens obstructions of the womb. Externally, it softens and ripens swellings, for which reason it is mixed in various plasters; being applied

to the navel, it mitigates hysterical disorders, and spasmodic motions of the intestines. The dose is from one scruple to two.

MYRRHA, *Myrrh*, is a gum resin, brought to us in grains or masses of various sizes, some of which are as big as a hazel-nut, and some as large as a walnut; the colour is yellow, or rather of a rusty red, and semi-transparent. The taste is bitter, sub-acrid, and aromatic, but nauseous, with a strong smell, which strikes the nose when it is pounded or burnt. The best is brittle, light, of the same colour, bitter, acrid, and of a pretty strong smell. It strengthens the stomach, helps digestion, discusses wind, and is good in all cold cachectic diseases, catarrhs, and all sorts of ulcers. It is given in substance in the form of a bolus, or pills, from half a scruple to half a drachm. Externally it attenuates, discusses, and is an excellent vulnerary; it cleanses old ulcers, preserves them from putrefaction, and cures the caries of the bones. It is bad in all sorts of hæmorrhages, as well as in spitting of blood, and ought not to be given to women with child, except with great caution. The tincture of myrrh is most in use, and is given from five drops to half a drachm. When outwardly applied, it often prevents gangrenes and mortifications; and that, which is improperly called the oil of myrrh, is good against freckles and pimples on the face.

OPOPANAX, *Opopanax*, is a gummy and resinous juice, concreted into grains about the size of a pea, which are reddish without, and within of a whitish yellow; the taste is intensely bitter and acrid, and the smell is strong. The best is in shining, fat, brittle tears, of a saffron colour without, and whitish or yellowish within; it is brought from the East-Indies, but we know not from what plant. It takes fire like resin, and dissolves in water, where it turns it of a milky colour. It incises gross viscid humours, discusses wind, and loosens the belly; it is good in hypocondriacal disorders, obstructions of the viscera, and is an ingredient in the gummy pills of the shops. The dose is from a scruple to a drachm.

SAGAPENUM, *Sagapenum*, is a juice between a gum and a resin, and is sometimes brought in grains, but more frequently in larger masses, which are reddish on the outside, and within are of the colour of horn; it has a biting acrid taste, with a strong smell, and seems to be of a middle nature between assa-fœtida and galbanum. It will flame when held to a candle, and will dissolve entirely in wine vinegar and hot water. That is best which is transparent, reddish without, and within full of whitish or yellowish specks, and which grows soft when handled. It is good in disorders of the breast, arising from a gross phlegm; as also in hard callous swellings, especially of the nervous parts. The dose is from a scruple to half a drachm.

SARCOCOLLA, *Sarcocolla*, is a gummy juice, and somewhat resinous; it consists of small whitish grains, or of a whitish red, that are spongy, brittle, and now and then mixed with shining specks; the taste is subacrid and bitter, with a disagreeable nauseous sweetness. It softens between the teeth, and when held to a candle it first bubbles, but afterwards breaks out into a clear flame, and yet it dissolves in water. It is brought from Persia and Arabia.

NATURAL HISTORY of JUICES extracted by ART from PLANTS.

ALOE, *vel SUCCUS ALOES*, *Alocs*, is of three sorts, the *Succotrine*, the *Hepatic*, and the *Caballine*. The first is brought from the island of Succotora, near Arabia, and is the best and purest

purest of them all; it is of a reddish or saffron colour, and when broken is shining, and, as it were, transparent; the taste is bitter, astringent, and somewhat aromatic, with a strong, but not disagreeable smell. The *Hepatic* is dense, dry, opaque, and of the colour of liver, with a strong smell and taste. *Caballine*, or *Horse Aloes*, is the worst of all, and is heavy, dense, black, and full of sand; it has an exceeding bitter nauseous taste, and a very strong disagreeable smell. The best *Succotrine Aloes* is shining, transparent, fat, and brittle in the winter, but in the summer a little softer, and is of a yellowish or purple reddish colour, but when powdered is of a shining gold colour, with an aromatic bitter taste, and a strong aromatic smell, almost like myrrh. *Succotrine Aloes* is the best for internal uses, and the *Hepatic* for external, but the *Caballine* is only for horses. Aloes in general is not only a purge, but is a remedy against disorders of the bile; but if it be given in too large a dose, or too often, it is apt to create hæmorrhages, and particularly the piles. Aloes has this peculiar property, that a few grains of it will loosen the body as much as a scruple. Some give it from one scruple to two scruples in substance; but the most common way of taking of it is in tinctura sacra.

SCAMMONIUM, *Scammony*, is a concrete resinous and gummous juice, and is a noted purge. There are two sorts, one of which is brought from Aleppo, and the other from Smyrna; the first is light, spongy, brittle, and of a blackish ash colour, shining when broken; when it is pounded it turns to a whitish or ash coloured powder; it has a bitterish acrimonious taste, and a very strong smell. *Smyrna Scammony* is more dense and heavy, and of a black colour. However, that *Scammony* is best, which will readily break and powder, and bites, or burns the tongue very little, but when mixed with spittle turns whitish like milk. The black, heavy, and impure, is bad. All strong purges are in some sense or other dangerous, and this in particular is not without its bad effects; for sometimes it purges too violently, and at other times not at all; it is sometimes attended with sickness, and produces wind, as well as occasions thirst and a fever. Therefore the best way is to grind it with sugar, so as to divide its resinous particles, and then it may be given safely to ten or twelve grains.

GUMMI GUTTA, *Gumboge*, is a concreted juice, partly of a resinous, and partly of a gummous nature; it is inflammable, dense, dry, hard, shining, opaque, and of a yellowish saffron colour; it is brought over in pieces of various sizes, and has very little or no taste. It will dissolve both in wine and water, in which last it will turn a little milky, and yet tinge any thing with yellow. When held to the candle it will flame, and emit a copious smoke. It is reckoned among the violent purges, and brings away ferous humours, as well upwards as downwards, and that speedily, though it will not gripe. It is frequently used in the dropsy, cachexy, jaundice, catarrhs, and other chronic disorders. It has been given from two to fifteen grains, and from two to four grains it will not vomit, but from four to eight grains it will both vomit and purge without violence, especially if plenty of water gruel be drank after it. The best way is to give it either in a bolus or pills; however, it should be used with caution, especially because vomiting will not suit with some patients.

OPIUM, *Opium*, is a concreted resinous and gummous juice, which is heavy, dense, clammy, inflammable, and of a blackish colour. It has a strong soporiferous smell, with an acrid bitter taste, and is usually brought over in roundish cakes about an inch thick, and weighing from half a pound to a pound, which are wrapped up in poppy leaves. It is

brought from Natolia, Egypt, and the East Indies. Authors differ greatly about the effects of Opium; however, it is certain that in a proper dose it will generally procure sleep, and ease pain; we say generally, because it will keep some waking, and prevent sleep; though at the same time it will ease their pains. Too large a dose, that is a few grains, will not only produce sleep, but blunt all the senses, hinder breathing, and prevent the patient from ever waking again. It is doubtless a most useful remedy, and will stop the process of many diseases; but then it is palliative only, and never cures any. It is exceeding hurtful to the weak, and should never be given where the motions of the patient are languid; likewise in some cholics it has often produced paralytic disorders; for which reason it should never be given to infants, and persons weakened with age. When exhibited in a proper dose, it excites an agreeable sensation, and inclines to mirth, like a moderate quantity of wine; for which reason the Turks always take large doses of it when they are going to engage in a battle. It stops all sensible evacuations for a time, except sweating, and enlarges the pulse. When too large a dose has been taken, it will be best to bleed and vomit, if the strength will permit; and then acids must be given, as vinegar, and the juice of lemons, or spirits of vitriol, properly diluted. Some cases will require strong sneezing powders, and blisters or sinapisms applied to the soles of the feet and nape of the neck, with painful frictions, scarifications, or burnings. The dose is generally a grain, but in some cases two may be given.

ACACIA VERA, *True Acacia*, is an inspissated gummous juice, brown or blackish without, and reddish or yellowish within; it is of a hard firm consistence, of an austere astringent taste, and is brought over in round masses, weighing from four to eight ounces. It is brought from Egypt. It is said to strengthen the stomach, stop vomiting and looseness, as well as some sorts of hæmorrhages, by abating the acrimony of the humours, and strengthening the solid parts. The dose is from half a drachm to a drachm, in some convenient liquor.

CATECHU, improperly called Japan earth, is a gummy, resinous, inspissated juice, of a reddish black without, and a brownish red within, with an astringent bitterish taste, but no smell. There are two sorts, whereof one is better than the other, and melts more readily in the mouth. It is brought from the East Indies, is a moderate astringent, strengthens the gums, and is good in small ulcers of the mouth, as also in coughs and hoarseness. It strengthens the stomach, helps digestion, and is good in loosenesses. The dose is from half a scruple to a drachm.

SACCHARUM, *Sugar*, is of several sorts, which are so well known to every one that they need no description. Some are great enemies to Sugar, and affirm, it produces we know not what bad effects; but as those who have used it very freely, have never received any damage from it, we may conclude it to be entirely harmless. Compositions of Sugar are allowed on all hands to be good in disorders of the breast, and that, mixed with oil and sweet almonds; it is good in coughs, hoarseness, and the like. Externally, Sugar is a very great vulnerary, especially when mixed with a little brandy, for then it will heal wounds, cleanse ulcers, and prevent putrefaction.

TARTARUS, or **TARTARUM**, *Tartar*, is a saline hard substance, of an acrid and subaustere taste, which adheres to the bottoms and sides of wine vessels, from whence it is scraped off. It is of two sorts, the white and the red, both of which proceed from wines, of the same colours. The best Tartar is heavy, hard, with that part next to the

wine rising into chryftalline points, but when broken appears like sponge, or pumice stone, it being porous and mixed with earth, though it is a hard shining substance.

Tartar unprepared is seldom or never used internally; but is taken when purged, and then it is called cream or crystals of tartar; and is good to temperate the heat of the bile, and to quench thirst in burning fevers. It attenuates gross humours, opens obstructions of the viscera, and is good in cachectic and hypocondriac disorders. It is a laxative, and is often mixed with milder purges with success. When given from half a drachm to two drachms it is an aperient only, but from half an ounce to an ounce it is a purge. Cream of tartar will not dissolve in cold water, but it will in hot.

Salt of Tartar, which is procured by calcining tartar in an open fire, is a fixed alkali, and somewhat of a caustic quality. It serves for many chemical operations, and especially to extract the resinous and sulphureous parts of medicine in making of tinctures. When given alone, dissolved in a sufficient quantity of water, the dose is from twelve grains to half a drachm; it will attenuate gross humours, and cure the heart-burn proceeding from acids in the stomach. Among the medicines that are usually procured from tartar, are soluble tartar, vitriolated tartar, and emetic tartar.

NATURAL HISTORY of TUBERA, FUNGI, and Substances that adhere to certain VEGETABLES.

TUBERA CERVINA, or **BOLETUS CERVINUM**, *Deers Balls*, is a tuberose fungus, without a root, and is of a dusky yellow, with a hard, thick, and granulated rind; but the inside is of a purplish white. It is of the size of a walnut, though sometimes of that of a hazel nut, or less; and it is divided into cells that are soft and downy, in which are exceeding small seeds, lying together in a mass, and connected with filaments; when this substance has lost its seeds, it is then contracted into a small round ball. The smell and taste when fresh are rank, but when dry and laid up for some time, they become almost insipid. They are of little use;

C H A P. II.

Containing the NATURAL HISTORY of INDIGENOUS HERBS, PLANTS, SHRUBS, and TREES, and their various uses in Medicine.

INDIGENOUS plants are those which are produced in our climate, some of which have been, or are, used in medicine; while others are quite useless, at least as far as is hitherto known; and therefore they may be passed over in silence. In giving an account of them, we shall observe an alphabetical order, that each of them may be more readily found.

ABROTANUM MAS, *Southernwood*, of which there are two kinds of use in medicine, one of which is called the male, and the other the female; but the first of these is properly the Southernwood. In its characteristics it is much the same as wormwood, and its root is woody, with a few fibres proceeding from it. It has many branches, which sometimes rise to the height of four cubits; though they are generally much lower; they are hard, brittle, and full of a white pith, somewhat of a reddish colour, and are streaked and branched. It has many leaves, somewhat broader than those of fennel; and

for they are never eaten, nor have they any remarkable qualities to recommend them for physical purposes, whatever authors have said to the contrary.

AURICULA JUDÆ, or **FUNGUS SAMBUCINUS**, *Jews-ear*, is a membranaceous fungus, in the shape of an ear, from whence it has its name. It is a spongy substance, growing at the bottom of old alder trees, and is light, coriaceous, and membranaceous; it is ash coloured beneath, and blackish on the top, and the taste is earthy and flat, but it has no smell; it has little or no pedicle, but sticks close to the body of the tree. It is said to be astringent and drying, but is seldom or never taken inwardly.

AGARICUS, or **FUNGUS LARICIS**, *Agaric*, is a fungous substance, of a roundish, angular, unequal shape, and of different sizes, from the bigness of a man's fist to that of his head. It is very light, as white as snow, and may be readily rubbed into meal between the fingers; but it has a few fibres, and a callous ash coloured reddish rind, whose lower part is perforated by exceeding small seeds that lodge in the holes; the taste is at first sweetish, then bitter, acrid, and nauseous, with a slight astringency. It grows to the trunk of the larch tree, and is seldom or never found on the boughs. The best is white, light, and brittle. It goes under the denomination of a purge, though some deny it has any such quality, and is at best a useless medicine.

AGARICUS PEDIS EQUINI FACIE, *Touchwood*, or *Spunk*, grows to the ash and other trees; but that is supposed to be the best that grows to old oaks that have been lopped, and which has been gathered in August and September. This has of late been mightily cried up for stopping of blood upon the amputation of a limb, without making any ligature; but it has had the fate of many new discoveries, and is now almost entirely laid aside; though it might doubtless be of use in many cases. The inward part is best which feels to the touch like buff, which must be taken out, and beaten a little till it may be easily teased between the fingers. This being done, so much of it must be applied to the wound as will somewhat more than cover it, and over this a broader piece must be laid with proper bandages.

those below are divided into several parts, but those above have only one or two segments. They are of a hoary colour, with a strong agreeable smell, and a bitterish taste. The flowers on the sides of the branches are like those of wormwood; and consist of many small blossoms that are tubulated and divided at the top into five parts, in each of which there is a single seed, and they are all comprehended in a scaly cup. It is cultivated in gardens, by slips or cuttings, planted in the beginning of April on a bed of light fresh earth, observing to water them two or three times a week, till they have taken root. These leaves are often used in fomentations,

ARBOTANUM FOEMINA, by some called *Santolina*, and *Chamaecyparissus*, *Lavender Cotton*, has a thick, hard, woody root, from which there proceed branches above a cubit in height, which are woody, slender, covered with a hairy down, and divided into several branches, round which there are slender leaves about an inch in length, a little denticulated,

culated, or rather beset with small tubercles. They are all of a hoary colour, and of a physical smell, with somewhat of a sweetness; the taste is partly acrid, and partly of an aromatic bitter. On the top of each branch there is a yellow flower, consisting of several tubulous florets, divided at the top into five parts, with imbricated intermediate leaves, and contained in a common scaly cup. The cup of each floret, or embryo, turns into a streaked oblong brown seed, not at all furnished with down. These flowers are larger than those of southernwood, by which it may be distinguished from it, as well as by the whole appearance of the plant. This plant is cultivated in gardens, and may be propagated by planting slips or cuttings during the spring, which should be put into a border of light fresh earth, and watered and shaded in hot dry weather, until they have taken root. It is of little use in medicine, except in fomentations.

ABSINTHIUM VULGARE, *common Wormwood*, has a lignous and fibrous root, with stalks of an indeterminate height, branched out into many small shoots, with hoary leaves of a bitter taste, and furnished with spikes of naked flowers, hanging downwards, which are placed in long rows towards the top. They are composed of many tubulous florets, divided into five parts at the top, and are of a yellow colour; they are all contained in a common scaly cup, in each of which there is an embryo, which turns into a naked seed. It differs from other sorts of wormwood, in having larger leaves and more jagged. It is very common in all parts of England by the sides of high roads and in dung-hills. It is planted in gardens for common use, and may be propagated by slips in March and October; or it may be raised from seeds, which may be sown soon after they are ripe. Wormwood has always been looked upon as a valuable medicine, to promote the heat and circulation of the blood, and to recover the oscillation of the fibres while sluggish; by which means the gross humours are attenuated, and brought back into the common road of circulation. It restores the debilitated functions of the viscera, and is an excellent stomachic. It is good in the dropsy, green sickness, cachexies, and agues; which last it has often been known to cure. It also by its great bitterness is of some service against worms, by resolving the mucilaginous humours in which their eggs are contained; however, in all hot diseases and in inflammatory dispositions it is not safe.

ABSINTHIUM MARITIMUM, *Sea Wormwood*, has leaves much smaller than the common; they are hoary on the upper side as well as the lower, and the stalks are also hoary all over. It grows wild about salt marshes and near the sea coasts. The virtues are much the same as those of the former.

ABSINTHIUM ROMANUM, *Roman Wormwood*, differs much in appearance from the former. It has a great number of small and woody roots full of fibres, and the stalks are about a cubit in height, which are round, smooth, greenish, or of a reddish green or purplish colour. They are full of leaves from the top to the bottom, which have much the same appearance as those of southernwood, only they are shorter. The flowers are much like those of common wormwood, but less. It is cultivated in gardens, and may be easily raised by the planting and cutting of slips in the spring or autumn. The roots of this plant creep so much, that they will soon spread over a large piece of ground. It is not so bitter as the common wormwood, but is more aromatic; for which reason it is more agreeable to the taste. It has the same virtues as the common wormwood, but weaker.

ACANTHUS, BRANK-URSINE, has a thick fleshy root, black without, and white within, from

whence proceed great numbers of fibres. The leaves that lie on the ground are a cubit in length, and a span in breadth; but the stalks rise to two cubits high, are strong, and adorned with a long row of flowers elegantly disposed like a thyrsis. The leaves are somewhat like those of a thistle, and after them the Romans adorned the capitals of the Corinthian order of columns; that is, with the shape of these leaves; they were likewise imitated by embroiderers, in the time of Virgil. The flowers are labiated, and are of a sort of a flesh colour; the under lip of the flower is divided into three segments, which at the beginning is curled up in the form of a short tube. There is no upper lip, but in its place there are stamina that support the pointals, and the cup of the flower is composed of prickly leaves; the upper part of which is bent over like an arch, and supplies the defect of the upper lip of the flower. The pistil arises from the hinder part of the flower, and turns to a fruit in the shape of an acorn, which is divided into two cells, each containing a single smooth seed. The whole plant is full of a glutinous and mucilaginous juice. It grows spontaneously in Sicily and Italy; but is here cultivated in gardens, and is easily propagated by parting the roots in February or March, or by sowing the seeds at that time. It is seldom used in medicine.

ACETOSA, *common Sorrel*, has a long, fibrous, yellowish, bitter root, and leaves placed alternately on the stalk, in the shape of a spade. The stalk is streaked a foot in length, and is divided into several branches. The impalement of the flower is composed of three small leaves that are bended back, and the flower has three leaves, which are larger than those of the impalement. In the center of the flower is a three cornered pointal, or pistil, supporting three small styles, which are attended with six stamina. It afterwards becomes a triangular seed, inclosed by the petals of the flower; in short, it agrees with the dock in all its characters, except in having an acid taste. It is but a small plant in the fields, but in the gardens it produces large leaves. It must be sown early in the spring, in a shady moist border; and if it be afterwards planted out into another shady border, it will produce still larger leaves, and continue longer. The medicinal virtues are to cool and quench thirst, and their decoction makes a useful drink in fevers. It is also an excellent antiscorbutic.

ACETOSA ROTUNDIFOLIA, *round leaved or French Sorrel*, has the same characters as the former excepting the leaves, which are now and then almost round. This is the best sort for the kitchen use, for which reason it is often planted in gardens. The roots are very apt to spread, by which means it is easily propagated, and must be planted at larger distances, that is, a foot square at least. It is a cooler like the former; and quenches thirst as well as excites an appetite.

ADIANTHUM VERUM, *the true or French Maiden-hair*, is a capillary plant, and has a fleshy fibrous root, from whence arise slender, black, shining, branched pedicles, above a palm in height, which sustain leaves placed alternately, that are about a quarter of an inch broad, and somewhat shorter; they are green, crested, smooth, and streaked as it were with rays, and are like those of coriander. It seems to be without seeds; however, in September, certain notches appear in the leaves, which adhere to each other, and contain a fruit or round membranaceous capsula, which is very small and surrounded with an elastick ring, which by its contraction opens the capsula, which then emits a seed like dust, that is too small to be examined by the naked eye. It grows spontaneously in the northern parts of France, and continues green all the year. This herb was formerly celebrated for its pectoral virtues,

virtues, but is now greatly neglected. A syrup is made of this herb, which is sold in the coffee-houses, and called Capilaire; but it is generally supposed to be counterfeit.

AGNUS CASTUS, *the Chaste-tree*, is a shrub full of branches, so tough that they are not easily to be broken. The leaves are joined to a pedicle an inch or two long, and divided into five particular leaves, of an oblong shape, and sharp at both ends. The flowers grow in spikes, and are of a purple, or purple and white colour. They consist of one leaf, which looks as if it had two lips, and the fore part is tubulous. From each calyx arises a pointal, or pistil, which is fixed on the back part of the flower like a nail, and afterwards turns to an almost spherical fruit like pepper, divided into four cells, containing oblong seeds. It is cultivated in gardens, is very hardy, and may be propagated by planting the cuttings early in the spring, before they shoot. They require a fresh light soil, and must be frequently watered till they have taken root. They will grow to eight or ten feet high, and flower in autumn; the flowers grow in spikes at the extremity of every strong shoot. This shrub is acknowledged to be good in hysterical complaints, and in hypocondriacal spasms, especially if they proceed from gross viscid humours. The seed, in powder, is given from half a drachm to a drachm, or in an emulsion.

AGRIMONIA, *Agrimony*, has a blackish, thick, fibrous root, and a hairy branched stalk, two cubits high, with leaves above a palm in length, alternately placed, which are rough, hairy, pennated and grow alternately on the branches. The calyx, or flower-cup, consists of one leaf, which is divided into five segments, and the flowers, which have five or six leaves, form a long spike, which expand in the form of a rose, and are of a yellow colour. The fruit is oblong, dry, and prickly like a burdock, and in each there are two kernels. It is common in the hedges in many parts of England, and is noted for its astringent quality. It is said to be good in the cachexy, dropsy, jaundice, and in fevers arising from the obstructions of the viscera. It is also good in ulcers of the kidneys. The dose of the dried leaves is a drachm in a proper vehicle.

ALCEA, *Vervein Mallows*, have a woody whitish root, from whence proceed several stalks to the height of a cubit, which are round, full of pith, and thinly beset with longish hair. The leaves that proceed from the root and lower part of the stalks are roundish, with incisures on the edges; but those that grow near the top, and placed alternately, are remarkably jagged, and of a blackish green colour and hairy, particularly on the lower part. The flowers are like those of mallows, and of a purplish flesh colour, though they are sometimes white; they are succeeded by seeds, which are black when ripe, are shaped like those of mallows, and have the same faculties as that plant.

ALCHIMILLA, *Ladies Mantle*, has a root as thick as one's little finger, and is fibrous and black; from whence arise long pedicles, a palm and a half in length, which are hairy, and each sustain a single leaf, nearly like that of mallows, but more hard and crisp, and divided into eight or nine acute angles. The cup of the flower is divided into eight segments, which are expanded in the form of a star; the flowers are collected into bunches on the top of the stalk, which consist of several stamina with yellowish heads. The calyx becomes a capsula, containing generally two little round yellow seeds. It delights in mountainous places, such as the Alps and Pyrenees. It also grows wild in some parts of England. This plant is seldom made use of in medicine.

ALKEKENGI, *the Winter Cherry*, has a genicu-

lated root beset with small fibres, from whence arise reddish hairy branched stalks, a cubit in height, from the knots of which arise two leaves with long pedicles. The leaves are like those of garden nightshade, and the flowers consist of one leaf, expanded at the top, and of a whitish colour, but of a pentagonal figure. The fruit, which is about the size of a cherry, is inclosed in the flower cup, and swells over it in the form of a bladder. The fruit is only in use, and is good to promote urine, as well as to cleanse the kidneys and bladder. From three to eight of these cherries may be taken as a dose, and are said to have had a very good effect in preventing the gout, when eight of them were taken every change of the moon. It is very common in English gardens, and the fruit, which is ripe in October, often continues till the beginning of December. It is of the size of a common cherry, and of a fine red colour; the bladder that incloses it is of a deep red, which bursts when ripe, and exposes the fruit to sight. It may be propagated by sowing the seeds in the spring, or by the roots, which creep very much, so as to overspread a large tract of ground; and therefore they should be placed in pots, and set in a shady place in summer. If well watered in dry weather, it produces great numbers of cherries.

ALLIUM, *Garlick*, has a bulbous root, consisting of several membranes, and is of a whitish colour, with a purplish cast. The leaves are oblong, and not fistulous as in onions, but like grass, and the flowers consist of six whitish leaves, with a pistil in the middle, which turns into a roundish fruit of the size of a pea, and of a purplish colour without, but the pulp within is whitish. It is divided into three cells, full of roundish and blackish seeds. Garlick is proper to warm and stimulate the solids, and to dissolve the gross clammy fluids, whence it is good in cold constitutions, and in moist asthmas, as well as all defluxions on the breast. It has been found very serviceable in the dropsy, for it will sometimes cure it without any other medicine. It may be given alone, in a decoction, or made into a syrup; but it must be avoided in all inflammatory dispositions and hot diseases. It may be easily propagated in gardens, by planting the cloves, or small bulbs, in August or September, about four or five inches from each other. In the middle of June the leaves should be tied in knots, to prevent their running to seed, and then the bulb will be greatly enlarged. Towards the end of July, the leaves will begin to wither, and then the root should be taken out of the ground, and hanged up in a dry room.

ALNUS, *the Alder-tree*, is strait and upright, and of a moderate thickness, with a rough, brittle, blackish bark. The wood is reddish, soft, light, easily worked, and the boughs are very brittle. The leaves resemble those of the hazle, and the male flowers, or catkins, are produced at remote distances from the fruit, which is scaly, conical, and of the size of a hazle-nut. The bark, catkins, and fruit, are astringent, and the decoction has been prescribed in inflammations of the tonsils, as a gargle. Some recommend the bark in intermitting fevers.

ALTHÆA, *Marsh-mallows*, has a great number of white roots, about as thick as a finger, which all proceed from one head. The stalks are a cubit or two in height, and are slender, round, villous, and beset with leaves alternately, which are roundish, but sharp at the end, hoary, and beset with a soft down; they are about three inches long, and are sinuous and ferrated. The flowers come out between the pedicles of the leaves and the stalk, and are of a pale reddish colour. They are monopetalous, but divided into five segments, almost to the center, in which is a pyramidal tubulou style, loaded with stamina; and in the cavity there is a pistil, which turns

turns into a round flat fruit, consisting of several capsula, disposed like a ring about the cake in the middle. Marsh-mallows is very much in use to abate the acrimony of the urine; in disorders of the lungs, to thicken a sharp salt defluxion; and consequently is good in hoarsenesses, coughs, catarrhs, and the asthma. It is likewise good in erosions of the intestines, its decoction being drank, or given in clifters. It is also good for softening hard tumours, and easing pain. The leaves are much preferable to the roots. Syrup of marsh-mallows is a medicine commonly known, and is often prescribed to render the urinary passages slippery to those who are troubled with the gravel.

AMYGDALUS, *the Almond-tree*, has strong branched roots, with a rough trunk, and leaves like those of the peach tree, which are sharp at the ends, and crenated on the edges. The flowers are rosaceous, consisting of five petals, of a whitish, or light purplish colour; the calyx is single, but divided into five segments, with a pistil that turns to a fruit an inch in length, which is long and flat. The outer coat is thin and pretty dry when ripe, under which is a shell that is not so rugged as that of the peach. As for the almonds themselves, they are too well known to need a description. When they are bruised, they yield a large quantity of limpid oil, and when made into an emulsion with water, have a sweet pleasant taste, but if it be kept long it will turn sour like milk. Sweet almonds, when fresh, are nourishing, but they should be well chewed before they are swallowed. In all medicinal uses they should be blanched, that is, the outer skin should be taken off. The emulsion of sweet almonds is prescribed in burning fevers, too great watchfulness, heat of urine, and inflammations of the kidneys and bladder, as well as in all cases where the acrimony of the humours is to be corrected. It is given from one to four, and in some cases to eight ounces, and should be repeated every third or fourth hour. When children are griped, it should be given by spoonfuls, mixed with syrup of marsh-mallows.

AMYGDALUS AMARA, *the bitter Almond tree*, agrees with the former in all respects, except the bitterness of the fruit. They have been found to be poisonous when given to dogs and some other animals, but they may be eaten by men without any damage. The oil that is expressed from bitter almonds differs in little or nothing from the former, and may be used in the same cases; as also for softening the wax in the ears, when put therein with a bit of cotton wool. Almond trees are chiefly valued for the beauty of their flowers, which are produced early in the spring, and make a fine appearance. They are propagated by inoculating one of their buds into a plum, almond, or peach stock, the latter end of July. The best season for transplanting these trees into a dry ground, is when the leaves begin to decay; but for a wet soil, in February.

ANAGALLIS MAS, *male Pimpernel*, has a white single root, with a few fibres, and the stalks are so weak that they lie upon the ground; they are of the length of a palm, are square and smooth, and the leaves are placed by pairs, and sometimes three at a time opposite to each other; but they have no pedicles. The lower surface is spotted with blackish red spots; and the flower consists of one leaf, shaped like a wheel, and divided into five sharp segments, which are of a purplish red, with purple stamina, on which are yellow heads. The flower cup is also divided into five parts, from which a pistil arises, fixed in the middle of the flower like a nail, and turns to a fruit, or globous shell, which when ripe opens transversely into two parts, one of which lies upon the other, and incloses many angular wrinkled seeds. This is one of those called the sleeping

plants, whose flowers open about eight o'clock in the morning, and never close till past noon.

ANAGALLIS FEMINA, *female Pimpernel*, differs only from the former in the colour of the flower, which is blue, and being common in our corn fields; but this is more scarce. The male pimpernel is used as a salad and a pot-herb in many parts of England.

ANETHUM, *Dill*, has a slender white fibrous root, with a branched stalk, a cubit and a half in length; the leaves are like those of fennel, but less, and of a bluish colour, with a strong smell. The flowers are placed at the top of the stalks in umbels, and are rosaceous, consisting of five yellow petals, whose calyx or flower cup is changed into two palish yellow seeds, which are oval, flat, streaked, and have a foliaceous border. It is propagated from the seeds, which should be sown in autumn, soon after they are ripe, and thrive best in a light soil, where they are to remain, for they will not bear a removal. The seeds are only in use, and they have been commended in the flatulent cholic, and against wind. The essential oil is a carminative, and is given from two to four drops on a lump of sugar.

ANISUM VULGARE, *Anise*, has a slender annual fibrous white root, with pleasant green leaves, above an inch in length, which are divided into three parts, or particular leaves, which are smooth and crenated. On the upper part there are many divisions, and the stalk is ramous, streaked, hollow, and sustains flowers disposed in an umbel, which are small, rosaceous, and consist of five cloven white petals, with the flower cup, that turns into an oblong turbinated fruit, in which are two small gibbous streaked seeds, of a greenish ash colour. The taste and smell are sweet and very agreeable. The seed is only in use, which contains a great deal of essential oil. It is numbered among the four hot seeds, and is recommended for the helping of digestion, in the wind, cholic, and in shortness of breath. It is good for gripes in children, and to increase milk in the breasts of nurses. The dose, in powder, is from a scruple to a drachm, and that of the essential oil, from two drops to twenty.

ANONIS *five* ONONIS, *Rest Harrow*, has roots above a foot long, which creep every way, and are not easily broken. The stalks lie on the ground, and are slender, tough, reddish, hairy, and full of prickles; they are beset with leaves, placed three together alternately, and are roundish, slightly crenated, hairy, of a dark green colour, and glutinous to the touch. The flowers are papilionaceous, of a light purple, or flesh colour, and grow in spikes at the top of the branches. The pistil is near a quarter of an inch long, and consists of one bivalved flat capsula, containing a single seed in the shape of a kidney. It is said to open obstructions of the liver, and to cure the jaundice; but it is now out of use.

APARINE, *Goose-grass*, or *Clivers*, has a slender fibrous root, with slender, quadrangular, geniculated, rough, climbing stalks, three or four cubits long. At every genicula, or knee, there are from five to seven leaves placed like a star, which are narrow, rough and terminate in prickles. The flowers proceed from the knees towards the top, and are very small, white, monopetalous, in the shape of bells, and divided into four segments, as well as the flower cup, which turns into a dry, hard, cartilaginous fruit, covered with a thin blackish skin, and consist of two globes full of umbilicated seeds. It is met with almost every where in hedges. It is inciding and aperient, and not only promotes urine but sweat. Two ounces of the juice have been found to be very serviceable in the dropsy, carrying off the water by urine.

APIUM PALUSTRE, *Smallage*, has a thick, whitish stait root, descending deep into the ground, and is sometimes deeply divided into different heads; it has an acrid, bitter, disagreeable taste, with a strong aromatic smell; from the root proceed many leaves standing upon long pedicles; they are reddish, streaked, concave, and are divided into wings, or grow upon a branched rib; they are also cut into five segments, and are smooth, neat, juicy, and of a pleasant green; when rubbed with the fingers they have a strong smell, and the taste is not very disagreeable. The flowers proceed from the joining of the pedicles to the stalk, as well as the top, where they are collected into an umbel, and are small, rosaceous, and consist of five white petals; the calyx turns to a fruit, containing two very small seeds, which are streaked, ash coloured, depressed on one side, and gibbous on the other. It delights in moist marshy places, and is by some transplanted into gardens. The seeds are reckoned among the four lesser hot seeds.

AQUILEGIA, *Columbines*, has a white root an inch thick, which is branched and fibrous, and of a sweetish taste. It has leaves like meadow rue, they being cut on the edges, and are bluish underneath, but above of a dark green, with a bluish cast. The flowers are pendulous, and consist of many petals unlike each other; from the middle of the flower arises the pistil, beset with stamina, which turns to a membranous fruit, consisting of many husks, or pods, each of which is full of black shining seeds. The colours of the flowers are various, as blue, red, white, flesh coloured, and green, upon which account it is cultivated in gardens, and they flower in May and June. For raising them, the seeds should be sown in a nursery-bed in September, and in March following the young plants will appear above ground, which should be transplanted in the middle of May into good fresh earth, and set at nine inches distant every way. At Michaelmas they may be removed into the borders of a flower garden, and the May following they will produce flowers. It has been looked upon as an aperient and sudorifick; but it is now out of use.

ARGENTINA, *Silver Weed*, or *Wild Tansey*, has a blackish root, which is sometimes single and sometimes fibrous; the leaves are conjugated like agrimony, and they are deeply dentated on the edges; they have several small leaves set between them, and the upper part is of an herbaceous green; but the under like that of silver, they being covered with a soft down. The flowers are placed singly on long hairy pedicles, and consist of five petals of a gold colour, with a calyx divided into five sharp parts, between which are many small ones; and there are many stamina of the same colour, with heads thereon. The pistil changes into a spherical head, a quarter of an inch in diameter, full of seeds of a yellowish colour, and like those of poppies. Many physicians have a great opinion of this herb; for Boerhaave affirms it has the same virtues as the Peruvian bark. The dose of the juice is from four ounces to six, and of the seeds to half a drachm.

ARMENIACA MALUS, *the Apricot-tree*, has roundish acuminate leaves, serrated on the edges, and four or five of them are placed together. The flowers, that come out early in the spring, before the leaves, are rosaceous, consisting of five whitish petals, disposed in a ring, with a calyx divided into five segments, from which a pistil arises that turns to a fleshy succulent fruit, very well known. There are seven sorts cultivated in the English gardens, which are, I. *The Masculine Apricot*, which is the soonest ripe of all, and has a small roundish fruit, of a red colour towards the sun, which as it ripens fades to a greenish yellow on the other side. It is only valuable for being soonest ripe, for it has little flavour. II. *The*

Orange Apricot, which is the next that becomes ripe, and is of a deep yellow. The flesh is dry, and is better for tarts than for eating. III. *The Algier Apricot* ripens next, and is of an oval shape, only a little compressed on the sides. It turns to a pale yellow or straw colour when the flesh is dry, with a faintish taste. IV. *The Roman* is next, and is larger than the *Algier*, but not compressed on the sides; the colour is deeper, and the flesh is moister. V. *The Turkey Apricot* is the next in order, because it ripens later than the former, and is bigger than any of them, and has a globular shape. It is of a deeper colour, has a firmer flesh, and a better taste. VI. *The Breda Apricot* was brought originally from Africa, and is a large roundish fruit, turning to a deep yellow when ripe, and is of a deep orange colour on the inside. The flesh is soft, full of juice, and better tasted than any of the whole tribe. VII. *The Brussels Apricot* is the latest, it not being ripe till near the middle of August, unless exposed to a south sun; however too much heat spoils the taste. It is red on the side next the sun, with many dark spots, and of a greenish yellow on the other side; the flesh is firm and of a high flavour; but it often cracks before it is ripe. The best standard trees are those that are about two feet and a half, or three feet in the stem; but they may be planted as dwarfs against an espalier, where, with good management, they will produce a large quantity of fruit. These fruits are all propagated by budding them on plumb stalks; and they are all, except the two last, planted against the walls, which should be either east or west. The borders under these walls should be six feet wide at least, and if the earth be two feet deep, or two and a half at most, it is enough. The soil should be fresh earth from a pasture ground, taken about ten inches deep with the turf, and laid to mellow at least twelve months before it is used, often turning it. The trees that are budded should be but of one year's growth, and if the soil is dry, October is the best month for planting. At Michaelmas, or soon after, when the trees have grown, you must unnailed the branches and shorten them, in proportion to their strength; for a vigorous branch may be left eight or nine inches long; but a weak one only five or six. When they are shortened they should be nailed as horizontally as possible.

With regard to the medicinal uses of apricots, there is little to be said, only that they agree best with persons of hot constitutions; for in weak stomachs they readily corrupt, and then produce feverish disorders, which however are easily cured with emetics and purges.

ARTEMISIA, *Mug-wort*, has a creeping fibrous root, about as thick as one's finger, with a sweet aromatic taste. The stalks grow to two cubits in height or upwards, and are round, streaked, strong, stiff, generally of a purple colour, and covered with short hair; they have also pith in the middle, and are branched, with leaves thereon, placed alternately, that are not unlike those of wormwood; they are of a dark green above, and hoary underneath, by which they may be distinguished from wormwood. The flowers grow on the top of the branches like spikes, consist of many florets of a purplish colour, and divided into five parts, which are comprehended in a scaly cup. Among the florets there are naked embryoes, which turn into a double capillament, which afterwards, as well as the embryoes of the florets, turn into seeds like those of wormwood, but have not so strong a smell. It is generally accounted anti-hysterical, and is very often in use among the women for female disorders. In some parts of the kingdom it is used as a pot-herb. The dose of the dried herb is three drachms, drank in wine, and is said to be a good remedy against the hip-gout.

ARUM, *Cuckow Pint*, or *Wake Robin*, has a tube-

rose, fleshy root, as thick as one's thumb, but roundish, white, and full of a milky juice; the leaves are about eight inches long, a little triangular, and somewhat in the shape of the head of an arrow. The stalk rises to a cubit in height, and is round, streaked, sustaining a membranaceous flower like an ass's ear, contained in a sheath of a whitish green, in which is a pistil of a palish yellow, from which proceed berries, that are almost globous, and disposed into an oblong head; they are of a reddish purple, soft, full of juice, and contain a seed or two, that are hard, small, and roundish. The whole plant has a most acrid taste that burns the tongue. The root is only in use, and when tasted bites the tongue so much, that it may be felt a whole day. It has many virtues, but is good in ferous disorders, the cachexy, the green sickness, agues, the dropsy, the jaundice, and is excellent in all diseases that proceed from clammy humours, as well as for opening the obstructions of the viscera. It is also good in a moist viscid catarrhal cough, and to restore the tone of the stomach. It has this peculiarity, that it will cause those to sweat who can hardly be brought to it any other way, when taken to the quantity of a drachm in any good spirit; but if it be dried and taken in powder, then this medicine will fail. The best way of giving it is by beating the fresh root with gummy resins, and making the mass into pills. Outwardly it is very proper to cleanse ulcers, particularly those that are fistulous. The common dose is from half a drachm to four scruples.

ASARUM, *Asarabacca*, is an ever-green herb, which has a slender, angular, knotty, fibrous, ash coloured root, with a bitterish, nauseous, aromatic taste, somewhat like garden valerian; the leaves are round, stiff, shining, of a dark greenish colour, and are sustained by long pedicles; they are somewhat in the shape of an ear, for which reason they are called in French, *Orielle d'homme*, that is, man's ear. The flowers are hid in the leaves near the root, and are of a purple colour, which are scarcely perceivable, except the flower-cup, which is divided into three or four segments, and of a blackish purple colour. The fruit is divided into six cells, full of oblong seeds, that look like the stones of grapes. It delights in woody places, and is found wild in some parts of England, though but seldom. The flowers appear in April; but grow so close to the ground as not to be seen, unless you put away the leaves with your hand. It is best raised by slips. The leaves are a strong vomit, as well as the roots; working both upwards and downwards; but the leaves are chiefly in use, to make a sneezing powder, and are said to be the principal ingredient in Major's Patent Snuff.

ASCLEPIAS, *five* VINCETOXICUM, *Swallow-wort*, or *Tame Poison*, has a root full of fibres, which proceed from a single head, and has an acrid, bitterish, disagreeable taste, with a nauseous smell; the stalks are tough, hairy, and geniculated, and rise to a cubit in height; the leaves are placed by pairs over against each other, and are a little hairy on the hedges; they are in the shape of the leaves of ivy, but are longer, more wrinkled, and have very short pedicles. From the joints of these pedicles, with the stalk, proceed whitish monopetalous flowers, in the shape of a bell, and are divided into five parts, expanded in the form of a star, with five apices of the same colour, and a cup divided into the same number of parts, with a pistil fixed in the hinder part of the flower, like a nail, that turns to a fruit composed of two membranaceous husks that open from the bottom to the top, inclosing many seeds, that are covered with fine down, and are fixed to the membrane like scales on the skins of fishes. It has no milky juice like dog's-bane, by

which it may be distinguished from it. It is propagated by parting the roots, either in spring or autumn, which will grow almost in any soil. It has been cried up as an antidote against poison, but is now neglected for that purpose. It is much more proper for acute, than chronic diseases; because it is a gentle resolvent, and promotes both sweat and urine.

ASPARAGUS, *Asparagus*, corruptly called *Sparrow grass*, has a great number of roots, proceeding from a single head, that are round, fleshy, whitish, sweetish, and clammy. Early in the spring they emit tender, long, round, green shoots, without leaves, that are so well known they need no description. When they are grown up they arise to the height of two cubits, and are divided into slender strong branches, with green, capillaceous, soft leaves, an inch in length. The flowers are rosaceous; with six petals of a pale green colour, and a pistil that turns to a soft berry of the size of a pea, that is globous, purplish, soft, sweetish, and contains two or three umbilicated black seeds. It is cultivated in gardens for the use of the kitchen. Asparagus provokes the appetite, but yields little nourishment, and gives the urine a particular strong smell. It has little or no medicinal virtues.

ATRIPLEX FOETIDA, *Stinking Orach*, or *Ar-rach*, has a slender fibrous root, from whence generally proceed branched stalks, about nine inches in length, with roundish small leaves, terminating in a point, and are covered over with a mealy whitish powder. The flowers grow on the top of the stalks, and are without petals; for they consist of many stamina, arising from a calyx divided into five parts, with a pistil that turns into a single, small shining; blackish, and roundish flat seed in a capsula, in the form of a star. It grows in uncultivated places, and near the sides of roads. It is antihysterick; and the infusion of the leaves taken hot is an excellent medicine against the hysterick passion.

AURANTIA MALUS, the *Orange-tree*, is not very tall, but has a thick, woody, branched root, which spreads very much, and is of a yellow colour on the inside. The trunk is hard, whitish within, has an agreeable smell, and is covered with a greenish, smooth, white bark. The branches are numerous, flexible, and of a beautiful green, with a few thorns thereon. The leaves are somewhat like broad leaved laurel, and are always green, thick, smooth, broad, and ending at each end in a point, with a foliated pedicle in the shape of a heart. When held up to the light there appears to be a sort of holes in them like St. John's wort. The flowers grow in bunches, and are rosaceous, consisting of five white petals placed in a ring, with many stamina, which have yellow apices, or heads; at the bottom and center of the cup there is an orbicular placenta, which sustains a roundish pistil with a long tube, that runs into a globous fruit, covered with a rind, which is very well known. There are several kinds of Oranges, as the *common Seville Orange*, the *sweet Seville Orange*, the *China Orange*, the *curled leaved Orange*, the *striped curled leaved Orange*, the *horned Orange*, the *common striped Orange*, the *Hermaphrodite Orange*, the *willow leaved Orange*, commonly called the *Turkey Orange*, the *striped Turkey Orange*, the *Purple Nose*, or *Shaddock Orange*, the *double flowered Orange*, the *common Dwarf*, or *nutmeg Orange*, the *dwarf striped Orange*, the *dwarf China Orange*, the *childing Orange*, the *distorted Orange*, the *large warted Orange*, the *starry Orange*, and the *Orange with a sweet rind*. Many sorts of these oranges are cultivated in England, though more for curiosity than the fruit they produce; and of late years some of them have been planted against walls, with frames of glass to cover them in the winter. Some curious persons have likewise planted them in

the open ground, and have had covers for them, which have been taken away in the summer; by this means the fruit has ripened so well as to be extremely good for eating. However, in hard winters it is very difficult to preserve them.

Orange peel is an excellent bitter, especially that of Seville oranges, which strengthens the stomach, helps digestion, attenuates gross humours, discusses wind, and eases cholic pains proceeding therefrom. It is an ingredient in tinctures, called stomachic bitters, and is now common in taverns, where they mix it with a glass of wine, and drink it before dinner to create an appetite. The essential oil distilled from the rind is also proper for the same uses, when two or three drops are taken upon sugar, as well as the peel, when it is candied. The pulp of sweet oranges is cooling, quenches thirst, and excites the appetite; but the juice of four oranges not only serves to make a cooling drink in hot weather, but is of late found to be excellent against the scurvy.

BARDANA, *Burdock*, has a thick, single, straight root, a foot in length, blackish on the outside, white within, and of a sweetish subaustere taste. The leaves are large, being a foot long and upwards; they are sharpish at the points, hairy, and of a dark green colour, but hairy underneath. The flowers consist of many purple florets, deeply cut into five segments, resting on the embryo, which is contained in a cup made of many scales, that terminate in hooks, and bend inward. The embryo turns into an oblong, flat, streaked, flattish seed, with short down or rather tufts of hair. It is to be met with every where by the way sides. The root is diuretic, sudorific, pectoral, uterine, vulnerary, and febrifuge. It has been of late greatly recommended in the gout. It is given to a drachm in powder, and to an ounce in decoction. The seeds of burdock are of a bitter subacid taste, and are a powerful diuretic, when a drachm of them is taken in white wine, or any other proper vehicle.

BECCABUNGA, *Brook-lime*, has fibrous, white, creeping roots, with upright stalks, that are round, spongy, reddish, and branched. The leaves are roundish, smooth, thick, crenated, of a dark green colour, and above an inch in length. The flowers proceed from the places where they join to the leaves, and are placed on spikes, a palm, or a palm and a half, in length; they are monopetalous, but divided into four segments, and are of a bright blue colour. There are three blue apices, and a pistil that turns into a membranaceous flat fruit, of the shape of a heart, and a quarter of an inch long. It is divided into two cells, containing many small flat seeds. This herb has no remarkable taste, and yet some prefer it to other more acrid antiscorbutics. The dose of the juice is four ounces; but it is best mixed with the juice of oranges, and then it may have a very good effect in hot scurvies.

BELLA DONNA, *Deadly Night-Shade*, has a thick, long, juicy, whitish root, divided into several branches; the stalks are two cubits high, and are round, as thick as one's thumb, branched, hairy, and of a reddish black. The leaves are like those of garden night-shade, which are twice or thrice as large, and are soft and somewhat hairy. From the place where the leaves join to the stalks the flowers proceed, which are monopetalous, in the shape of a bell, divided into five segments, streaked, a little hairy, and of a dark purplish black, with five stamina, and as many whitish apices. From the calyx it is hairy; and divided into five parts; the pistil proceeds, which is fixed into the hinder part of the flower, like a nail, and turns into a soft round fruit, like a grape, of a shining black colour, and full of a vinous juice. It is divided by a partition in the middle into two cells, full of many minute oval seeds. It grows in woods, near walls and hedges, and in

other uncultivated places. The fruit, or berries, have often proved of dangerous consequence to children who have eat them. They produce a delirium, laughter, various gesticulations, and at last madness.

BELLIS MAJOR, *the greater, or Ox-eye Daisy*, has a fibrous creeping root, with stalks two cubits high, that are erect, of a pentagon shape, villous, and branched, with flat leaves placed alternately, two inches long, half an inch broad, and crenated. The flowers are large, radiated, and their disk consists of many gold coloured florets, divided into five segments, with a style in the middle of each; but the crown is composed of white semi-florets, resting upon embryos, and placed in a hemispherical scaly blackish cup. The embryos at length turn into slender, oblong, streaked, naked seeds. The heads, after the petals are fallen off, resemble obtuse combs.

BELLIS MINOR, *the common Daisy*, has many small roots, with a great number of leaves lying on the ground, that are flat, hairy, long, and narrow towards the root, sensibly increasing to the end, where they are roundish, and they are slightly serrated. It has no stalk, but there are many pedicles between the leaves, a palm or upwards in length, which are slender, round, hairy, and on the top of each there is a flower, whose disk is composed of many yellow florets, and the crown of semi-florets, of a white colour with a reddish cast. The embryos are placed in a single cup divided into many parts. The embryos afterwards turn to small naked seeds: it is every where common in meadow or pasture lands. Besides these there are the *small striped Daisy*, the *red garden Daisy*, with double flowers, the *white double garden Daisy*, the *double striped garden Daisy*, the *hen and chicken Daisy*, the *white cock's comb Daisy*, and the *red cock's-comb Daisy*. The garden Daisies are propagated by parting the roots in autumn, and should be planted in gardens of strong earth, and be exposed to the east, for the great heats of summer will sometimes kill them. The leaves of the ox-eye daisy gathered before the flowers appear, yield a decoction of an acrid taste, not much unlike pepper. It is commended in purulent spitting. The lesser daisy has been generally accounted good for internal wounds, and for dissolving and discussing grumous blood.

BERBERIS, *the Barberry-tree*, is a tall shrub, having fibrous, yellowish, creeping roots, and the branches are beset with sharp thorns. The leaves are small, oblong, narrow at the bottom, but broader towards the top, are crenated on the edges, and beset with short thorns. They are smooth, green, and have an acrid taste. The flowers consist of six leaves, that expand in the form of a rose, consisting of six petals of a yellow colour, with as many stamina, and a greenish pistil, turning into a cylindrick red soft fruit, one third of an inch in length, and full of an acrid juice, containing one or two oblong kernels. The fruit grows in clusters hanging down, and the bark of the tree is whitish. The best method of planting them is to place them eight or ten feet asunder, keeping their middles thin and free from dead wood. The branches should seldom be shortened, but when it is done it must be at Michaelmas, when the leaves begin to decay. The fruit is cooling and astringent, and proper to strengthen the stomach and intestines, as well as to excite the appetite. The dose of the expressed fruit is an ounce, though they are eaten commonly when ripe. The juice, or decoction, abates the inflammation of the fauces and tonsils, and heals loose rotten gums. Dyers make use of the bark for colouring yellow.

BERULA, *five SIUM, Water Parsnip*, has geniculated, creeping, white, fibrous roots, from whence proceed stalks above a cubit in height, which are hollow

hollow, round, strait, branched, and have many leaves that are set thereon by pairs, with a single leaf at the end; they are fat, smooth, and cut all round the edges like a saw. The flowers are disposed in umbels, and placed at the end of the stalk; they are rosaceous; and consist of five white petals, placed in a ring. The flower cup turns to a roundish fruit, containing two small streaked and gibbous seeds. It delights in being in and near rivulets and ditches. It is accounted an antiscorbutic and aperient, and is thought to open obstructions. Three ounces of the juice is a dose; however, it is seldom used in physic, but in some countries is eaten as a salad.

BETA, *white and red Beets*. The *white Beet* has a round, woody, long, white root, about as thick as one's little finger, with large, broad, smooth, thick, succulent leaves, sometimes of a pale, and sometimes of a deeper green, with a thick broad rib. The stalks are slender, streaked, branched, and two cubits high. The flowers proceed from the hollow between the stalk and the pedicle of the leaf, of which there is a long row; and they have no visible leaves, but consist of many stamina, or threads, which are collected into a globe; the cup of the flower is divided into five segments, which turns into a globous fruit, containing two or three small oblong seeds of a reddish colour.

Red Beet has a white root, and shorter leaves than the former, more or less red, and sometimes of a blackish red. This is distinguished from the former by the number of the leaves.

The *Turnip rooted red Beet* has a higher stalk than the common red beet, and the root is two or three inches thick, bellying out; on the outside it is of a deep blood colour. All these beets are cultivated in gardens for the use of the kitchen; but they were in greater esteem formerly than they are at present. However, the red beet is still used to garnish dishes.

BETONICA, *Betony*, has a thick, transverse, fibrous, hairy root, from whence proceed quadrangular knotty stalks, growing to the height of a cubit. Some of the leaves proceed from the knots by pairs, placed over against each other, and others lie on the ground; they are oblong, villous, wrinkled, and of a darkish green colour, and are crenated on the edges. The flowers grow in spikes, and are monopetalous, labiated, and of a purplish colour; the upper lip is fulcated, and as it were reclines backwards; but the lower consists of three lobes, with stamina of the same colour as the former. The flower cup is cut into five segments, from whence proceeds a pistil fixed in the hinder part of the flower, like a nail, with four embryoes, that change to as many roundish seeds, contained in a capsula, that was the cup of the flower. It is common in woods and shady places throughout England. *Betony* is discutient and aperient, and has been always accounted an excellent medicine for the head, and the leaves reduced to powder promote sneezing; for which reason, and for its being a cephalick, it is always an ingredient in the herb snuffs.

BISTORTA, *Bistort*, or *Snake-weed*, has a thick, oblong, geniculated root, in shape like a finger when it is close bent, and has many hairy fibres. It is of a blackish brown without, and of a reddish colour within. The leaves are oblong, broad, and acuminate like those of the dock; but less; they are full of veins, and of a blackish green colour above, but bluish below; the stalks are about a foot in height, and are slender, smooth, round, geniculated, and beset with a few smaller leaves; for the largest grow at the bottom. The flowers grow like a spike at the end of the stalk, and are without petals; for they consist of many stamina, with flesh coloured apices or heads. The cup is divided into five segments, and the pistil turns to a triangular reddish black shining seed, contained in a capsula, that was the

cup of the flower. The root is only in use. It is said to be balsamic, vulnerary, and astringent, and is used in all cases where astringency is proper, particularly in hæmorrhages, spitting of blood, and overflowing of the menses. The decoction of half an ounce to an ounce of the fresh root is a dose, or rather it may be taken at several times; and the powder may be given from half a drachm to a drachm, made into a bolus with conserve of roses.

BONUS HENRICUS, *the English herb Mercury*, has a thick yellowish root, furnished with a few fibres, from whence proceed concave stalks, to the height of a cubit, which are a little hairy; the leaves are triangular, smooth above, but below sprinkled with a sort of meal, and they have long pedicles placed on the stalks alternately. The flowers, that grow in several bunches on the top of the stalks, are small and without petals, but they have several yellow stamina proceeding from the flower cup, which is divided into many segments. The pistil turns into a small seed, in the shape of a kidney, which is black when ripe. It grows in uncultivated places by the way side, and among the ruins of old walls and buildings. It is often used for food in many parts of England, and is reckoned as good as spinach. It is emollient, and has been sometimes used as a cataplasm to appease the pains of the gout, and that without any danger.

BORRAGO, *Burrage*, has a white, thick, fibrous root, and broad, roundish, rough, wrinkled, blackish green leaves, that lie on the ground; but those that are higher are furnished with exceeding small prickles. The stalk is hairy, round, hollow, branched, and grows to the height of a cubit. The flowers, that grow on the top of the branches, are of a fine blue, placed on pedicles, an inch in length, that are crooked and bend downwards. The flowers have only a single petal, which is deeply divided into five segments, sharp at the ends, and placed like a star; the apices in the middle of the flower are sharp pointed, and adhere together in the shape of a pyramid. The flower cup is green, hairy, and divided into five acuminate segments, from which a pistil arises, fixed in the hinder part of the flower, like a nail; and there are four embryoes, that turn into as many seeds in the shape of a viper's head. It is common in all parts of England, and is often found in dunghills and on public roads. The seeds of this plant may be sown in the spring or autumn, soon after they are ripe; it will grow almost in any soil, but that which is dry is best. It is often used in the summer time with balm for making cool tankards, and the flowers are said to be cordial, and to have many other virtues, as well as the herb, that are now disallowed.

BRASSICÆ, *Cabbages*, are of several sorts, as the *common white Cabbage*, the *Russian Cabbage*, the *red Cabbage*, the *flat sided Cabbage*, the *sugar loafed Cabbage*, the *early Battersea Cabbage*, the *white Savoy Cabbage*, the *green Savoy Cabbage*, the *green Broccoli*, the *Italian Broccoli*, the *turnip Cabbage*, *curled Colewort*, the *must Cabbage*, the *branching tree Cabbage from the sea coast*, *brown Broccoli*, *common Colewort*, the *Cauliflower*, the *Boorcole*, *Alpine Colewort*, *perfoliated wild Cabbage*, *white Cabbage with a white flower*, and the *perfoliated wild Cabbage with a purple flower*.

BRASSICA CAPITATA ALBA, the *common white Cabbage*, is very well known, and bears, like all the rest, flowers that consist of four leaves or petals, in the form of a cross, which are of a yellow, or pale yellow colour, placed in a cup divided into four segments, from which arises a pistil that turns into a round, long, slender fruit, or pod, divided by a partition in the middle, and consisting of two cells, full of roundish blackish seeds.

BRASSICA CAPITATA RUBRA, the *red Cabbage*,

bage, has leaves like the common cabbage, but the colour is various, for sometimes they are of a blackish purple, sometimes of a greenish black, and at other times more greenish; but they have all red ribs and nerves.

BRASSICA RUBRA VULGARIS, the *common red Cabbage*, is taller than the former, and has a stalk that grows sometimes to the height of two yards, which is thick, of a blackish purple colour, and watry on the lower part. The leaves are irregularly placed, and are all of a greenish red, with some shades of blue, and wrinkled, with thick veins. The flowers that grow on the top of the stalks are yellow, and change into pods a palm in length, that contain red round seeds. The leaves are not collected into heads as the former, but continue expanded and open. It stands the winter very well, and continues several years. The ends of the branches in the spring are eaten as a sallad.

BRASSICA ALBA CRISPA, the *white Savoy Cabbage*, has round extremely wrinkled leaves, which seem to be divided into cells, and have short pedicles. They are collected into a small whitish head; but their extremities are of a dark green. The flowers and seeds are like the former.

BRASSICA CAULI FLORA, the *Cauliflower*, has large leaves, upwards of half a yard in length, which are sharper than those of the common cabbage, but not so broad; they are of a light green with a bluish cast, and the nerves on the outsides are whitish. The leaves are collected into a head, but not so close as a cabbage, between which there is a heap of thick whitish soft flowers, that are generally in great esteem. When they are not gathered for the kitchen, they arise to a considerable height in time, and turn from flowers to pods like the former. These are all the sorts mentioned by medicinal writers, for the rest are only for the kitchen.

The *common white, red, and long-sided Cabbages*, are chiefly cultivated for winter use, and the seeds must be sown at the end of March in beds of good fresh earth. Towards the end of April, when the young plants have about eight leaves, they should be pricked out into shady borders, about three inches square, to prevent their being long shanked. They should be transplanted in the latter end of May to the place where they are to grow, and should be set in rows, two feet and a half distant. If the season should prove dry when they are transplanted, they must be watered every other evening, till they have taken fresh root. As they advance in height, the earth must be drawn about the stems with a hoe, which will greatly strengthen the plants. Some of these cabbages will be fit for use soon after Michaelmas, and the rest will continue till the beginning of March, if not destroyed by bad weather: to prevent which the gardeners near London pull up their cabbages in November, and trench their ground up in ridges, laying their cabbages against the ridges as close as possible on one side, and bury their stems in the ground. They are suffered to remain in this manner till after Christmas, when they cut them for the market.

The *Battersea, and sugar loaf Cabbages*, are for summere use, and are usually named Michaelmas cabbages. The seeds are to be sown in the beginning of August, in an open spot of ground, and when they have eight leaves they must be pricked into beds at three inches distant every way. Towards the end of October they must be planted out for good, two feet and a half distant from each other, and the rows must be three feet asunder. In the spring the earth must be drawn up about the stem with a hoe, and in May their leaves will begin to cabbage, to promote which they may be tied together with a slender osier twig.

The *Savoy Cabbages* are propagated for winter use;

for a frost is thought to make them better. They must be sown about the middle of April, and cultivated in the same manner as common white cabbage, but somewhat nearer to each other.

The BRASSICA FIMBRIATA, that is, the *Boorcole*, may be treated in the same manner, but need not be planted above a foot square. These are never eaten till the frost has rendered them tender; for otherwise they are tough and bitter. The seeds of the several kinds of broccoli should be sown the latter end of May or beginning of June, and when the plants have eight leaves they should be transplanted into beds, like the common cabbage; and at the end of July they will be fit to plant out for good, which should be in a sheltered spot of ground, but not under trees, and about a foot and a half distant each way. Towards the middle of December they will begin to show their small heads, which are somewhat like a cauliflower, but of a purple colour; and they will continue to be fit to eat till the beginning of April. The brown sort should be sown in April, and be managed like the common cabbage.

The *Turnip cabbage* is not so much cultivated as formerly, though some yet esteem them for soups. The seeds must be sown on a bed of light fresh earth, and when the plants are about an inch high, they should be removed to a shady border, and set at about two inches distant every way, watering them till they have taken root. Near the middle of June they should be transplanted out where they are to remain, and set at two feet distance every way, watering them till they have taken root; the earth should be drawn about them with a hoe, to prevent them from drying, and in the winter they will be fit for use.

The seeds of the curled colewort may be sown in the middle of July, and when they are strong enough for transplanting, they should be set in rows, nine inches asunder, and at five inches distance in the rows, in a moist season. They will be fit for use after Christmas, and continue good till April.

BRYONIA ALBA, *white Bryony, or Wild Vine*, has a root sometimes as thick as a man's thigh, is fleshy, and divided into large branches; when it is dried it is spongy, and marked with circles and rays. The taste is acrid, bitterish, and disagreeable, and the smell while fresh is very strong. The stalks are long, slender, streaked, a little hairy, and climbing with tendrils like a vine. The leaves are angular, set alternately on the stalks, and are shaped pretty much like those of a vine, only they are less, and a little rough. The flowers proceed from the hollows where the leaves join to the stalk, and consist of a single petal, which is open in the shape of a bell, and divided into five parts, of a whitish green colour, marked with veins. Some of these flowers are large, and without embryoes; others are less, and contain one embryo, which turns into a spherical berry of the size of a pea; it is at first green, then red and full of a nauseous juice, as well as round seeds, covered with slime. It may be cultivated in gardens by sowing the berries in the spring of the year in a dry poor soil, where they will in two years time grow to be large roots. It grows wild under hedges, and climbs upon the bushes. The juice of the root is so sharp that it eats into the skin; however, when they are dry, they lose a great part of their acrimony; it is a strong cathartic, and we have some notable instances of its killing and bringing away worms; it has been used in madness, and some kinds of dropsies with success, as well as in a moist asthma. The dried root reduced to powder, is given from a scruple to a drachm; but the extract made by water is much the best and safest, because it works in a milder manner, and the dose is from half a drachm to a drachm. Externally, it is a powerful resolvent, and has been recommended against pains in the side,

side, the hip-gout, and scrophulous tumours. The fresh root being bruised, and laid to the small of the back, has promoted urine and cured the dropsy; likewise, when it has been grasped in the hand when fresh for some time, it has been known to purge. For the hip-gout it should be bruised, mixed with linseed oil, and laid warm to the part.

BRYONIA NIGRA VULGARIS *feu* **RACEMOSA**, *black Bryony*, has a large, thick, long, tuberoso root, black on the outside, but white within, and full of a thick sily juice, with no disagreeable taste. The stalks are like those of the vine, but without tendrils; however, they are slender, long, climbing, woody, and of a dark reddish colour, with soft, green, shining leaves, placed alternately thereon, like those of the great bind-weed. The flowers proceed from the hollows between the leaves and the stalks, and grow in bunches; they consist of a single petal in the shape of a bell, and are divided into six segments of a yellowish green colour, some of which are barren, and others fruitful. These last sort have an embryo, which turns to an oval red berry, or of a brownish red, full of roundish seeds. Its common use is as a resolvent; for it will take off the black and blue marks of the skin arising from bruises, when it is bruised and laid thereto in the form of a cataplasm.

BUGLOSSUM, *garden Bugloss*, has a long round root, about as thick as one's finger, which is reddish or blackish without, but white within, and abounding with a clammy juice. The stalks rise to above a cubit in height, which are round and beset with stiff hairs. The upper part is branched, and has leaves set thereon without pedicles; they are narrow, oblong, of a bluish green, and terminate in a sharp point, but are not wrinkled like burrage. They are hairy on both sides, and their edges are even. The flowers grow at the top of the stalks and branches, and are in the shape of a funnel, consisting only of a single petal. The flower cup is composed of five oblong, narrow, sharp, hairy segments, and the flower consists of the same number, and is of a bluish purple colour. The pistil is oblong, and fixed in the hinder part of the flower like a nail; there are four embryoes, which turn to as many seeds in the shape of vipers heads. The tops of the stalks and the cups of the flowers are purple. It is cultivated in gardens. The flowers are in the number of those that are said to be cordial, and are proper to restrain the heat of the blood, as well as to promote its circulation, according to some. The flowers may be used in the same manner as tea.

BUGULA, *Bugle*, or *middle Confound*, has a slender, fibrous, white root, with roundish, soft, sinuated leaves, of a dark greenish colour, and two inches in length. It grows in stony places; the lower part is generally purplish, and the taste at first is sweetish, but afterwards bitterish and astringent. Some of the stalks are slender, roundish, and creep on the ground, while others rise to the height of a palm, and are quadrangular, with hair on two of the opposite sides. The flowers are placed in whirls round the stalks, and consist of a single petal, one of whose lips is divided into three parts, the middlemost of which is split in two. The place of the under lip is supplied by small teeth, with a pistil and blue apices like the flower. The flower cup is short, hairy, and divided into five segments, from whence the pistil rises, and is fixed in the hinder part of the flower like a nail. It is attended with four embryoes, that turn to as many roundish seeds shut up in a husk, which before was the flower cup. It delights in meadows and shady places. It is a vulnerary herb, and is good in all cases where mild astringents are proper.

BURSA PASTORIS, *Shepherd's-Pouch*, has a

white, strait, fibrous, slender root, with a stalk that rises to a cubit in height. The lower leaves are sometimes whole, but more generally jagged like dandelion; but those that grow on the stalks are much less broad at the base, with even edges; and terminate in a point. The flowers are placed in rows on the tops of the branches, are small; and in the form of a cross; they consist of four roundish petals with small stamina, bearing yellow apices or heads. The flower cup consists of four leaves; and the pistil turns into a flat fruit in the shape of a heart; or as some fancy like a purse, and is a quarter of an inch long; it is divided into two cells, in which are contained exceeding small seeds. It is said to be a vulnerary, astringent, cooling herb, and is given in all hæmorrhages and fluxes; but some think it is so binding as not to be safe.

BUXUS, the *Box-tree*, is a shrub which seldom grows to any considerable size in England, though it has sometimes been seen as thick as a man's thigh. The largest were found in great plenty upon Box-hill, near Darking in Surry; but of late they have been pretty much destroyed; however, there are many still remaining, of a considerable bigness. Some have thought that the box wood, made use of by mathematical instrument makers and others, was the product of England; but this is a mistake, for it is brought from the Levant in large blocks. This shrub is an ever-green, and very bushy, having oblong, small, hard, thick, shining leaves, of a disagreeable bitterish smell and taste. The flowers are of two sorts, the barren and the fruitful: the first are without petals, and consist of many stamina, generally proceeding from the bottom of a foliated square flower cup, of a yellowish colour; the fruitful, or rather the fruit, is shaped like a pottage-pot turned upside down, and is divided into three cells of a green colour, containing two seeds, each of which when ripe is thrown out by the elasticity of the vessels; the seeds are brown, long, and shining. These shrubs are a very great ornament to cold and barren soils, where few other things will grow: They may be propagated by planting the cuttings in a shady border, observing to keep them watered till they have taken root. The best season for transplanting these into nurseries is in October; or the seeds may be sown soon after they are ripe in a shady border, which must be duly watered in dry weather; and from these you may expect the largest trees.

There are several sorts of Box-trees, as the *common Box-tree*, the *narrow leaved*, the *striped*, the *gold edged*, the *silver beaded*, the *dwarf*, and the *dwarf striped Box*. The dwarf kind is used for bordering flower-beds, for which purpose it is excellent, as it will bear all weathers, and is kept handsome with little trouble. This is easily propagated by parting the roots, which is much better than planting the slips. It is seldom used in medicine.

CALAMINTHA, *common Calamint*, has a fibrous root, with stalks growing to the height of a palm and upwards, which are quadrangular, branched, and have leaves growing by pairs opposite to each other. They are from half an inch to an inch in length, and are roundish, obtusely acuminate, a little serrated and hairy, with an acrid taste, and a disagreeable smell. From the middle to the top, the flowers grow where the pedicle of the leaves join to the stalk in bunches; they are long and tubulous, and open at the top with two lips; the uppermost of which, or crest, is roundish, and divided into two segments; but the lowermost, or beard, is divided into three. They are of a purplish colour, and placed in a hairy streaked calyx, from whence rises a pistil fixed in the hinder part of the flower like a nail, and as it were attended with four embryoes, which turn into as many light blackish

blackish seeds, whose calyx was the capsula of the flower.

Calamint (of which there are several sorts, but they differ so little from that already described, as to require no particular description) powerfully incises gross humours, excites the appetite, and discharges wind. It is taken in the manner of tea, and is generally accounted a good hysteric.

CALENDULA, *garden Marygold*, is otherwise called *Caltha Vulgaris*, and has a root divided into many thick fibres or branches; but the stalks are slender, a little angular, hairy, and clammy to the touch. It is divided into many branches, and the leaves are narrower at the base than at the top; they are hairy, and of a light green colour. The flowers grow on the top of the branches, and are of a gold colour and radiated; the disk consists of many tubulous florets, divided into five parts; and the crown is composed of crenated semi-florets, placed upon embryos in a hairy flower cup, divided into many parts. The embryos turn into crooked margined capsulæ full of oblong seeds. It is cultivated in gardens, and if the seeds are permitted to scatter, they will multiply greatly, and become as troublesome as weeds. The flowers are said to be aperient and dissolvent, and proper to open obstructions of the liver, spleen, and womb; but they are not very efficacious for these purposes; however, infused in wine, they will open a slight obstruction of the liver.

CAMPHORATA, *stinking ground Pink*, has a long woody root, about the thickness of a man's thumb, with many woody, thickish, branched, hairy, whitish stalks, with small knots placed alternately, from whence proceed a great many leaves, not a third of an inch in length, which are thin, hairy, pretty thick, have an aromatic smell, and when rubbed between the fingers smell pretty much like camphire. The flowers are without petals; for they consist of four stamina, with rose coloured apices, or heads, proceeding from a cup, which is only a single herbaceous leaf, divided into three, and sometimes into five, segments; from whence arises a pistil, that turns into a small, oblong, black, roundish seed, contained in a capsula, which was the calyx of the flower. It promotes urine and sweat, and is good in recent obstructions of the viscera, as well as in the moist dropsy. It may be drank as tea, but is very heating, and therefore must be used cautiously.

CANNABIS SATIVA, *manured Hemp*, has a single, white, woody, fibrous root, with a square hairy stalk, rough to the touch, and hollow within; it grows two yards high, and has a rind that may be divided into threads. The leaves consist of five segments or upwards, which are narrow and divided to the very pedicle; they are oblong, acuminate, serrated, veinous, rough, of a blackish green colour, and of a strong smell. The flowers and fruit do not grow upon the same plant; the former proceed from the places where the leaves join to the stalk, and have no visible petals; they consist of five stamina with yellow apices or heads, placed in a cup composed of five leaves, purplish without, and whitish within. The fruit on other stalks are without flowers; but they have pistils contained in a membranaceous capsula of a yellowish green colour, which turn into a roundish smooth seed, covered with a thin shining shell. The plants of both kinds proceed from the same seeds, which are sown in almost all parts of the world. The use of hemp is every where well known, it being made into ropes, thread, linen, and paper.

Hemp is always sown in a deep, moist, rich soil, such as is found in Holland, in Lincolnshire, and the fens of the Isle of Ely, where it is cultivated to great advantage. The land should be well ploughed and rendered fine by the harrow; the latter end of

April is the best time of sowing the seed, of which the heaviest and brightest coloured is best; when the plants come up, they should be hoed up like turnips, leaving them a foot or sixteen inches asunder; about a month after they should be hoed again, to destroy the leaves. The first season of pulling the hemp is about the latter end of August, and they first begin with the *finble hemp*, which is the male plant; but a fortnight or three weeks longer would be better, that none of the seeds may prove abortive. The second pulling is about the middle of October, when the seeds are ripe, and this is usually called *karl-hemp*, they being the female plants.

Hemp seed is recommended by Sir John Floyer, and others, against the jaundice, for which purpose two ounces may be boiled in a quart of milk till they break; and five or six ounces of this decoction may be taken several times in a day. It is also good in coughs, and heat of urine. The oil expressed from the seeds is recommended by some to ease the pain proceeding from burns.

CAPPARIS, *the Caper-bush*, has a large woody root, from whence proceed various shoots, armed with hard sharp prickles, and on which the leaves are alternately disposed, which are almost round, half an inch broad, and very bitter. The flowers proceed from the hollows where the leaves join to the stalks, and are rosaceous, white, and consist of four petals, from whose middle arises many stamina, with a long pistil; the flower cup consists of four green leaves, and the extreme part turns into a fruit almost in the shape of a pear; they are of the size of a large olive, and contain many small whitish seeds, almost in the shape of a kidney. In Italy it grows wild among the ruins of old walls and buildings, but in other places it is cultivated. There are several sorts of caper-bushes, as the *large fruited Caper without thorns*, the *prickly round leaved Caper with a small fruit*, the *sharp leaved Caper*, the *American tree Caper with a bay leaf*, and a *long fruit*, the *American tree Caper with a bay leaf and an oval fruit*, the *American tree Caper with laurel leaves and an oblong fruit*. In England it is very difficult to preserve these plants, and therefore nothing need to be said about their cultivation. What we call capers are the buds of the flowers before they are opened, which at first are laid in the shade for about four hours, and then put into vinegar for eight days; after which they are taken out, lightly pressed, and put into fresh vinegar for eight days more; this is repeated a third time, and then they are put up into casks for sale. They are every where known as a sauce; and are used to excite a languid appetite. Some put them into a brass vessel to give them a finer green colour, and then they are noxious. It is not used in medicine.

CAPRIFOLIUM, *Woodbind*, or *Honey-suckle*, has a woody creeping root with large fibres; the stalks are divided into branches, and are creeping or climbing, on which the leaves grow by pairs opposite to each other; they are oblong, sharp, soft, of a light green above, and hoary beneath. The flowers grow on the tops of the branches, and in some plants are white, and in others red or yellowish; they have a very sweet smell, and consist of a single tubulated petal, which grows open towards the top, and is divided into two lips, the uppermost of which is again divided into two, and the lowermost into many segments. The tube of the flower is bent, and sometimes resembles a huntsman's horn; they are produced in clusters, and placed in a cup consisting of a single leaf; this turns to a soft fruit, or berry, of which several grow together in bunches, almost in the manner of alder-berries. They are red when ripe, and are full of hardish, roundish, flattish seeds. It is found growing in the hedges in many parts of England, as well as in our gardens.

CARDIACA; *Mother-wort*, has a root consisting of fibres, proceeding from one head, from whence arise quadrangular hard stalks, two or three feet high, of a reddish black colour. The leaves are veinous and wrinkled, and, though smooth, are covered on both sides with down. The lowermost are round and of a pale green; but they are divided into three segments, dentated about the edges. The higher they are the narrower they grow, and end in a long point, having on each side a single tooth. The cups consist of a single leaf, are hard, and divided into five stiff sharp thorns, attended with many others. The flower is labiated, and consist also of one ear, whose upper lip is imbricated, with pieces laid over each other in the manner of tiles, and is much longer than the lower lip, which is cut into three parts. The pistil rises from the flower cup, attended with four embryos, and is fixed in the hinder part of the flower like a nail; the embryos turn into as many small, oblong, angular, smooth seeds, taking up the whole capsula, which was the cup of the flower. It is found wild in England near gardens, from whence it has been thrown out. It is said to cure convulsions, open obstructions of the viscera, and to kill worms; some account it excellent in diseases of the spleen, and the hysteric passion. The dose of the leaves in powder is a drachm, and must be taken in wine.

CARDUUS BENEDICTUS, *the blessed Thistle*, has a white fibrous root, and leaves lacinated like dandelion, but deeper, hairy, and terminating in short pedicles; they are alternately placed on the stalks, which are villous, streaked, and sustain large flowers, consisting of florets that are divided into segments, five with a pistil cut into three or five small stamina, on which are long apices or heads adhering to each other, and as it were forming a tube. The calyx is scaly, in the shape of a pear, and armed with branched spires, as well as with large leaves in the form of a head, covered with a great deal of down; the leaves are long, streaked, yellowish and downy. The whole plant is remarkably bitter, except the root, which is milder. It is resolvent and strengthening, promotes sweat, and restrains putrefaction. It is good in weaknesses of the stomach, the moist asthma, the hooping cough, the jaundice, and in all cold diseases; but in spotted fevers and the plague, it is not so good as some authors have pretended. It has often cured agues, when used some time before the fit. In chronical diseases, the infusion of the tops may be taken several times a day. The decoction is often used to provoke vomiting, when a former emetic has failed. A slight infusion is excellent in the loss of appetite after hard drinking; and one that is stronger will occasion a plentiful sweat, and promote all the secretions in general. Some give from an ounce to two ounces and upwards of the juice, and a drachm of the seeds in emulsions, which last, with distilled poppy water, has been given with great success against the pleurisy and rheumatism.

CARDUUS MARIÆ, *Ladies Thistle*, has a long, thick, fibrous root, and long, broad, sinuated leaves, crenated on the edges, with many hard, shining, smooth, stiff prickles, of a light green colour, and variegated with lines or stripes of white. The stalks are about as thick as one's finger, streaked, covered with a hairy down, are branched, and two or three cubits high. The flowers grow on the heads of the branches, and consist of many purple tubulous florets, divided into five parts at the top, each of which is placed on an embryo in a scaly prickly calyx. Each embryo turns into a smooth oval seed, a little flattish, and furnished with down. It grows in uncultivated places, and by the way sides. The tender leaves, after the prickles are taken off, are eaten by some as a sallad, and are said to have the same vir-

tues as *carduus benedictus*. The seed is excellent for the pleurisy, rheumatism, and pains of the breast; it is given in emulsions from one drachm to two.

CARYOPHILLUS, *Clove July flowers*, or *Carnations*, have a single fibrous root, with many smooth stalks rising to a cubit in height; they are geniculated, knotty, and branched, with leaves proceeding from every knee, which are narrow like grass, pointed at the end, and of a greenish blue colour. The flowers grow on the top of each branch, and are of different colours, as is well known to all; they have a spicy smell like cloves, and the stamina and apices are white, with a pistil terminating in two or three crooked filaments; the flower cup is scaly at the bottom, denticulated at the top, and membranaceous. The pistil turns to a cylindraceous fruit contained in the calyx, and is full of flat rough seeds, that are black when ripe. There is a great deal of difference, as well in the size and colours of the flowers, as in the number of the petals, which varieties proceed from the difference of their cultivation. They are propagated either from seeds or from layers. The seeds ought to be well chosen, and should be sown in pots or boxes about the middle of April, in fresh light earth, mixed with rotten cow-dung, well incorporated together, covering them about a quarter of an inch thick with the same earth. These should be placed so as to receive the morning sun only till eleven o'clock, and in a month's time they will come up, and be fit for transplantation in the middle of June, into beds of the same sort of earth lying in an open airy situation. They should be planted about three inches square, observing to water and shade them as the season shall require. They may remain thus till the middle of August, and then they should be removed to beds of the like earth, setting them at six inches distant every way, and not above four rows in a bed. When the flowers begin to blow, those that do not break their pods should be reserved to plant in borders, to preserve the seeds; those that burst their buds, and seem to have good properties, should be planted in pots; but you cannot be certain of the value of the flower till the next year. These flowers were formerly greatly esteemed by physicians for their excellent virtues; but they are now of no other use with us but to make syrup, for which purpose the red should be chosen, as they have a pleasant aromatic smell.

CARUUS, *Caraway*, has a single long root, about as thick as one's thumb, with a few fibres, and an acrid aromatic taste. The stalks rise to the height of a cubit, or a cubit and a half, and are smooth, streaked, and branched. The leaves are winged, narrow, conjugated, and cut into small segments, of a dark green colour. The flowers are placed in umbels; are small, rosaceous, and consist of five petals, in the shape of hearts, placed in a ring, and contained in a green cup, with very slender whitish stamina, and green apices or heads. The calyx turns to a fruit, consisting of two small longish seeds, streaked and gibbous on the one side, and on the other plain; they are blackish, acrid, and aromatic. It is sometimes found wild in England in rich moist pastures. There are several sorts, as the *common*, the *large seeded*, the *narrow leaved*, with *asphodel roots*, and the *alpine Caraway*. They are all to be seen in the gardens of the curious, and are cultivated by sowing their seeds in the spring of the year, in a moist rich soil. They should be hoed out to about six inches square, which will greatly strengthen them, and promote their seed plentifully. When the seeds are ripe, in autumn, the plants should be cut, and laid upon mats to dry, after which their seeds may be taken out and kept for use. They are stomachic and diuretic, and numbered among the four greater

hot seeds. They incide gross humours, disperse wind, appease the cholic, and help digestion; but they are bad in very hot constitutions and inflammations. The dose, in powder, is from a scruple to a drachm.

CASTANEA, the *Chestnut-tree*, is large, tall, and full of branches, and sometimes grows to a large size. The wood is solid, durable, and not obnoxious to putrefaction; it crackles in the fire, and has smooth, spotted, blackish bark, inclinable to an ash colour. The leaves are large, being about two inches broad, and four or five long; are thin, rough, wrinkled, and cut on the edges, with many transverse veins on the back, which run from the rib in the middle. The male flowers, or catkins, consist of many stamina, which proceed from a green cup, composed of five leaves, and have yellow heads. They are fixed to a small capillament or axis, and are barren. The outer coat of the fruit is very rough, and prickly, and grows distinct from the flowers. In each husk, or covering, there are two or three kernels or nuts, which are sometimes an inch in length, and of a roundish flat shape. This is the tree that is planted, but there is another sort which grows wild, and differs from the former only in being less in every sense. Chestnuts are of great use in many countries, where they eat them instead of bread, especially in the mountainous parts of France. Some boil them, and others roast them in pans over the fire; but whatever way they are prepared, they are windy and hard of digestion; and consequently seldom agree with any, except laborious working people.

CENTAURIUM MAJUS, the *greater Centaury*, has a thick, solid, heavy root, three feet in length, and blackish without, but reddish within, with a sweetish, astringent, biting taste. The stalks are round, and rise to the height of two or three cubits, with many branches; the leaves are large, and divided into several parts in the form of a wing. The particular leaves, of which they are made up, are near a span in length, and three or four inches broad, not unlike those of walnuts; they are smooth, serrated on the edges, full of nerves, and of a deep green colour. On the tops of the branches there are small heads or flowers, consisting of blue florets, divided into five parts, and placed upon an embryo in a scaly cup, but the scales are without points. The embryo turns to an oblong, smooth seed, furnished with down, like those of *carduus benedictus*. It grows wild among the Alps, from whence it is brought to us; but it is cultivated in gardens, and may be propagated either by sowing the seeds, or parting the roots, the latter of which is most commonly practised in England. The best seasons for this work, are October and February.

CENTAURIUM MINUS, *lesser Centaury*, has a small, white, woody, fibrous root, with a branched angular stalk, about a span in height. Some of the leaves lie on the ground, while others are placed on the stalk by pairs. The flowers grow in clusters on the top of the branches, and consist of single petals, in the shape of a funnel, and are of a beautiful reddish colour. The cup of the flower is composed of five sharp leaves, and a pistil, fixed in the lowest part of the flower, which turns to a membranaceous fruit, half an inch long, of a cylindrick shape, and full of exceeding small seeds. It grows wild upon dry arable land, and chiefly among corn. Both the flowers and leaves are extremely bitter, and the florid tops incide gross humours, strengthen the stomach, help digestion, open obstructions of the viscera, cure the jaundice, and the suppression of the piles. The dose in powder is to a drachm. Outwardly, it is vulnerary, and cures recent wounds, and old ulcers.

CEPA, the *Onion*, is of several kinds, but the

most usual are, the *common Onion*, the *red Spanish Onion*, the *Scallion*, and the *Ciboule*.

CEPA VULGARIS CANDIDA, the *common white Onion*, has a bulbous root, consisting of various coats, the outermost of which are membranaceous, and the innermost fleshy, with many fibres at the bottom. The leaves are long, fistulous, round, and sharp at the points; the stalk is naked, upright, and sometimes rises to the height of two or three cubits, especially in hot countries; this is likewise hollow, swells out in the middle, and the flowers are collected into a spherical head; they are composed of six petals or leaves, in the middle of which are six stamina, and a pistil, which turns into a roundish fruit, divided into three cells, full of roundish black seeds. They are propagated by seed, which should be sown in the beginning of March, on good rich sandy ground; and eight pounds is sufficient for a whole acre of land. About a month or six weeks after sowing, they will be ready to hoe, which should be done with one two inches and a half broad, cutting out, not only the weeds, but the onions, where they are too thick. This is best done in a dry season, and should be repeated twice more, cutting out the weeds as before. Towards the beginning of August, the onions will be at their full growth, which is known by the blades falling to the ground, and shrinking; but before they are quite withered, they should be drawn out, cropping off the extreme part of the blade, and then laying them upon a dry spot, turning them every other day for a fortnight, lest they should take root again. The Spanish onions are much in esteem, but will not long preserve their kind here, without fresh seeds from Spain or Portugal. They are chiefly preserved for the kitchen use, and are eaten raw by some, and roasted by others; but they are generally boiled. They are windy, heating, occasion troublesome dreams, and cause thirst; and therefore are bad for hot constitutions. However, when boiled, and mixed with honey, they are good in disorders of the lungs, arising from a thick clammy phlegm. When roasted, they are used by some to ripen boils.

CEPA ASCALONICA, *Scallions*, consist of several bulbous roots, somewhat larger than a hazel nut, have the taste of common onions; but not so strong nor so disagreeable. The leaves are slender, fistulous, round, smooth, and have the same taste. It is used in the spring, instead of green onions, in some countries, but it is now much neglected here. It is easily propagated, by parting the roots in the autumn, and then they will be ready for use in the spring. They must be planted three or four together, in a hole, at about six inches distant every way, for they multiply exceedingly. They have the same virtues as onions.

CEPULA, *five* CEPA FISSILIS, the *Ciboule*, is intirely like the *Scallion*, only it is larger in every sense, and differs in the acridity of its taste. They are planted for the same use as the former.

CERASUS, the *Cherry-tree*, is of different kinds, as the *red garden Cherry*, the *large Spanish*, the *red heart*, the *white heart*, the *bleeding heart*, the *black*, the *May*, the *black* or *Mozzard*, the *arch-duke*, the *yellow Spanish*, the *Flanders cluster*, the *carnation*, the *large black*, the *rose-flowered*, and the *double-flowered Cherry*; the *common white Cherry*, the *wild northern English*, with late ripe fruit, the *rock* or *perfumed*, the *Cherry-tree with striped leaves*, the *amber*, the *morella*, and the *Hertfordshire duke Cherry*.

CERASUS SATIVA FRUCTU ROTUNDO RUBRO ET ACIDO, the *common red* or *garden Cherry*, is a tree that is neither tall nor strait, which consists of a great many brittle boughs, with a moderately thick trunk, covered with a reddish bark, and the heart is of a blackish colour, but the

sap is whitish. The leaves are large, oblong, shining, and crenated on the edges. The flowers are rosaceous, consisting of several white petals, with stamina of the same colour; the flower cup is divided into five crooked segments, from whence arises a pistil, that turns to a well known fruit with long slender pedicles. It produces a yellowish shining gum, without taste or smell.

The *large Spanish CHERRY* grows on a tree not much unlike the former, but it is not so high, and therefore the sooner bears fruit. The stalk or pedicle is shorter and thicker than in the other kinds. Both these are cooling; and boiled in water, with a little sugar, make a pleasant drink for persons of hot constitutions; but those that have a weak stomach, abounding with acid humours, ought to abstain from them.

Heart CHERRIES are so called from being shaped somewhat like a heart, and the trees have larger leaves than the common sort; for they are somewhat like those of the chestnut tree, and hang downwards. The fruit has a harder and sweeter flesh, and are consequently more wholesome. All sorts of cherries are propagated by budding, or grafting the several kinds into the stocks of the black or wild red Cherries. The stones of these two kinds are sown in beds of light sandy earth in autumn, and when they rise, they must be carefully weeded. They should remain in these nursery-beds till the second autumn after sowing, at which time you should prepare an open spot of good fresh earth, into which you should plant out the young stocks, at three feet distance from row to row, and about a foot asunder in the rows. The second year after they are planted out, they will be fit to bud, if intended for dwarfs; but if for standards, they will not be tall enough till the fourth year; for they should be budded or grafted near six feet from the ground.

CERASUS NIGRA, the black Cherry-tree, is tall, with an upright trunk, and covered with a smooth, spotted, ash coloured bark, that is greenish on the inside. The leaves are oblong, shining, and deeply crenated. The flowers are joined together, as it were in a sheath, with slender, long pedicles or stalks, from which proceed round, small, sweet fruit, with somewhat of bitterness. It is not now kept in the shops; but it is common to steep them in brandy for a dram, which is known by the name of cherry brandy.

CHÆREFOLIUM, Chervil, has a single white fibrous root, with a stalk rising to a cubit and a half high, which is brown, streaked, hollow, geniculated, smooth, and branched. The leaves are like those of hemlock, but less, and they, as well as the pedicles or foot stalks, are of a faint reddish colour, and a little hairy. The flowers grow in umbels on the tops of the stalks, and are rosaceous, consisting of five white unequal petals, in the shape of a heart, with as many white stamina, and a flower cup, that changes into two oblong seeds, gibbous on one side, and flat on the other, which are black when ripe, and in shape like the bill of a bird. It is planted in gardens for sallads, by sowing the seeds in autumn, soon after they are ripe, or very early in the spring. If it be suffered to sow itself, it will thrive better than when cultivated by art. It is said to be inciding, attenuant, and aperient. It promotes urine so much, that Geoffroy takes it to be a specific against the dropsy, and he affirms, if chervil will not cure it, he does not know what will. The juice should be expressed from the fresh herb, or put in an earthen pan, and exposed to a violent heat, after which the juice is to be expressed out. The dose is three or four ounces, every third or fourth hour; or a decoction may be made of it with water, and then five or six ounces is a dose.

CHAMÆDRYS, *Germander*, or *ground Oak*, has fibrous creeping roots, with quadrangular stalks, that are branched and hairy, on which the leaves are set by pairs, and are of a beautiful green; they are half an inch long, and near a quarter broad, with a narrow base, and crenated from the middle to the end. The flowers arise from the places where the leaves join to the stalk, and consist of a purplish, labiated, single leaf; but the upper lip is wanting, and in its place there are crooked stamina, with a forked pistil. The beard, or lower lip, is divided into five parts, and the middle segment, which is largest, is hollow like a spoon, and sometimes divided into five segments, containing four roundish seeds, that proceed from the pistil. Both the leaves and flowers are in use, and grow wild in many parts of England. The leaves are bitter, and a little aromatic; they incide gross humours, restore the tone of the solids, and promote urine and sweat.

CHAMÆMELUM, *Camomile*, has a slender fibrous root, and slender branches, divided into many wings, which are eight inches high or higher. The leaves are slender, and cut into five segments; the flowers grow at the top of the stalks, and are for the most part radiated with white petals, and a yellow disk, which consists of many yellow florets; but the crown is composed of white semi-florets, and placed upon embryos, comprehended in a scaly cup. These turn into slender, oblong, naked seeds. The whole plant has a physical smell, which is not disagreeable. It grows wild in great plenty, on most of the large heaths near London, and is propagated for use, in physic gardens, by parting the roots, and planting them about eight or ten inches distant, every way, for they spread greatly. The proper time is in March, and they thrive best in a poor soil.

CHAMÆMELUM FOETIDUM, *five COTULA FOETIDA*, *stinking Camomile*, has a fibrous root, with round, greenish, brittle, succulent stalks, divided into many wings. It is thicker and higher than common camomile, with larger leaves, of a blackish green colour; but the flowers are much the same. It is easily known by its strong smell. The floret tops, and the leaves of both, are in use, but more particularly the flowers. Common camomile is an excellent carminative, and powerfully discusses wind, curing the cholic proceeding from thence, as well as in the convulsive cholic. They are also good in diseases of the breast, and more particularly in tumours of the stomach, proceeding from a violent heart-burn; as also in pains of the gravel. Externally, they are emollient and discutient, and are excellent in bruises, to disperse coagulated blood. Hence they are used in fomentations, cataplasms, paregoric clisters, uterine injections, and baths. The common method of taking them is as tea.

CHAMÆPITYS, *ground Pine*, has a slender, fibrous, white root, with stalks partly upright, and partly lying on the ground. They are villous, nine inches high, and two leaves proceed from every knot, an inch in length, and are somewhat in shape like those of the pine-tree, from whence it has its name; they are of a yellowish green. The flowers proceed from the places where the leaves join to the stalk, and have only a single petal, and a single lip; they are of a yellowish colour, and the lower lip is divided into three segments, the middlemost of which is parted in two. In the room of the upper lip, there are a few teeth, with stamina, of a light purplish colour. The flower cup is villous, divided into five segments, and contains four triangular brown seeds. The whole herb is in use, and has a pitchy or turpentine smell.

CHAMÆPITYS MOSCHATA, *Musk ground Pine*,

Pine, creeps on the ground like the former, but the stalks are harder. It has the same sort of flower, but of a purple colour, and the seeds are black, curled, and longish. The whole herb is very hairy, with a bitter taste, and a strong resinous smell, with somewhat of the scent of musk. These are numbered among the vulnerary, aperient, cephalic, hysterick, and nervine plants. The dose of the powder is a drachm, either alone, or with that of germander, in red wine; but it may be boiled in whey, when wine is not proper, and the decoction drank every morning.

CHEIRI, the *Wall-flower*, has a flower composed of four yellow petals, which are placed in the form of a cross, and out of the flower cup rises the pistil, which becomes a long flat pod, divided by a partition, into two cells, to which the valves adhere on both sides, and are furnished with smooth round seeds, with borders round their edges. The leaves are green, and acuminate at the end. It grows upon old walls, and flowers in June. They are said to be cordial, to ease pains, and to be good in the apoplexy and palsy.

CHELIDONIUM, *Celandine*, has a fibrous hairy root, and the lower leaves are large, a span long, lobated, of a fine green above, but of a bluish green below, and a little hairy. The lobes are roundish, have ears, and are placed one against another; they have also large veins and incisures. The stalks rise to a cubit in height, and upwards, are knotty, brittle, fistulous, and branched with leaves alternately placed. From the places where they join to the stalks at the top, flowers proceed, with a pedicle, a palm in length, and flowers collected in umbels. The flowers consist of four gold coloured petals, placed in the form of a cross, and the calyx consists of two leaves which soon fall off. The pistil of the flowers turns to a pod, an inch and a half long, which is round, slender, bivalved, and a little wrinkled; it is at first green, afterwards reddish, and pours out black, shining, roundish, flat seeds. The whole plant has a strong smell, and wherever it is wounded, pours out a liquor of a saffron colour, which is acrid and biting. It delights in watery shady places, and may be propagated, by sowing the ripe seeds in any corner of the garden. The colour of the root is red, and it is full of a bitter, acrid, burning juice. Some have given it inwardly to open obstructions, to promote urine and sweat, and to cure the dropsy; but others think it not safe for inward use, for in some cases, an infusion of two ounces of the root has been attended with dreadful symptoms. It is common to rub warts with the juice, to take them away.

CHELIDONIUM MINUS, *Pile-wort*, has a root consisting of tubercles, of the size of a grain of wheat, with many slender whitish fibres, which are pale without, but white within. The stalks rise to a palm in height, are slender, and most of them lie on the ground; the leaves are roundish, smooth, and shining, like those of ivy; and on the top of the stalks there is a rosaceous flower, like a ranunculus, consisting of eight or nine petals of a gold colour, placed in a circle. There are many saffron coloured stamina in the middle, placed in a cup, consisting of three leaves. The pistil is placed in the middle of the flower, and turns to a roundish prickly fruit, of a greenish yellow colour. It grows in meadows, and by the sides of high-ways. The leaves are without acrimony; but the roots are said to cool and moisten. It is looked upon as an antiscorbutic plant, and the fresh leaves are eaten in some places as a sallad.

CICLORIUM, *wild Succory*, has a root a foot in length, and about as thick as a man's thumb, with a few fibres, and full of a milky juice. The stalk is strong, hairy, branched, and grows to a cubit and a

half high, with leaves like those of dandelion, but larger, and they are hairy, and of a dark green colour. The flowers consist of many bluish semi-florets, placed upon an embryo, contained in a calyx, which being contracted, turns to a capsula, full of angular, naked, short seeds. The leaves and roots are bitter, and it not only grows wild, but is planted in gardens, and flowers in June. The fruit, leaves, and flowers, are in use, but the wild is better than the garden succory. Some use it as a sallad, when young. It is accounted good to resolve thick clammy humours, and to strengthen the solid parts, as well as to temperate the hot intemperaries of the viscera; for which reason, it has been given in recent obstructions of the liver, and against the jaundice. The juice taken in large quantities, so as to keep up a gentle diarrhoea, and continued for some weeks, has been found to be excellent against the scurvy, and other chronical disorders. The dose of the juice is four ounces.

CICUTA, *Hemlock*, has a root a foot in length, and as thick as one's finger, and before the stalks are produced, solid, and before they are grown, fungous. The stalk is streaked, fistulous, smooth, and grows to the height of three cubits and upwards; some are greenish, others reddish, and others again spotted like serpents. The winged leaves are cut into many minute segments, and nearly resemble those of parsley, for which it has been often taken white young. The flowers are collected in umbels, on the top of the stalks, and are rosaceous, consisting of five white petals, in the shape of hearts. The calyx turns to a globous fruit, containing two small seeds, gibbous on one side, and streaked on the other; and of a palish green colour. The whole plant has a disagreeable strong smell. We have several histories both of its good and bad effects, which render it probable, it was not the same plant that was eaten. We shall take no notice of the properties ascribed to this plant by Dr. Stork; for, though we greatly admire that gentleman, and believe what he says respecting *Hemlock*, and its effects in Germany, yet we have the mortification to find it does not produce the same effects in England. Outwardly it is sometimes applied to hard and scrophulous tumours, and to reduce the size of women's breasts, when they are grown too large; as also to keep back the milk in those that do not give suck.

CINARA HORTENSIS, the *Artichook*, has a thick strong root, with leaves a foot, or a foot and a half in length, divided into several broad segments, beset with a hairy down. At the top of each branch there is a turbinated head, surrounded with large acuminate scales, which are fleshy, and of a bluish green colour, and are very thick at the bottom. The scaly head or calyx being taken off, there are seen underneath flowers, consisting of many florets, of an elegant greenish purple; which are divided into five parts, and placed upon embryos; each of which turns to an oblong swelling seed, covered with a smooth ash coloured rind, and furnished with long down. The lower part of the cup or placenta, is fleshy, and is the part which is eaten.

CARDONES, the *spiny Artichook*, differs in nothing from the former, but in having prickles at all the corners of the leaves and flower cup.

The manner of propagating the first sort, is from slips or suckers, taken from the old roots in March, which, if planted in a good soil, will produce large fair fruit in the autumn following. The prickly artichook, or chardon, is propagated by seed in the middle of March, which should be sown in an open bed of light rich earth. When the plants appear above ground, they should be carefully weeded, and in dry weather often watered. In the middle of May, they will be fit to transplant into beds of light rich

rich earth, placing them in rows a foot asunder, eight inches distant from each other, observing to water them constantly, till they have taken root. In the beginning of July, they will be strong enough to plant out for good, in a spot of light rich ground, placing them in rows of four feet distant each way, observing to water them constantly as before, till they have taken root. In August they will be fit to tie up with hay bands, in a dry day, bringing the leaves as close together as possible, without bruising them. Then with a spade the earth must be banked up round the plants, leaving about ten inches, or a foot of the tops uncovered, taking care that the earth does not get into the middle. As the plants advance in height, they must be earthed up from time to time; for, if they thrive kindly, they will grow to the height of four feet, and will, when taken up for use, be near three feet, when trimmed of their outer leaves; for the tender branched part is only valuable. This by some is accounted a great delicacy.

Some eat the flesh of the smooth Artichoaks with salt and pepper, they being thought proper to help digestion. As for their physical uses, they are not said to have any, only the roots are commended to promote urine.

CITREUM CITRUM, *five* MALUS MEDICA.

The *Citron tree* is called MALUS MEDICA, because it was first brought into Europe from Media; it is of a moderate height, with a branched spreading root, yellowish without, and whitish within. The trunk is slender, the wood white and hard, and the bark of a pale green. The boughs are numerous, long, slender and tough, and the oldest of them are of a light yellowish green, and armed with pale prickles; but those that are more recent, are of a beautiful green. The tops of the branches are tender, and of a brownish red green, as well as the leaves, which are of the size of those of the walnut-tree, generally blunt, but now and then acuminated, and they are three times as long as they are broad; the lower part is not so green as the upper; and the edges are a little serrated. The tree is always clothed with them, both winter and summer, and when they are held up against the sun, they appear to have holes in them, like St. John's wort, or rather full of transparent specks. The flowers grow on the tops of the branches, and are rosaceous, with fleshy petals, which are generally five in number, and stand almost upright; without they have a reddish blush, but are white within, and placed in a ring. The calyx is small, and divided into five segments, and under the yellow apex there are a great many stamina, and part of the flowers are fruitful, and part barren. Among the stamina there is a longish pistil, the rudiment of the fruit, and those flowers that are without never produce any. The shape of the fruit is oblong, but sometimes globous, and some terminate in a point, while others are blunt; the surface is wrinkled and tuberose, and is often nine inches in length, and upwards. The size is different, as well as the weight; for some weigh six, nine, and even thirty pounds. The outer rind is tough, thin, bitter, and hot, and the colour is at first green, which turns to that of gold, when ripe; the inner or white rind is thick, firm, sweetish, with a little acidity. Within it is divided into several cells, full of an acid juice; the seeds are numerous, for sometimes an hundred and fifty have been found therein; they are oblong, half an inch in length, and sharp at both ends; they are bitter, yellow without, covered with a streaked skin, and contain a double white kernel. In hot countries both flowers and fruit may be seen on the tree at the same time, as well in the spring as the autumn; but they are more plentiful in the last.

CITRONS are not used as an aliment, but as a

No. 36.

saucy, and are cut into small slices, as we do lemons, to garnish the dishes, and to squeeze upon the meat. The acid is very agreeable, excites a weak appetite, and helps digestion, when used moderately. The outward rind, on account of its hardness, is not easy of digestion. It is an excellent remedy against the scurvy, and is a kind of specific to cure that disease, as well as the juice of oranges and lemons; when the gums of patients, afflicted with that disease, are ulcerated, this juice will cure them. The juice is also good in burning and malignant fevers, to quench thirst, and to restrain the heat and effervescence of the blood. Besides, the juice of citrons is diuretic, cleanses the kidneys of small gravel, and restrains vomiting, proceeding from bilious humours. The flowers, as well as the leaves, have an exceeding fine refreshing smell, though they will not prevent contagion on this account, as some pretend. The outer yellow bark has also a very fine aromatic smell, because it has a prodigious number of vesicles full of essential oil. Being chewed, it mends the breath, and by its bitterness strengthens the stomach; it powerfully discusses wind, and concocts crude humours in the stomach and intestines. However, the juice is not good in the pleurisy, inflammation of the lungs, spitting of blood, a consumption, and the like.

MALUS LIMONIA, the *Lemon tree*, is placed here on account of its affinity with the former, and is pretty tall, though not very full of branches; the leaves are like those of the citron tree, but shorter, and the prickles are more numerous, but less, and venomous. The flowers have much the same smell, and the shape of the fruit is likewise oval, but shorter, and not of so deep a yellow. Likewise, the rind is thinner, and they are much more full of juice, which is more acid than that of citrons. Upon which account it is thought to be more cooling, and more efficacious in hot diseases; in short, what has been said of the juice of citrons, may in most respects be applied to this.

COCHLEARIA HORTENSIS, *garden Scurvy-grass*, has a white, thickish, strait, fibrous and hairy root, with many roundish leaves, of a deep green colour, about an inch in length, which are hollow, almost like a spoon; they are thick, full of juice, and placed upon pedicles, a palm in length. The stalks are branched, upright, smooth, a cubit in height, and have leaves that are more jagged than those next the root; they are also longer, and without pedicles. The flowers have four petals, which are white, and in the form of a cross, with a calyx, consisting of four leaves, and a pistil that turns to a membranaceous round fruit, the sixth part of an inch in length, and composed of two cells, full of small, round, reddish seeds. But a distinction ought to be made between the garden and sea scurvy-grass; for the leaves of the former are always roundish, and of the latter sinuous. It is propagated by sowing the seeds at the latter end of July, soon after they are ripe, in a moist shady spot of ground. When the plants are come up, they should be thinned so, as to be left at four inches distance each way, and in the spring they will be fit for use; for those that are suffered to remain will run up to seed in May. They must be sown every year.

This plant has its English name from its virtue in curing the scurvy, against which it is accounted a specific. In some parts of England they brew an ale therewith, which is recommended by many to cure the same distemper. However, it is more effectual when mixed with sorrel, or some such acid herb, because of itself it is too hot, and if used too freely, will produce bad symptoms. The people that inhabit cold countries, are not ignorant of this mixture, for they have learnt by long experience, that scurvy-grass, and sorrel together, make an excellent remedy

remedy against this disease. Scurvy-grafs is not ufeless in other difeases; for it is excellent in recent obstructions of the viscera, in the green sickness, and some sort of asthma; but the dried leaves are not near so valuable as the fresh. The dose of the leaves, in decoction, is from a pugil to a handful, and of the juice from one ounce to three. Externally it is good in scorbutic disorders of the mouth, in the bloody swelling of the gums, and to fasten loose teeth, the gums being rubbed with the juice, or held in the mouth as a gargle.

COLCHICUM, *meadow Saffron*, whose flowers appear, near the beginning of autumn, before there are any leaves. These flowers consist of a single petal, which proceed from the root itself, and are in the form of a very small white tube, divided into six segments. They are somewhat like the florets of saffron; but of a lighter colour, with internal stamina, of a pale yellow, and a pistil arising from the bottom of the flower, and terminating in slender hairs. In a day or two's time they begin to wither; but in the following spring, three or four oblong, broad, smooth, flat leaves, shoot out, like those of the white lily. Between these are seen three or four thick, oblong, triangular bladders, like pods, divided into three cells, which open when they are ripe, and are full of a reddish, black, roundish seed. The root is bulbous, turbinated, but flat on one side, on which is a furrow, when in flower, that does not appear at any other time. It is covered with a blackish coat, and has a few fibres at the bottom. The bulb itself is fleshy, white, and when fresh, it pours out a milky juice as soon as taken out of the ground; but when it is dried, it is blackish without, reddish within, and of a sweetish taste, with a little bitterness. The smell of the whole plant is strong and nauseous. Both antients and moderns agree, that the root is poisonous, and those that eat it feel an itching all over the body, with a biting pain of the internal parts, and of the stomach, with great heat, which afterwards turns to a bloody flux.

CONSOLIDA MAJOR, the *greater Comfrey*, has thick fleshy roots, divided into several parts, black without, but white and clammy within. The stalks grow to the height of a cubit and a half, and are light, hairy, rough, and winged. The leaves are two spans in length, and a palm in breadth; they are of a dark green, rough, hairy, and sharp at the point. The flowers grow at the top of the branches, and are placed in elegant rows, and before they open are rolled up like the tail of a scorpion; they are pendulous, consist of one flower, in the shape of an oblong funnel, and are of a whitish or purplish colour; they are a quarter of an inch in length, and slightly divided into five segments; the cup is also divided into five parts, and has a long pistil of the same colour with the flower, which turns into four seeds, that are black and shining, and resemble vipers heads. It grows wild on the sides of banks and rivers, in several parts of England, and may be propagated by sowing the seed, or parting the roots in autumn, which is best. They should be planted about eighteen inches asunder, that they may have room to spread. The root is only in use, and has the same qualities as that of marsh-mallows. The dose of it in powder, is to a drachm, and in decoction or infusion to an ounce. It is commended in ulcers of the lungs, and other disorders that proceed from the acrimony of the humours.

CORIANDRUM, *Coriander*, has a slender, white, single root, with a few fibres; as also a single, slender, round, smooth stalk, full of pith, that is branched, and rises to the height of a cubit and a half. The lower leaves are broad, and conjugated, but the upper are deeply cut into five segments; the flowers grow in umbles, at the top of the branches, and are rosaceous, and of a whitish pur-

ple colour; they consist of five petals, in the shape of a heart, with a calyx that turns to two seeds, that, when together, make up a whole sphere; they are green at first, but afterwards of a palish yellow. The smell of the whole plant is strong and aromatic; but that of the seeds becomes more mild, and they have a sweet agreeable taste. This plant is propagated by sowing the seeds early in the spring, in an open situation, and in a bed of good fresh earth; when the plants are come up, they should be hoed out to about four inches every way. The seeds have a carminative virtue, and are good against catarrhs, flatulencies, worms, the cachexy, and slight obstructions of the glands. The dose of the seed, in powder, is from a scruple to a drachm.

COTONEA MALUS, the *Quince tree*, is of several kinds; as the *Pear Quince*, the *Apple Quince*, the *Portugal Quince*, the *Quince tree, with oblong, smooth, sweet fruit*, the *Quince tree with lesser oblong, downy fruit, which are not eatable*, and the *common Quince tree, with narrow leaves*.

It is a dwarf tree, with a branched root, and is covered with a brown bark; it is sometimes strait, and has many slender branches on the top. The leaves are roundish pointed, and of the size of those of the apple tree; they are not cut on the edges, and on the lower part they are covered with a soft down, but on the upper they are greenish and smooth. The flowers grow single, and are rosaceous like the wild rose, consisting of five roundish petals, half an inch broad, and of a flesh colour; in the middle there are many purple stamina, with yellow apices, and the flower cup is composed of five greenish, hoary, villous leaves, which, when the fruit is grown, appears at the top thereof. The fruit is of different shapes, which have been above taken notice of; the seeds are in the middle of the quince, and are like those of pears; but they are rendered slippery by a sort of slime that covers them. When quinces are unripe, they are seldom or never eaten, especially raw; but when they are boiled, they are very well liked by some. They are greatly astringent, strengthen the stomach, and may be of some use in all sorts of fluxes. The use of quinces is very well known for the making of marmalade; the seeds are so mucilaginous, that an ounce of them will render three pints of water thick and ropy, like the white of an egg. A spoonful of the marmalade is good in coughs, for it incises clammy phlegm, and causes expectoration; and it is the more valuable, because those that refuse other medicines will take this.

CUCUMIS SATIVUS VULGARIS, the *common Cucumber*, has strait roots, with many white fibres, and thick, long, branched, hairy stalks, creeping on the ground, on which are leaves alternately disposed, a palm or two in breadth, serrated on the edges, and rough to the touch. They are furnished with clasps, and the flowers proceed from the places where the leaves join to the stalks, which are in the form of a bell, divided into five segments, and half an inch in length. They are of a pale yellow, and some are fruitful, others barren; the fruitful have an embryo, which turns to a fruit that is sometimes six inches long, and is extremely well known. The seeds only are in use, and are reckoned among the four greater cold seeds. As for the flesh or pulp, it is unfit for nourishment, and is generally offensive to the stomach, especially if not corrected with a good deal of pepper, as well as vinegar. However, they agree extremely well with some who eat them frequently, without any bad consequence. The seeds are cooling, and sometimes emulsions of them have been prescribed in burning fevers, a fit of the gravel, and heat of urine.

CUCUMIS AGRESTIS, *wild Cucumber*, has a root two or three inches thick, and divided at the bottom into various fibres; it is white, fleshy, and

has a bitterish and nauseous taste. The stalks lie on the ground, and are rough, thick, and furnished with leaves above a palm in length, that are roundish, acuminate, and have ears at the base. The flowers proceed from the hollows where they join to the stalk, and consist of a single petal in the shape of a bell, which is deeply divided into five parts, and is of a yellowish colour with greenish veins. The fruit grows to two inches in length, is in the shape of a cylinder, and covered over with rough studs. It is divided into three cells full of a bitter juice, and when ripe, they pour it out upon the slightest touch in a violent manner with the slippery seeds, which are broad, smooth, and blackish. It grows in the southern parts of France, near the highways and among rubbish, and is also planted in gardens, not only for variety, but for diversion upon the above mentioned account. It may be propagated by sowing the seeds in the spring in an open warm border; and, when the plants are come up, they should be transplanted into an open bed, about six or eight feet distant, because they creep very far. The fruit is ripe in autumn, and the seeds will sow themselves without any farther trouble. Elaterium is made of the juice of the ripe fruit, and is a most violent purge, and particularly evacuates serous humours both upwards and downwards; for which reason some prescribe it in a dropsy, and give half a grain at first, and afterwards from two or three to five; however, it should be exhibited very cautiously.

CUCURBITA, *the Gourd*, has stalks as thick as one's finger, that run along the ground, or climb by the help of clasps; the leaves are round, and are from a foot to a foot and a half broad, and covered with a down, as well as a little crenated at the edges. The flowers proceed from the hollows where the leaves join to the stalk, are white, and in the shape of bells; they are cut into five segments, but so deep that they seem to be so many petals. Some of the flowers are barren, others fruitful, which last have an embryo that turns into a fruit, which is sometimes two yards long; but this is very rare. It has a thick neck and a moderate belly; and, when ripe, has a hard rind, of a yellowish colour, with a white tasteless pulp, or flesh, that is pretty spongy. It is divided into five cells, containing oblong flat seeds, almost an inch in length; but have sometimes a border round them. There are four sorts, namely, the *Long Gourd*, with a soft leaf and a white flower; the *Sickle shaped Gourd*, with a soft leaf and a white flower; the *flat Gourd*, with a soft leaf and a white flower, commonly called *Squashes*; the *bottle shaped Gourd*, with a soft leaf and white flower. There are several other varieties every year brought from America; but the seeds will not produce fruit of the same shape for two years together. They may be all propagated by sowing the seeds on a hot bed; when the plants are come up, they should be removed to a moderate bed; and when they have got four or five leaves, they should be transplanted into holes made upon an old dunghill; but they should be allowed a great deal of room to creep, because some have run forty feet from the holes; and if the side branches were permitted to remain, they would overspread twenty rods of ground. The seeds are numbered among the four greater cold seeds, and emulsions made therewith temperate the acrimony of the urine, and often procure rest.

CUPRESSUS, *the Cypress tree*, is of five kinds, namely, the *common Cypress tree*, the *male spreading Cypress*, the *Virginian Cypress*, with leaves like *Acacia*, that fall off in winter, the *spreading Portugal Cypress* with smaller fruit, and the *American Cypress* with the least fruit, commonly called *white Cedar* in America. The first sort has a strait thick trunk, palish, and sometimes reddish, and a very sweet smell. The male

has a spreading top, but in the female it is collected as it were into a point. It is an ever-green, and the leaves are like those of savine, the shoots being very small, and seemingly covered with scales. The catkins consist of very small leaves, or scales, and under them are apices that pour out an extremely fine powder; the fruit grows on other parts of the tree; this is roundish, and composed of many woody tubercles; and in the clefts between them there are reddish, hard, angular seeds, round at one end and sharp at the other. It is very common in many of the old gardens in England; but at present is not much in request, though for what reason is hard to say. These trees are all propagated from seeds, which should be sown early in the spring, on a bed of warm, dry, sandy earth, fitting the same earth over them to half an inch thick; in a month's time the young plants will appear above ground, and should be often watered in dry weather. In two years time they will be strong enough for transplantation into a nursery, and the best season is the middle of April, in a cloudy day, at the distance of eighteen inches in rows, observing to close the earth well to their roots. They may remain here three or four years; and when they are planted out for good, it should be at the distance of twenty feet every way, taking care not to shake the earth from the roots.

CYANUS, *Blue-bottle*, has a woody fibrous root, and stalks that sometimes rise to the height of a cubit and a half, which are angular, hollow, covered with down, and branched. The lower leaves are sinuated, not much unlike those of dandelion; but the rest are narrow and long, with a single nerve running through the whole length. The flower has a scaly hairy cup, and the disk is almost flat, but the outer florets round the border are large, tubulous, and deeply cut; the inner florets are less, and the colour of them all is generally blue, though sometimes they are of other colours. The first are always barren, but the others are succeeded by a single naked seed. It increases greatly by its creeping root, and is only fit for large borders under trees, or in wildernesses, because it will overspread the plants that grow near it. They are propagated by taking off sets from the old roots, either in spring or autumn, and will grow in any soil or situation.

CYCLAMEN, *Sow-bread*, has a thick, globular, fleshy root, but somewhat flattish, white within, and blackish without. It has a pungent, burning, disagreeable taste, and from it proceed leaves that are almost round, growing on pedicles a palm in length; they are pretty much like those of cuckow-pint, but not so thick, and are of a blackish green above, with white spots; but below they are purplish, and a little sinuated on the edges. The flowers have long tender pedicles, and consist of a single globous petal divided into five or six segments, that turn down almost to the bottom; they are sometimes of a light, and sometimes of a dark purplish colour, with a sweet smell; the pistil is fixed in the hinder part of the flower, like a nail, and when the flower falls off it curls and bends down to the ground, where it turns to a globous membranaceous fruit, full of oblong angular seeds, adhering to a placenta. These being sown always turn to a root, from whence the leaves afterwards proceed; but it does not flower till autumn, and then it is before they have any leaves. There are several sorts, and particularly one with a white flower; they are both propagated by sowing the seeds soon after they are ripe, in tubs of fresh earth, and in four or five years time they will begin to flower. At first the roots are small, and will produce but few flowers; but they will grow to upwards of fourteen inches in diameter, and then they will produce above an hundred flowers. When the root is dried it will lose its acrid taste, and yet it will

will continue to be a violent purge. Country people will take a drachm of it in powder, and half an ounce in decoction; but the internal use of it is not very safe. However, outwardly, it is recommended against hard scirrhus and scrophulous tumours, when applied in the form of a cataplasim.

DAUCUS CRETICUS, *the candy Carrot*, has a long root, about as thick as a man's finger, and has a taste somewhat like a parsnip; the stalk, which is round, streaked, and hairy, grows to the height of about nine inches, on which there are downy ash coloured leaves, divided into narrow segments; however, they are sometimes smooth, and of a blackish green colour. The flowers grow in umbels at the top of the stalks, and are small, rosaceous, and consist of five white petals, whose calyx turns to a fruit composed of two oblong streaked seeds, that are gibbous on one side and flat on the other; they are hairy, and in shape resemble lice.

DENS LEONIS, *Dandelion*, has a root as thick as one's little finger, and the leaves are oblong, acuminate, and lactescent, with deep incisions on the edges like wild fuccory, but are smoother, and lie on the ground. It has no stalk, and the pedicles are naked, fistulous, round, and above a palm in length; though there is sometimes a little hair, which comes readily off; on these the flowers are placed, which consist of many petals that open in the form of a marygold, and are of a yellow colour. The cup of the flower is smooth and divided into many parts, without which there are four or five green leaves that turn backwards; the semi-florets in the middle have each their proper embryo, and turn to a reddish or citron coloured seed, furnished with long hairy down. It is accounted an aperient, and to open the obstructions of the viscera. Boerhaave is of opinion, that, when it is used for a considerable time, it will dissolve almost all kinds of coagulations, and open the most obstinate obstructions of the viscera.

DIGITALIS, *Foxglove*, has many slender fibrous roots, with a stalk that sometimes grows to two cubits in height; it is thick, angular, hairy, reddish, and hollow, with oblong, acuminate, hairy leaves, serrated on the edges, of a blackish green above, and hoary below. Those at the root have long pedicles, and those at the stalks are placed without any regular order. The flowers are disposed in a long spike, and always pendulous, growing on one side of the stalk, with short hairy pedicles; they consist of a single petal, and somewhat resemble the finger of a glove, from whence it has its name; but it is open at the top, and has, as it were, a lip on each side; it is of a purple colour, excepting the lower part, where it is whitish or flesh coloured. In the lower part of the flower there are purple or white crooked stamina, with apices of a saffron colour. The pistil is slender, purplish, fixed in the back part of the flower, like a nail, and turns to a fruit, or pod, which ends in a point and opens in the middle, it being divided into two cells full of small, angular, reddish seeds; the cup of the flower is generally composed of five leaves. This plant is by many thought to be poisonous, and yet there are country people who give it as a purge in agues; but it works very violently. Some recommend it externally against scrophulous swellings, and for that purpose set the flowers in the sun in May butter, in order to extract their virtues, and this is used as an ointment; but it must be continued a long while.

DRACUNCULUS, *five* DRACONTIUM, *Dragons*, or *the many leaved Arum*, has a root that lies deep in the earth, which is almost of an orbicular form, and fills the palm of the hand, with many white capillaments and a yellow rind. The stalk is single, strait, and thicker than one's thumb; it grows to a

cubit and a half high, and is round, smooth, and of several colours, like the skin of a serpent. The leaves have pedicles nine inches in length, and are divided into digitated segments, which are six or seven in number or upwards; they are oblong, narrow, smooth, shining, and there are shafts not so thick as a man's little finger, and at the top there is a vagina, or sheath, a foot long, of an herbaceous colour without, but within of a reddish purple; when it is unfolded, it turns to a flower with a single petal, in shape like an ass's ear, within which there is a blackish, long, thick pistil, bigger than that of arum, and ends in a sharp point; at the base there are a collection of several apices and embryos, each of which turns into a globous juicy berry, disposed like a bunch of grapes, and are all at first green, and afterwards red; they contain a hard seed or two that are somewhat wrinkled. The berries have a hot biting taste. It is cultivated in gardens, and is propagated by the knobby roots, which in two or three years time will afford many off-sets. The best season for transplanting them is in autumn, after the decay of the leaves; they should be set in an open place and in a light soil. The root and leaves have the same virtues as arum, and are said to dissolve gross humours in the lungs and viscera, to open obstructions, and promote urine. The dose of the dried root, in powder, is from one drachm to two. Externally, the root is an excellent remedy against inveterate ulcers; but the fruit is more powerful than the leaves or root.

DRACUNCULUS PRATENSIS, *meadow Dragon*, sometimes grows to three cubits in height, and has a crooked geniculated root, furnished with large long fibres; the stalk is round, smooth, fistulous, slender, and yet pretty stiff. The leaves are placed in no regular order; they are serrated with sharp rough teeth on the edges, and are of a blackish green shining colour, of a hot taste, but milder than pellitory of Spain. The highest part of the shaft is angular, hairy and divided into sprigs, on which are umbellated white radiated flowers, twice or thrice bigger than those of yarrow; their disk consists of several florets set close together, and divided into five segments; but the crown of semi-florets is placed upon embryos in a slender short cup, that afterwards turns to slender seeds; it flowers in July, and the root and leaves have been sometimes in use. The root being eaten is said to purge the head and cure the tooth-ach. Some eat them in fallads.

DRACUNCULUS ESCULENTUS, *Tarragon*, grows to the height of two cubits and upwards. At first the leaves are divided; but when they are full grown, they become like those of flax or hyssop, of a shining blackish green colour. The flowers grow on the top of the branches in bunches, and consist of florets so small that they are hardly visible; however, upon examination, they appear to be tubulous, and divided into five parts at the top, under which are embryos placed in a scaly cup; each embryo turns to a small naked seed. The whole plant is very acrimonious, is aperient, diuretic, and proper to open obstructions; being chewed it provokes spittle like pillitory of Spain. It is mixed with fallads by some to correct the coldness and crudity of other herbs, and because it is good for a cold stomach.

EBULUS, *dwarf Elder*, is somewhat like common elder, but seldom grows so tall as a man; the root is long, fleshy, white, spreading, and of a bitterish, subacid, and nauseous taste; the stalks are herbaceous, angular, streaked, and geniculated, with frequent joints, and are pithy like common alder; the leaves consist of three or four conjugations, with a single leaf at the end; they are longer than the leaves of common alder, as well as sharper, and are serrated on the edges. The flowers are small, grow

in umbels, are white, and consist of a single petal divided into five segments; they have five white stamina, and as many rusty coloured apices; when the flowers are fallen off, the flower cups turn into berries, which are black when ripe, and the juice will colour the fingers purple. It is found wild in some counties of England, but near London is cultivated for use. It multiplies exceeding fast, and, if permitted, will soon over-run a large spot of ground. The off-sets of these roots may be transplanted any time from September to March, and will grow in any soil or situation. The leaves of this plant are bitterish, and the berries very bitter, with somewhat of an astringency. It is a strong purge; but the roots are most powerful as well as its bark. They have been frequently given in the dropsy, but with different success; however, it should not be exhibited at all, except to those that have strong constitutions. The powder of the seeds is given to a drachm; but a rob made of the berries is the most proper to purge off water in dropical patients, and may be exhibited from half an ounce to an ounce.

ENDIVIA, *five* **INDYBUS**, *Endive*, is of three sorts, the *broad leaved* or *common Endive*, the *narrow leaved* or *lesser Endive*, and the *curled* or *Roman Endive*. The first has fibrous roots full of milk, and the leaves spread on the ground before the growing of the stalk. The leaves are like those of lettuce, and now and then crenated on the edges, and a little bitterish: those that grow on the stalk are like those of ivy, but less. The stalk rises sometimes to a cubit and a half in height, and is smooth, streaked, light, and divided into many crooked branches, which pour out a milk when wounded. The flowers and seeds are like those of fuccory. *Narrow leaved Endive* differs only from the former in having more narrow leaves, and a more bitter taste. The *Roman* or *curled Endive*, has leaves that are bigger than those of the common, which are sinuated on the edges; the stalk also is larger, thicker, and more tender, and the seeds are black. The first and second sorts are now disused in kitchen gardens, as being vastly inferior to the curled kinds. The seasons for sowing the seeds are in May, June, and July, at four or five different times; but that which is first sown is very apt to run to seed, especially if the autumn prove warm and dry; however, it is necessary to have a little sown in May for the first crop. They should be sown in an open situation, and in a good rich soil, but not too thick. When they are come up, and grown to about two inches high, they must be transplanted into another good open spot of ground, at about ten inches distant every way, observing to cut off the largest leaves before you plant them, as also to water them constantly every other evening until they have taken fresh root. Some of the largest must be tied up with osier twigs to blanch, which should be done in a dry afternoon. You must first gather up all the inner leaves of the plant regularly into one hand, and then those on the outside that are sound, pulling off all that are rotten and decayed, placing them as near as possible in the natural order of their growth; then tie it up with a twig very close, about two inches below the top, and about a week after go over the plants again, and give them another tie about the middle. This must be done for the two first sowings; but those of the latter sowings should be taken up in a very dry day, and, with a sharp pointed dibble, plant them into the sides of trenches of earth, which are laid very upright, sideways towards the sun, with the tops of the plants only out of the ground, so that the heavy rains may run off, and the plants be kept dry and secured from frost. They will be fit for use in about a month's time, after which they will not keep good long, and therefore fresh ones should be put into the

No. 36.

trenches every fortnight at least, that you may have a constant supply. The blanched leaves are more tender and more agreeable to the palate than the green. They are cooling and aperient, and serve to temperate the heat of the blood and bilious humours. They are good in the jaundice and bilious fevers, and four ounces of the juice is a dose.

ENULA CAMPANA, *Elecampane*, has a thick fleshy root, of a dusky colour without, but white within, with an acrid, bitterish, aromatic taste. The leaves are a cubit in length, and almost a span broad; they are of a pale green above, hoary underneath, crenated on the edges, sharp at both ends, and soft to the touch. The stalks rise to three or four cubits in height, and are strait, villous, streaked, branched, and support radiated gold coloured large flowers, whose florets are hermaphrodites, but the semi-florets are female; the embryoes which are placed on a naked placenta are crowned with down, and are all included in a scaly cup. Elecampane grows wild in moist fields and meadows in several parts of England, and is cultivated in the gardens near London. It may be propagated by seeds, or with the small off-sets furnished with buds at the top. The seeds should be sown in a moist bed of light earth soon after they are ripe, and they generally remain in the ground till the following spring; when the plants appear, they should be weeded and watered in a dry spring; should remain in the bed till the Michaelmas following, and then be transplanted in rows about a foot asunder, and nine inches distant in the rows, making the holes deep enough, and putting the crown of the root just under the surface of the ground; then tread the earth gently about them with your feet. The roots will be fit for use the Michaelmas following. The root is of great use as well recent as dry: it opens obstructions of the glands, helps catarrhs, and has often been found good in atrophies. It is sudorific and diuretic, and has been found of service in feverish disorders. It is likewise good in difficulty of breathing, and the moist asthma. The dose of the fresh root is from half an ounce to an ounce in decoction, and of the dry, in powder, from a drachm to two drachms. It also helps digestion, by restoring the lost tone of the stomach, and by inciding and expelling the impurities contained in the stomach and intestines. For the same reason, it is good in cholic pains proceeding from wind, and cleanses the kidneys. Spirituous liquors extract its virtues much better than the watery.

ERUCA, *Rocket*, has a white, woody, slender root, with hairy stalks that rise to a cubit, or a cubit and a half in height. The leaves are like those of mustard, they being long and narrow, with deep incisions on each side. The flowers at the top of the stalks consist of four petals, in the form of a cross, of a whitish yellow colour, with blackish streaks. The cup is hairy, from whence rises a pistil, that turns into a pod like that of mustard, but longer, with a partition in the middle. It is divided into two cells full of yellow seeds, larger than those of mustard, and not so round. The smell of this plant is strong and disagreeable, as well as the taste. There are several sorts of rocket that are planted in physic gardens, but are of no great use. They may be propagated by sowing their seeds in the spring, on a bed of light earth, where they will soon come up, and will be large enough for use in a short time; when young, they are eaten by some as a salad. This plant is said to excite the appetite and help digestion, to strengthen the stomach, and to promote urine.

ERYSIMUM, *Hedge Mustard*, has a single, white, woody root, about as thick as one's little finger, and the stalks rise to two cubits in height, which are round, firm, rough, and branched. The first leaves

are a palm in length, and are hairy, being divided into several triangular segments, of which the uppermost is the biggest. The flowers are small, and placed in rows on the branches; they consist of four yellow petals, in the form of a cross, with a hairy calyx consisting of four leaves. The pistil is changed into a pod half an inch or longer, which is horned and divided into two cells, containing many small bay hot seeds. It is accounted good in old coughs, the asthma, and other disorders of the lungs; for it not only dissolves viscid matter in the lungs and fauces, but also in the stomach and intestines, whence it is good in cholics proceeding therefrom. The dose of the leaves in decoction is a handful, and of the seeds, which are best, to a drachm. These last are good in a suppression and difficulty of urine; and some esteem them very much for their good effects against the gravel.

ESULA MINOR, *the lesser Spurge*, has a woody fibrous root, about the thickness of the little finger, which has a nauseous, acrid, pungent taste; the stalks grow to a cubit in height, and the leaves are placed very thick thereon; they are at first like those of toad flax, but afterwards grow much more slender and capillaceous. The flowers grow on the top of the branches as it were umbellated, and consist of a single petal, which is in the shape of a flower, and of a greenish colour, but divided into four segments. The pistil changes to a triangular fruit, in which are three cells containing three roundish seeds. The whole plant is full of milk, and grows by the way sides and in woods.

EUPATORIUM CANNABINUM, *Hemp Agrimony*, has a thick crooked root, with many large fibres; the stalks rise to two or three cubits high, and is strait, round, downy, of a purplish green colour; and also full of white pith. The leaves grow thick upon the stalks, and are like those of hemp, they being oblong, acuminate, and serrated on the edges. The flowers are collected into umbels on the top of the branches, and consist of many tubulous florets of a purplish colour, divided into five parts at the top, with long capillaments or double pistils, placed upon an embryo in a long, round, scaly cup. The seeds are pappous, or furnished with a long hairy down. It grows in waters, and in watery places. It is said to be hepatic, aperient, and vulnerary; and the leaves have a very bitter taste, with a great degree of pungency. It is said to be greatly prevalent against the cachexy, and Boerhaave informs us, that it is the constant medicine of the turf-diggers in Holland against scurvies, foul ulcers, and swellings of the feet, to which they are subject. Many drink it like tea several times a day; and others give three ounces of the juice. Externally, the leaves and floret tops boiled in wine are good against watery swellings.

EUPHRASIA, *Eye-bright*, has a single slender root, with a few large fibres; the stalks rise to the height of a palm and a half, and are round, a little hairy, and blackish, with leaves about a quarter of an inch long, that are roundish, smooth, though a little wrinkled, and of a dusky green. They are placed by pairs opposite to each other, without any pedicles. The flowers grow on the top of the branches, and consist of a single whitish petal, streaked with purple and yellow lines, and divided into two lips. The upper lip is upright, cloven, obtuse, crenated, and hides a few stamina; but the lower is divided into three segments, in the shape of hearts. The calyx is divided into four parts, and contains a pistil fixed in the back part of the flower, like a nail, which turns to a fruit or flat capsula a quarter of an inch long, divided into two cells full of exceeding small, oblong, ash coloured seeds. It is common in mountainous and woody places. This plant has been greatly celebrated for curing disorders of the

eyes; but it is not acknowledged at present to have any such virtues. It is said to dissolve the thick gross humours, especially of the brain. The dose of the leaves, in powder, is from one drachm to three, thrice a day.

FABA MAJOR HORTENSIS, *Windsor Beans*, has a root that is partly strait and partly creeping, with a quadrangular stalk, that is light and has several ribs. The conjugation of the leaves are not exact; for there has been sometimes three, four, five, or more, of an oblong roundish shape, that are flat, of a bluish green, veinous and smooth. The flowers proceed from the hollows where the ribs join to the stalk, and, though several of them are together, they have but one pedicle; they are papilionaceous, and are succeeded by a long pod, so well known that it needs no description. There are several sorts of beans, as the *Mazen Bean*, which is the first and best sort of early beans at present known, and are brought from a settlement of the Portuguese on the coast of Africa, near Gibrona. The seeds of this sort are much less than those of a horse-bean, and if they are sown in October, under a warm hedge or wall, and are carefully earthed up as they grow, they will be ready for the table in May. The *early Portugal Bean* differs little from the former, though it is not so well tasted; but is commonly used by gardeners for their first crop. The *small Spanish Bean* will come up soon after the former, and is much sweeter. The *Sandwich Bean* comes up soon after the *Spanish*, and is almost as large as the *Windsor bean*; but, being more hardy, is commonly sown a month sooner. The *Toker Bean* comes up about the same time with the *Sandwich*, and, as it is a great bearer as well as that, it is now much planted. The *white and black blossomed Beans* are in great esteem by some; but all these sorts are very apt to degenerate, if their seeds are not preserved with great care. The *Windsor Bean* is allowed to be the best of all, and is the largest. It is seldom planted before Christmas, because it will not bear the frost so well as any of the former. Those that are planted in October will come up about a month after, and, as soon as they are two inches above ground, the earth should be carefully drawn up with a hoe to the stems; and this must be repeated two or three times, which will protect them against the frost; but, if the winter proves very severe, it will be proper to cover them with pease haulm, fern, or some other light covering, which must be taken off in mild weather. The *Horse Bean* delights in a strong moist soil, that lies quite open; for they never thrive well on dry warm land, or in small inclosures. The season for sowing these beans is from the latter end of February to the beginning of April, according to the nature of the soil.

With regard to the nature and faculty of beans, authors are not agreed; but the common opinion is, that they are windy and hard of digestion. Some have doubted the nourishing quality of beans; but innumerable experiments have established their credit beyond all contradiction. The meal of dried beans is reckoned among one of the four resolvent meals, and is used by some as a cataplasm, boiled in milk, to resolve and suppurate tumours. The water distilled from the flowers is looked upon as a cosmetic, and is still in use, to take away spots on the face.

FILIPENDULA, *Drop-wort*, has a fleshy blackish root, which terminates in several branches or fibres, and near the ends there are knobs, or bulbs, somewhat longer than an olive. There are several leaves that proceed from the root, which are finely cut into narrow segments, and are of a blackish green colour; the stalk is generally single, erect, and about a foot in height. It is streaked, branched, and has but few leaves, and the flowers grow on the top of the

the stalks in umbels; they are rosaceous; consist of six white petals, which are a little reddish on the outside; there are many stamina and red apices, placed in a cup consisting of a single leaf that has a great number of points. The pistil turns into a globous fruit, composed of eleven or twelve rough flat seeds, and are so placed together in a head, resembling a tub. It grows wild in many parts of England, upon heaths and commons. The leaves of drop-wort have an astringent, saltish, glutinous taste; the whole plant is said to incise and attenuate gross humours, and to carry them off by urine. The dose of the root, in powder, is a drachm, and some have looked upon it as a secret to cure the bloody flux, when given in wine or the yolk of an egg.

FOENICULUM VULGARE, *common Fennel*, has a perennial root, and is about as thick as one's finger; it is strait, white, and has a sweetish aromatic taste; the stalk rises to the height of three cubits, which is strait, round, streaked, geniculated, smooth, slender, and covered with a greenish rind; it is full of a spongy white pith, and divided into many twigs towards the top. The pedicles surround the stalk and branches like a sheath, from whence proceed the leaves, that are divided into slender segments, or capillaceous jaggs, of a dark greenish colour, with a sweet taste and smell. It is an umbelliferous plant; for the flowers grow in umbels at the ends of the branches, and are rosaceous, and consist of five yellow petals; the calyx turns to a fruit composed of two oblong thickish seeds, gibbous and streaked on one side, and plain on the other.

FOENICULUM DULCE, *sweet Fennel*, differs little from the former, only the stalk is not so high nor so thick, and the leaves are less; but the seeds are larger, streaked, whitish, more sweet, and less acrid. They are propagated by sowing the seeds soon after they are ripe, and when the plants are come up, they should either be transplanted, or hoed out, to the distance of sixteen or eighteen inches each way. The seeds must not be suffered to shroud on the ground; for then they will overrun every thing that grows near them. The Sweet Fennel is annual, and must be sown in March, in a warm soil and open situation. They should be hoed out at the distance of ten inches from each other, and in August the seeds will be ripe; soon after which the roots will decay. The best seeds are those that are brought from abroad, which are so cheap, that it is not worth cultivating here. These plants are diuretic, aperient, sudorific, stomachic, pectoral, and febrifuge. The root is numbered among the five aperient roots. The powder of the seeds is given from half a drachm to a drachm, with sugar in wine. The whole plant, as well as its seeds, is greatly cried up against dimness of the eye sight, especially for those that have hurt their eyes by reading in the night time; for which purpose the powder of the seeds should be taken every morning fasting with sugar. The essential oil is a great carminative, and from six to twelve drops, on a lump of sugar, are a dose. It is good against the flatulent cholic, and helps digestion. The use of green fennel with fish is very well known.

FOENUM GRÆCUM, *Fenugreek*, has a slender, white, single, woody root, from whence proceeds a stalk, that rises to the height of half a cubit, which is slender, green, hollow, and divided into wings or branches; and there are three leaves growing upon one pedicle, like those of meadow trefoil; they are slightly serrated on the edges, and are sometimes more broad than long; they are green on the upper side, and of an ash colour below. The flowers proceed from the places where the pedicles join to the stalk, and are papilionaceous and whitish, changing to pods a palm, or a palm

and a half in length; they are flattish, a little crooked, narrow and slender, with a long, light, slender, sword-like point; they contain many seeds that are yellowish, and have no very agreeable smell. They have a mucilaginous taste, and the meal made therewith softens, digests, ripens, discusses tumours, and eases pains.

FRAGARIA, the *Strawberry plant*, has a perennial reddish root, consisting of many capillaceous fibres, of an astringent taste. The pedicles are a palm in length, and are slender, hairy, and branched at the top, some of which sustain leaves, and others flowers; there are three leaves on every pedicle that resemble those of cinquefoil, which are veinous, hairy, serrated on the edges, of a greenish colour above, but whiter below. There are four or five flowers upon one pedicle, that are rosaceous, and consist of five whitish petals, with as many short stamina sustaining yellow apices. The pistil is globous, and placed in a cup composed of ten parts or segments. The pistil turns to a globous fruit, which when ripe is red, though sometimes whitish, and is very well known. It grows wild in shady places, and is cultivated in gardens. They are of several sorts, as the *common*, or *wood Strawberry*; the *common Strawberry with white fruit*; the *Hautboy*; the *Virginian Strawberry with scarlet fruit*; the *large Chili Strawberry*; the *globe Hautboy*; and the *Strawberry with a small greenish white fruit*. The first and second sorts are found wild in the woods, from whence they are transplanted into gardens, where the fruit is improved, the best season for which is early in the spring, if the weather proves moderate. The best soil for these plants is fresh loam, not over rich, and the ground should be well dug. It should be made quite level, and marked out into beds about three feet and a half wide, leaving a path between each bed two feet broad. In these beds may be planted four rows, and the plants should be at least eight inches asunder in the rows, when they are designed for the wood strawberry, for the others will require more room. If it is a dry spring, they should be well watered, otherwise there will be no fruit; and the beds must be well weeded from time to time. They will not continue to bear well above three years. Strawberries are cooling, quench thirst, loosen the belly, promote urine, and expel small gravel. They should be eaten with cream, because with milk they curdle upon the stomach. The roots and leaves are diuretic and aperient, for which reason they are recommended by some in obstructions of the viscera, and the jaundice.

FUNGUS CAMPESTRIS ESCULENTUS VULGATISSIMUS, the *common esculent Mushroom*, when it first appears is globous, after which it expands by little and little, and underneath there are reddish plates placed near together all round; on the upper part it is smooth and white; the flesh is extremely white, and it has a short thick pedicle. The smell and taste are good when it first appears out of the earth, and it should be gathered before it is expanded; for when it is older, it has a stronger smell, and is of a brownish colour. It grows almost every where in woods and pasture grounds after rain. They have now a method of cultivating it in gardens; in order for which some are to be sought for in August and September, and having found them you must open the ground about the roots, where you will often find the earth full of small white knobs, which are off-sets, or young mushrooms. These should be carefully gathered, preserving them in lumps with the earth about them. The beds to receive this spawn should be made with dung, in which there is plenty of salts. These beds should be made on dry ground, and the dung should be laid upon the surface; the breadth should be two feet and a half from the bottom, and

the length in proportion to the quantity of mushroom desired. The dung should be a foot thick, and covered with about four inches of strong earth; then lay more dung ten inches thick; and then another layer of earth, still contracting the sides of the bed so as to form it like the ridge of a house. This done, it should be covered with litter, or old thatch, to keep out the wet, and to prevent its drying. It must remain thus eight or ten days, and the spawn, which should be always kept dry till it is used, should be thrust into the bed after the covering is taken off, and another of earth put on, about an inch thick. It should be laid in lumps two or three inches asunder, and then covered with the same light earth half an inch thick, over which the litter must be laid again to keep out the wet. The spring and autumn are the best seasons for this purpose; for then the mushrooms will appear in about a month. The bed will continue good for several months, and produce great quantities of mushrooms; and they will likewise supply you with fresh spawn, which must be laid up in a dry place till the proper season.

GALEGA, *Goats Rue*, has slender, woody, white, fibrous, perennial roots, and stalks that rise to the height of two cubits and upwards, which are light, streaked, and divided into several branches. The leaves are winged like those of vetches, and there is always a single one at the end; but they are longer and terminate in a soft thorn. The flowers are of the papilionaceous kind, and are white, or of a whitish purple colour. It consists of the standard, the wings, and the keel; and the pistil becomes a long taper pod, containing oblong seeds, in the shape of a kidney. It grows wild in Italy, but with us is cultivated in gardens. This may be propagated either from the seeds, or by parting of their roots. The best season for sowing the seeds is in the beginning of March, in a light soil, and in an open situation; when the plants are come up, they should be well weeded, and, if they are too close, some of them should be pulled up, leaving the rest at eight or nine inches distant from each other. The next year these plants will flower, and produce ripe seeds. The roots may be parted into small heads, in order for their increase in autumn. It is accounted a great alexipharmic, and has been commended in pestilential fevers, and for the epilepsy in children. The herb may be eaten either crude or boiled, or a spoonful of the juice may be given for a dose. Some look upon this herb as a great preservative against the plague, and likewise affirm it to be good to kill worms.

GALEOPSIS, *dead Nettle*, or *stinking dead Nettle*, has a creeping root, with slender fibres proceeding from the joints; the stalks rise to the height of a cubit, or a cubit and a half, and are square, hairy, light, and branched. The leaves are placed by pairs opposite to each other, and are somewhat broader than the common nettle, but sharp at the points, and serrated on the edges; they are covered with a sort of down, and on the tops of the stalks and branches there are spikes of flowers, which consist of a single petal, which is labiated, and the upper lip is hollow like a spoon; but the under one is divided into three segments, of which the middlemost is the largest; the stamina, as well as the flower, are of a purple colour, with a strong disagreeable smell. The cup of the flower is in the shape of a funnel, divided into five parts, the pistil is fixed to the back part of the flower like a nail, and is attended with four embryoes, that turn to as many oblong seeds, which when ripe are black. It is said to be vulnerary, and that when the fresh leaves are bruised and laid upon old ulcers it will heal them in a short time.

GALEOPSIS ANGUSTIFOLIA FŒTIDA;

narrow leaved stinking dead Nettle, differs very little from the former in either form or virtues.

GALLIUM LUTEUM, *Ladies Bed-straw*, or *Cheese Rennet*, has a small, creeping, slender, woody, brown root, from which square stalks proceed to a cubit in height. The leaves are placed at the joints of the stalk, in a radiated form, and are five or six in number; they are long, narrow, slender, soft, and of a darkish green colour. From every joint proceed two branches, on which are flowers consisting of a single petal, in the form of a bell, which is expanded towards the upper part, and divided into four segments. The calyx turns to fruit composed of two dry roundish seeds. Some of the modern physicians commend it against the epilepsy, and give a drachm of the powder for a dose. of the juice four ounces, and a handful in decoction.

GENISTA, *Broom*, is a shrub that sometimes grows to be as tall as a man; the root is hard, woody, tough, yellow, and furnished with crooked fibres. The stalks are slender, woody, and many twigs proceed from them, that are angular, green, tough, and about them there are small, hairy, dark green leaves, sometimes growing three together, and sometimes single. The flowers that grow thereon are of a beautiful yellow, and papilionaceous, with crooked stamina, and saffron coloured apices; to which succeed flat broad pods, which are blackish when ripe, and full of flat, hard, reddish seeds in the shape of a kidney. It grows in barren grounds all over England. There are several sorts of these plants cultivated in gardens, and they may be propagated by seeds, which should be sown on a moderate hot bed in the spring; as soon as the plants are strong enough to remove, they should each be set in a pot filled with light earth, and it will be safest to plunge the tender kinds of them into a very temperate hot bed, where they should be shaded till they have taken root; then they should be inured to the open air by degrees; but in winter they should be placed in a good green-house, and in mild weather they should have as much free air as possible. Several of them are useful in dying, and therefore they have the name of dyers weeds. Common broom is intensely bitter, and the leaves; tops, and branches, decocted in wine or water, are useful in dropsies, and in all obstructions of the kidneys and bladder; for they partly purge off the serous humours by stool, and partly by urine. A drachm and a half of the seeds will purge very briskly, and sometimes vomit. In some places they mix the flowers with sallads, without any bad effects.

GERANIUM SANGUINEUM, *bloody Cranes bill*, has a red thick root, and many long thickish appendages, with a few fibres, and every year new shoots proceed from the roots. It has several stalks that arise to a cubit in height, that are reddish, hairy, geniculated, and divided into many wings. A pair of leaves proceed from every knot, which are divided into several parts, and are hairy and green above, but hoary below; there are oblong pedicles that proceed from their upper wings, which sustain a single flower, and is the largest of any that belong to this kind of plants; it is of a beautiful red colour, composed of five petals of the same colour, and ten small stamina, that are supported by five hairy, greenish, small leaves. The bill is in the shape of a pentagon, and contains swelling tailed seeds, which are thrown out by the twisting of the bill. There is another Geranium, called *Geranium Batrachoides*, *Crow-foot Cranes-bill with a blue flower*, which has all the characters of the former, except the colour. Bloody cranes-bill is styptic, and has been used in vulnerary decoctions, or broths. Doves foot cranes-bill

bill has the same virtues as the former, and a syrup made of the juice is commended against the bloody flux.

GROSSULARIA, *the common Gooseberry*, is a shrub; and has a woody root; it is sometimes two cubits high or higher, and is full of branches; with a bark, when full grown, of a purplish colour, and there are long sharp thorns at the rise of the leaves, two or three of which are placed together. These have short pedicles, and are of the breadth of a man's nail, or somewhat broader, and are lacinated or jagged. The flowers are small, and several of them proceed together from the same tubercle as the leaves, and have a very short, hairy, reddish pedicle; they are rosaceous, consisting of five petals of an herbaceous whitish colour, with a calyx consisting of a single leaf in the shape of a basin, and divided into five reddish segments bending downwards, with five stamina and a greenish pistil. The hinder part of the calyx turns into a globous berry universally known. There are several sorts of gooseberries, besides this, cultivated in gardens, as the *large manured Gooseberry*, the *red hairy*, the *large white Dutch*, the *large amber*, the *large green*, the *large red*, the *yellow leaved*, and the *striped leaved Gooseberry*. These are propagated by suckers taken from the old plants, or by cuttings, which is best. The best season for planting them is in autumn, just before their leaves begin to fall, always taking the handsomest shoots, that proceed from branches that bear the greatest quantity of fruit. They should be six or eight inches long, and planted in a border of light earth, about three inches deep, and exposed to the morning sun, observing to water them a little when the weather proves dry; when they begin to grow, the under shoots should be rubbed off, leaving only the uppermost and strongest. In October following, these plants will be fit to remove to an open spot of fresh earth, in which place they may remain for a year, and all the lateral shoots should be taken off, so as to leave the stem clear about a foot above the surface of the earth. In a year's time they may be removed to the place where they are to remain. The best season for transplanting them is in October. As to their physical virtues, nothing need to be said about them, they being only eaten for pleasure, or used to make gooseberry wine.

HEDERA TERRESTIS, *Ground Ivy*, has a creeping fibrous root, with slender, quadrangular, reddish, hairy stalks, on which the leaves are placed by pairs on long pedicles; they are roundish, an inch broad, hairy, and crenated; the flowers grow on the top of the stalks, and consist of a labiated single petal. The upper lip is divided into two segments, that turn back to the sides, and the lower into four segments, and the tube is variegated within with deep purple spots and lines, and the opening of the mouth is covered with a sort of white down. The pistil is slender and forked, and the calyx is oblong, narrow, streaked, and divided on the edges into five short segments, which, when the flower decays, has a swelling belly, containing four oblong, roundish, smooth seeds. The whole plant is opening, cleansing, discutient and vulnerary. It is excellent for wounds and ulcers of the viscera, and is good in the beginning of a consumption. The dose of the tops, reduced to powder, is from half a drachm to a drachm twice a day. It is also good against the gravel as well as the cholic. Ray affirms, that the powder, snuffed up the nose, will cure a violent headache. It is common about London to infuse the dried leaves in malt liquor, and then it goes by the name of gill-ale.

HEDERA ARBOREA, *common Ivy*, is well known in most parts of England, and sometimes grows very large, forming a sort of a tree; at other times fastening itself to trees, walls, houses, and churches. It

No. 36.

sends forth roots or fibres from its branches, by which it fastens itself to whatever is near it, from which it receives a great part of its nourishment; the leaves are angular, and the flowers consist of six leaves, that are succeeded by black berries, which grow in round bunches, each of which contains four seeds. The leaves are said to be heating, drying, and subastringent; but are seldom given inwardly, because they are offensive to the nerves. The berries purge upwards and downwards, and the leaves applied to corns will take them away in a short time. The gum has been treated of in the former part.

HELIANTHEMUM TUBEROSUM, *five HE-*
LIANTHEMUM INDICUM TUBEROSUM,
the Potatoe plant. One stalk or more rises from each root, which is green, streaked, rough, hairy, and attains the length of twelve feet or upwards, full of a white spongy pith. The leaves are many, placed in no order, and from the bottom to the top; are greenish, rough, broad, and acuminate like those of the common sun-flower, but not so much wrinkled nor so broad. The stalks soon after their rise are branched, and the leaves decrease in size from the bottom to the top. The flowers grow on the top of the stalks, and are of the size of marygolds, and radiated. The disk consists of many yellow florets, with a crown composed of twelve or thirteen streaked pointed gold coloured semi-florets, placed on embryos in a scaly villous cup. The embryos turn into small seeds, and the stalk emits several slender creeping roots, that spread themselves on all sides, between which there are many tuberose roots, sometimes adhering to the chief root, and sometimes connected to long fibres a foot distant from them. One root will produce thirty, forty, fifty, or more potatoes. These are reddish or whitish without, and consist of a whitish substance, or flesh, with a sweetish taste, and are often bigger than a man's fist. They continue in the ground all the winter, and the next year they spring again. This plant has been greatly propagated in England for more than fifty years past; for, though it was brought from America in 1623, it was not much cultivated before, because they were then thought only fit for poor people; but now they are in general esteem. It is propagated here by the roots, which if large are cut into pieces, preserving a bud or eye in each; but the best method is to plant the finest roots entire, allowing them a pretty large space of ground between the rows, as also each root, and then those that are produced will be large the following autumn. A light sandy loam is best, if not too dry or moist; it should be well ploughed two or three times, and the deeper the better. They are very nourishing, abate the acrimony of the blood and juices, and are consequently good in disorders of the breast. Some people in France eat them raw with salt and pepper.

HERNIARIA GLABRA, *smooth Rupture-wort*, and HERNIARIA HIRSHUTA, *hairy Rupture-wort*, are both small herbs that lie on the ground, and are divided into several branches that proceed from a small root, which descends directly downwards; the stalks are round, reddish, and full of joints, at each of which there are very small leaves, placed in pairs opposite to each other, less than those of dodder, and of a yellowish green colour. From the same joints there proceed many flowers that are small, yellowish or white, without petals; but there are many stamina. The pistil turns into a very shining small black seed, contained in an oblong streaked capsula, that was the calyx of the flower. It is a very mild astringent, and is likely to be of some service in a flaccid state of the viscera. The dose of this herb, in powder, is a drachm; and, when a handful of the herb is steeped in a pint of

wine

wine or water, five or six ounces may be given at a time.

HORMINUM, *Clary*, has a single, woody, brown root, with many fibres, from whence arises a stalk to the height of two cubits, about as thick as one's finger, quadrangular, hairy, geniculated, and divided into branches; it is full of a white pith, and the leaves are set by pairs opposite to each other, which are hoary, wrinkled, of a roundish oblong shape, a span in length, and half a span broad, terminating in a point, and a little dentated or crenated on the edges; they are a little hairy, and gradually decrease in size from the bottom to the top. The flowers proceed from the places where they join the stalk, and consist of a labiated single petal, whose upper lip is long and falcated, with a slender crooked pistil, cloven at the top, and attended with four embryos; there are two stamina with oblong apices, that are hid thereby; but the lower lip is divided into three segments, the middlemost of which is hollow like a spoon. The calyx is tubulated, streaked, glutinous to the touch, and divided into five small spines, whereof three arise above the flower, and the other two are below. The embryos at the bottom of the calyx, when they are ripe, turn to four large roundish seeds, gibbous on one side, angular on the other, slippery, and bright, and of a reddish colour. It is found dry on many banks in various parts of England; but there are many other sorts that are cultivated in gardens. The leaves and flowers are given in decoction in water and wine, in some cases peculiar to women. It is usually drank as tea.

HYOSCYAMUS NIGER VULGARIS, *black Henbane*, has a thick, wrinkled, long root, divided into many parts, brown without, and white within, with broad, soft, hairy leaves, of a light green colour, and deeply cut on the edges; they are placed in an irregular order, or branched, thick, roundish, hairy stalks, that arise to a cubit in height. There are long rows of flowers on the stalk, that consist of a single petal in the shape of a funnel, with a short cylindraceous tube, and is divided into five obtuse segments, of a yellowish colour on the edges with purplish veins; but the middle is of a blackish purple, with five short purple stamina, and thick oblong apices; the pistil is long and white, with a round apex, and the calyx is hairy, oblong, and consists of a single leaf, having stiff acuminate teeth on the edges, of which there are five in number; this turns to a fruit in the shape of a pot with a cover to it, and is divided into two cells, containing several ash coloured, small, roundish, wrinkled, flat seeds. The whole plant has a disagreeable smell, that renders the head heavy and produces sleepiness. It is very common in England, growing on the sides of banks and old dunghills every where.

HYOSCYAMUS ALBUS, *white Henbane*, differs from the former in having softer and lesser leaves, covered with a greater plenty of white down, as also whiter seeds. They have been only used externally to ease pains, and to abate the acrimony of the humours; however, it is not safe used any way, for it produces extreme sleepiness, and strange fantastical dreams.

HYPERICUM, *St. John's-wort*, has a woody, fibrous, yellowish root, with many stiff, woody, round, reddish, branched stalks, that rise to the height of a cubit or higher; the leaves are placed thereon by pairs opposite to each other, but without pedicles; they are above half an inch long, a quarter of an inch broad, smooth, and with nerves that run throughout the whole length; when they are held up to the sun, they seem to be perforated with a great number of holes, which are nothing else but vesicles full of an oily juice. The flowers grow on the extremities of the branches, and are rosaceous, consisting of five gold coloured petals, in the mid-

dle of which there are a great number of capillary stamina, with golden apices. The cup is composed of five leaves, contains a thick pistil divided into three parts, and placed in the center of the flower; turns to a capsula divided into three cells, containing very small, oblong, brownish black seeds. Both the flowers, and the head full of seeds, when rubbed, yield a red juice. The leaves have a saltish, bitterish, styptic taste, and the whole plant is accounted the principal of the vulnerary kind; for which reason it is recommended to cure wounds both inwardly and outwardly, as well as for spitting and pissing of blood. The dose of the floret tops, in decoction or infusion, is a handful, and sometimes the leaves and seeds are prescribed to a drachm. *St. John's-wort*, applied outwardly, is an excellent vulnerary, and cures wounds, bruises, and ulcers.

HYSSOPUS, *Hyssop*, has a woody, hard, fibrous root, about as thick as one's finger, with stalks that grow to the height of a cubit, which are branched and brittle. The leaves are placed by pairs opposite to each other, and are from an inch to an inch and a half in length, and only a sixth part of an inch broad. They are sharp, smooth, of a dusky green, with an acrid taste, and a sweet smell. The flowers grow at the tops of the stalks, and are large, blue, labiated, and consist of a single petal, whose upper lip is upright, roundish, and divided into two segments, and the lower into three; the middlemost of which is hollowed like a spoon, having a double part, and is somewhat winged. There are four oblong blue stamina, with small dark blue apices. The flower cup is long, streaked, and divided into six segments, from which the pistil arises, fixed in the back part of the flower like a nail, attended with four embryos, which turn into as many small, roundish, brown seeds, contained in a capsula that was the cup of the flower. Hyssop is propagated either by seeds or cuttings, and must be sown in March, on a bed of light sandy soil, and when they are come up they should be transplanted out to the places where they are to remain, placing them at least a foot asunder every way. The cuttings should be planted in April, or May, on a border where they may be defended from the violent heat of the sun, and being frequently watered they will take root in two months, after which they may be transplanted where they are to continue. Hyssop has an acrid taste, and a strong aromatic smell. It strengthens the stomach, helps digestion, incides viscid mucus of the lungs, and promotes expectoration: whence some account it a specific in the moist asthma. It is given in infusion, or decoction, in water, wine, or ale, from half a handful to a handful and a half.

JASMIMUM, *the Jessamine tree*, has a pinnated leaf, and the cup of the flower consists of a single leaf divided into five segments; the flower also consists of a single leaf, in the shape of a funnel, and divided into five segments, with small apices; the embryo is roundish, with a pistil like a thread, of the length of the stamina, with a double apex. The embryo turns to an oval smooth berry, divided into two cells, in each of which there is a large oblong oval seed, wrapped up in a membrane, convex on one side, and flat on the other. It is very common in most English gardens, where it is cultivated for the sweetness of the flowers, and is propagated by laying down the tender branches in the spring. In the succeeding spring, they will be rooted strong enough to be transplanted; and it must be placed against a wall, or pales, where the flexible branches may be supported. It was formerly in some esteem for its medicinal virtues, but is now out of use.

IBERIS, *Sciatica Cresses*, whose flower consists of four unequal parts, that are vertically oval, blunt, and open, with oblong erect heels, of which the outer ones are by far the greatest, and the innermost least

and

and bent back. The flower cup has four leaves, vertically oval, concave, open, small, equal, and soon fall off; the stamina are six subulated erect filaments, of which the two lateral are the shortest, and the apices are roundish. The germen, or embryo, is roundish and flat, and the stile, or pistil, single and short, with a blunt apex, and turns to a small roundish flat pod, consisting of two cells, in each of which there is an oval seed. It has the same virtues as water cresses, and, when bruised together with salt and hog's-lard, makes an excellent cataplasm against the hyp-gout. It is only to be met with in botanic gardens.

JUGLANS, *the Walnut-tree*, is very large, and stands upon many very long roots. The trunk, or stem, is very thick, infomuch that in some countries it is three cubits in circumference, with many branches at the top. The bark is thick, of a greenish ash colour, and smooth; but, when it grows old, is full of chinks. The wood is well known for making or covering curious cabinets, chests of drawers, and the like, and is greatly esteemed for its beautiful variegations. The leaves are disposed in wings, and there are five, six, or seven adhering to one rib, consisting of conjugations, with a single leaf at the end. At first they are tender, reddish, and have a sweet smell; but, when they are full grown, they are a palm and a half in length, and almost a palm broad, and pointed at both ends, with veins that run from the middle nerve, and are smooth, of a beautiful green, with the smell of laurel, but much stronger, and of an astringent taste. The smell of the walnut is at first pulpy and white, and of a bitter acrid taste; but, as it ripens, it becomes woody, and divides into two parts, in which is a kernel with four lobes, and covered with a thin skin. The taste is sweet and agreeable when fresh; but, when dry, it becomes oily and rancid. The skin is bitter, acrid, and when the kernels are fresh may be easily taken off. Walnuts are of different species, as the *largest Walnut*, the *thin shelled*, the *hard shelled*, the *late ripe*, the *black Virginia*, the *black Virginia with long fruit*, the *Hickary*, the *shag bark*, the *small Hickary* or *white Virginia*, and the *least Virginia Walnut*. The four first sorts are propagated every where in England, and the first and second are preferred for their large nuts. The Virginian sorts are only rarities, but are worth cultivating for their timber. All sorts of walnuts, that are propagated for timber, should be sown in places where they are to remain, but such as are designed to produce good fruit, are greatly mended by transplantation. The nuts should be preserved in their outer covers till February, when they should be planted in lines at the distance they are intended to remain. When these trees are transplanted, neither the roots nor branches should be pruned. The best season for this is as soon as the leaves begin to decay, and this may be done till they are eight or ten years old. They delight in a firm, rich, loamy soil, or such as is inclinable to chalk or marl. They should be placed forty feet asunder, when any regard is had to the fruit; but, when for timber, they must stand near each other, because it promotes their upright growth.

The inner bark of the Walnut tree is a strong vomit, but the catkins are more gentle, and have been given in powder from half a drachm to a drachm. Some account the leaves an excellent cataplasm against the gout, when they are placed while green in a glazed earthen vessel one layer upon another. The juice of the root is a violent purge, unless it proceeds from the wounded root in February, and then it is recommended in chronic diseases, especially in the gout, gravel, and head-ach; for it greatly promotes urine. The green outer rind is astringent, and is said by some, when recent, to have an emetic faculty. The kernels are best while

fresh, because when old they grow rancid, as was before observed. The membrane, or pith, powdered and given to a drachm, is good in the cholic, and by some esteemed as a secret against fluxes of the belly.

JUNIPERIS, *the Juniper tree*, is a shrub well known in all parts of Europe, and grows in woods and mountainous places. The stem rises sometimes to the height of a man, but is slender, and has many branches, with a rough reddish bark. The wood is pretty firm and reddish, especially when it is dry, with an agreeable resinous smell. The leaves are very sharp, exceeding narrow, and seldom above an inch in length, but often shorter; they are stiff, pungent, always green, and several of them grow together, with some distance between. The catkins appear in April and May, in the places where the leaves join to the stalk, and are a quarter of an inch long, variegated with purple and saffron colours; they consist of several scales, whose lower part is furnished with three or four vesicles, less than poppy seeds, which are full of a fine golden coloured powder. This is the male flower, but the cup of the female flower is very small, adhering to the embryo, and divided into three parts, and there are three stiff sharp petals. The pistil is divided into three single styles, with each a single apex; and they turn to a fleshy roundish berry, containing three seeds each, convex on one side and angular on the other. Some trees produce only the male or female flowers and others both. The berries do not grow ripe till the second year, and there are some that are three years old. The berries are resolving, discutient, attenuating, heating, abstergent, and strengthening. They are good in a cold stomach, discuss wind, help digestion, promote urine, and ease the pains of the cholic. They are likewise good against coughs, and in the moist asthma; they restore the fluidity of the blood, and promote sweat. The dose is a drachm, which may be either eaten, or their infusion may be drank in the manner of tea, before meals, to help digestion. Many will eat a pugil at a time, without any manner of harm, and found they have not only brought away gravel but small stones.

LACTUCA SATIVA NON CAPITATA, *common garden Lettuce*, has a long thick root with many fibres, and oblong, broad, wrinkled, smooth, palish green leaves, which are very agreeable while young, but bitterish when old. When it shoots up to a stalk, it is strong, thick, round, and grows to the height of a cubit and a half and upwards. The flowers are collected in a sort of umbel, and the flower cup is imbricated, consists of many acuminate scales, and is of an oblong oval shape. The flowers consist of many yellow semi-florets, with five very short capillary filaments, on which are cylindrical tubulated apices. The pistil is like a thread of the length of the stamina, on which are two apices bent backwards, to which succeed small seeds, sharp at both ends, furnished with down, and of an ash colour.

LACTUCA SATIVA CAPITATA, *Cabbage Lettuce*, has shorter and broader leaves than the former, which are soon collected into a round head; the seeds are like the former but black. Besides these, there are the *Silicia Lettuce*, the *Dutch brown*, the *Aleppo*, the *imperial*, the *green capuchin*, the *upright white Cos*, the *black Cos*, the *white Cos*, the *red Capuchin*, the *Roman*, the *prince*, the *royal*, and the *Egyptian Cos Lettuce*. The first of these is commonly sown for cutting very young, with other small salad herbs. They may be sown any time in the year, but in winter it should be under glasses. The *Cabbage Lettuce* may be also sown at different times of the year, particularly in February for the first crop, in an open warm spot of ground, and when they

they are come up they should be thinned to the distance of ten inches every way. The seeds, that are sown for the succeeding crop, should be in a shady moist situation, but not under trees. Those for the last crop should be sown in August, on a good light soil, and in a warm situation. In the beginning of October, they should be transplanted into warm borders, where, if the winter is not very severe, they will stand very well. Most of the other sorts may be sown in March, upon a warm light soil, and in an open situation, and afterwards in April, May, and June; and in August, those that are intended for the winter, which should be transplanted either under glasses, or in beds arched over with hoops, in order to be covered over in the winter.

The *Roman Lettuce* has longer and narrower leaves than the two first, and not so wrinkled, and underneath, on the sides of the rib, there are small prickles. Some, as these lettuces grow, tie the leaves together, by which means they become exceeding white and tender; and then they are thought by many to excel all other kinds. In general lettuces are easy of digestion, abate the acrimony of the humours, and quench thirst; for which reason they are frequently used in the summer season. Many take them to be anodyne, and to procure sleep, which is done not by any narcotic quality, but by relaxing the fibres, and temperating the heat of the viscera. They are good in dry constitutions, and help those that are costive.

LAPATHUM MAJUS, *five* RHABBARBARUM MONACHORUM, *Monks Rhubarb*, has a long thick root, from which proceed many fibres, and is brown without, but within of a deep saffron colour. The stalk, which sometimes rises to the height of a man, is reddish, streaked, and divided into many branches at the top; the leaves are from a foot to a foot and a half long, and are broad, acuminate, firm, smooth, of a darkish green, but not hard and stiff; the edges are sometimes a little turned up, but they are even, and have long pedicles. The flowers grow in long rows on the stalks, and are like those of sorrel, to which succeed angular seeds contained in membranaceous cells, and are like those of the dock; they are said to purge bile gently, to be a powerful astringent, and to open obstructions of the liver; whence the powder or decoction is given in some fluxes of the belly. The dose, in powder, is from a drachm to half an ounce, when it is designed to purge.

LAPATHUM SANGUINEUM, *Blood-wort*, is not unlike the garden dock, but may be easily distinguished from all other docks by its blood-red juice, and by its numerous nerves; the juice first tinges the hands with a purple colour, which afterwards changes to blue. The leaves are eaten by some after they are boiled, and have likewise been prescribed in emollient and cooling broths. The seed is strengthening, astringent, and anodyne, and the powder of them is given from half a drachm to a drachm to stop uterine fluxes, and those of the belly attended with gripes.

LAPATHUM ROTUNDIFOLIUM, *five* LAPATHUM MONTANUM, *bastard Monks Rhubarb*, has a long branched root, and each of the branches are as thick as a man's thumb; they are wrinkled and fibrous, and of a deep yellow, with a bitter taste. The stalk sometimes rises to three cubits high, and is hollow, furrowed, reddish, and has many wings. The leaves are like those of burdock, and are remarkably round, smooth, and of a yellowish green, with a reddish streaked pedicle. There are several flowers placed upon the stalks, consisting of many yellow stamina and apices, with a calyx composed of six leaves, to which succeed triangular reddish seeds. The root is variegated with yellow and red, like true rhubarb, and some pretend it has the same virtues, but weaker. Its dose, in powder, is to two

drachms. When the roots are taken fresh out of the ground, and dried in the shade, they are used in fomentations, liniments, and ointments against diseases of the skin.

LAPATHUM AQUATICUM, *five* HYDROLAPATHUM, *great water Dock*, has a more fibrous root than the former, which is black without, and of the colour of box within. The stalks rise to the height of two or three cubits, and the flowers and seeds are like the former, but larger; the leaves are broad, long, and somewhat like those of monks rhubarb; but are almost a cubit and a half in length, terminating in a sharp point, with the edges slightly curled. It grows in marshy places, and by the sides of ditches. The leaves of this plant are styptic and bitterish, and the taste of the root is very bitter. The root is a laxative, opens obstructions of the viscera, and is good in diseases of the skin. The fresh root is given from an ounce to two ounces in decoction, and in substance, when dry, from a drachm to two drachms.

LAPATHUM SPINACIA DICTUM, *Spinage*, of which there are three kinds, the *common Spinage*, the *common barren Spinage*, and the *common Spinage with a capsula of the seed not prickly*.

The *common Spinage*, or the *common prickly narrow leaved Spinage*, has a slender, white, single root, with a few fibres, and the stalks, which rise to the height of a foot, are fistulous, round, streaked, divided into wings, and have long pedicles. The leaves at the bottom are sometimes jagged on both sides, with sharp points; but those on the top have only two processes, like ears at the base, with a fine sort of meal thereon. The flowers are placed on the stalks from the middle to the top, and are without petals; but they have many stamina and small herbaceous, or purplish small apices, placed in a cup, consisting of four leaves. Those that arise from the wings of the leaves, or the female plants, have no petals, but only greenish embryoes, with four whitish filaments; that turn to a pretty large fruit, or capsula, with prickles adhering thereto. It is planted in gardens.

Common smooth seeded Spinage, with broader leaves, has much larger leaves than the male and barren or female kinds, and are also rounder, and the capsula of the seeds is quite smooth and of an ash colour. These are common kitchen herbs throughout Europe. In general, they are said to temperate acrid bilious humours in the first passages; but, as they are watery, some correct them with salt, pepper, and other spices. They do not yield much nourishment, but are not unwholesome, and generally keep the body open. The seeds of the male and barren kinds should be sown in an open spot of ground in the beginning of August, when it is likely to rain; when the plants are come up, they should be thinned, leaving them three or four inches asunder; and this should always be done in dry weather. In October they will be fit for use, and then you should only crop off the largest leaves, leaving those in the center of the plants to grow bigger. Thus you may continue cropping it all the winter and spring, till the young spinage, sown in the spring, is large enough for use, which is commonly in April. The other sort is likewise to be sown in an open spot of ground. The plants should be left about three inches asunder, and, when they are grown large enough to meet, part may be taken up for use, that so the plants, being thinned, may have room to spread; this may be repeated twice, and at the last, they should be eight or ten inches asunder.

LAVANDULA, LATIFOLIA; *greater, or broad leaved Lavender*, has a woody root divided into fibres, and the plant consists of many thick, slender, quadrangular, geniculated branches, that rise to the height of a cubit and a half, or two cubits. The

lower leaves are thickly placed, and irregular; but the upper are set by pairs alternately, and are fleshy, hoary, and oblong, with a nerve running along the middle; as also a strong agreeable smell, and a bitterish taste. It is a verticillated plant, and the flowers grow on the tops of the branches in spikes, which are blue, labiated, and consist of a single petal; the upper lip is upright, roundish, and cloven into two parts, and the lower into three, that are almost equal. The calyx is oblong and narrow, and from it rises a pistil fixed in the back part of the flower like a nail, and attended with four embryoes, that turn to as many seeds, contained in a capsula, that was the cup of the flower.

LAVANDULA ANGUSTIFOLIA, *narrow leaved Lavender*, is in all respects like the former, only it is less, shorter, and the leaves are lesser, narrower, and not so long or white, nor is the smell so strong; but the flowers are larger. Sometimes they both vary in having white flowers. They are propagated by cuttings or slips, and the best season is in the latter end of March, when they should be planted in a shady situation; or at least be shaded with mats till they have taken root; after which they may be exposed to the sun, and, when they are strong enough, may be removed to the places where they are designed to remain. They delight in a dry gravelly soil, where they will endure our severest winters. Lavender is cephalic, nervous, and uterine; for by its aromatic, subtile, acrid particles, it stimulates the nervous fibres to an oscillation, and restores their tone; it dissolves thick humours, and renders them fit for motion. It is good in catarrhs, the apoplexy, palsy, spasms, the vertigo, lethargy, and trembling of the limbs. The dose of the flowers, or seeds, is from a scruple to a drachm; or the infusion may be drank in the same manner as tea. The dose of the conserve of the flowers is half an ounce, and of the essential oil, from two drops to six, on sugar.

LAUREOLA MAS, *Spurge Laurel*, has a tough, thick, long, woody root, divided into several branches, with several ash coloured or whitish stems, rising to the height of two cubits, with leaves like those of laurel, but less, or somewhat like those of myrtle, they are blackish, thick, smooth, shining, and pointed at both ends, and are thickish near the ends of the branches. It is an ever-green, and the flowers that grow on the top, are of a greenish yellow, consisting of a single petal, that is fibrous on the back part, but before divided into four acuminate segments; there is no cup, but there is a pistil that turns to a berry, in the shape of an olive, though much less. It is at first green, but black when ripe, and contains a hard oblong seed, full of a white pulp. The leaves, fruit, and bark, are very acrimonious, biting the tongue, as it were setting them on fire.

LAURUS VULGARIS, the *Bay-tree*, in hot countries, grows to a considerable height, and has a smooth trunk without knobs, and long branches; the leaves are long, sharp, hard, nervous, smooth, but have little juice, though they have a fine smell, and an acrid, bitter, astringent taste. The flower consists of a single petal, shaped like a funnel, and divided into four or five segments. The male flowers, which are produced on separate trees from the female, have eight stamina, which are branched into arms; and the embryo of the female flowers becomes a berry, inclosing a single seed within a horny shell, which is covered with a skin. Besides this, there are several sorts of Bay-trees, that are cultivated in gardens, most of which have been lately brought from distant countries. They are propagated either from the seeds, or by laying down the tender branches, which will take root in a year's time, and may then be taken

No. 37.

off, and transplanted into a nursery, or the places where they design to remain. The leaves are aromatic, bitterish, with somewhat of an astringency, and they are heating, resolvent, strengthen the stomach, help digestion, and discuss wind; for these purposes, the infusion may be drank as tea, or the powder may be given to a drachm. The berries are more heating than the leaves, and two scruples in infusion is a dose; but their principal use in the present practice is in clysters, and the leaves as a fomentation.

LEPIDIUM LATIFOLIUM, *common broad Dittander, or pepper wort*, has a white root, as thick as one's finger, that creeps in the ground, and has an acrid hot taste, that immediately vanishes. It has several stalks, two cubits in height, that are round, smooth, branched, and full of pith; it is covered with a blueish meal, which may be easily wiped off. The leaves are long, broad pointed, and like those of the citron-tree, but larger and softer, of a darkish green, and serrated on the edges. The flowers grow on the tops of the branches, and are small in proportion to the size of the plant; they consist of four petals, placed in the form of a cross; and the pistil, that rises out of the calyx, turns into a very small flat fruit, with a sharp point, and a partition in the middle, that divides into two cells, full of small, oblong, red seeds. The whole plant has an acrid taste, and grows wild in some parts of England; but it is generally cultivated in gardens for use. It is easily propagated, by planting small bits of the root, either in spring or autumn; but it should be placed in some corner of the garden, because the root will spread and over-run the ground. This plant incides gross humours, opens obstructions of the liver and spleen, and is accounted by some a great antiscorbutic. When the leaves are eaten fasting in the morning, they excite the appetite, and help digestion.

LEVISTICUM, *Lovage*, has a large fleshy root, blackish without, and white within, and the stalks often rise to the height of a man; these are thick, light, streaked, and divided into many branches. The leaves are like those of parsley, but larger every way, and they are smooth, shining, of a dark green colour, with a strong smell. The flowers grow in umbels on the tops of the branches, and are roseaceous, consisting of five yellow petals, or upwards. The calyx turns to a fruit, composed of two oblong, thick seeds, gibbous and streaked on one side, and on the other flat, and of a dirty colour. Lovage is said to be alexipharmic, carminative, diuretic, urine, and vulnerary. It strengthens the stomach, helps digestion, discusses wind, attenuates gross humours, eases pains of the cholic, and is good in the asthma. It is looked upon as a specific against the jaundice, especially when it proceeds from a clammy bile. The dose of the root, in powder, is from half a drachm to a drachm, and of the seed from a scruple to half a drachm.

LIGUSTRUM, *Privet*, is a shrub divided into a great number of branches, covered with an ash coloured bark, and the wood is whitish and hard. The leaves grow by pairs opposite to each other, and are oblong, and narrow like those of willow; but they are shorter, thicker, smooth, shining, and of a blackish-green colour. The flowers grow on the top in bunches, and consist of a single petal in the shape of a funnel, divided on the top into five segments. They are white, have a sweet smell, and in the middle there are placed yellowish green apices, with a green pistil that turns to a soft and almost globous berry, of the size of juniper berries, and are blackish when ripe, and full of juice. They contain generally four globous seeds, with a bay coloured skin, and a whitish pulp. It is com-

4 S

mon

mon in hedges in most parts of England, and generally grows to about eight or ten feet high. The leaves are bitter and styptic, and therefore they, as well as the flowers, are recommended by some against hæmorrhages.

LILIUM ALBUM, the *white Lily*, has a bulbous root, consisting of several fleshy scales, united together, and fixed to an axis, under which there are many fibres; the stalk is upright, and sometimes rises to the height of a cubit and a half; it is single, brown, and at the bottom there are oblong, broadish, fleshy, smooth leaves, without a pedicle, of a shining light green colour, but towards the top they become gradually less and narrow, and, if they are rubbed between the fingers, they have a smell like boiled mutton. There are several flowers placed on the top, that do not grow at the same time; they are composed of six leaves, in shape somewhat like a bell, and in the middle there is a longish pistil terminating in three points, of a greenish white colour; the stamina are also six in number, and of the same colour with the petals, with apices of a saffron colour. The pistil turns to an oblong triangular fruit, divided into three cells full of reddish seeds with borders, and lie upon each other in a double row. They are cultivated in gardens for the sake of their beauty and sweet smell. There are many other kinds of lilies, all which may be propagated by sowing their seeds in square boxes about six inches deep, with holes at the bottom, and filled with light, fresh, sandy earth. They are to be sown soon after they are ripe, pretty thick, and must be covered with light sifted earth about half an inch; then the boxes are to be placed where they have the morning sun only, and must be watered in dry weather. They must continue thus till October, when they must be removed to places where they may have as much sun as possible, and yet screened from the north and east winds during the winter; but in the spring, about the middle of April, they must be removed to their former position; for then the young plants will appear above ground. Here they must remain till August, when they must be taken out of the boxes with the earth, and planted in beds of fresh light earth; that is, the small bulbs, together with the earth, must be strewed over the beds, covering them about half an inch thick with fine sifted earth, observing to water them in hot and dry seasons. They must be shaded in the middle of the day, and refreshed now and then with water. In the spring, when the hard frosts are over, the surface of the beds must be cleared, and a little fresh earth sifted thereon; but this should not be deferred too long, lest the shoots should be coming up and broken by this means. When the leaves are decayed, you should stir the surface of the beds again, to prevent the weeds from growing, and in September you must sift some more fresh earth, to the thickness of half an inch. In September following, they will require to be transplanted to a greater distance in moist weather.

The flowers are used in emollient cataplasms, and the oil made by insolation is of common use in pains and tumours of all kinds. The roots are also in great request for softening and ripening tumours, and are particularly recommended for burns and bruises, when roasted under the ashes.

LILIUM CONVALIUM, *Lily of the Valley*, has a slender, white, fibrous root, creeping near the top of the ground, and produces two or three leaves, a palm and a half in length, two inches broad, shining, of a light green, nervous, and terminating in a point; among these the stalk arises to a span in height, which is slender, angular, naked, and from the middle of which, and at the top, there proceeds a long series of flowers, growing

at some distance from each other, but almost all looking the same way; they have very short pendulous pedicles, and consist of a single white petal, in the shape of a bell, divided into six segments, with as many stamina, of a greenish yellow, and adhering to the bottom; the pistil is triangular, and turns to a spherical, soft, red fruit, full of pulp, and three hard, horny, bitterish seeds. The flowers only are in use, which have a very pleasant agreeable smell. It increases very fast by its creeping roots, for which reason it may be propagated in great plenty, by parting the roots in October; they must be planted in a shady situation, and in a moist soil, placing them near a foot asunder. The flowers have a bitterish taste, and when dried, powdered, and snuffed up the nose, they occasion sneezing. It is accounted a cephalic nervous remedy, and to be good in all diseases of the head and nerves. The dose of the powder is a drachm, and of the conserve half an ounce.

LINUM VULGARE, *common Flax*, has a slender root, with a few fibres, and a round stalk, that is generally single, light, smooth, and grows to the height of a cubit, or a cubit and a half. The leaves are acuminate, of the breadth of a straw, and about two inches long; they are alternately placed on the stalk, and are soft and smooth. The flowers grow on the tops of the branches, on slender longish pedicles, and are of a blue colour; they consist of five petals, and when expanded, are in the shape of a clove gilly-flower. The flower cup is tubulous, consisting of a single leaf, and is divided into five parts at the top. The pistil, which rises from the center of the flower cup, turns into a globous fruit, that is slightly acuminate, and is composed of several cells, opening inward, full of flattish oval seeds, blunt at one end, and sharp at the other; they are smooth, shining, and of a yellowish purple colour. It is cultivated for use in many parts of Europe, and is accounted, with good management, a very advantageous plant. The seeds are mucilaginous, abate the acrimony of the fluids, and are greatly recommended against heat of urine. The expressed oil loosens the belly, appeases coughs, and promotes expectoration; it is accounted a specific against the pleurisy, when given from two to four ounces every fourth or sixth hour; but it must be fresh, and have a sweet taste. Externally it is emollient, and relaxes the contractions of the tendons. It is called linseed oil, and its use in painting is very well known.

LITHOSPERMUM, *Cromwell*, has a woody fibrous root, about as thick as one's thumb, with upright, stiff, round, rough, branched stalks, that rise to a cubit and a half in length; there are many leaves, placed alternately, that are two or three inches long, sharp, rough, without pedicles, and of a blackish green colour. The flowers proceed from the places where the leaves join to the stalk, and consist of a single white petal, in the form of a funnel, divided into five blunt segments, with a hairy calyx, consisting of a single leaf, cut almost to the bottom in five narrow hairy segments; the pistil is green, and attended with four embryoes, that turn to as many roundish, hard, smooth, shining seeds, of the colour and shape of small pearls. It grows in shady lanes, and uncultivated places, in various parts of England. The seed is accounted a great diuretic, and a gentle anodyne; for which reason it is recommended to promote urine, and expel gravel. The dose is to two drachms.

LUJULA, *wood Sorrel*, is a low plant, with a thickish, scaly, reddish, white root, from whence proceed weak, slender, brown pedicles, a palm in length, on which are three leaves, that are thin, broader than long, smooth, in the shape of a heart, and of a pale green colour. Among these there

there are other pedicles, each sustaining a single flower, that consists of one petal, in the shape of a bell, and divided into five segments; it is white, open, transparent, and the calyx is divided into five parts, with a pistil fixed in the lowest part of the flower like a nail, that turns to a cylindraceous five cornered fruit, divided into five cells, containing shining reddish seeds, which, when ripe, burst out with violence. It grows in most parts of England, and has much the same virtues as common sorrel. It quenches thirst, mitigates heat, and resolves viscid blood; whence it is said to cool the liver, and is accounted a good antiscorbutic. The dose of the juice is an ounce.

LUPINUS, FLORE ALBO, *the white Lupine*, has a single, woody, fibrous root, and a stalk that rises to a cubit and a half in height, which is pretty thick, upright, round, a little downy, and full of pith. The flowers, which grow on the top, are papilionaceous, and appear in spikes at the top of the branches, on short pedicles. The pistil, which rises from the calyx, turns to a thick, broad, flat pod, three inches long, with a yellowish colour, and a little hairy on the outside, but smooth within, and contains pretty large, roundish, flat seeds, white without, but yellowish within, and very bitter. The leaves are irregularly placed on pedicles, two or three inches long, and consist generally of seven oblong, narrow segments, proceeding from the same point of the pedicle, like those of cinque-foil. Lupines are used externally, in decoctions, against diseases of the skin; and their meal is mixed in cataplasms, being reckoned among the four resolvent meals.

LUPULUS, *the Hop-plant*, has a creeping root, with such weak stalks, that they could not support themselves without twisting about whatever is near them; they are exceeding long, rough, angular, hairy, and hollow; the leaves proceed from the stalks by pairs, and are placed over against each other; they are like those of the mulberry-tree, and terminate in points; they are generally divided into three, and sometimes into five segments, and are serrated on the edges. That sort, which bears flowers, has no seeds, and that, which has seeds, has no stamina. The male flowers consists of a calyx divided into five parts, and surrounds the stamina, but there are no petals; the flowers of the female plants are collected into scaly heads, which grow in bunches, and have some resemblance to pine-apples; they are composed of several membranaceous loose scales, of a yellowish green colour, and adhere to a common axis; the seeds are small, flat, and red, and have the smell of garlick. The people that cultivate hops reckon three varieties, as the *long square garlick Hop*, *the long white Hop*, and *the oval Hop*, all which are cultivated in England, and particularly in Kent, where they account new land best for their growth. The first shoots of hops, or rather their heads, are commonly called hop-tops, and are by some accounted not inferior to asparagus. They gently loosen the belly, and are good in obstructions of the viscera; as for the use of hops, it is very well known throughout the world, it being brewed in malt liquors, to prevent their growing sour.

MAJORANA, *sweet Marjoram*, has slender roots, and the stalks rise to a palm in height, and upwards; they are slender, woody, often square, a little hairy, and reddish, about which the leaves are placed opposite to each other. It is a very verticillated plant, and the flowers grow on the tops of the branches, and consist of a single, labiated, whitish petal, whose upper lip is upright, roundish, and divided into two parts, and the lower into three. The flowers are collected into thick, short, round heads, and proceed from a four-fold order of leaves, placed like scales. It is cultivated in gardens, and is an

annual plant; for which reason the seeds must be sown every year, which are brought from the southern parts of France, where it grows wild. They must be sown in the beginning of April, in a dry warm spot of ground, and in June the plants will be strong enough to be removed into beds of rich light earth, where they are to be placed four inches distant from each other; they will flower in the beginning of August, and then is the time to pull them up for medicinal use.

MAJORANA TENUIFOLIA, *gentle Marjoram*, differs only from the former, in having more slender, and fragrant leaves. They both consist of fine oleous, aromatic, active particles, and are used as pot herbs, and sometimes in salads, to promote digestion, and to discuss wind. They attenuate gross viscid humours, excite the sluggish, languid oscillations of the fibres, and open the pores of the brain and nerves, upon which account it is good in cold diseases of the head, and trembling of the joints. A scruple, or half a drachm of the powder, mixed with a proper conserve, and taken every morning, has been greatly commended in the epilepsy; it is also an ingredient of the cephalic snuffs, because it is said to purge the head.

MALVA VULGARIS, *common Mallows*, has a single white root, with a few fibres, and a stalk that rises to a cubit and a half in height, and upwards; many of these proceed from the same root, and are round, hairy, branched, and full of pith. The leaves grow single about the stalk on long pedicles, and are roundish and jagged on the edges, with a little down, are of a blackish green colour, and crenated on the edges. The flowers proceed from the places where the pedicles of the leaves join to the stalk; they are large, in the shape of a bell, and consist of a single petal, divided into five segments, in the shape of hearts; they are purplish, and streaked with deep purple lines, but are sometimes variegated with white. From the bottom of the flower proceeds a tube, in the shape of a pyramid, on which are purplish stamina. It has a double calyx, the innermost of which is divided into five parts, and the outermost into three. The pistil arises from the bottom of the calyx; it is placed in the tube, and turns to a flat round cake, somewhat in the form of a cheese; for which reason they are commonly called cheese-cakes by children. They contain a great number of seeds, in the shape of kidneys, which are disposed round an axis, in such a manner, that they appear to be very artificially jointed. *Mallows* were formerly used for food; but is now only in request on account of its medicinal virtues, for it is an emollient, and abates the sharpness of urine. It is also used in emollient cataplasms.

MALUS SATIVA, *the Apple-tree*, grows to a considerable size, and the branches are spreading, but more depressed than those of the pear-tree. The flowers consist of five leaves, which expand in the form of a rose, with yellow apices in the middle, and a green calyx, divided into five parts, which turns to a fleshy roundish fruit, generally umbilicated at each end; however, they are of different sizes and shapes, according to their different kinds, which are generally so well known, that they need no description. The first apple which is brought to market is the codlin, and the next is the margaret-apple, which is not so long as the codlin, and the side next the sun changes to a faint red when ripe; but the other side is of a pale green. This fruit is firm, and has a pleasant taste, but does not keep long. The summer pearmain is an oblong fruit, striped with red next the sun, and the flesh is soft, and grows mealy in a short time. The Kentish fill-basket is of a large size, is of a somewhat longer shape than a codlin, and ripens a little later. Loan's pearmain is a beautiful fruit, and of a fine red next the sun; the flesh is vinous, but soon grows mealy.

The QUINCE APPLE is of the size of a golden pippin, but shaped like a quince, especially towards the stalk; the side next the sun is of a russet colour, but the other side is inclining to yellow. It is an excellent apple, but will not keep above three weeks in September. The golden rennet ripens about Michaelmas, and continues to be a good fruit about a month. The aromatic pippin is of the size of a nonpareil, but a little longer, and the side next the sun is of a bright russet colour. It ripens in October. The winter pearmain is rather long than round, of a fine red next the sun, and striped with the same colour on the other side; the flesh is juicy, but it is not a good eating apple. The Kentish pippin is large and handsome, and of a pale green colour. It is a very good kitchen fruit, and will keep till February. The Holland pippin is larger than the former and of a darker green. It will keep longer than the former. The monstrous rennet is very large, of an oblong shape, reddish towards the sun, and of a dark green elsewhere; it is of no great value. The embroidered apple is pretty large, with red broad stripes, from whence it has its name; it is a tolerable kitchen apple. The royal russet is of a deep russet colour, and is large, and of an oblong shape, but broad towards the base, and the flesh is a little yellowish. It will continue good from October to April, and is the best of all kitchen apples. Wheeler's russet is of a light russet colour next the sun, and of a pale yellow on the other side. The size is middling, the flesh firm, and has a quick, tartish taste; it will keep a long while. Pile's russet is oval, and of a russet colour next the sun, but of a dark green on the other side; it is a good baking apple, and will keep sound till April. The nonpareil is very well known, but there is another apple generally sold for it, that is a larger fruit, and more inclining to yellow. It is ripe earlier, sooner gone, and is not so flat as the true nonpareil; which last is not ripe before Christmas, and will keep good till May. The golden pippin is peculiar to England, for it will not succeed well in other countries. It is an excellent apple, and would be still better, if proper care was taken in its cultivation. There are a great many other sorts of apples, which have no particular names, except such as serve for making cyder; the redstreak, the whitfour, the Hertfordshire under leaf, the John apple, the everlasting hanger, and the gennet moil. They are all propagated by grafting or budding upon stocks of the same kind. Apples in general are used for eating and baking; but, as for their medicinal virtues, they are scarcely worth mentioning, though they are said to temperate the bile, and to be good in fevers to allay thirst. Some pretend they are excellent pectorals, and will appease coughs; but this may be doubted.

MALUS GRANATA, *five* PUNICA, *the Pomegranate*, is a low tree, or rather a shrub, with slender angular branches, beset with long thorns or prickles. The leaves are like those of the myrtle tree, or olive, only not so sharp, and are of a shining green, with reddish pedicles and veins. The flowers are rosaceous, consisting of five petals of a red or scarlet colour, in the middle of which there are many stamina, with their apices, and the calyx is also red, above an inch long, in the form of a bell, and divided into five pointed jaggs, which, after it is turned to a fruit, are placed round the navel at the top. Pomegranates are of various sizes, some being as big as large apples. The rind is pretty thick, hard, and brittle; before it is ripe it is green, and smooth, but afterwards reddish and wrinkled, and last of all it becomes of a bay colour, and yellowish within, with an astringent taste; it is full of seeds disposed in various cells, and the pulp has a sweetish vinous flavour; though it is sometimes acid. There are several kinds, as the common pomegranate, the

sweet, the wild, the double flowered, and the American double pomegranate. The first and second of these are hardy enough to resist the severest cold of our climate, in the open air; and, if planted against warm walls, the first sort will often produce fruit, which in warm seasons will ripen tolerably well; but they are seldom well tasted in England. These plants may be easily propagated, by laying down their branches in the spring, which in one year's time will take good root, and may then be transplanted where they design to remain; and the best season for this is the spring, just before they begin to shoot. The flowers always proceed from the extremity of the branches which are produced the same year, for which reason all the weak branches of the former year should be cut out, and the stronger should be lengthened according to their strength. The best time for this is the beginning of October.

MALICORIUM, *or the rind of the Pomegranate*, has a bitterish austere taste, is very astringent, and will supply the place of oak bark, for tanning of leather, as well as of galls for the making of ink. It is good in a diarrhoea, and all fluxes of the belly whatever, as well as in hemorrhages. It strengthens the tone of the parts, and sometimes proves an aperient as well as an astringent. The dose, in powder, is from half a drachm to a drachm, and in decoction to half an ounce.

BALAUSTIA, *Balaustines*, are the flowers of all sorts of pomegranates, with their flower-cups; but those of the double sort are generally chosen, because they are large, and have a great number of petals. The cup is not so long as in the first sort; it is however more flat and broad, and the colour is of a yellow purple. They are astringent, but not so much as the rind, and therefore they have been in frequent use in all sorts of fluxes whatever; but they are seldom met with in extemporaneous prescriptions, though often in shop medicines. The dose, in powder, is to a drachm, and to half an ounce in decoction.

MALUS PERSICA VULGARIS, *the common Peach tree*, rises to a moderate height, and has a pretty thick stem, with many brittle branches, and a reddish and brownish bark. The leaves are thin, oblong, acuminate, crenated, and like those of the almond tree; but larger, and have a bitter taste, like those of peach kernels, though not so pleasant. The flowers appear in the beginning of the spring, before the leaves, and without pedicles; for they adhere to the tubercles of the branches, and are rosaceous, consisting of five broad petals, of a light reddish colour, and in the middle there are many longish stamina, that are either purple or white, with a pistil of the same length, that proceeds from a reddish calyx, divided into five acute segments, and turns to a fruit that is almost globous, though a little flattish on one side, and is furrowed according to the length, and covered with a thick, soft, whitish down, in many of the species; but some are smooth, of a yellowish herbaceous colour, and these are commonly called Nectarines, which contain a woody, oblong, oval stone, consisting of two valves, deeply furrowed, and the pulp in some adhere very obstinately thereto, but in others it readily parts from it. When the bark is wounded, a gum will proceed from it like the plumb tree gum.

Some Peach trees are cultivated for the beauty of their flowers, as the peach tree with double flowers, the dwarf peach tree with single flowers, and the double flowering dwarf peach tree, though some place these two last among the almonds. The peach trees, that are cultivated for their fruit, are the white nutmeg peach, which has serrated leaves, and large open flowers, but the fruit is small and white, as is also the pulp at the stone, from which

it easily parts. It is esteemed for being the soonest ripe.

The *early purple* PEACH TREE has leaves even at the edges, and the flowers are large and open; the fruit is large, round, and of a fine red colour, and the flesh is white except at the stone, where it is very red. It is full of juice of a rich vinous flavour, and is an excellent peach; it is ripe towards the latter end of August.

The *large French Mignon* PEACH TREE has leaves that are even at the edges, and the flowers are large and open; the fruit is a little oblong, and has generally a swelling on one side. It has a fine colour, and the juice is very sweet, with a high flavour; the flesh is white, but very red at the stone, which is small; it is ripe towards the end of August. It is separated easily from the stone, and is one of the best sorts.

The *Belle Chevreuse* PEACH TREE has smooth leaves, and the flowers are small and contracted; the fruit is of a middling size, a little oblong, and of a fine red; the flesh is white, but very red at the stone, from which it easily parts; its juice is sweetish and rich, and it ripens in the beginning of September.

The *red Magdalen* PEACH TREE has deeply serrated leaves, with large open flowers, and the fruit is large and round, and of a fine red; the flesh is white, but very red at the stone, from which it readily parts. The juice is sweetish, and has a very fine flavour; it is ripe at the beginning of September, and is one of the best peaches.

The *Chancellor* PEACH TREE has leaves that are even at the edges, and has small contracted flowers; the fruit is shaped somewhat like the belle chevreuse, but is rounder, with flesh that is white, and melts in the mouth; it parts freely from the stone, where it is of a fine red. The skin is very thin, and the juice rich; it ripens in the beginning of September, and is one of the best sort.

The BELLEGARD has leaves that are even at the edges, with small contracted flowers; but the fruit is very large and round, and is of a deep purple colour, next the sun; the flesh is white, melts in the mouth, and parts readily from the stone, where it is of a deep red; the juice is very rich. It ripens in the middle of September, and is an excellent peach.

The *Bourdine* PEACH TREE has leaves that are even at the edges, with small contracted flowers, and large round fruit, of a fine red colour next the sun; the flesh is white, melts in the mouth, and parts readily from the stone, where it is of a fine red; the juice is vinous and rich, and ripens in the middle of September.

The *Rosanna* PEACH TREE has leaves that are even at the edges, with small contracted flowers, and large fruit; the flesh is yellow, and parts readily from the stone, where it is red. The juice is rich and vinous, and it ripens in the middle of September.

The *Rambouillet* PEACH TREE has leaves that are smooth at the edges, with large open flowers, and fruit of a middling size, rather round than long, and divided by a deep furrow in the middle; it is of a fine red colour next the sun, and of a light yellow next the wall. The flesh is of a bright yellow, melts in the mouth, and parts readily from the stone, where it is of a deep red, and the juice is rich, with a vinous flavour; it ripens at the latter end of September.

The *Nivette* PEACH TREE has serrated leaves, with small contracted flowers, and large fruit, somewhat longer than round, of a bright red colour next the sun, and of a pale yellow on the other side; the flesh melts in the mouth, is full of a rich juice, and is

very red at the stone, from which it parts. It ripens towards the latter end of September.

The *bloody* PEACH TREE bears fruit of a middling size, of a deep red next the sun, and flesh that is of a deep red to the stone; but it seldom becomes quite ripe in England. Besides these, there are a very great variety of other species of peaches; but as these we have here described are the most usual sorts planted, we shall not tire the reader with a long catalogue of names, which he may never have occasion to peruse. A good peach ought to have a firm flesh, a thin skin, of a fine red colour next the sun, and of a yellowish cast next the wall; the flesh should be of a yellowish colour, full of juice, and high flavoured, with a small stone, and the pulp or flesh very thick.

All Peach trees have been originally obtained from the stones, which should be planted in autumn, on a bed of light dry earth, about three inches deep, and four inches asunder; in the winter the beds should be covered to protect them from the frost, and in the spring, when the plants come up, they should be carefully cleared from the weeds, as well as all the summer observing to water them when the weather is dry. They should remain here till the following spring; when they should be carefully taken up, without breaking the tender roots, and transplanted into a nursery in rows, three feet asunder, and eighteen inches distant plant from plant in the rows, observing to lay a little mud about the roots; they must also be watered in dry weather once a week, till they have taken root. Here they may continue two or three years, till they are transplanted, where they are to remain. When this is done, the downright roots must be pruned pretty short, and the bruised parts cut off, as well as the small fibres; but the heads should not be meddled with. These are generally designed for standards. As for the planting, budding, and management of peach trees that are to be placed against walls, we must refer the reader to books entirely devoted to the use of the common gardener, as it would take up more room than this treatise will allow.

The NECTARINES are properly peaches, though generally distinguished from them, of which the following are the most remarkable sorts; and indeed it may be doubted whether there are really any more or not.

Fairchild's early NECTARINE TREE produces fruit the soonest ripe of any we have; it is small and round, about the size of a nutmeg peach, and of a beautiful red; it has a very good flavour, and ripens towards the end of July.

The *Etruge* NECTARINE TREE has serrated leaves, with small flowers of a dark red or purple next the sun; but of a pale yellow or greenish colour towards the wall; it parts from the stone, melts in the mouth, and is ripe in the beginning of August.

The *Newington* NECTARINE TREE has serrated leaves, with large open flowers, and a fair large fruit, of a beautiful red next the sun, but of a bright yellow towards the wall; it has a very rich juice, and the pulp or flesh adheres closely to the stone, where it is of a deep red. It ripens in the middle of August, and has a better flavour than any of the rest.

The *scarlet* NECTARINE TREE bears fruit a little less than the former, of a fine red or scarlet next the sun, but of a paler red towards the wall; it ripens in the beginning of August.

The *Brugnon* or *Italian* NECTARINE TREE has leaves that are even on the edges, and small flowers, with a fair large fruit, of a deep red next the sun, but yellowish towards the wall; the pulp is firm, of a rich flavour, and closely adheres to the stone, where

it is very red; it ripens towards the latter end of August.

The *Roman red* NECTARINE TREE has leaves that are even at the edge, and flowers with large fair fruit, of a deep red or purple colour next the sun, but has a yellowish cast towards the wall; the pulp is firm, of a rich flavour, and adheres closely to the stone, where it is very red. It ripens towards the latter end of August.

The *Murrey* NECTARINE TREE bears a middle sized fruit, of a deep red next the sun, but of a yellowish green towards the wall; it has a pretty good flavour, and ripens towards the end of August.

The *golden* NECTARINE TREE bears a handsome fruit, of a light red next the sun, and of a bright yellow towards the wall; the pulp is very yellow, has a rich flavour and closely adheres to the stone, where it is of a faint red; it ripens towards the middle of September.

The *Temple's* NECTARINE TREE bears a middle sized fruit, of a light red next the sun, and of a yellowish green towards the wall. The pulp melts in the mouth, and is of a white colour at the stone, from which it readily parts, and has a fine flavour; it ripens towards the end of September.

The *Peterborough, or late green* NECTARINE TREE, bears a middle sized fruit, of a pale green next the sun, but of a whitish green towards the wall. It has a firm well flavoured flesh in a good season, and ripens in the beginning of October.

The flowers have an aromatic bitter taste, and, when fresh, an infusion of half an ounce in water, or a drachm when dry and sweetened with sugar, is a useful laxative for children. Peaches themselves agree very well with persons of hot constitutions, and costive, especially if they are eaten in a morning fasting. Peach kernels are bitterish, diuretic, and good against worms. The leaves have the same virtues, and the gum resembles gum arabic.

MANDRAGORA MAS, seu CANDIDA, *Mandrake* has a thick long root, generally divided into two parts, and sometimes more; it is whitish without, or of a rusty ash colour, and pale within. It has no stalk, though it has leaves a cubit in length, and a palm and a half broad, and sharp at both ends; among these pedicles arise stalks, a palm in length, on each of which there is a single flower, in the shape of a bell, consisting of a single leaf, divided into five segments; it is a little hairy, of a dirty white, or purplish colour, with a hairy green calyx, divided into five parts; from whence arises a pistil, fixed in the bottom part of the flower, that turns to a fruit, like a small apple, at first green, and then yellowish, fleshy, soft, of a strong nauseous smell, and in the pulp there are roundish flat seeds, somewhat in the shape of a kidney.

MANDRAGORA FEMINA seu NIGRA, *female Mandrake*, has leaves like that of the former, but narrower, less, and blacker; the flowers are of a bluish purple, and the fruit are paler, less, and in the shape of a pear. They both grow wild in Italy and Spain, as well as other hot countries, and delight in woody and shady places. With us they are cultivated in gardens, and the seeds are sown in a bed of light earth, soon after they are ripe; they come up in the spring, and in very dry weather they must be refreshed with water. They should remain here till the end of August, and then they should be transplanted to the places where they are to remain. The roots will continue sound for above fifty years; but as to the resemblance to a human form, as many assert, it is nothing but an imposture, owing to persons that would deceive the publick, who form the fresh roots of Bryony into such shapes, and show them for Mandrakes. Many wonderful things have been said of its virtues, by different authors; however, they all agree it is a narcotick, and, when taken

in too large a dose, will produce dangerous symptoms. Some have given it from half a scruple, to procure sleep. Some affirm, that the leaves applied outwardly, as a cataplasm, will resolve hard swellings of the spleen.

MARRUBIUM, *Hoar-bound*, has a single woody root, which sends forth many fibres, and several stalks, to the height of a foot and upwards; these are hairy, square, branched, and the leaves proceed from the joints in pairs, which are placed opposite to each other; they are roundish, hoary, wrinkled, and crenated on the edges. The flowers likewise proceed from the joints, and surround the stalks; the calyx, or flower cup, is hairy, streaked, and terminates in prickles; the flower consists of a single labiated leaf, of a whitish colour, whose upper lip is upright and forked, and the lower divided into three segments. The pistil is fixed in the back part of the flower, like a nail, and attended with four embryos, that turn to as many oblong seeds, contained in a capsula, that was the calyx of the flower. The whole plant has a strong disagreeable smell, and grows near highways, and on the sides of fields, in neglected places. It is aperient, powerfully resolves viscid humours, and by some is accounted a specific in a moist asthma.

MARRUBIUM NIGRUM, *black Hoar-bound*, has a perennial fibrous root, and hairy, square, light, branched, reddish stalks, with leaves that proceed from the joints in pairs, and are placed opposite to each other; they are like those of the Balm, or rather red Archangel, only they are rounder and blacker; they are hairy, soft to the touch, and wrinkled. The flowers likewise proceed from the joints, and consist of a labiated single petal, whose upper lip is hollow like a spoon, and the lower divided into three segments, of which that in the middle is biggest, and in the shape of a heart; the colour is purple, streaked with deeper lines of the same; the flower cups are streaked, oblong, and divided into four or five sharp segments. The pistil is fixed in the back part of the flower, and is attended with four embryos, that turn into as many small oblong seeds, that are blackish when ripe, and contained in a tubulated capsula, with five sides, that was the calyx of the flower. It grows wild by the sides of hedges. The leaves are bitter, have a strong smell, and by some are accounted an excellent remedy in hypochondriac and hysteric disorders.

MARUM VERUM, seu MARUM CORTUSI, *Syrian herb Mastich*, has a fibrous root, and a stalk that rises to the height of a foot, or rather several hoary downy stalks; with leaves like the end of a lance, a quarter of an inch long, two broad, and of a light green above. The flowers are like those of Germander, and consist of a single, labiated, purple petal, whose stamina are in the room of an upper lip; but the lower is divided into five segments, the middlemost of which is hollow like a spoon. The calyx is likewise like that of Germander, and the pistil is fixed on the back part of the flower, with four embryos, that turn into as many roundish seeds. This plant has the appearance of a shrub, and has a hot volatile smell. It is propagated by cuttings, in any of the summer months, on a bed of fresh light earth, observing to water and shade them, till they have taken root; after which they may be transplanted either in pots or borders of the same earth; but the greatest difficulty is to preserve it from cats, which will come from a great distance, to tear this plant in pieces; for which reason, it is hard to preserve it near towns and cities. The best way is to plant large quantities thereof, and then they will not come near them. When they are placed in pots, they may be cut into any figure, for they will grow to near three feet high. It is said to be good in cold and moist diseases, and to be an excellent diuretick; though

though it is of little use with us, except in making herb-snuff. However, it is certainly better than Marjoram, and the dose of the powdered leaves is a drachm.

MARUM, *herb Mastich*, is a small woody shrub, with many branches, and slender woody roots, with leaves like Thyme, but hoary, and which smell like Mastich. The flowers are white, and consist of a single labiated petal, whose upper lip is upright, and divided into three segments, but the lower into three in such a manner, that it looks like a flower with five leaves, and have a white down growing upon their oblong heads. This plant is propagated by cuttings, in any of the summer months, in a bed of light rich earth, observing to water and shade them till they have taken root, after which they may be transplanted into a light dry soil, in a warm situation. It produces great numbers of flowers in July, has an agreeable smell, and deserves a place in the borders of every good garden. The virtues are the same as those of the former, and it is undoubtedly an excellent cephalic.

MATRICARIA, *Feverfew*, has a white fibrous root, with several stalks, that rise to the height of a cubit and a half; these are strong, streaked, smooth, thick, and full of a spongy pith, with many leaves of a light green colour; they are conjugated, and divided into many segments, which are by some called wings. The flowers grow in umbels, on the top of the stalks; they are radiated, but not large, and the disk consists of many yellow florets, and the crown of white semi-florets, placed over the embryos of the seeds in a semi-spherical scaly cup. The seeds are oblong, small, streaked, and fixed in a bed at the bottom of the cup. The whole plant has a very strong smell, and is found wild upon dunghills and uncultivated places, in many parts of England; it is likewise planted in gardens for medicinal purposes. They are propagated by seeds, which should be sown in the latter end of March, upon a bed of light earth, and when they are come up, they should be removed to nursery beds, and placed about eight inches asunder, where they may remain till the latter end of May; then they may be taken up, with a ball of earth at their roots, and planted in the middle of large borders, where they will flower in July and August. It is an hysterical plant, and is excellent in uterine disorders. The dose, in powder, is from half a scruple to two scruples, and of the juice to an ounce or two. It is certainly a very good carminative, as it discusses wind, strengthens the stomach, and helps digestion. Outwardly, it is prescribed in fomentations, with camomile flowers.

MELILOTUS, *Melilot*, has a white, slender, tough root, with many short fibres, and generally several stalks, which sometimes rise to a cubit and a half in length; these are smooth, round, streaked, and weak, and the leaves are placed alternately thereon, by threes, on the same slender pedicle; they are smooth, oblong, denticulated, and of a dusky green. The flowers grow on long spikes, and are papilionaceous, small, yellow, and consist of four petals; these are succeeded by short, single, pendulous, wrinkled, naked pods, not hid in a calyx, as in trefoil, and they are black when ripe, containing one or two roundish seeds of a yellowish colour. It is found near hedges, and among corn. It is seldom given inwardly, but is often used outwardly, and in clysters. It is said to be emollient, anodyne, and resolvent, and is used by some in all kinds of external inflammations.

MELISSA, *Balm*, has a round, long, fibrous, woody root, with stalks that rise to a cubit high, and upwards; these are square, almost smooth, branched, hard, stiff and brittle. The leaves are oblong, of a brownish green, and pretty much like those of cala-

mint; but they are shining, covered with a little down, and dentated on the edges. The flowers grow at the places where the leaves proceed from the stalks, and are somewhat verticillated, though they do not grow quite round the stalks; they consist of a single labiated petal, whose upper lip is roundish, upright, and divided into two parts; but the under lip is cut into three. The hairy calyx is divided into two parts; and the pistil is attended with four embryos, that turn to as many seeds, joined together, of a roundish shape, and contained in a capsula that was the cup of the flower. It is cultivated in gardens, and flowers in June, July, and August. It is propagated by parting the roots, either in spring or autumn, or by planting slips at the distance of eight or ten inches. Balm is said to be cordial, cephalic, and to fortify the stomach. It is taken in the manner of tea, is a little aromatic; and has done service in a lax state of the viscera.

MELISSA SYLVESTRIS, *wild Balm*, is nothing less than the former in its primitive state, before it is cultivated in gardens. This plant has a bad smell, and grows in woods, flowering in May and June. It is reckoned a vulnerary, and is said to be an excellent remedy against suppression of urine.

MELO VULGARIS, *common musk Melon*, is a plant, with stalks that creep along the earth, and are rough to the touch, as well as the leaves, which are smaller and rounder than those of Cucumbers. The flower consists of a single petal, in the shape of a bell, cut into several segments, exactly like those of a Cucumber, and some of them are barren, while others are fruitful, and turn into a fruit of an oval shape, and different sizes; the rind is harder than that of a Cucumber, pretty thick, variegated with green and ash colour. The pulp is tender, moist, clammy, yellow, or red, and when ripe, has a very agreeable flavour. It is divided into three cells, containing oblong, flat, whitish yellow seeds, covered with a hard skin, containing an oily kernel, but is very white; and has a sweetish taste. There are several sorts of Melons, besides that already mentioned; as the *Portugul*, or *pocket Melon*, the *netted or wrought Melon*, the *great musk Melon*, with a smooth green skin, and a green seed, the *white Spanish Melon*, the *green fleshed Melon*, the *Cantaleupe Melon*, the *Zatta Melon*, the *Melon with a hairy skin*, and the *winter Melon*. The seeds should not be sown till they are three years old, and it should be at two or three different seasons, the first of which is the latter end of February, when the weather is mild, on the upper side of a Cucumber bed, and the plants must be raised and managed in the same manner as Cucumbers. The second season is about the latter end of March, and they both should be planted under frames. Those that are designed to be raised under bell-glasses, must be sown about the latter end of April, if the season proves forward; but if it be cold, it had better be deferred somewhat later. There are particular rules required for their management, that are too long to be inserted here, and therefore we shall only observe, that when the fruit is fully grown, they must be carefully watched, to cut them at a proper time; and therefore they should be looked over at least twice a day; for if they are left growing a few hours too long, they will lose much of their delicacy. If they are cut early in a morning, before the sun has warmed them, they will be much better flavoured.

The seeds of Melons are one of the greater cold seeds, and serve to make emulsions; but at present they are not so much taken notice of as formerly.

MENIANTHES, *five TRIFOLIUM PALUSTRE*, the *Buck-bean*, has a long, knotted, creeping root, which has fibres by intervals, and there are three

three leaves that grow on the same pedicle, that are of the same size and shape as those of beans, and smooth to the touch. Among these there arises a stalk to the height of a foot and a half, which is slender, smooth, green, and bears a tuft of flowers at the top, in the shape of a funnel, and of a whitish purple colour. Before they open they are red, and after they are open they divide into five pointed segments; their internal surface is covered with very slender, white, curled filaments, that appear like down. The cup of the flowers is in the shape of a mug, and dentated, and each flower contains five white stamina, with yellow apices; the pistil is placed in the middle, and is shorter and greener than the stamina. These are succeeded with roundish or oblong fruit, that contains oval seeds like those of the Sun flower. This plant grows wild in marshes, and flowers in May or June. Buck-bean has gained great reputation for its virtues, and is found very efficacious in the gout, king's-evil, the cachexy, and dropsy. In a fit of the gout, the patient must drink a glass of the decoction every four hours; but Boerhaave was relieved in this distemper, by drinking the juice mixed with whey. It will be likewise proper to apply the leaves that have been boiled, to the painful part, after the decoction is strained off. The seed is good against the moist asthma, for it incises the gross phlegm that stuffs the lungs. This plant is in such reputation in Germany, that they give it in almost all diseases.

MENTHA VULGARIS, *garden, or spear Mint*, has a creeping root, furnished with fibres, that extend far and near; the stalks rise to a foot and a half in height, and are square, a little hairy, strong, and reddish. The leaves are placed by pairs opposite to each other, and appear at first sight like Balm; but those at the top of the stalk are longer, and more pointed, and of a deep green colour; they are also more deeply dentated. The flowers grow in spikes, and consist of a single labiated petal, whose upper lip is arched, and the lower divided into three parts; but both of them are so cut, that the flowers seem to be divided into four parts, the two lips scarcely appearing. Each flower is succeeded by four seeds contained in the flower cup. Mint has a peculiar well known strong smell. It is cultivated in gardens, and flowers in July and August. Besides this, there is the *pepper Mint*, the *long leaved horse Mint*, *water Mint*, commonly called *water Calamint*; *orange Mint*, *Spear-Mint with a variegated leaf*, the *great round leaved water-Mint with a variegated leaf*, *Spear-mint with a rugged leaf and a strong scent*, and *narrow leaved Aleppo Mint*. They are all propagated by parting the roots in the spring, or by planting the cuttings in any of the summer months.

SPEAR-MINT is stomachic, cephalic, and carminative, and is excellent in the loss of appetite, retchings to vomit, and weakness of the stomach. It resolves coagulated blood, eases pains of the cholic, and does a great deal of service in fluxes of the belly. It may be drank as tea, especially when the leaves are dry, and the infusion must be strong. Water Mint has a bitter, acrid, aromatic taste, is stomachic and diuretic, and, like the former, may be drank as tea. The juice is good against the gravel, stops vomiting, and hiccoughing, cures the gripes, and swelling of the stomach.

MENTHA ALBA, *five MENTASTRUM, Horse-Mint*, has a fibrous creeping root, and sends out stalks to the height of a cubit, and upwards, which are square and hairy. The leaves are almost round, wrinkled, and covered with a white wool. The flowers are like those of garden Balm, and are of a whitish red colour, with dentated flower-cups. Each flower is succeeded by a small black seed.

The leaves have a bitter, acrid, astringent taste, with a strong smell, and it grows by the sides of brooks, and in moist places in most parts of England. It is said to kill worms; to help the moist asthma; and many apply a cataplasm made with this plant, to the affected part, against the hypogout; they affirm it raises blisters, which when broken ease the pain.

MENTHA PIPERITES, *Pepper-mint*, has shorter and fuller spikes than the common Mint, but the leaves are like them, only they are covered with a short hairy down. This plant has been lately brought into esteem, and is of great use in flatulent cholics, and in many cold diseases; its effects are almost immediately felt; for it causes a glowing warmth to be felt throughout all parts of the body. It readily communicates its pungency to water, as well as to that which is distilled from it.

MERCURIALIS, *male and female French Mercury*. The male has a tender, fibrous, annual root, and sends forth stalks to the height of a foot, that are angular, geniculated, smooth and branched. The leaves resemble those of pellitory, and are oblong, pretty broad, sharp, smooth, and green; they are placed by pairs opposite to each other on the stalk, and are crenated on the edges; the flower cup consists of one leaf cut into three segments, as well in the male as in the female. The flower of the male has no petals, but has from eight to twelve stamina collected into a spike. There are two embryoes contained in a sort of purses, and, when they are ripe, there is in each a small oval seed.

The *female Mercury* resembles the male in all respects, except the flowers; for these produce neither fruit nor seed. The virtues are both alike, and they flower all the summer. The leaves are said to be aperient and laxative, and they are placed among the five emollient plants. It is sometimes made use of in clysters, and a syrup made of the leaves is a mild and useful laxative; the dose is two spoonfuls, which is to be given three hours before meals. Warts rubbed with this plant will frequently soon wither away.

MESPILUS APII FOLIIS SYLVESTRIS SPINOSA, *five SPINA ALBA*, the *White Thorn* or *Hawthorn*, is a shrub that has a pretty thick firm trunk, full of branches, and armed with strong thorns, that are much harder than the wood. The branches are strong and flexible, and the leaves are like those of parsley, and have a clammy taste. The flowers grow in tufts, and have pedicles about an inch and a half in length; they are white, have five petals, placed in the form of a rose, and reddish stamina, like those of the pear-tree. The fruits, or haws, are a little larger than Myrtle-berries, are red when ripe, and hang in bunches. They have a black navel, and are full of a clammy, soft, sweetish pulp, wherein are two hard white stones. It grows every where in hedges, and flowers in May; the berries grow ripe in September, and continue a great part of the winter, when the leaves are falling off.

MESPILUS PYRIFOLIA, *five PYRICANTHA*, the *ever-green Thorn*, is a thorny shrub, covered with a blackish bark, whose branches are armed with thorns, whereof some are an inch in length, and others shorter. The leaves resemble those of the wild pear-tree, or rather the almond tree; some are oblong, and a little pointed, while others are almost round, smooth, and dentated on the edges, especially the lowermost. The flowers consist of several petals, of a reddish colour, and disposed in the form of a rose. The berries are like those of the hawthorn, and of a golden scarlet colour, growing together in bunches, and furnished with a sort of a crown. The pulp is a little tartish,

and contains four or five whitish yellow seeds, of a triangular shape, and a little shining. It grows in the hedges in Italy, and the southern parts of France; but elsewhere it is cultivated in gardens. It flowers in May, and the berries grow ripe in autumn. Children are very fond of them, and they have the same taste and properties as haws.

MILIUM, *Millet*, has many fibrous, and strong, whitish roots, that send forth stalks to the height of two or three feet, which have several knobs. The leaves are large, long, and about an inch broad, in the shape of those of reeds; they are covered with a sort of thick down, at the places where they surround the stalk, after which they become smooth; the flowers grow in loose panicles at the top of the stalks, and are generally yellow, though sometimes blackish; they are composed of three stamina, that proceed from the middle of the flower-cup, which generally consists of two leaves. When the flowers are fallen off, they are succeeded by oval grains, that are yellowish or white, hard, shining, contained in three sorts of thin tender shells. These plants were originally brought from the eastern countries, where they are still greatly cultivated, and from whence we have the grain, which is highly esteemed by many for making puddings. It is a common aliment in the eastern countries, where they boil it in milk, and it has the same virtues as rice. It is good in disorders of the breast and obstinate coughs; but it is a little binding and windy.

MILLE FOLIUM VULGARE, *Yarrow, or Nose-bleed*, has a woody, fibrous, blackish, creeping root, from whence proceed a great number of stalks, to the height of a foot, or a foot and a half, that are stiff, angular, hairy, reddish, and branched at the top. The leaves are divided and subdivided into a vast number of segments, adhering to a long rib, and have some resemblance to those of camomile; but they are more stiff, and somewhat like the feathers of a bird. The flowers are collected into round umbels, each of which is radiated, whitish, and placed in a scaly cylindric calyx, and are succeeded by very small seeds. It grows in uncultivated sandy places, where the leaves generally lie close to the ground till the stalks begin to rise. It is called Noose-bleed by the country people, because a sprig of it put up the nose will bring away a little blood. It flowers in May and June, and has an acrid, bitter, aromatic taste. It is a vulnerary plant, and is said to cure wounds, tumours, and inflammations without repulsion.

MYAGRUM, *Gold of Pleasure*, has a fibrous root, a little woody, which sends forth a stalk to the height of a cubit and upwards, from whence proceed several cylindric, strait, slender branches, a little downy, and full of a spongy pith. The leaves are longish, pointed, soft, of a palish green, slightly dentated on the edges, and their bottoms surround their stalk in such a manner, that the sides represent two wings or ears. The flowers consist of four petals, placed in the form of a cross, and of a yellowish colour; the pistil arises out of the calyx, and afterwards becomes a fruit in the shape of a pear, with one cell, including an oblong seed, and two empty cells at the point. It is an annual plant, that decays as soon as the seeds are ripe, and grows wild in several parts of Europe. The oil of these seeds is emollient, and moderately heating, and it is given inwardly in a painful costiveness.

MYRRHIS, *sweet Cicely*, has a long, thick, white, soft, and somewhat spongy root, with stalks that rise to the height of four or five feet, which are branched, downy, and hollow. The leaves are large, and winged like those of hemlock, but whiter, and often marked with white spots; they are soft to the touch, a little downy, and have the smell of chervil. The flowers grow in umbels on the tops of the branches,

and are composed of five unequal petals, disposed like those of the flower-de-luce. The calyx turns to a fruit, composed of two seeds, resembling the bill of a bird, and are gibbous on one side; but plain on the other. It may be propagated at the beginning of March, by sowing the seeds on a bed of light earth in a shady situation; and when the plants come up they should be transplanted into the like earth in a moist shady situation, about two feet asunder. Some use the leaves as a salad, and think it is as good as common chervil; it flowers in June, and the seed is ripe in July. It is looked upon as a pectoral, and the leaves when dried in the shade, and smoked like tobacco, help those that are troubled with an asthma.

MYRTUS MINOR VULGARIS, *Box-leaved Myrtle*, is a shrub that has a hard woody root, that sends forth a great number of small flexible branches, furnished with leaves like those of box, but much less, and more pointed; they are soft to the touch, shining, smooth, of a beautiful green, and have a sweet smell. The flowers grow among the leaves, and consist of five white petals, disposed in the manner of a rose, and have a calyx cut into five segments. There is a great number of stamina, which have a fine smell, and when the flower is fallen off, the calyx becomes an oval oblong berry, adorned with a sort of crown, made up of the segments of the calyx. The berry is green at first, but grows black when ripe, and is smooth, juicy, and divided into three cells, containing hard seeds in the shape of kidneys. This sort of myrtle is the most common in the gardens of the northern countries, and is propagated from cuttings, the best season for which is in July. The shoots should be six or eight inches long, and the leaves on the lower part should be stripped off above two inches high, and the part twisted which is to be placed in the ground. They should be planted in pots, two inches distant from each other; the earth should be pressed close about them, and there should likewise be some water to settle it. The pots should be plunged in old dung, or tanner's bark, and shaded with mats in the heat of the day, watering them occasionally. In about a month's time they will take root; and, towards the beginning of September, they should be removed to a place sheltered from cold wind, where they may remain a month, and then be removed to the green house. At the beginning of the next April, they should be taken out carefully, and placed in separate pots, with a ball of earth at the root.

MYRTUS BRABANTICA, *Dutch Myrtle*, is a small shrub, with a hard flexible root, and rises to the height of a cubit or upwards; it has the look of a small willow, for which reason it is called by some Sweet Willow. There are male and female flowers on different plants, and those of the male are oblong; loose, scaly catkins, and in each of the scales there is a flower in the shape of a half moon, but without petals, though there are from five to six stamina. The female flowers have no stamina, but an oval pistil, supported by two styles, which afterwards changes to a berry, containing one roundish seed. It grows plentifully upon bogs in many parts of England, and flowers in May and June; and the seeds grow ripe in July and August. Where this shrub grows in plenty, it is so fragrant, especially after a shower of rain, as to perfume the air at a great distance, during the spring and summer. The leaves have been said to have many virtues, and they are still used in some places to kill worms.

NARCISSO-LUCOIIUM, *Snow-drop*, has a bulbous root, composed of several white coats, except the outermost, which is brown, and underneath there are whitish fibres. It sends forth three, four, or five leaves, like those of leeks, which are green, smooth, and shining; among these arise an angular,

furrowed, hollow stalk, six inches high, cloathed with leaves as far as the middle, which form a kind of white sheath. It generally bears but one flower at the top, though sometimes two, but seldom three. The sheath of the flower is oblong, blunt, compressed, and opening sideways becomes a dry skin; the flower itself has three oval oblong petals, which are spread open, and are equal; the nectarium is seated in the middle, and is cylindrical, blunt, and bordered. The pistil is placed in the center of the flower, attended by six stamina, and afterwards becomes an oval capsula, with three cells full of roundish seeds. They are of two sorts, the single and the double; and they are valued for their early appearance, which is commonly in February. The roots should never be planted single, because the flowers make the best appearance when they grow in bunches. When there are twenty or more roots together, they have a very good effect. The root is of no use in medicine.

NASTURTIUM HORTENSE, *garden Cresses*, have a single, woody, white root, that is not so acrid as the leaves. This root sends forth several stalks, to the height of a foot, or a foot and a half, that are round, smooth, solid, branched, and covered with a sort of bluish dust, that will readily come off. The leaves are oblong, deeply cut, and have no disagreeable taste. The flowers grow on the tops of the branches, and consist of four petals, placed in the form of a cross, and of a whitish purple colour. The pistil, which rises from the center of the flower-cup, becomes a roundish smooth fruit, divided into two cells, containing small, oblong, yellowish seeds. It is cultivated in gardens as a salad herb, and is in most esteem in the winter, and in the spring. During the winter they must be sown on a gentle hot-bed, covered with mats or glasses; in the spring upon warm borders, and in the summer upon those that are shady. They attenuate and cut gross thick humours, and are good in obstructions of the viscera. It may be eaten plentifully as a salad, and therefore nothing need to be said of the dose.

NASTURTIUM AQUATICUM, *Watercress, or Cresses*, have a small white root, full of knots, from each of which several capillary fibres proceed, that enter into the water. The stalk arises to the height of a foot, and is crooked, thick, hollowed, furrowed, smooth branched, and of a green colour, with a reddish cast. The leaves are almost round, juicy, of a greenish brown colour, and have a biting agreeable taste. The flowers grow on the top of the stalks, and are small, white, composed of four petals in the form of a cross, with several yellow stamina and apices; these are succeeded by pods, that are a little crooked, and divided into two cells full of roundish, small, reddish seeds, of an acrid taste. It grows on the sides of brooks and ditches, and flowers in July and August. It is used as a salad herb, especially in the winter. When the leaves first appear, they are almost round, but afterwards they are cut like those of rocket. It has much the same virtues as garden cresses, but stronger, and is accounted one of the best antiscorbuticks in these parts of the world.

NEPETA, *Nep, or Cat-mint*, has a woody root, divided into several branches, and sends forth a stalk three feet high and upwards, which is square, hairy, branched, reddish near the ground, and the upper part whitish; the branches are always produced opposite to each other by pairs; the leaves are like those of the nettle or betony, and are serrated on the edges; they are pointed, downy, whitish, and have long pedicles, and have a strong smell of mint, with a biting acrid taste. The flowers grow on the tops of the branches, where they are collected into six spikes; they are purple or whitish, and they each consist of a tube, whose upper lip is cut into two segments, and

the lower into three; the middle segment is broad and hollowed like a spoon, and elegantly crenated on the edges; it is sustained by a calyx, in the shape of a horn, and succeeded by four naked oval seeds. It is called cat-mint, because the cats will not suffer it to grow, and is propagated by sowing the seeds in March, in beds or borders of common earth; but it is found wild in many parts of England. It is aperient, has all the virtues of common mint, and may be drank in the manner of tea. When the cats eat too much of it, it will make them drunk; but, what is very remarkable, if it be raised from seeds the cats will not touch it.

NICOTIANA MAJOR LATIFOLIA, *the greater broad-leaved Tobacco*, has a white fibrous root, which sends forth a stalk to the height of five or six feet; as thick as one's thumb, and round. It is hairy, and full of a white pith. The leaves are large; without pedicles, and placed alternately on the stalks by their large appendages; they are hairy, full of nerves; a little pointed, clammy to the touch, and of a pale green, inclining to yellow. They are divided into several branches at the top, that support flowers in the shape of a bell, divided into five deep segments, as well as the calyx, which expand like a star. They are of a purple colour, and the apices of the stamina are sprinkled with a fine powder of an ash colour. The embryo becomes an oblong, roundish, membranaceous fruit, divided into two cells full of reddish seeds, that are exceeding small, in proportion to the bigness of the plant. It is a summer plant with us, though it will sometimes, in moderate winter, continue all the year. It is known by the American planters, under the title of Oroonoko Tobacco; but it is not in such esteem with the English, as the other sorts. In Brasil it flowers continually, and will live ten or twelve years.

NICOTIANA MAJOR ANGUSTIFOLIA, *the greater narrow-leaved Tobacco*, differs only from the former in their leaves, which are narrower, and more pointed, and are fixed to the stalk by pretty long pedicles.

NICOTIANA MINOR, *the lesser, or common English Tobacco*, has a single thick root, sometimes divided into several tender white fibres, and sends forth a stalk to the height of two feet, which is hairy, solid, sometimes as thick as one's finger, branched, and clammy to the touch. The leaves are rounder than those of the former sorts, and are placed alternately on the stalks; they are flat, blunt at the end, of a greenish brown, and have short pedicles. The flowers are numerous on the top of the branches, and are divided into five segments like the former; they have five stamina, whose apices are of an ash colour, as well as the pistil; they are less than those of the former kind, and the colour is of a greenish yellow. The calyx is hairy, clammy and divided into five parts. The flowers are succeeded by roundish capsula, in the form of a navel, and, when ripe, open into two parts, and are full of a vast number of yellow tawny seeds. Besides these, there are other sorts, as *the greater narrow-leaved perennial tobacco; the lesser tobacco with larger and rougher leaves; the great broad-leaved tobacco with white flowers, and a short seed vessel; the dwarf tobacco with a primrose leaf; and the small tobacco with a leaf in the shape of a heart, and a flower with a longer tube.* The first of these sorts is most common in England, and is generally raised by the gardeners near London. They were all brought originally from America, and at first were in high esteem for their medicinal qualities. It is called tobacco from the island of Tobago, from whence it was brought in the year 1560.

The taste and smell of tobacco is well known, as well as its common use. Some use it as a vomit, which should be never done, except in cases of necessity. The watery extract made by long boiling, and

and preserved dry, has a cleansing anodyne quality, and is excellent for appeasing an asthmatic cough. It may be taken in broth, or with a stomachic remedy to four or five grains. In some delicate constitutions, it will occasion a retching to vomit, which may be easily remedied with a draught of burnt wine. Outwardly, the plant is cleansing and healing, and will soon cure malignant ulcers, when other things fail. Some make an ointment of tobacco for the killing of lice, but it should be used very cautiously. When it is beaten into a cataplasm with vinegar or brandy, it will remove hard swellings of the liver and spleen, as we learn from the Edinburgh essays. Some recommend the smoking tobacco in the time of the plague, and other infectious diseases. We know an instance of the efficacy of smoking tobacco in a person, who was thereby cured of a dry asthma, when all other remedies had failed. Having smoked part of a pipe, merely for good company sake, he found such an abatement of his cough, as induced him to pursue it, which at last effectually cured him, by gradually bringing off his lungs the coagulated matter, with which they were clogged. However, this may not succeed in every constitution; and it will be prudent not to continue it, if after once or twice smoking, the patient has not some substantial encouragement to proceed, which may compensate for the sickness tobacco always occasions those, who are not used to smoking it.

NIGELLA ROMANA, *Roman Fennel-flower*, has a root with many furrowed slender stalks, a foot in height; the leaves are pretty large, green, and cut into slender segments. The flowers are placed at the tops of the branches, distinct from each other, and are composed of five petals, of a pale colour, and disposed in the form of a rose. There are several stamina in the middle, surrounded with a crown, and are succeeded by a membranous fruit, and divided into several cells, that terminate in horns. This plant is cultivated in gardens, and flowers in July, August, and September. The seeds brought from Italy are the best, and should be fresh, large, and of a fine yellow colour or black. It is resolvent, discutient, and strengthening, and is proper for correcting the impurities of the stomach, breast, and kidneys. It is good against catarrhs of the head, the head-ach, arising from thence, the vertigo, and obstructions of the nose, either in fumigations, or snuffed up when powdered. The dose inwardly is from one scruple to a drachm. It is of great use among the Germans, but neglected by us.

NOLI ME TANGERE, *five* **BALSAMINE**, *Balsamine*, has a root that runs level with the ground, and sends forth a stalk to the height of a foot and a half, which is tender, of a bright green, smooth, shining, light, branched, geniculated by intervals, with tuberosities. The leaves are placed alternately, and are deeply dentated on the edges. From the places, where the leaves join to the stalk, there proceed long pedicles, that bend down to the ground, which are divided into three or four branches, on which hang small flowers, with four unequal petals, supported by two small green leaves; but the flower is yellow, representing a kind of a sea-monster, with a small body, and a slender, short, crooked, pointed tail, like an ox's horn, sprinkled with deep red spots; the mouth is wide, and in the middle there are several stamina, of a whitish colour. They are succeeded by long, slender, knotted fruit, of a whitish green, streaked with green lines, bending to the ground. They open as they grow ripe, and when the wind blows a little stronger than ordinary, or by the least touch, they shoot out their seeds, at the same time writhing themselves like worms; the seeds are either ash coloured, brown, or red. Those that are not used to this plant, are always startled

when the seeds burst out in the above manner; and from its not bearing to be touched without this effect, it is called *Noli me tangere*, that is, *touch me not*. It grows wild in some places, and flowers in June, and it is also cultivated in gardens, for the diversion it affords. It is propagated by the seeds, and if suffered to cast them, it will come up every spring without any care; but it delights most in moist shady places. It is very aperient and diuretic, and frees the kidneys from gravel.

NUMMULARIA, *Moneywort*, has a very creeping slender root, and sends forth several long, slender, angular, branched stalks, that creep on the ground, and whose leaves are placed in pairs opposite to each other; they are about as broad as one's finger, and are almost round, though a little curled; and of a yellowish green; where the leaves join to the stalk, the flowers proceed, which are large, and consist of a single petal, cut into the shape of a rose. On some branches there are three leaves, and as many flowers at each knot. They are succeeded by small round fruit, containing seeds hardly visible. It is called moneywort from its roundness of the leaves, and is common in moist places, and by the sides of ditches. It begins to flower in May, and continues to do so most of the summer. The leaves are astringent and vulnerary, and proper to stop hæmorrhages, both inwardly and outwardly. The dose of the juice is from one ounce to three, and, in decoction, from one handful to three. Boerhaave recommends it greatly against the hot scurvy.

NYMPHÆA ALBA, *white Water-lily*, has a long root, as thick as one's arm, and sometimes as the leg; full of knots of a brown colour without, and white within; it is fleshy, spongy, full of clammy juice, and adheres at the bottom of the water to the earth; by several fibres. It sends forth large roundish leaves, in the shape of a heart, that are thick, fleshy, veinous, and of a whitish green colour on the top, and of a brownish green beneath, and swims on the surface of the water; these are supported by long pedicles, as thick as a child's finger, which are cylindrical, reddish, tender, juicy, and spongy. The flowers are large and broad when blown, consisting of several leaves, disposed in the form of a rose, of a fine white colour, but of little or no smell. The flower cup consists of five whitish leaves, and there are other leaves on the edges, of a whitish green colour. There are a great number of stamina, with a pistil that turns to a globular fruit, like the head of a poppy, divided into several cells, full of oblong; blackish, shining seeds. It grows wild in marshes and standing waters, and flowers in May and June.

NYMPHÆA LUTEA MAJOR, *the great yellow Water-lily*, differs from the former, in having leaves not quite so round, and in the flower, which is yellow; besides which the fruit is of a conical shape, and contains larger seeds. It is found in the same places, and flowers at the same time as the former. The roots have both the same virtues, and have a clammy bitterish taste. They are proper in heat of urine, want of rest, and all internal inflammations, but are now seldom used. The powder of the dried root is given from a scruple to a drachm.

OLEA MAJOR, *five* **HISPANICA**, *the manured Olive tree*, has a trunk that is knotted, and more or less high, with a smooth ash coloured bark, and yellowish wood, that has somewhat of a bitter taste. The leaves are oblong and narrow, almost like those of willow; they are pointed, thick, fleshy, hard, of a greenish yellow above, and whitish below, but without down; they have very short pedicles, and are generally placed by pairs opposite to each other. The flowers proceed from the places where the leaves are joined to the stalks, and grow in whitish branches, like those of the alder; they consist of a single petal, the

the lower part of which is hollowed, and the upper is divided into four parts; the embryo of which is fixed in the center of the flower cup, and becomes an oval, green, fleshy, succulent fruit, of different sizes; for in Spain it is as big as a middling plumb; whereas in Italy and Languedoc, it scarce arrives at the size of a common acorn. This is the olive, which is at first green, then yellowish, and at length blackish, when it is full ripe; though there are some in Spain that turn white. They are oily, have an acerb disagreeable taste, and contain an oblong stone, which is very hard, and within it is a kernel of the same shape. It is cultivated in the southern parts of Europe, and delights in dry, marly places, that are exposed to the south or east; and it flowers in June and July. This tree continues a long time, and the wood which has a fine smell, will burn as well green as dry. They produce a large quantity of fruit, of which they make oil-olive, or salad-oil, well known all over Europe. They are planted out of curiosity in England, in pots or cases, but must be removed into the green-house all the winter. There are several sorts of olives that differ in shape, colour, size, and juice. They are pickled, and then become agreeable to the taste; and are well known in England by the name of pickled olives; they are then said to create an appetite, and strengthen the stomach.

ONOBRYCHIS, *Cock's-head, or Sain-foin*, has a long, hard, woody root, black without, and white within, which sends forth several straight strong stalks, about a foot in height, and of a reddish green colour. The leaves which are like those of vetches, but smaller, are green above, white and downy below, pointed, and placed by pairs on one side. The flower is papilionaceous, and the pistil rises out of the downy flower cup, which afterwards turns to a crested pod, in the shape of a cock's-comb, and is rough, with prickles; each of these contain a seed, in the shape of a kidney, which has a pretty good taste when it is green. *Sain-foin* is a French word, which signifies wholesome hay, and is so called, because it is thought to fat all sorts of cattle the soonest of any other. The hay made of it is accounted among us the best sort of food for most cattle, especially in the spring, there being no danger attending it, as there is in clover; it breeds abundance of milk, and the butter that is made of it is very good. There is a sort with a deep red flower, which, when disposed in the large borders of pleasure gardens, afford an agreeable variety; for they are of a beautiful colour, grow in long spikes, and continue a great while. Some observe, that if *Sain-foin* be carefully gathered, well dried, and kept in boxes, it has the smell of tea, inasmuch that it has been mistaken by good judges for green tea; but then it must be gathered before it flowers.

OPULUS, *five* SAMBUCUS AQUATICA, *Marsh elder, or Gelder-rose*, has a thick, firm, white root, that sends forth a stalk to the height of five or six cubits, divided into several branches, like those of the elder tree, and is knotted by intervals; it is covered with a smooth ash coloured bark or rind, is full of white spongy pith; and is very tender and brittle. The leaves proceed from the knots, and are large, angular, and like those of the maple tree. The flowers consist of a single petal or leaf, divided into five parts at the top, and expanded in the form of a rose. Those about the circumference of the umbel are larger than the rest, and of a fine white, with a calyx that proceeds from the middle of the cup, but they are barren. Those in the middle or centre are smaller, open later, and in their bottom there is a hole that receives the point of the calyx, and they are of a yellow colour. This turns to a berry a little larger than that of the common elder, which is soft and red when ripe; in each of these

there is a flat red seed in the shape of a heart. This shrub delights in moist woods, and on the banks of rivers, and it flowers in May; but the berries are not ripe till autumn, and they continue all the winter. There is another *Gelder-rose*, that differs from the former, only in having the flowers collected into a globe, and is common in old gardens in most parts of England. At a distance the flowers resemble snow-balls, for which reason it is called in some countries the *Snow-ball tree*. It is of no use in medicine.

ORCHIS, *feu.* SATYRIUM, *Fool-stones*, has a root composed of two tubercles almost round, which are fleshy, and of the size of nutmegs; whereof one is full and hard, and the other wrinkled and spongy. At first it sends forth six or seven leaves, that are long, pretty broad, smooth, and like those of the flower-de-luce, but smaller, and generally marked at the top with brownish red spots. The stalk rises to the height of a foot, and is round, streaked and encompassed with one or two leaves; on the top there is a long spike of beautiful purple flowers, that are whitish towards the center, and sprinkled with specks of a deeper purple. Each flower is composed of six unequal petals, of which the five uppermost compose a sort of helmet; and the lower petal, which is larger than the rest, has a sort of a head or helmet at the top, and terminates in a tail, or sharp point like a spur. The calyx becomes a fruit, with three sides, and is divided into three cells, containing many small seeds. It flowers towards the end of April, and the beginning of May, and is found in many parts of England.

ORCHIS LATIFOLIA, *feu* MAJOR, *Dog's-stones*. This plant has a root composed of two bulbs, or fleshy tubercles, but larger, and in the shape of large olives. The stalk rises near the height of a cubit, and has long pyramidal flowers at the top, which are large and beautiful, whitish within, and sprinkled with purple spots; but they are reddish on the outside, and represent a man in armour, without hands or feet. The leaves are big, long, and broad, and are roundish at first when they rise out of the earth in November. The seed is like that of the former, and flowers in May. There are several other sorts of these plants, the under part of whose flower represents several shapes, as a naked man, a butterfly, a fly, a drone, a pigeon, an ape, a lizard, and a parrot; and these all grow wild in several parts of England; but deserve a place in every good garden. The Turks have a preparation of a certain root that is called *lalep*, which they make use of to recover their strength. It is supposed to be a kind of orchis, and the following preparation of this root will answer the same purposes. Take the roots or bulbs of orchis, that are well nourished, and after they are skinned, throw them into cold water; after they have been there some hours, boil them in a sufficient quantity of water, and then strain them; this done, put them on a string, and dry them in the air; this is best done in a dry hot season. They will become transparent, very hard, and will resemble pieces of gum tragacanth. If they are kept in a dry place they will always remain good, and may at any time be reduced to a very fine powder. A scruple of this, put by little and little into boiling water, will entirely melt, and will be sufficient for a pint of water; it may be rendered more agreeable; by putting in a little sugar, and is exceeding useful when mixed with milk, in all diseases of the breast; for it is very emollient, and will abate the sharpness of the humours; it is excellent in consumptions, and bloody fluxes of the bilious kind.

OREOCELINUM, *five* APIUM MONTANUM, *Mountain Parsley*, has a root consisting of many fibres, adhering to one head, which creep greatly in the earth; they are blackish on the outside.

side, white within, and are full of mucilaginous juice. It has a single ferulaceous stalk, that rises to the height of four or five feet, which is furrowed, and divided into wings. The leaves proceed as well from the root as the stalk, and are large, but like those of the common parsley, only they are more firm and smooth. The flowers grow in umbels at the top of the stalks and branches, and are small, whitish, and consist of five purplish petals, disposed in the form of a rose. These are succeeded by a fruit, which was the calyx of the flower, composed of two seeds, that are oval, flattish, radiated on the back, and bordered with a membranous leaf, of a reddish colour. It grows in mountainous places, where there are pastures.

OREOCELINUM, *five APIUM MONTANUM MINUS*, *smaller mountain Parsley*, has a pretty thick, soft root, that is fibrous on the upper part, and white both within and without; the stalks rise to the height of a cubit and upwards, and is pretty thick, firm, furrowed, knotted by intervals, reddish and branched. The leaves lie on the ground, and are like those of garden parsley. The flowers grow in umbels on the top of the stalk and branches, and are of a white colour. The seeds that succeed them have a more acrid taste than the leaves. It delights in mountainous and sandy places, and flowers in July and August. The seeds are accounted an aperient, and proper to open the obstructions of the liver and spleen; they are also diuretic, and free the kidneys from gravel; but they are seldom used among us.

ORIGANUM VULGARE, *wild Marjoram*, has a slender, woody, fibrous root, creeping obliquely into the ground, which sends forth several stalks, that rise to the height of two or three feet, and are hard, square, and downy. The largest leaves resemble those of common calamint, and the lesser those of marjoram; they are downy, have an agreeable smell, and an acrid, aromatic taste. The flowers are collected into scaly spikes, and are labiated, consisting of a single petal, whose upper lip is erect, roundish, and divided into two segments, but the lower into three. The pistil arises from the calyx, and is fixed in the back part of the flower like a nail; it is attended with four embryoes, and turns into as many small seeds, contained in a capsula, that was the calyx of the flower. It grows wild on dry chalky hills, and on gravelly soil, in several parts of England, and it flowers in the summer. Wild marjoram is diuretic, and diaphoretic, and may be used in the manner of tea in the asthma, and a violent cough. The powder of the leaves and the flowers dried in the shade are cephalic, and being taken as snuff, will make the nose run considerably. It helps digestion, discusses wind, and is employed externally in baths for the feet.

ORNITHOPODIUM MAJUS, *the greater Bird's-foot*, has a small, white, single, fibrous root, accompanied with several grains or tubercles, with several flexible, weak, branched, round, hairy stalks, that seem to creep on the ground. The leaves are less than those of the Bastard Sena, and the flowers are small, papilionaceous, and disposed in spikes on the top of the branches; the pistil arises out of the calyx, which afterwards becomes a hooked jointed pod, that is generally undulated, and at every joint there is a round seed; and several of these pods grow together in such a manner, as to resemble the foot of a bird. It flowers in summer, and generally in June, and delights in dry cultivated places. The whole plant is accounted aperient and diuretic, and when powdered, the dose is a drachm in a glass of white wine; but it is not now in use.

ORYZA, *Rice*, has a root like that of wheat, and furrowed stalks, that rise to the height of three or four feet, which are thicker and stronger than those

of wheat or barley, and knotted by intervals. The leaves are like those of reeds in shape, but they are fleshy like leeks. The flowers which grow on the tops are of a purple colour, and are disposed into panicles. The seeds are almost oval, white, transparent, hard, and are contained in a yellowish, rough, furrowed, angular, downy capsula, somewhat like barley; they are placed alternately on each side of the branches. This plant is cultivated in hot countries, in moist marshy land, and the use of the seeds is principally for food. However, they destroy the acrimony of the humours, and are good in fluxes of the belly. Rice serves instead of bread in most of the eastern countries, and is their principal nourishment. It is now planted in South Carolina, where great quantities have been produced, and as good as in any other part of the world. It is chiefly used here for puddings, and to make rice-milk.

PÆONIA MAS, *Male Peony*, has an oblong, thick, tuberose root, brown without, and pale within, and is often divided into several branches; it sends forth stalks to the height of two or three feet, that are a little reddish, and divided into branches. The leaves are large, and composed of several other leaves, almost like those of the hazel tree; but they are broader and thicker, and of a shining, brownish green colour; they are also covered underneath with a down, and have long reddish pedicles. The flowers grow on the tops of the stalks, and are large, consisting of several petals, that expand in the form of a rose, sometimes of a purple colour, and sometimes of a palish red. The calyx is composed of five leaves, and in the middle there are purple stamina with saffron coloured apices. They are succeeded by fruit, composed of several small, white, downy, shining, crooked horns, that are open when they are ripe, and contain many globulous seeds, that are red at first, and afterwards of a dark blue or black. It flowers at the beginning of May, and they fall off soon afterwards. It is cultivated in gardens for the sake of the roots, which are used in medicine. They are propagated by parting the roots, and are extremely hardy, for they will grow in any soil or situation: the best season for this is in the beginning of September.

PÆONIA FÆMINA, *female Peony*, has a root composed of several tubercles, connected together with fibres, and sends forth a tall stalk, that has scarce any redness at all; the leaves are of a greenish pale colour above, and whitish, and a little downy underneath. The flowers are like those of the former, but neither they nor the fruit are so large. This is a very common sort, and is to be met with almost every where in gardens. The *Male Peony* is principally used in medicine, and the roots and seeds have been thought by many to be a specific against the falling-sickness, convulsions, and the palsy. They are reduced to powder, after they have been dried in the shade, and then the dose is a drachm or two; or an ounce of the roots is given in decoction, while they are fresh.

PALIURUS, *Christ's-iborn*, has a hard woody root, with a stem that grows so high, that it sometimes deserves the name of a tree. The branches are long and thorny, but those that are near the leaves are smaller, and not so prickly as in other places. The leaves are almost round, pointed, and of a dark green, with a reddish cast. The flowers are small, yellow, grow on the tops of the branches, and are generally composed of five petals, in the form of a rose. The pistil arises from the flower cup, which turns to a fruit almost in the shape of a bonnet, having a shell that is nearly globular, divided into three cells, on each of which there is a single roundish seed. This shrub grows wild in the hedges of Italy, Spain, Portugal, and the south of France, from whence its seeds are procured. It flowers in May and June, and

and the fruit is ripe in the autumn. It is called *Christ's-thorn*, because they suppose his crown of thorns was made of the branches of this tree. It may be propagated by laying down the tender branches in the spring, which will take root in a year's time; the best season for transplanting them is in autumn, soon after the leaves begin to decay. The fruit is said to be diuretic, and to help the moist asthma, by promoting expectoration; but it is not in use among us.

PAPAVER CORNUTUM, seu CORNICULATUM, Yellow horned Poppy, has a root as thick as one's finger, which is long, blackish, and full of a yellow juice, as well as all the plant, which has a particular taste and smell. It sends forth long, fleshy, thick, downy leaves, cut deeply on the sides, and dentated on the edges; the colour is of a sea-green, and they lie upon the ground, where they continue all winter. The stalk, which does not rise till the second year, is strong, solid, knotty, smooth, and divided into several branches, sending forth leaves from the knots that are smaller, and not so jagged as those below. The flowers grow on the top of the stalks and branches, and are as large as those of garden poppies, being each composed of four yellow petals, placed in the form of a rose, in the middle of which there are a great number of stamina of the same colour. They are succeeded by fruit, or a sort of pods; a span in length, or longer, and are very slender and crooked like horns; they are rough to the touch, blunt at the ends, and contain a double row of seeds, separated by a partition, and as round as those of the common poppy, and very black. It grows wild on the sea-shore, and in sandy maritime places. If it be sown in gardens in autumn, it will come up in the spring, and will flower in June and July, and the pod will be ripe in August. This plant is accounted diuretic, and very good for those who make thick urine: in Portugal they give an infusion of half a handful of the leaves in a glass of white wine for the gravel and stone; but it has not been brought into use in England.

PAPAVER RHÆAS, the greater wild Poppy, or Comrose, has a single white root, as thick as one's little finger, furnished with a few fibres, and has a bitter taste. It sends forth several stalks, to the height of a cubit, or upwards, which are round, solid, hairy, and branched; the leaves are jagged like those of succory, hairy, of a brownish green, and dentated on the edges. The flowers grow on the top of the stalks and branches, are composed of four large, thin, deep, red leaves, which are ready to fall off with each blast of wind; these are succeeded by small heads of the size of hazel nuts, that are oblong, smooth, and much of the same shape with those of the garden poppy. They are divided into several cells, containing blackish, or dark-red seeds. This plant grows almost every where in the fields, especially among corn. It flowers in May, June, and July. The flowers are made use of in medicine, and are in some measure anodyne and narcotic. They are good in acrimonious catarrhs, roughness of the face, and in commotions of the fluids. They may be drank as tea, and are of very great service in all cases where a gentle opiate is useful; there is a syrup made with these flowers, kept in the shops, which will serve for the above purposes.

PAPAVER HORTENSE NIGRO SEMINE, the lesser Garden Poppy, has a root about the thickness of one's little finger, full of a bitterish milk, as well as the whole plant. It sends forth an upright stalk, to the height of two cubits, which is generally smooth, though sometimes a little hairy, and the leaves are oblong, broad, dentated, curled, and of a sea green colour. The flowers grow on

the top of the stalks and branches, and are large, in the shape of a rose, of a reddish colour, sometimes single, and sometimes double; as also, sometimes fringed on the edge, and sometimes not. The calyx consists of two leaves, that generally fall off as soon as the flower is blown. It is succeeded by roundish heads of different sizes, crowned with a sort of cover, in the form of a star, and contains in their cavities or membranous cells, seeds of a blackish colour. There is a great variety of these plants, as well in colour as shape, that are sown in gardens for the sake of their flowers; but they are not so much used in medicine as the white poppy. They may be all propagated by the seeds sown in autumn, and will flower in May and June, and sometimes during all the summer.

The heads of the stalks of these plants contain a milky juice, which may be collected in a considerable quantity, by slightly wounding them when almost ripe; this, exposed for a few days to the air, thickens into a clammy mass of the same quality as opium, but weaker. Poppy heads boiled in water communicate their virtues to it very freely; and when the liquor is strongly pressed out, clarified with the whites of eggs, and evaporated to a due consistence, yields an extract that weighs about one sixth of the weight of the heads. Some count it more safe than opium, but it must be given in a double dose.

PARIETARIA, Pellitory of the wall, has a fibrous reddish root, with several stalks that rise to the height of two feet, which are round, reddish, brittle, and branched. The leaves are oblong, and are pointed, downy, of a brownish green colour, shining, rough, and apt to hang to the cloaths of passengers; they have long pedicles, and are placed alternately on the stalks. The flower has no petals, but has generally four stamina, that rise out of a flower-cup, divided into four parts, which is sometimes in the shape of a bell, and sometimes like that of a funnel; they surround a pistil that generally turns to an oblong seed, contained in a capsula that was in the cup of the flower. It grows upon old walls and buildings in great plenty, and flowers in May. It is looked upon as aperient, temperating and resolvent, whether taken inwardly or applied outwardly. The dose, in infusion, is from one handful to three; and of the juice from one ounce to three. It is accounted one of the five emollient herbs, and is made use of occasionally for that intention, particularly in decoctions, fomentations and clysters.

PASTINACA, Parsnep, or the Garden Parsnep, has a long, thick, fleshy root, of a yellowish colour, in the middle of which there is a nerve, that runs throughout its whole length. The stalk rises to the height of three or four feet, and is upright, firm, furrowed, hollow, and branched. The leaves are large, and composed of other leaves, that are villous, dentated on the edges, winged, and are placed on a pretty large rib; they are of a brownish green, and placed by pairs along the rib, which is terminated by a single leaf. The flowers grow on the tops of the stalks and branches in large umbels, and each flower has four yellow petals, placed in the form of a rose; these are succeeded by large, oval, flattish, slightly furrowed seeds, bordered by a small membranous leaf, resembling those of angelica. The root of this plant is of great use as food, for which it is chiefly employed. It flowers in July and August, the second year, after it has been sown. The taste of parsneps is well known, and they are more nourishing than carrots, though some have a natural aversion to their use.

PASTINACA SYLVESTRIS, wild Parsnep, has a white single root, that has sometimes large fibres, and has the same taste and smell as the garden parsnep. The stalk is two or three cubits high, and is upright,

upright, stiff, furrowed, hairy, hollow within, branched, and has leaves alternately placed like the former; but they are smaller, of a deeper green, and are sometimes hairy, especially towards the root. The flowers grow in umbels, and are small, yellow, and composed of five petals each; these are succeeded by double seeds, as in the former. It grows in uncultivated places, in dry fields, and upon hills, and flowers in the summer. Some make use of it as an aliment, and pretend, when the seeds are sown in the garden, they will produce as good parsneps as the garden sort. Both the seeds and root have been commended as a remedy against agues; but they often fail.

PERIPOLCA, *Virginian silk*, or *climbing dog's bane*, of Montpellier, has a root almost as thick as one's finger, that is long, white, fibrous, and creeping; as also full of milky juice, as well as the rest of the plant. The stalks rise to the height of two cubits, and are slender, round, branched, pliant, and creep upon any tree that stands near it. The leaves stand opposite to each other, are large, thick, whitish, pointed, and cut in the form of a cross, near the pedicle, and are full of a milky juice. The flowers proceed from the places where the leaves join to the stalk, consisting of a single petal that is white, and cut into five segments in the form of a star. The pistil is succeeded by a fruit, so like that of dog's bane, as not to be distinguished from it; and when it is opened, it discovers a downy substance, under which the seeds lie. It grows wild about Montpellier, but with us it is propagated in gardens, by laying down the branches at the spring of the year; it flowers in June, July and August; and the milky juice being inspissated over the fire, becomes blackish, and greatly resembles scamony, but is not so purging; and therefore requires a large dose to procure that effect.

PERSICARIA MITIS, *dead or spotted Arse Smart*, has a slender, oblique, woody, fibrous root, difficult to break, and sends forth stalks to the height of a foot, that are round, hollow, reddish, branched and knotted. The leaves are like those of the peach-tree, and sometimes marked with blackish spots. The flowers grow in spikes, and consist of single petals, cut into five segments, and are without a calyx; but there are five stamina that are purple and shining, though sometimes whitish; they are succeeded by oval, flattish, pointed, smooth, blackish seeds. It has not so acrid a taste as the following, and is a little tart. It grows in watery, marshy places, as well as in moist ditches, almost every where, and flowers in July and August. It is looked upon as astringent, detersive, and vulnerary, and its decoction is said to be good in fluxes of the belly, and for ulcers of the intestines.

PERSICARIA URENS, *biting Arse Smart*, has a small, single, woody, white, fibrous root, that sends forth several stalks to the height of a foot and a half, which are firm, round, smooth, knotty, branched, sometimes reddish, and sometimes of a greenish yellow. The leaves proceed from the knots of the stalk, which they embrace by their membranous appendages, and are of a pale green, and like those of the peach-tree. The flowers grow in long spikes on the top of the stalk and branches, and consist of a single petal, cut into five segments; there is no calyx, but there are five stamina generally of a purple colour, which are succeeded by pretty large seeds, somewhat triangular, shining and blackish. It has an acrid biting taste, like pepper, and grows in watery marshy places on the sides of brooks and ditches; it flowers in July and August. It is said to be cleansing and vulnerary, and to be good in the dropsy, jaundice, and obstructions in the viscera. Its distilled water, given

to two or three ounces, is by some accounted a specific against the gravel. All authors agree, that this herb, applied to old ulcers, eats away proud flesh, and cleanses and dries them; being applied as a cataplasm to the bruises of horses, it resolves the coagulated blood; if the wounds and ulcers are washed with the juice, the flies will never come near them.

PERVINCA, *five CLEMATIS DAPHNOIDES*, *Periwinkle*, has a fibrous root, with slender, long, round, green, knotty, creeping, climbing stalks; the leaves are oblong, green, smooth, and placed by pairs, opposite to each other, and are of a bitter styptic taste. The flower cup consists of a single leaf, divided into five long, narrow segments; and the flower of a single petal is cut into five segments, that expand into the form of a salver. The pistil is fixed in the lowest part of the flower, like a nail, and turns to a fruit composed of two husks or pods, which contain oblong, cylindrical, furrowed seeds. Some call it Ground Laurel, because its leaves resemble those of that tree. This plant is an evergreen, and is propagated by the branches that take root in the earth. It flowers in the spring, and continues to do the same for a long while. It is accounted vulnerary, and is found almost every where, in hedges, and among shrubs.

PERVINCA LATIFOLIA, *five FLORE CÆRULEO*, *greater Periwinkle*, with a blue flower, has a fibrous creeping root, with several thick, round, knotty, green, creeping branches. The leaves are placed by pairs, facing each other, along the stalks, and are of a shining green, with a bitter acrimonious disagreeable taste. The flowers, like the former, are generally blue, though sometimes white and without smell; it differs from the former only in being larger in all its parts. It is said to be vulnerary, astringent, and febrifuge, and is given to abate all kinds of bleedings.

PETASITES, *Butter Bur*, has a thick, long root, brown without, and white within; the stalks are thick, hollow, and hairy, and rise to the height of half a foot; the leaves are small, narrow, and pointed; and the flowers grow at the end of the stalks in tufts, and consist of many florets, divided into several parts; they are contained in a cylindrical calyx, cloven almost down to the bottom, into many segments. There is a single embryo that becomes a seed, furnished with down. The flowers appear before the leaves, which are very broad, and have a hollow in the middle, and round that a hollow expansion in such a manner, that they resemble bonnets. It grows in moist places on the sides of rivers, brooks, lakes, and ponds, and flowers early in the spring. In some places, the leaves grow to the height of a man, and continue all the winter. Some authors have confounded this plant with the great burdock, because the leaves have some resemblance to each other. The root, which is the part made use of is aperient, resolvent, hysteric, and vulnerary, and brings up phlegm in asthmas and obstinate coughs.

PETROSELINUM, *Parsley*, has a single root as thick as one's finger, and often much thicker, that is furnished with a few fibres; it is whitish, long, and good to eat. The stalks sometimes grow to the height of three or four feet, and are round, furrowed, knotted, and branched. The leaves are composed of others that are cut into jags, are green, and have long pedicles. The flowers grow on the top in umbels, and are composed of five pale petals, disposed in the form of a rose; these are succeeded by seeds that are joined by pairs, and are slender, furrowed, grey, and roundish at the back. It is cultivated in gardens, and will endure all sorts of weather. It delights in a moist ground, for which reason it should be often watered. It sends forth

a stalk the second year after it is sown, flowers in June and July, and the seed is ripe in August. It is aperient, and is said to open obstructions; but its chief use is only as a kitchen herb. The seed is one of the four hot seeds, is attenuating and diuretic, and is said to be good in the gravel and dropsy.

PETROSELINUM MACEDONICUM, *Macedonian Parsley*, has a long, thick, white, wrinkled, woody root, which sends forth a stalk to the height of a foot and a half, that is thick, hairy, and branched. The leaves resemble those of garden parsley; but are more large, a little more cut, and dentated. The flowers grow on the top of the branches in umbels, are whitish, and composed of five petals in the form of a rose. They are succeeded by slender, hairy, oblong, aromatic seeds, of an acrid taste. It grows wild in Macedonia, and was greatly valued by the ancients; but is here cultivated in gardens. The seed only is in use, and has the same virtues as that of common parsley, but stronger, and is an ingredient of Venice treacle.

PHASEOLUS, the *Kidney bean plant*, has a slender, fibrous root, and sends forth a long, round, branched, climbing stalk. The leaves come out by threes, in the manner of trefoil, and are large, pointed at the end, fleshy, smooth, and almost like those of ivy, with long, green pedicles. The flowers are papilionaceous, and a pistil rises out of the flower cup, which turns to a long pod full of seeds, generally shaped like a kidney. The use of kidney beans is well known, and therefore need not be mentioned here. They are opening, emollient, resolvent, and promote urine, and generally agree with most constitutions. The meal of the seed is sometimes mixed in emollient cataplasms.

PHILLYREA, *Mock Privet*, has a thick strong root that runs deep into the ground, and the stems rise to eight or ten feet high, and are covered with a white or ash coloured bark, a little wrinkled. It is an ever-green shrub, with leaves like those of the privet, and a flower that consists of a single petal in the shape of a bell, cut into four parts at the top; the colour is a whitish green or herbaceous. The pistil that rises from the center of the calyx afterwards turns to a spherical fruit or berry, that is black when ripe, and contains one seed. They have been formerly in great request, for hedges and to cover walls; but they are most proper for wildernesses. It flowers in May and June, and the fruit is ripe in September. It is of little or no use in medicine.

PHYTOLLACA, *American night shade*, has a root a foot long, that sometimes grows to the thickness of a man's thigh, which is white, and perennial. The stalk rises to the height of five or six feet, and is thick, round, strong, reddish, and divided into several branches. The leaves are placed irregularly, and are large, veinous, soft, and of a pale green, though sometimes reddish; the shape is like those of common night shade. The flowers grow in bunches, each of which consists of several petals, placed in a circular order, which are of a pale red colour. The pistil rises from the center, and the flower is succeeded by a soft fruit or berry, that is roundish, full of juice, and like a button flattened above and below; when it is ripe, it is of a brownish red colour; and contains several round black seeds, placed orbicularly. It is very common in our northern American plantations, and is cultivated in England, for the beauty of its flowers. It may be propagated by sowing the seeds in the spring, upon a bed of light rich earth; and when the plants are come up, they should be moved into the borders of large gardens, allowing them room enough to grow, for they will become very large. The berries are full of a purple juice, which gives a fine tincture to paper; but it will not last long.

PILOSELLA, *common Mouse Ear*, has a short, slender root, furnished with fibres, that send out slender, hairy stalks, which creep upon the ground, where they take root again. The leaves are oblong and roundish at the end, like the ears of a mouse, from whence it has its name, and they are covered with hair; they are green above, but downy below, and have an astringent taste. The flowers are only a single floret, of a yellow colour, with a scaly single calyx, which is succeeded by slender, black, downy seeds, in the shape of a wedge. It grows in dry barren land, and on the sides of highways. It flowers in May, June, and July. It is very bitter and accounted astringent, vulnerary, and detergent. The extract, given to two drachms, is said to be very useful in internal ulcers; likewise eight ounces of the infusion of this plant, in white wine, is boasted of as an infallible remedy against the ague, given an hour before the fit.

PIMPINELLA, *Burnet, or Pimpernel Parsley*, has a round, slender root, divided into several reddish branches, among which are sometimes found certain red grains, which they call wild cochineal, and which are useful in dying. The stalks are red, angular and branched; the leaves are oblong or roundish, dentated on the edges, and placed by pairs on the ribs. The flowers grow on the ends of the stalks, in round heads, and consist of a single petal, divided into four parts, in the form of a rose, and of a purple colour; in the middle there is a tuft of long stamina, the flowers are of two sorts, the one barren, and furnished with stamina, the other fruitful, that have a pistil. This is succeeded by a quadrangular fruit generally pointed at both ends, and of an ash colour when ripe, containing oblong, slender, reddish brown seeds, with an astringent and somewhat bitter taste. It grows wild in many parts of England, particularly on dry chalky land, and on hills and mountains. It is said to be detergent, vulnerary, and diuretic, and some pretend it stops hæmorrhages, as well internal as external, either given in decoction or powder. The dose, in infusion or decoction, is from half a handful to two handfuls, and of the juice, from an ounce to three ounces, or by spoonfuls.

PINGUICULA, *Butter wort*, has a fibrous root, that sends forth six or seven leaves, and sometimes more; they lie upon the ground, are of a yellowish green, and somewhat thick and shining, as if butter had been rubbed over them; they are two inches long, about one broad, somewhat blunt at the extremities, and even on the edges. In the middle a pedicle arises as high as one's hand, at the top of which is a purple violet, or white flower, like that of a violet; but it consists of a single petal, divided into two lips, and sub-divided into several parts; but, at the bottom, it terminates in a spur. It is succeeded by a fruit or shell, whose lower part is inclosed in the calyx, which when open discovers a button, containing several small almost round seeds. It grows in meadows, and other moist and marshy places, and flowers in the spring. It is vulnerary, and heals green wounds very soon; and the juice makes an excellent liniment for chaps of the nipples.

PIPER INDICUM, *five CAPSICUM*, *Guiney Pepper*, has a short, slender root, furnished on each side with a great number of fibres, which send forth a stalk to the height of a foot and a half, and upwards, especially in hot countries; this is angular, hard, hairy, and branched; the leaves are long, pointed, and broader than those of arse-sinart; they are somewhat thick and fleshy, of a greenish brown, and without hair. The flowers, which grow under the joints of the leaves, where they adhere to the branches, are rosaceous, and of a whitish colour, very much resembling those of

common nightshade, but larger, and supported by a pretty long, fleshy, red pedicle. They are succeeded by a long capsula, as thick as one's thumb, strait, and formed of a fleshy, shining, polished skin, which is green at first, afterwards yellow, and then red; it is divided into two or three cells, that contain many flattish seeds of a whitish colour, inclining to yellow, and generally of the shape of kidneys. It grows naturally in the Indies, and particularly in Guiney and Brasil. It is easily propagated by seeds in hot countries, and there are several sorts of it; as the capsicum with long hanging pods; that with long pods which turn up at the end; the broad leaved capsicum, with long streaked pods, commonly called bonnet pepper; African capsicum, with rough hanging pods; African capsicum, with pyramidal rough pods, generally growing erect; capsicum with long hanging pods that are not hot; capsicum with red pods, in the shape of hearts, generally hanging downwards; capsicum with pyramidal, thick, red pods, generally growing upright; upright olive shaped capsicum; capsicum with small, red pods, growing upright, called Barbary pepper; capsicum with small, round, very hot pods, named bird pepper; American capsicum, with round shaped fruit, broad leaves; American capsicum, with oblong white pods, growing erect, and capsicum with large, rough, red pods, generally hanging downwards. There are two or three other sorts, but these are the principal, and they are sown in many curious gardens, in hot beds. They are pretty hardy, and may be planted abroad about the middle of June. The inhabitants of the West Indies make a great use of the bird pepper, which they dry, reduce to a powder, and mix with other ingredients. They send some of the pots to England, under the name of Cayan pepper, and this is in great esteem by some. They likewise eat the fruits of some of these kind raw, but they will burn the throats of those that are not used to them. The last makes one of the finest and wholesomest pickles in the world, if they are gathered before the skins grow tough. It is at present of no use in physic.

PISUM, *the Pea Plant*, has a slender, fibrous root, that sends forth long, hollow, brittle stalks, of a sea green colour, that would lie upon the ground if they were not supported by props. The leaves are oblong, of the same colour as the stalks, and some are so placed that the stalks seem to run through them, while others grow by pairs on the ribs, that are terminated by tendrils or claspers, which lay hold of every thing they meet with; two or three flowers proceed together from the places where the leaves join to the stalks, and are papilionaceous and white. The pistil is succeeded by a long pod, full of roundish seeds, which are very well known. There are several sorts of peas, as the great garden pea, with white flowers and fruit; the hotspur pea; the dwarf pea, the French dwarf pea; the pea with an esculent husk, the fickle pea, the common white pea, the green rouncival pea, the grey pea, the marble rouncival pea, the rose pea, or brown pea, the Spanish morotto pea, the marrowfat pea, the union pea, the English sea pea, and the pig pea. The English sea pea is found wild on the shores of Suffex, and several other counties in England; and in times of scarcity they have been a very great help to poor people. The propagating of peas is so well known, that the manner of it needs not to be taken notice of here. The use of peas is also very well known, they being common food in all parts of England; but they are windy, and do not very well agree with weak stomachs. Green peas are very good eaten raw, for those that have the sea scurvy.

PLANTAGO MAJOR, *great Plantain*, has a short root, as thick as one's finger, and is furnished with whitish fibres on the sides; it sends forth large

shining leaves, seldom dentated on the edges, and have each eight nerves, that run throughout their whole length. The stalk, which rises from the middle of the leaves to about a foot in height, is round; hard to break, and sometimes reddish, as well as a little hairy. There grows on the top an oblong point, with small whitish flowers; each of these is a pipe, close shut at the bottom, open at the top, and cut into four parts, in which are several stamina. It is succeeded by a fruit, with a thick, oval, pointed shell, that opens crossways, and contains several small, oval, reddish seeds. This plant is very common, and grows almost every where. It flowers in May and June, and the fruit is ripe in August.

There is another sort of plantain, that has a thick root, which seems to be bit off at the end; the leaves are narrower than those of the former, and contain only five nerves; there are likewise a third that contains but three, and this is called the Lesser Plantain. They all have the same medicinal uses, and the leaves are bitter and astringent. It is accounted resolvent and febrifuge; for the juice being given from two to four ounces, in the beginning of intermitting fevers, often cures them. A ptisan, made with the leaves of plantain, is good in the bloody-flux, spitting of blood, and all other hæmorrhages whatever. The decoction is an excellent gargle in ulcers of the mouth; and with lime-water it cures ulcers of the legs. Made into an ointment, with fresh butter, it is said to cure the piles.

POLYGONATUM, *Solomon's seal*, has a long root, as thick as one's finger, and full of large knots or tubercles, of a whitish colour, and furnished with many fibres. The stalks rise to the height of a foot and a half, and are round, smooth, and without branches. The leaves are placed alternately, and are large, oblong, full of nerves, and of a brownish, shining green above, but of a sea-green or bluish colour below. The flowers grow in the places where the leaves join to the stalks, sometimes single, and sometimes double and treble; they are in the shape of a bell, cut at the top into six segments, but they have no calyx; the colour is white, except the edges, which are greenish. The embryo, which is seated on the center of the flower, becomes a berry, like those of ivy; it is a little soft, green, purple, or blackish, and generally contains three large seeds, like those of vetches. It is very common in all parts of England, and grows in shady places by the sides of hedges, and in woods and forests. There are several sorts of this plant, which may easily be propagated, by parting the roots in the spring, before they begin to shoot; they should be planted in fresh, light earth, that is not very rich, where they will thrive exceeding well. It flowers in May and June, and the berries are ripe in August; but the root is chiefly used in medicine. All authors look upon this plant as astringent and vulnerary, and it has been often used for the cure of ruptures; but it is now intirely neglected among us.

POLYPODIUM, *Polypody, or Oak Fern*, has a root six inches in length, and almost as thick as a man's little finger, that creeps along the surface of the ground; it is full of tubercles or warts, and is easily broken. It sends forth leaves, which are like those of male fern, but much less; they are deeply cut almost to the rib, into long narrow segments, which are covered on the back with a sort of reddish powder. This, examined through a microscope, appears to be spherical, membranous shells, which open, and let fall small yellow seeds, in the form of a kidney. It is a capillary plant, and consequently bears no flowers; it grows in forests, valleys, and among stones covered with moss, as well as on the trunks of old trees. The root only is used in medicine,

dicine, and that is accounted best that is found upon oaks. It is green all the year, and in April it sends forth fresh leaves. The ancients accounted this root to be purgative; but it does not so much loosen the belly, or at least very weakly. Some affirm, that it opens obstructions of the viscera; but the best authors are not agreed in its virtues, though it has been much used in medicine.

POPULUS NIGRA, *the black Poplar tree*, has a root that spreads very deep in the earth, and grows to a tall tree, with leaves that are almost round, and cut on the edges. They are of a blackish colour, and always tremble, though there is no wind. Some bear no flowers or fruit, except catkins, which consist of many pointed small leaves; for the fruit grows on those trees that bear no catkins, and they consist of several small leaves, under which lies a bell, containing the embryo; this turns to a membranaceous spiked pod, that opens two ways, and is full of downy seeds. In the beginning of the spring it produces many buds, about the size of capers, which are oblong, pointed, of a greenish yellow, and full of a clammy juice, which sticks to the fingers of those that touch them. It grows in moist watery places, on the sides of brooks and rivers; the buds appear in April, and the catkins in May or June. The buds are only made use of in medicine, and a tincture may be extracted from them with spirits of wine, which, according to Tournefort, is excellent to stop inveterate fluxes of the belly, and to heal internal ulcers. The dose is a drachm morning and evening, in a spoonful of hot broth. They are also employed in making the unguentum populeum.

POPULUS ALBA, *the white Poplar tree*, has a root that spreads on the surface of the earth, and the trunk is high, and full of branches, with a smooth, whitish bark. The wood is white, but not so hard as that of the black poplar, and is more easily cloven. The leaves are broad, and deeply cut on the edges, they being not very unlike those of the vine, or the large maple, but they are more small, green, smooth, and without hair above, but underneath they are white, and downy, and have long pedicles. The catkins and fruit grow on different trees, and are like those of the former. It delights in moist places, and grows to a considerable height in a little time. It may be easily propagated by the shoots that grow on the foot of the tree, and may be planted in meadows, but not in the places where the spreading roots will damage the grass. It grows almost every where, and the wood is of greater use than that of the black. In France they make wooden shoes with it, and it serves every where for the heels of women's shoes. No part of it is now used in medicine.

PORRUM COMMUNE CAPITATUM, *the common Leek*, has an oblong, almost cylindrical, smooth, shining, white, bulbous root, consisting of several white coats, joined one to another, and furnished below with several fibres. The leaves proceed from the coats of the root, to the height of a foot, and are pretty broad, and placed alternately; they are flat or folded in the form of a gutter, and are of a pale greenish colour. Between these leaves there rises a stalk to a considerable height, and in some countries it is five feet high, and as thick as a man's finger. It is firm, solid, full of juice, and has at the top a bunch of flowers, each of which consists of six petals, composed in the shape of a bell, with as many large cylindrical stamina, terminating in three capillaments, of which the middlemost is furnished with a chive. The pistil is seated in the center of the flower, which becomes a roundish fruit, divided into three cells, containing roundish seeds. It has somewhat of the smell of an onion, and is a common kitchen plant, used almost every where. It flowers in July, and its seed is ripe in August. It is

somewhat hard of digestion; and is a little windy; but these inconveniences may be avoided by boiling them well. They are diuretic, and a drachm of the seeds in particular may be given in a glass of white wine for that purpose. It is cultivated by sowing the seeds in the spring, along with those of onions; and when these last are drawn up in July; the leeks will have time to grow large afterwards.

PORTULACA, *Purslane*, has generally a single root with a few fibres, which becomes woody in length of time; the stalks grow to the height of a foot, and are thick, roundish, reddish, tender, full of juice, smooth, and divided into several branches; the leaves, which are ranged alternately, are almost round, thick, fleshy, shining, of a yellowish colour, and a clammy taste. The flowers grow at the places where the leaves join to the stalks, and are of a yellow or pale colour. They are each composed of five leaves, which expand in the form of a rose. The calyx consists of a single leaf, somewhat like a mitre, from which rises a pistil, which, together with the flower-cup, turns to a fruit, or oblong capsula, that is like a small urn, and of an herbaceous colour. These capsula open transversely into two parts, and contain many small black seeds. It is propagated almost every where in gardens, by seeds, which must be sown in beds of light rich earth, during any of the summer months, and it will be fit for use six months after sowing. It is cooling, abates the acrimony of the humours, and is excellent in the scurvy. It is only proper for young persons, and those of a hot, bilious constitution. The leaves of purslane being chewed, abate the pains of the teeth, that arise from having been set on edge by eating green fruit.

PRIMULA VERIS, *Primrose*, has a thick, scaly, reddish, fibrous root, that sends forth large, rough, wrinkled leaves in the spring of the year, which lie on the ground, and are covered with so short a down, that it can hardly be perceived. From among these leaves there arise several stalks, to the height of a palm, that are round, a little hairy, naked, firm, and sustain the bunches of flowers at the top; they consist of a single petal, the lower part of which is tubulous, but the upper part expands in the form of a salver, and is cut into several segments. The pistil arises from the flower-cup, which is fistulous, and, when the flower is decayed, turns to an oblong fruit or husk, lying almost concealed in the flower-cup; it opens on the top, and discovers many roundish seeds, fastened to the placenta. It grows almost every where in the fields, in shady places, from whence they may be transplanted into the garden, and placed under hedges. The best time for this is about Michaelmas, and then the roots will produce flowers early in the spring. It has always been observed, that this plant has somewhat of a soporiferous quality. The medicinal uses of this flower are not yet properly ascertained.

PRUNUS, *the Plumb tree*, has a flower that consists of five petals, placed in a circular order, and expanded in the form of a rose. The pistil arises from the flower-cup, which afterwards becomes an oval, globular fruit, with a soft fleshy pulp, surrounding an hard oblong stone, generally pointed. The pedicles, or foot stalks, are long and slender, and there is only a single plumb on each. There are several sorts of plumb trees, as the *Jean hantive*, or white Primordian, which bears a small, longish, white plumb, of a clear yellow colour, covered over with a white flue, that easily wipes off. The juice is sweet, and it ripens in the middle of July.

The *early black Damask*, commonly called the *Morocco PLUMB*, is pretty large, of a round shape, and furrowed in the middle like a peach; the outside is of a dark black, covered with a light violet bloom; the flesh is yellow, and it parts readily from the stone.

It ripens towards the end of July, and is in good esteem.

The *little black damask* PLUMB is small and black, with a violet bloom, and the juice has a rich sweetish taste; the flesh parts readily from the stone; it is a good bearer, and is ripe towards the latter end of July.

The *great damask violet* PLUMB of *Tours* is pretty large, inclining to an oval shape, and the outside is of a dark blue, covered with a violet bloom; the juice is rich and sweet, the flesh yellow, and parts readily from the stone; it ripens towards the latter end of July.

The *Orleans* PLUMB is of a reddish black colour, and is a fruit so well known to almost every person, that it needs not be described; it is a very plentiful bearer, and is planted by those who supply the markets with fruit, though it is but an indifferent plumb.

The *Fotheringham* PLUMB is of a blackish red, is somewhat long, and deeply furrowed in the middle; it has a firm flesh, that readily parts from the stone; the juice is very rich, and it ripens towards the latter end of July.

The *Perdrigon* PLUMB is of a middle size, and an oval shape, with a very dark outside, covered over with a violet bloom. The flesh is firm, and full of an excellent rich juice; it is in great esteem, and is ripe in the beginning of August.

The *violet Perdrigon* PLUMB is a large fruit, and rather round than long; it is of a bluish colour on the outside, but the flesh is yellowish, pretty firm, and adheres closely to the stone; the juice is extremely rich, and it ripens in the beginning of August.

The *white Perdrigon* PLUMB is of a middle size, and an oblong shape, with a yellowish outside, covered with a white bloom. The flesh is firm and well tasted, and it is a very good fruit, either to eat raw, or make into a sweet-meat; for it has a pleasant sweetness, mixed with an acidity.

The *red imperial* PLUMB has a large fruit of an oval shape, and of a deep red colour, covered with a fine bloom. The flesh is very dry, but it makes excellent sweet-meats, and is ripe in the beginning of August.

The *white imperial Bonum magnum, or white Holland, or Mogul* PLUMB, is a large fruit, of an oval shape, and a yellowish colour, powdered over with a white bloom. The flesh is firm, and adheres close to the stone; the taste is acid or sour, which renders it unfit to be eaten raw; but it does very well baked, or to make sweet-meats thereof. It is ripe in the beginning of September.

The *Cheston* PLUMB is of a middle size, and of an oval shape, with a dark blue outside, and a violet bloom. The juice is rich, and it is ripe in the beginning of August.

The *Apricot* PLUMB is a large round fruit, of a yellow colour, powdered over with a white bloom; the flesh is dry, the taste sweet, and it parts readily from the stone. It ripens in the beginning of August.

The *Maitre Claud*, though it has a French name, is not so called in France; it is of a middle size, rather long than round, and the colour is finely variegated with red and yellow; the flesh is firm, has a delicate flavour, and parts readily from the stone; it is ripe in the beginning of August.

The *red diaper* PLUMB is a large round fruit, of a reddish colour, powdered over with a violet blue; the flesh has a very high flavour, and adheres closely to the stone; it is ripe about the middle of August.

St. Catherine's PLUMB is large and oval, but somewhat flat, and the outside is of an amber colour, powdered over with a whitish bloom; but the flesh is of a bright yellow, and is dry, firm, and adheres

closely to the stone. It has a very agreeable sweet taste, and makes an excellent sweet-meat; it is ripe in the beginning of September.

The *royal* PLUMB is a large fruit, of an oval shape, inclining to a point next the stalk; the colour is of a light red, powdered over with a whitish bloom, and the flesh, which has a fine sweet taste, adheres to the stone; it is ripe about the beginning of September.

The *Brignole* PLUMB is of a large oval shape, and of a yellowish colour, mixed with red; the flesh is of a bright yellow, and, though it is dry, has an excellent rich flavour. It ripens towards the latter end of August, and is thought to be the best plumb for sweet-meats yet known.

The *black Bullace* grows wild in the hedges all over England, and is seldom or never cultivated in gardens.

The *white Bullace* grows wild as the former, and is very rarely planted in gardens.

The *Black-thorn, or Sloe-tree*, is very common almost every where, and is chiefly used for planting hedges, like the white thorn, and its being of a quick growth renders it very proper for that purpose. All sorts of plumbs are propagated by budding or grafting on the stocks of any sort that shoot freely; however, budding is much preferable to grafting.

PLUMBS are in great esteem every where, and may be planted to grow in various manners, as in standards, espaliers, or against walls. They require a soil neither too dry nor too wet, and those that are planted against walls should be placed to an east or south-east aspect, which are better than a direct south. Plumbs in general are moistening, laxative, and emollient, except the bullaces and sloes, which are astringent. They are cooling, quench thirst, and create an appetite, and therefore they agree best with hot constitutions; but they do not at all sit easy with those that have weak stomachs. In those years that plumbs are very plenty, and consequently much eaten by all sorts of people, fluxes of the belly generally abound, which often turn to bloody fluxes; hence it appears, that they ought always to be eaten very moderately, and then they should be quite ripe and sound.

PULEGIUM, *Penny-royal*, has a creeping, fibrous root, with square hairy stalks, some of which are upright, and others creep upon the ground. The leaves are like those of marjoram, but softer to the touch, and blacker; the smell is agreeable, but strong, and the taste is hot. The flowers proceed from the places where the leaves join to the stalks, and are disposed in rings round them; they are of a bluish or purple colour, though sometimes of a pale red; they are labiated, and the upper lip is cut into two segments; these are succeeded by small seeds. It flowers in July and August, at which time it ought to be gathered for use. This plant is aperient, hysteric, and good for disorders of the stomach and breast. It is proper for inveterate coughs, and rheums, and some recommend it to cure hooping-coughs. It may be taken in the manner of tea.

PULMONARIA, *Lungwort, or Sage of Jerusalem*, has a white fibrous root, and angular, hairy stalks, which rise to a foot in height, and are of a purplish colour, resembling those of bugloss. Some of the leaves proceed from the root, and lie upon the ground, while others embrace the stalks without pedicles; they are all oblong, broad, terminate in a point, have a nerve that runs through the whole length, are covered with a soft down, and generally marbled with whitish spots. The flowers grow in bunches, and each consist of tubes, that terminate in the shape of basons on the upper part; they are cut into five segments, and are of a purple or violet colour, with a calyx that is a dentated tube. They are

are succeeded by four roundish seeds; contained in the flower-cup like those of bugloss. It grows in woods, groves, and in mountainous and shady places. It is also cultivated in gardens, and flowers in March and April.

PULMONARIA ANGUSTIFOLIA, *Lungwort*, or *narrow leaved Sage of Bethlehem*, has a root like the former, which sends forth angular hairy stalks, to the height of a foot, and the leaves are oblong, narrow, and hairy, like those of wild bugloss, but softer, and not so rough; they have no pedicles, and they embrace their stalk by the middle. The flowers grow on the top of the stalks, and are like the former, only they are of a fine purple colour, mixed with blue. It grows almost every where, in woods and shady mountainous places.

PULMONARIA GALLORUM, *French Lungwort*, has a long, thick, jointed, reddish, fibrous root, full of a bitter milky juice, and the stalks rise to the height of a foot and a half; these are slender, hairy, and divided into several branches. The leaves proceed from the root, lie on the ground, and are sinuated towards the pedicle, they are greenish and hairy above, downy and whitish below; but generally marbled with long blackish spots. The flowers grow on the tops of the branches, and consist of yellow semi-florets, placed in a scaly cup; they are succeeded by oblong, small, tufted seeds, of a blackish colour. It generally grows on old walls, and in uncultivated places; it flowers in June and July, and sometimes later. They have all three the same virtues, and are accounted good in diseases of the lungs.

PULSATILLA, *Pasque-flower*, has a long, thickish, single root, which is divided into several heads, that are hairy on the upper part and black. The leaves proceed from the root, and are jagged and hairy; they are placed on long, reddish, very hairy ribs, that lie near the ground. From between the leaves there proceeds a round hollow stalk, to the height of a foot, covered with a thick soft down, and is without leaves, except one a little below the top. The flower consists of six oblong, pointed petals, disposed in the form of a rose, of a purple colour, hairy without, and smooth within. The pistil is placed in the middle, surrounded with yellow stamina or chives; this turns to a fruit, with a round head, that consists of several seeds, that terminate in a tuft like a feather. It grows in stony, dry, mountainous places, flowers near Easter, and is called Pasque by the French, from whence it has its name. It is cultivated in gardens, for the sake of the flowers. It is said to be a vulnerary plant, and the powder of the dried leaves and flowers, snuffed up the nose, provoke sneezing; but it leaves a burning heat behind it, that reaches as far as the brain; for this reason it is accounted good in sleepy diseases.

PYROLA, *Winter-green*, has a flexible, slender, fibrous, creeping, whitish root, which sends forth five or six fibrous leaves, like those of the pear tree; they are fleshy, thick, of a deep brownish green, and are smooth, have long pedicles lying on the ground, and continue green all the winter. The stalk rises to the height of a foot among the leaves, and is angular, single, and sometimes furnished with small pointed leaves; the flowers grow on the top, and are beautiful, scented, and are composed of five petals, placed in the form of a rose; they are white, and have ten shortish stamina, with a crooked pistil in the middle, like the trunk of an elephant; this turns to an angular fruit or button, consisting of five furrowed cells, containing reddish seeds, that are exceeding small. It grows wild in the north of England, on mossy moors, hills, and heaths; for which reason it is difficult to cultivate them in the southern parts; it flowers in June and July, and is looked upon to be an astringent vulnerary plant, and proper

to stop internal bleedings; it may be taken in the manner of tea.

PYRUS, *the Pear tree*, has flowers that consist of several leaves, placed in a circle, which expand in the form of a rose; the flower-cup becomes a fleshy fruit, universally known, that has a hollow like a navel on the upper part; the cells, in which the seeds are lodged, are separated by soft membranes. The tree is so well known, that it needs no description, and therefore it will be sufficient to describe the several sorts of fruit.

The *little musk PEAR*, commonly called *the supreme*, is generally produced in large clusters, and is rather round than long, with short stalks; the skin is yellow when ripe, and the juice is somewhat musty; it is an excellent pear, if gathered before it is too ripe. It ripens towards the middle of July, and will continue good but a few days.

The *Ohio PEAR*, commonly called *the little Bastard musk pear*, is smaller than the former, but much of the same shape. The skin, when ripe, has a few streaks of red on the side next the sun, but it seldom hangs in clusters.

The *hasting PEAR*, commonly called *the green Chiffel*, is larger than either of the former, and is longer next the stalk. The skin is thin, and of a whitish green when ripe; the flesh melts in the mouth, and, if not too ripe, has a sweetish taste; it is fit to gather towards the end of July.

The *red MUSCADELLE* is a large early pear, of great beauty, and the skin is of a fine yellow, beautifully striped; the flesh has a rich taste, if gathered before it be too ripe; but it is apt to be mealy. The tree generally produces two crops in a year, the first of which is commonly ripe towards the end of July, and the second in September, but is seldom well tasted.

The *little MUSCAT* is a small pear, rather round than long, and the skin is very thin, and of a yellowish colour when ripe. The flesh melts in the mouth, and has a rich musky flavour; but will not keep long when ripe, which is towards the latter end of July.

The *JARGONELLE* is a very long pear, in the shape of a pyramid, with a long pedicle or stalk; the skin is pretty thick, and of a rusty colour towards the sun; but the other side is of a russet green; the flesh has a rich musky flavour, and it ripens towards the end of July. This is one of the best early summer pears.

The *Windsor PEAR* is of an oblong shape, and terminates almost in a point next the stalk; the skin is smooth, and when ripe, of a yellowish green, with a very soft flesh; but if it hangs two or three days after it is ripe, it grows mealy.

The *JARGONELLE*, now commonly called *Cuisse madame*, is somewhat like the *Windsor Pear*, but is longer towards the crown, and smaller next the stalk; the skin is smooth, and of a pale green, with a flesh that is apt to be mealy.

The *orange musk PEAR* is of a middle size, of a short roundish form, and a yellowish skin, spotted with black. The flesh is musky, but is apt to be a little dry and choaky; it is ripe in the beginning of August.

The *little blanket PEAR* is much less than the former, and more pinched in near the stalk, which is shorter, but slenderer than that of the former. The skin is soft, and of a pale green, with a tender flesh, full of a rich musky juice; it ripens in the beginning of August.

The *long stalked blanket PEAR* is shaped somewhat like the former, but the eye is larger, and more hollow at the crown; it is somewhat plumper towards the stalk, and a little crooked, with a very smooth white skin; the flesh is full of a rich sweetish juice, and it is ripe about the middle of August.

The *skinless* PEAR, or *early Ruffelet*, is middle-sized, long, and of a reddish colour, with an extremely thin skin; the flesh melts in the mouth, and is full of a rich, sweet juice; it ripens in the beginning of August.

The *musky rovine* PEAR, *the queen's* PEAR, or *the amber* PEAR, is small and round, and of a yellowish colour when ripe; the flesh has a rich musky flavour, and it ripens in the beginning of August.

The *musky drone* PEAR is middle sized and round, and the skin is of a yellowish colour when ripe. The flesh melts in the mouth, and is full of a musky juice; but, if it hangs too long on the tree, it grows mealy: it ripens in the beginning of August.

The *red orange* PEAR is middle sized and round, and of a greenish colour, except on the side next the sun; which is purple when ripe. The flesh melts in the mouth, and the juice is sweet, with a very hollow eye, and a short stalk; it ripens about the middle of August.

The *great onion*, PEAR, or *the Summer Arch-duke*, is of a middle size and round; and of a brownish purple next the sun; the flesh melts in the mouth, and is tolerable good; it ripens in the beginning of August.

The *August MUSCAT*, or *the royal* PEAR, is in shape much like a Bergamot, and the stalk is long, strait, and a little spotted. The skin is smooth, and of a whitish yellow colour, with a rich, sweet, perfumed juice; it is one of the best summer pears yet known, and grows ripe in August.

The *rose* PEAR is short and round, and of a yellowish green colour, but a little inclining to red next the sun. The stalk is very long and slender, and the juice is musky; it grows ripe in August.

The *prince's* PEAR is small, roundish, and of a bright red colour next the sun, but on the other side it is yellowish; the flesh has a very high flavour, and grows ripe in the middle of September.

The *great mouth-water* PEAR is large and round, with a smooth green skin, and a short thick stalk; the flesh melts in the mouth, and is full of juice, if gathered before it is too ripe, which is about the middle of August.

The *summer Bergamot* is a pretty large, round, flat pear, of a greenish yellow colour, and hollowed a little at both ends, like an apple; the flesh melts in the mouth, and it is ripe towards the latter end of August.

The *autumnal Bergamot* is smaller than the former, but of the same shape, with a yellowish green skin, reddish on the side next the sun; the flesh melts in the mouth, and it grows ripe towards the latter end of September.

The *Swiss Bergamot* is somewhat rounder than the former, with a tough greenish skin striped with red; the flesh is full of juice, melts in the mouth, and it is ripe in the beginning of October.

The *red butter* PEAR is sometimes of other colours, as green or grey, whence some have supposed them to be different fruits. It is large and long, and generally brown, with a melting flesh, full of rich sweet juice; it ripens in the beginning of October.

The *long green* PEAR is long, and very green when ripe, with a melting juicy flesh. It grows ripe in the middle of October, and in some years will keep till December.

The *white and grey Messieure Jean* is one of the best autumnal pears, when grafted on a free stock. It is a large roundish fruit, with a tough skin, that is generally brown; it is full of a rich sweet juice, and ripens about the beginning of October.

The *flowered Muscat* is an excellent pear, of a middle size, and round, with a dark red skin; the flesh is very tender, and of a delicate flavour; it ripens towards the end of October.

No. 38.

The *wine* PEAR is round, and of a middle size, with a dark red skin; the flesh is full of a clammy juice, and it grows ripe towards the end of October; but should be gathered before, otherwise it will soon rot.

The *Roussiline* PEAR has a smooth skin, of a deep red colour next the sun, with grey spots, but the other side is of a greenish-yellow; the flesh is tender and delicate, and the juice sweet; it is ripe towards the end of October, but must not be kept long.

The *Marquise* PEAR is like the Blanket, when planted in a dry soil; but, when it is rich and moist, it grows larger. It is flat at the top, with a small hollow eye, and a skin of a greenish yellow, inclining to red on the side next the sun. If it is yellow when ripe, the flesh is tender and delicate, and full of a sweet juice. It grows ripe at the beginning of November.

The *crassane*, or *flat butter* PEAR, is of a middle size, and hollowed at the crown like an apple. The stalk is very long and crooked, and the skin is rough, and of a greenish colour when ripe, or rather ruffet. The flesh is tender and buttery, with a rich sweet juice. It is the very best pear of the season, and is fit to eat about the middle of November.

The *Lansac*, or *Dauphine* PEAR, is about the size of a Bergamot, of a roundish shape, and flat towards the head; but it is a little longish towards the stalk; the skin is smooth, of a yellowish-green, with a yellow, tender, sweet flesh; the eye is very large, and the stalk long and strait; it grows ripe about the middle of November.

The *Martin sec* is like the ruffelet in shape and colour. The shape is oblong, and the skin is of a deep ruffet on one side, but on the other inclining to red. The flesh is fine and sweet, and it is fit to eat about the latter end of November.

The *little lard* PEAR, or *the ruffet of Anjou*, is of a bright green, with a few spots, and a large hollow eye. The flesh is extremely fine, with a sweet juice; it is fit to eat in December, and is one of the best fruits in that season.

The *Louise bonne* has a short fleshy stalk, a small eye and flower, and a very smooth skin; the colour is green, inclining to white, and the flesh is extremely tender, and full of a sweet juice. It is fit to eat in December.

The *Eschafforie*, or *the winter long green* PEAR, is shaped like a citron, with a smooth green skin, that becomes yellowish when ripe. The eye is small, and the flesh melting and buttery, with a sweet juice. It is fit to eat in the beginning of December.

Parkinson's Warden, or *the black Pear of Worcester*, commonly weighs a pound or upwards, and has a rough, dark, red skin next the sun. It is only fit for baking or stewing, and is in season from November to Christmas.

The *small winter butter* PEAR has a small oblong shape, and a yellow colour, spotted with red. The flesh has a very rich juice, and it is fit to eat in December and January.

The *Ronville* PEAR is about the size and shape of a large ruffelet, and the middle is swelled more on one side than the other; the skin is soft and smooth, and of a lively red colour next the sun, but yellow on the other; the flesh is full of a very sweet juice, that is a little perfumed.

The *winter citron* PEAR, or *the Musk-orange*, is a pretty large pear, and is in shape and colour very like an orange; the flesh is hard and dry, and apt to be stony, but it bakes very well, and is in season from December to March.

The *winter ruffelet* PEAR is of a greenish-yellow, inclining to brown, with a buttery melting flesh, which is generally very full of a very sweet juice; but

but it must always be pared, because the skin has a bad taste. It is fit to eat in January and February.

The *Bergamot Bugi* is a large pear, and almost round, but it is a little longish towards the stalk; the eye is flat, and the skin green, and there are many rough protuberances thereon; but as it ripens it becomes yellowish, and in a good season the flesh is sweet; it is good to eat from February to April.

The *Dutch Bergamont* is large and round, and of the shape of the common bergamot; the colour is greenish, the flesh pretty tender, and the juice of a high flavour. It continues good till April.

The *Naples PEAR* is pretty large, long, and greenish, with a sweet, and somewhat veinous juice; it is called in England the *Easter St. Germain*, and will keep till April.

There are many other sorts of pears that are still to be seen in some old gardens, but are of no great esteem; those that plant pears for use, ought always to choose them of the best sorts, because the trouble and expence is the same. They are propagated by budding or grafting them upon stocks of their own kind, which are commonly called free stocks; but quince stocks are greatly used in the nurseries, for all sorts of pears that are designed for dwarfs or walls.

As to wild pears, they are always so astringent and rough, that they are not fit to be eaten, though they may serve well enough to make perry. In general, pears are windy, and improper for weak stomachs; some think they are enemies to the nervous parts; however, those are best that are quite ripe, and have a sweet juice, and then they are seldom noxious, unless eaten to excess.

QUERCUS VULGARIS, *the common oak tree*, is well known in all parts of Europe, as also its wood, for its long duration, and various uses. The flowers are long catkins, which consist of a great number of small slender threads; but the embryoes are produced at some distance from these, and afterwards become acorns, with hard scaly cups. It grows in woods, forests, and high mountainous places; the leaves appear before the flower, and the catkins may be seen in April and May, but the acorns are not ripe till August. It is commonly said, that an oak tree is an hundred years coming to its full growth, an hundred years in perfection, and an hundred years in decaying. Some affirm the wood will continue good six hundred years in the open air, and five hundred under ground. Oak bark is of very great use for tanning of leather, and upon these accounts the oak is called by some the king of trees. The English oak is best for building of ships; but now there are great numbers constructed in New-England, of the oak wood that grows in those parts, though they are not so lasting.

The leaves of the oak are styptick, and a little bitterish, and all parts of it are astringent. They have often been prescribed for all sorts of hæmorrhages and fluxes of the belly, and some pretend that a decoction of the bark has cured a most terrible bloody-flux. In times of scarcity, a great many poor people have made bread of the acorns, and the poets tell us they were the food of the golden age; however, they are heavy, windy, and hard of digestion, and therefore mankind in those early ages must doubtless have a better digestion than us. They are now given to hogs, for which they are excellent nourishment, and render the flesh fat, firm, and sweet; for which reason that bacon is in most esteem, that comes from places where there are plenty of acorns.

There are a great number of trees that go under the name of oaks, in divers parts of the world, but there are no where so many different kinds, as in America; the wood however is not nigh so valuable as the English oak, which has been hinted at above.

QUINQUE FOLIUM, *Cinquefoil*, has a long fibrous root, blackish without, and reddish within, which sends forth several stalks to the height of a foot and a half, which are round, flexible, hairy, reddish, and knotted; from these knots the leaves and roots proceed, and by their means this plant multiplies greatly. The leaves are oblong, roundish at the ends, nervous, hairy, dentated on the edges, of a dark green, and placed like an open hand, to the number of five upon the same pedicel, which is three inches and upwards in length. The flowers grow single on the top of the stalks, and consist of five yellow petals, in the form of a rose, and are somewhat in the shape of a heart; there are five stamina, with their apices in the form of a half-moon, and the pistil becomes a round fruit, composed of many pointed seeds, placed in the form of a head, and contained in the cup of the flower. It grows in fields, and in sandy stony places, as well as in meadows on the sides of waters; it flowers in May and June, and the root is chiefly in use. It is accounted balsamic, vulnerary, and astringent, and has been given in all sorts of hæmorrhages, as well as in all kinds of fluxes of the belly; some affirm it succeeds better than ipecacuanha; for which purpose an ounce of the root has been boiled in three pints of water to two; this decoction is also recommended in spitting of blood. It is confidently said, that a drachm of this root, given in a glass of water, before a fit of an ague, will certainly cure it.

RANUNCULUS BULBOSUS, *Bulbous Crow-foot*, has a round bulbous root, with several upright stalks, that sometimes rise to the height of a foot, which are hairy, and have leaves that are cut into several slender jags, and on the top there are flowers of a fine yellow shining colour; they are generally single, and consist of five roundish petals, disposed in the form of a rose, the leaves of the calyx being bent back towards the pedicel. The fruit that succeeds the flower contains many roundish seeds, placed together in the form of a head. It flowers in May, and is to be met with almost every where in pasture grounds and meadows. When it is transplanted into gardens, the flower becomes double. The root of crow-foot is extremely acrid and caustic, and some authors recommend it to raise blisters; but this practice is dangerous, because it may cause a gangrene. There are quacks that apply it to the part afflicted with the gout, and on corns, to take them away; but we have much safer remedies. In some places it is common for beggars to make sores with this root, to raise compassion. The bruised leaves were once applied to the head of a patient, who had kept his bed for three years, on account of a violent head-ach, and they raised a blister, which ran freely, and he was soon cured.

RANUNCULUS NEMOROSUS, *Wood Anemone*, has a long creeping root, purplish or brown without, and yellowish within, when young. The stalk is small, slender, reddish, and rises to the height of a palm and a half, on the top of which there are three leaves, or reddish pedicles, each of which are cut down to the pedicel into three jags, and on the top there is a single flower without a calyx, sometimes white, and sometimes purplish or flesh coloured; it consists of six oblong leaves, in the middle of which there are several yellowish stamina. These are succeeded by naked, oblong, hairy seeds, collected into a head. It flowers towards the beginning of March, to the end of April. Some recommend a cataplasm of the leaves and flowers for scald heads, and affirm it will cure them in a few days, if it be renewed twice a day; but others think it unsafe, from the bad effects they have seen from such applications.

RANUNCULUS PRATENSIS REPENS, *Crow-foot*, has a small creeping root, composed of whitish fibres, and many slender, round, hairy, hollow, creeping

creeping stalks, that lie upon the ground. The leaves are cut into three segments, somewhat like parsley, and are dentated on the edges, and hairy on both sides; they are of a blackish green, and generally marked with fine spots on the upper part. The flowers are of a shining yellow, and composed of five petals, disposed in the form of a rose, with a great number of stamina in the middle, and a flower-cup, consisting of five leaves, that falls off with the flower, which are succeeded by black seeds, placed together in the form of a head, and full of small points or prickles. It flowers in May, and grows almost every where in meadows and shady places. This may be taken inwardly without danger, and the cattle that feed on it yield a great deal of milk. Some use it in a fomentation against the piles. There are other species of the crow-foot, which had best be avoided.

RAPA, *the Turnep plant*, has a tuberose, fleshy, bellied, round, thick root, that grows sometimes to the size of a child's head, and is universally known. The leaves are oblong, large, lie upon the ground, and are cut deeply into jags. They are rough to the touch, are of a greenish brown colour, and of the taste of a pot herb. The stalk rises from among the leaves, to the height of two feet, and sometimes to that of a man. The leaves embrace the stalk with their broad base, and terminate in a point. The flowers grow on the top of the stalk, are yellow, and consist of four leaves, disposed in the form of a cross, with a calyx fixed on a long slender pedicle. The pistil is succeeded by a pod, divided into two cells, by a partition, which contain two rows of roundish, reddish seeds. It flowers in the spring and summer.

RAPA OBLONGA, *five* FOEMINA, *oblong*, or *female Turnep*, differs from the former in having an oblong root that is not so thick. Besides these, there are the garden turnep, with a green root above ground; the ground garden turnep with a purple root; the round garden turnep with a rusty black root, and the round garden turnep with a yellow root both within and without; they all delight in a light sandy soil, for in a rich soil they will grow rank and sticky. The common season for sowing them is from the middle of June to the latter end of August, and in some places they sow them much later.

The use of turneps, as an aliment, is well known, and they are accounted an emollient, and proper to abate the acrimony of the humours; but they are windy, cause obstructions, and do not digest very easily. They are accounted a great pectoral, and many have been said to be cured of an asthma by their juice, that is, by taking a large spoonful in a morning fasting, for forty days together.

RAPHANUS MINOR, *the garden Radish*, has a long fleshy root, red or purple without, and white within. The leaves are large, rough, green, deeply cut, and much like those of turneps. A stalk arises from among these, to the height of a foot and a half, or two feet, that is round, branched, and is adorned with flowers, consisting of four petals, in the form of a cross; the pistil arises from the flower-cup, which turns into a pod of the shape of a horn, that is spongy within, and contains two rows of roundish seeds that are separated by a thin membrane. It is cultivated in gardens, and the root is chiefly in use in the spring, which is tender, full of juice, and eaten as food. It agrees very well with most constitutions, provided they have good stomachs, for it is apt to rise therein. The juice is good in the gravel, if four ounces be taken of it for four days, in a morning fasting.

RAPHANUS RUSTICANUS, *Horfe Radish*, has a long, thick, creeping, white root, that sends forth large long pointed leaves, of a fine green colour,

somewhat like monk's rhubarb. From among these there arises a stalk, to the height of a foot and a half, which is upright, hollow, furrowed, and furnished with leaves, a palm in length, and an inch in breadth, and cut deeply on both sides. On the top there are small flowers, composed of four white petals, in the form of a cross, which are succeeded by small roundish pods, divided into two cells, that contain smooth, roundish, reddish seeds. It flowers in the spring, and grows wild on the sides of brooks and rivers, but is cultivated in gardens. It is used as mustard, to promote the digestion of aliments, and to create an appetite. The distilled water is given to four ounces against the scurvy and gravel, and to cleanse the blood. The expressed juice of the roots and seeds mixed with honey, and taken in a morning fasting, for some time, in whey, cleanses the stomach, kidneys, and lungs; it cures coughs, and inveterate hoarsenesses, provided they are not dry, or attended with spitting of blood. It is said to be excellent against the scurvy, dropsy, and rheumatism, if continued for some time. The dose of the root in powder, is from one scruple to two; of the fresh root in decoction, from half an ounce to an ounce; and of the juice a spoonful. It is hard to say what a scruple of the root will do, since it is often eaten at meals in much larger quantities, therefore this seems to be a trifling dose.

RESEDA VULGARIS, *common bastard Rocket*, has a long, slender, woody, white root, which sends forth several stalks, to the height of a foot and a half, that are furrowed, hollow, hairy, branched, weak, crooked, and furnished with leaves, placed alternately; these are deeply cut, are curled, and of a dark green colour, with the taste of a pot-herb. The flowers are in loose spikes, and are each composed of yellow irregular petals, in the middle of which there are several small stamina, with yellow apices, and a pistil that turns to a four-cornered fruit, an inch in length, and like cylindric urns, full of small, roundish, black seeds. It flowers in June, July, and August, and is common in the fields. There are several kinds of this plant, that are propagated in the gardens of curious botanists. It is said to be emollient and resolvent, and is applied externally by some, to discuss inflammatory swellings, as well as to ease the pain.

RHAMNUS CATHARTICUS, *purging Buckthorn*, is a shrub with a long, hard, woody root, and it sometimes grows to the height of a tree, with a bark, like that of the cherry tree, and a yellowish wood; the branches are armed with thorns, like those of the wild pear tree. The leaves are roundish, of a blackish green, slightly dentated on the edges, and pretty much like those of the plumb tree. The flowers are small, of a greenish or yellowish colour, grow in bunches along the branches, and consist of single petals, in the shape of a funnel, divided at the top into four parts, and have as many stamina. These are succeeded by soft berries, green at first, and black when they are ripe; they are as large as juniper berries, are shining, and full of a greenish black juice, with four seeds, roundish on the back. This shrub is common in hedges, and flowers in May, and the berries are ripe towards October. When these berries are gathered in harvest time, and steeped in alum-water, they will yield a yellow or saffron coloured juice; if they are gathered in autumn, when they are ripe, and kept in a glass vessel, they will yield a good green; but if they are left on the tree till towards St. Martin's day, they will yield a scarlet, that is very useful to dye leather, and to colour cards with red. It is well known that the berries are a purge, which are said to be good in the dropsy, palsy, rheumatism, and gout. A drachm, or a drachm and a half, of the ripe berries, dried and powdered, is a dose. They generally occasion gripes,

gripes, sickness, a dryness of the mouth and throat, and thirst. About twenty of the fresh berries is a dose in substance, and twice or thrice this number in decoction, or an ounce of the expressed juice. A syrup made of the juice is kept in the shops.

RHUS FOLIO ULMI, *common Sumach*, has a long, creeping, woody root, and is a shrub that grows sometimes to the height of a tree; the leaves are oblong, pointed, hairy, winged, reddish, dentated on the edges. The flowers grow in bunches among the leaves of the branches, at the top, and are of a whitish yellow colour; they are composed of five leaves disposed in the form of a rose, sustained by a calyx, and divided into five parts. The pistil turns to a flat, oval, membranous, greenish capsula, that contains a single seed, almost of the shape of a kidney. It grows plentifully in the southern parts of Europe, as also in Turkey, where the branches are used for tanning of leather. This is not so common in England, as those brought from America, which are the *Virginian Sumach*, improperly called *the Stag's horn tree*; *New England Sumach*, with loose herbaceous panicles, and smooth branches, the *Canada Sumach*, with a longer leaf, smooth on each side, and the *dwarf Virginian Sumach* with narrow leaves. The first of these is very common in gardens, and produces bunches of small flowers in June, at the extremities of the branches, which are succeeded by seed included in red covers. They may be all propagated by seeds, which should be sown soon after they are ripe, and the plants will come up the following spring. The leaves and fruit have been sometimes used in decoctions, for fluxes of the belly, and against internal hæmorrhages.

RIBES VULGARIS, *the red Currant bush*, rises to the height of two or three cubits, and has a bay or ash coloured bark. The leaves are like those of the vine, but much less, and are smooth, of a dark green above, but covered with a soft down beneath. The flowers grow in bunches, and are composed of five purple petals, placed in the form of a rose, and are somewhat in the shape of a heart. The calyx is in the form of a basin, divided into five segments, and the hinder part turns to a berry, green at first, and afterwards red, which is universally known. Besides this, there are other sorts, as *the Dutch red Currant*, *the common white*, *the large Dutch white*, *the Champaign*, *the Gooseberry leaved*, *the small wild*, *the black*, and *the yellow striped leaved*; *the common Currant*, with leaves, beautifully variegated with green and white; *the white Currant* with striped leaves; *the striped gooseberry leaved Currant*; *the black Currant* with striped leaves; and *the American black Currant*. The manner of the flowering of this last is very different from the other sorts; but the fruit is not much valued. They may be all propagated by cuttings, from September to March, but autumn is best, and they will thrive almost in any soil or situation. Red currants, and their preparations, are generally accounted good to abate internal heats, and to restrain the effervescence of the blood; as they are somewhat astringent, they strengthen the stomach, excite an appetite, and are good against vomiting. Currants eaten too freely will cause loosenesses, attended with gripes, and are hurtful to the lungs.

The leaves of black CURRANTS have been accounted by some a sort of a panacea, and in some parts of France, after they have been bruised in wine, and the juice pressed out, it has been given to half a pint, twice a day, for eight days together, to those that have been bitten by a mad dog, that is, in the morning fasting, and three or four hours after dinner. Others say, that four ounces of the juice of the leaves, or rather the infusion in wine, for twenty-four hours, given to four ounces in a morning fasting, will cure the dropsy. In the Philosophical Transactions it is said, that the gelly of black cur-

rants, swallowed down leisurely in small quantities, is a specific against the quinsy; and in winter, when the gelly cannot be had, a decoction of the leaves and bark in milk, used as a gargle, is said to cure all inflammatory distempers of the throat.

ROSA PALLIDA, *five INCARNATA*, *the pale Rose*, has a long, hard, woody root, that sends forth several stalks, which form a shrub, that divides into firm long branches, covered with a dark greenish bark, and often furnished with strong prickles; the leaves grow by pairs, and are generally seven in number, on one rib, which is terminated by a single leaf; these are roundish, dentated on the edges, and rough to the touch. The flower is sometimes single, and composed of five large petals or leaves, with several yellow apices in the middle. It is sometimes double, and then the external petals are a little larger than the internal, and of an agreeable red or carnation colour, with a very sweet, though weak smell. When the flower is falling off, the calyx turns to an oval fruit, in the shape of a small olive, with a rind that is a little fleshy, and consists only of a single cell, full of angular, hairy, whitish seeds. It flowers in May and June, and is cultivated in gardens. The distilled water from these roses is accounted good against inflammations of the eyes; and some say when it is given inwardly, from one ounce to six, it will stop loosenesses and spitting of blood; but the syrup of pale roses is solutive, and is given from an ounce and a half to two ounces.

ROSA DAMASCENA PALLIDA, *the damask Rose*, has a root like the former, from whence arise stalks or stems, to the height of ten or twelve feet, which are thick, strait, and armed with reddish strong thorns, that are not so flat as those of the former; the leaves are also set at greater distances, are less wrinkled, more pointed, and are green above, and whitish below; they are dentated on the edges, and are sometimes seven, and sometimes nine on the same rib, placed by pairs opposite to each other, and terminating in a single leaf; it has crooked thorns on the base. Some of these rose bushes have flowers, consisting only of five petals, that have a very sweet smell. It is cultivated in gardens, and flowers in autumn. That with double flowers is not of a distinct kind, but only a variation of the former. The flowers are solutive, or rather purging; for two pugils infused in veal broth, and taken in a morning, will purge very well.

ROSA ALBA, *the white Rose*, has a root like the former, which sends forth stalks to the height of eight or ten feet, which are thick, woody, and armed with crooked pedicles. There are sometimes five, and sometimes seven, oblong, smooth, crenated leaves on one rib, that are sometimes prickly at the base. The flowers which grow at the extremity of the branches are large, beautiful, and have a sweet smell. It is cultivated in gardens, and generally flowers in May and June. All authors agree, that they are astringent, and the distilled water is made use of, in some parts, against inflammations of the eyes.

ROSA RUBRA, *the red Rose*, has a creeping, strong, woody root, with several stems, that are lower than those of the former, covered with a green bark, armed with prickles. The flowers are of a beautiful red, with a sweet agreeable smell; it is cultivated in gardens, where it flowers in June and July. These are reckoned astringent, cleansing, and proper to strengthen the stomach, to stop vomiting, fluxes, and hæmorrhages. The dose of the conserve is from two drachms to half an ounce, and is given against coughs, and in consumptions.

ROSA SYLVESTRIS VULGARIS, *the Dog-Rose*, has a long, creeping, hard, woody root, that sends forth long thick branches, armed with strong thorns or prickles; the leaves are large, oblong, smooth,

smooth, and like those of the common rose. The flowers consist of five white petals, with a mixture of red or carnation, and they fall off with the least blast of wind; they are succeeded by oval oblong fruit, which are green at the beginning, and as red as coral when they are ripe. The rind is fleshy, and has a sweetish tart taste; the seeds are angular, white, hard, and wrapped up in strong hair, that readily separates from them. It grows every where near or in hedges without cultivation. The fruit is called hips, and there is a conserve made of them kept in the shops. These flowers are purgative, like those of other roses; but the conserve is recommended in fluxes of the belly, to moderate the heat of the bile, and to abate the sharpness of urine; the dose is from two drachms to half an ounce.

ROSMARINUS HORTENSIS ANGUSTIORE FO. IO. *narrow leaved garden Rosemary*, has a slender, small, fibrous root, that sends forth a stalk that becomes a shrub, which in some countries rises to the height of three or four feet; the leaves are whole, narrow, hard, stiff, of a brownish green above, and white below. The flower consists of a single petal, of a pale blue colour, that is labiated, and whose upper lip, or crest, is cut into two parts, and is turned backwards, with crooked stamina or chives; but the upper lip or beard is divided into three parts, the middlemost of which is hollow like a spoon; the flower cup is dentated, being divided into three cells, from whence arises the pistil, attended with four embryos, that turn to as many roundish seeds, inclosed in the flower cup. It is cultivated in gardens, and flowers in April, May, and June; but it grows wild in many hot countries, such as Spain, Italy, and the southern parts of France. However, they are hardy enough to bear a moderate winter in these parts in the open air, provided they are planted on a poor, dry, gravelly soil. Besides this, there is the *broad leaved garden Rosemary*; the *gold striped Rosemary*; the *narrow leaved silver striped Rosemary*; the *Rosemary of Almeria, with a large spiked purplish flower*, and the *broad leaved Rosemary with an elegant striped leaf*. They may be all propagated by planting slips or cuttings at the beginning of the year, upon a bed of light fresh earth, and they should be transplanted in the beginning of September, to the places where they are designed to grow.

The flowers and leaves are made use of in medicine, and are used both internally and externally. They strengthen the brain, are good against the palsy and epilepsy, as well as obstructions of the viscera, they restore the tone of the solids, and incide and attenuate gross humours. The water wherein the flowers and leaves are steeped for a night, is good for the jaundice, and it strengthens the memory and sight. Hungary-water is made from the flowers, cups, and young leaves of this plant, after they have been digested in spirits of wine, and the spirit distilled off; the dose of this is a small spoonful, in a glass of water. The conserve of the flowers is cordial, stomachic, and cephalic, and the dose is from a drachm to half an ounce. Boerhaave looks upon the essential oil, to be the best remedy against the epilepsy; and a few drops of it are to be given in wine; the usual dose of this is five or six drops.

ROS SOLIS, *Sun dew*, has a fibrous, slender, hairy root, that sends forth several long, small, hairy branches, on which there are small roundish leaves that are hollow like an ear-picker, and of a pale green; the stalks are adorned with a reddish, hairy fringe, and are hollow, from whence transudes drops of a fluid into the hollow of the leaves, inso-much that their hair is always moist, as it were with dew, in the driest seasons. From among the leaves there arise two or three stalks, to the height of six inches, that are slender, round, reddish,

tender, without leaves, and on whose top are small whitish flowers, with several petals placed in the form of a rose. The flower cup is in the shape of a dentated horn, and the flowers themselves hang on one side. They are succeeded by small fruit, of the size of a grain of wheat, which contains several seeds. It grows in deserts, wild, sandy, moist, marshy places, and most commonly among water moss, of a whitish red colour, and flowers in June and July. This plant is said to be pectoral, and good against all disorders of the lungs; the dose is a drachm in powder, and two drachms in infusion. Boerhaave recommends this last in the vertigo, the epilepsy, and disorders of the eyes.

RUBIA TINCTORUM SATIVA, *cultivated dyer's Madder*, has a long, creeping, succulent root, divided into several branches, and of the thickness of a goose-quill. It is woody, and red both without and within. It sends forth long branches, that are square, geniculated, or knotty, and rough; and from each knot there proceed five or six oblong leaves, that surround the stalk in the form of a star; they are hairy, and crenated all round, with small furrows. The flowers grow on the tops of the branches, and consist of a single leaf, which is cut into four or five segments, expanded at the top; the flower cup becomes a fruit, composed of two juicy berries closely joined together, which are black when ripe, and full of juice; each contains a seed, which is generally hollowed like a navel, and is almost round. It flowers in July and August, is cultivated in many parts of Europe, and is made use of for dying. Though the propagation of it in England has been long neglected, it is now cultivated with greater spirit than ever, by which we are supposed to save near thirty thousand pounds annually. The root is taken out of the earth in May and June, and they dry it for transportation. The root is one of the five lesser opening roots, and is said to resolve gross humours, and to be useful in obstructions of the viscera. Boerhaave affirms, it is good against the gravel, and cleanses the kidneys and bladder from mucous matter. The dose of the root in powder is a drachm or two, and in decoction from half an ounce to an ounce. It has one very uncommon property, that is, it will turn the bones of those animals red, that have fed upon it for some time.

RUBUS VULGARIS FRUCTU NIGRO, *the common Bramble or Blackberry bush*, has a slender, creeping, knotty root, that sends forth several long, weak, bending, greenish, red, angular, pithy branches, that are armed with strong crooked prickles, which lay hold of the garments of those that pass by. The leaves are oblong, pointed, dentated on the edges, rough, and brown above, but whitish below; they are placed by three's, or five's, on the same pedicles, and never fall off in winter, till others come in their places. The flowers on the end of the branches consist of five petals or reddish leaves, disposed in the form of a rose, and the flower cup is cut into five parts, in the middle of which there is a pistil, surrounded with a great number of stamina, or chives. These are succeeded by round or oval fruit, nearly like mulberries, that are composed of several berries, full of juice, closely joined together, that are red at first, and black when ripe; each of these contain an oblong seed. It grows almost every where in the fields and woods, and flowers in June, July, and August: the fruit is ripe in autumn. The root is cleansing, astringent, and absorbent; and a syrup made of the fruit is recommended in heat of urine. Boerhaave affirms, that the roots taken out of the earth in February or March, and boiled with honey, are an excellent remedy against the dropsy. The leaves pounded and applied to ring-worms and ulcers of the legs, heal them in a short time.

time. The fruit when ripe is cooling, and quenches thirst.

RUBUS IDÆUS SPINOSUS FRUCTU RUBRO ET ALBO, the *Raspberry bush*, has a long creeping root, divided into several branches, and sends forth several stalks, to the height of a man, armed with thorns, that are not very prickly; the leaves are like those of the bramble, but more tender and soft, and of a brownish green above, but whitish below. The flowers are white, and consist of five petals, disposed in the form of a rose, and the calyx is divided into five parts; from the center of which the pistil arises, with many stamina, that afterwards turn to the fruit, which is larger than a strawberry. It is round, a little hairy, and composed of five berries, joined closely together; the colour is generally red, and they are full of a rich vinous juice, and each contain a seed. It grows wild in moist shady woods, and is cultivated in gardens and orchards; it flowers in May and June, and the root is ripe in July, but it will not keep. There are other sorts of raspberries, and particularly one, that has white fruit; but they have all the same qualities, and are said to be cooling, cordial, and to strengthen the stomach. They agree with people of hot constitutions, and there is a syrup made with them, that is kept in the shops.

RUSCUS LATIFOLIUS FRUCTU FOLIO IN NASCENTE, *narrow leaved butcher's broom*, or *Alexandrian laurel*, with the fruit growing on the leaves, has a long, white, hard, knotty, fibrous root, that sends forth stalks to the height of two feet, which are small, flexible, green, round, and furnished with pretty thick, broad, nervous, bending leaves, of a beautiful green, and resembling those of the common bay tree. The flowers proceed from the large nerve of the leaves, and are in the shape of little bells, but without pedicles; they are small, and of a greenish or pale yellow, with a pistil in the middle, that becomes a soft roundish fruit or berry, that is red when ripe, and contains two seeds as hard as horn. This shrub grows wild in mountainous places, and is cultivated in gardens. It flowers in summer, and the fruit is ripe in autumn. The roots are said to be aperient, and to be good in a suppression of urine; the leaves are vulnerary, and proper to cleanse and dry moist ulcers.

RUSCUS MYRTIFOLIUS ACULCATUS, the *common Knee-bolley*, or *butcher's broom*, has a thick, crooked, warty, hard, creeping, white root, furnished with thick long fibres, and sends forth stalks to the height of two feet, that are tough and hard to break; and are furrowed, and divided into several branches. The leaves are like those of the myrtle, but more stiff and rough, pointed, prickly, nervous, and without pedicles; they are always green, and have a bitter astringent taste. The flowers grow in the middle of the leaf, and consist of a single petal, cut into six parts, whose stamina, being united, are in the shape of a bell, but there is no calyx. These are succeeded by round berries, as large as peas, somewhat soft and red when ripe. It grows in rough, stony places, and in woods, forests, and hedges; it flowers in April and May. There proceed tender shoots from the roots in spring, that are green, and may be eaten as asparagus. If they are suffered to grow, they become leafy, woody, and tough; and in some places they make brooms with them. This plant is said to incise gross humours, and to carry them off by urine; and the root is one of the five greater opening roots. The dose is from half an ounce to an ounce in decoction, and has been recommended in the jaundice, dropsy, and gravel. Boerhaave affirms, that the decoction of the leaves, in white wine, is an excellent remedy in the gravel and dropsy, and the dose is a glass in a morning fasting; but it must be continued for some time.

RUTA HORTENSIS LATIFOLIA, the *common broad leaved garden Rue*, has a woody root, furnished with a great number of fibres; and sends forth stalks in the form of a shrub, that sometimes rise to the height of five or six feet; they are as thick as one's finger, woody, divided into several branches, and covered with a whitish bark. The leaves are divided into several segments, and are small, oblong, smooth, of a sea-green colour, and placed by pairs in a rib, terminating in a single leaf. The flowers grow on the tops of the branches, and generally consist of four somewhat oval leaves, of a pale yellow; the pistil arises out of the flower cup, which turns to a fruit, consisting of four capsulæ, fixed to an axis, that are full of angular seeds, in the form of a kidney. It is cultivated every where in gardens, flowers in June, and continues green all the winter.

RUTA SYLVESTRIS MAJOR, the *greater wild Rue*, is somewhat like the garden rue, but smaller, and the leaves are divided into longer segments, which are also more narrow, and of a darker green. It grows in the southern parts of Europe, in rough, stoney, mountainous places. They both have the same virtues, and have a disagreeable smell, with an acrid bitter taste. The leaves, when in perfection, will blister the skin, if much handled, and are said to be incising, attenuant, and discutive; therefore they are proper, as they have also a stimulating quality, to quicken the circulation of the fluids, to dissolve gross humours, and to open obstructions of the glands. Boerhaave had a high opinion of it, and affirms nothing can be more proper to promote sweat and perspiration, and to cure the hysteric passion, and the epilepsy. An extract, made with the rectified spirit, contains the whole virtue of the rue. The dose of the juice is to two ounces; but the leaves are best for those that can eat them; or they may be taken in powder, from a scruple to a drachm, or the infusion may be drank as tea.

SABINA MAS, the *common Savine*, has a strong, woody root, that sends forth a stem or shrub, that extends more in breadth than in height, and is always green. The leaves are like those of German tamarisk, but are more hard and thorny, and have a strong disagreeable smell, with an acrid burning taste. On the top of the branches there are catkins or flowers, that have three stamina without petals, and which are not succeeded by any fruit; however, if the shrub be very old, it sends forth small greenish flowers, that are succeeded by small flattish berries, less than juniper berries, that are of a blueish black when ripe. It is cultivated in gardens, but in our climate seldom or never yields any fruit.

SABINA FOLIO CUPRESSI, the *berry-bearing upright Sabine*, has a root like the former, but produces a higher stem, for it rises to a sort of a tree, whose wood is reddish within, and is covered with a reddish pretty thick bark. The leaves are like those of the cypress tree, but more compact, with a strong penetrating smell, and a bitter, aromatic, resinous taste. The flowers consist of three pointed petals, as well as the calyx, which is divided into three parts, and is of a yellowish colour. The berries are roundish, fleshy, and on the lower part there are three tubercles, with a navel, armed with three small teeth, and they contain three oblong stones, that are convex on one side, and angular on the other. It grows among mountains, woods and other uncultivated places, and is also planted in gardens. The first is only used in medicine, and is incising, penetrating and aperient. The dose of the leaves in infusion, is half an ounce, and, in powder, to a drachm, in a glass of white wine. The distilled oil taken upon a lump of sugar, has the same virtues, and is employed by some to kill worms. This plant is a good remedy for opening obstructions

obstructions of the viscera, proceeding from a weakness of the vessels, and the clamminess of the fluids.

SALICARIA, *five* **LYSIMACHIA PURPURA**, *purple spiked Willow herb, or Loose Strife, with long leaves*, has a thick, woody; white, perennial root, with branches that sometimes rise to the height of a man, that are stiff, angular, branched, and reddish. The leaves are oblong, pointed, narrow, and of a deep green; they proceed from the knots of the stalks by pairs, and sometimes by threes, but very seldom by fours; they surround the stalks by intervals, and have a dry astringent taste. The flowers are verticillated in the middle of the branches, and are collected in spikes, of a fine purple colour, and each consists of six leaves or petals, in the form of a rose, with twelve stamina of the same colour, placed in the middle. The pistil rises from the middle of the flower-cup, and turns to a husk, or oblong pointed capsula, divided into two cells, full of small seeds. It grows in moist marshy places, and by the sides of waters and rivers; it generally flowers in June and July. This plant is detersive, astringent, vulnerary, and cooling, but is seldom used in medicine, though some pretend it is an excellent remedy against the bloody-flux.

SALIX VULGARIS ALBA ARBORESCENS, *the common white Willow tree*, has a long, woody, white root, that produces a pretty large tree, with many firm green branches, covered with a smooth soft bark; the wood is white, pliant, and difficult to break. The leaves are long, narrow, downy, whitish, soft, and more or less dentated on the edges. The flowers and fruit grow distinctly from each other, and the male has only catkins, or long scaly spikes without petals, but there are two stamina in the center. The female willow has catkins like the former; but they have an oval, pointed pistil, somewhat longer than the fruit, which afterwards becomes a bivalved capsula of the same shape, full of oval tufted seeds. It grows every where in moist marshy places, and on the sides of brooks and rivers.

SALIX CAPREA seu MINOR, seu SALIX LATIFOLIA ROTUNDA, *the round leaved Willow*, has a root like the former, which produces a pretty large shrub, covered with a whitish bark. The leaves are roundish, broad, nervous, of a deep green above, and whitish and downy below, and the pedicle is often furnished with two small leaves, cut like ears; the catkins and flowers grow in distinct places, and it delights in moist woods, and along the sides of rivers and ditches, and is common in hedges. It flowers in March and April, and the wood, though more brittle than the white willow, serves to make hoops for barrels. The bark, leaves, and catkins, are said to be cooling and astringent, and they have been used in decoctions, and in all kinds of hæmorrhages, but they are now out of use.

SALVIA MAJOR, *the greater or common Sage*, has a perennial, hard, woody, fibrous root, with woody, branched, hairy, white, green stalks, generally square, with leaves placed opposite to each other; these are oblong, broad, obtuse, wrinkled, rough, and whitish, inclining to purple, and sometimes other colours; they are downy, thick, have a little juice, and are crenated on the edges. The flowers grow in spikes on the tops of the branches, and consist of a single labiated petal, with two stamina; they are of a bluish colour, inclining to purple, and are contained in a large calyx, in the shape of a horn, that is cut into five segments, and has the smell of turpentine. These are succeeded by four roundish blackish seeds, contained in a husk, that before was the flower-cup. It is cultivated in gardens, and flowers in June and July.

SALVIA MINOR, five PINNATA, *Sage of Vir-*

tue, has a root like the former, with several woody, whitish, downy stalks, as long as those of the common sage; but the leaves are less; whiter, wrinkled, rough, and generally attended at the base with two small leaves, in the shape of ears or wings. The smell and taste are stronger, more penetrating and aromatic. The flowers and seeds are like the former, and it is cultivated in gardens:

SALVIA HISPANICA, *Spanish Sage, with a lavender leaf*, somewhat resembles the former, but is less, and the leaves are narrower, and more white, as well as the flowers. It flowers in summer, but is very tender, and will not bear the cold very well. They may be all planted by slips, during any of the summer months, observing to shade and water them till they have taken root; after which they may be taken up and planted in a dry soil, where they may have the benefit of the sun. Sage of virtue is by most accounted the best, though the properties of all are much the same; they are cephalic, and very good against the apoplexy, epilepsy, palsy, and trembling of the limbs. They are all used in the manner of tea, against any of the disorders abovementioned, as well as for a preservative, and are very good for disorders of the brain, to promote the circulation of the fluids, to strengthen the stomach, and to help digestion. It is commonly said, that the Chinese wonder we should buy their tea, when we have so much sage of our own, which they take to be much more excellent. As to outward use, the leaves and flowers are often employed in fomentations, to strengthen the nerves, and to discuss the swellings of wounds.

SAMBUCUS FRUCTU IN UMBELLÀ NIGRO, *the common Elder tree with black berries*; has a woody, long, whitish root, and sometimes grows to a middle sized tree. The branches are large, round, and full of a white pith, that is green at first, and afterwards grey. The trunk is covered with a rough, ash coloured bark, full of cracks, under which there is another, which is green, and is used in medicine. There are five or six leaves that grow on one rib, which are dentated on the edges, and each rib is terminated with a single leaf, that is larger than the rest. The flowers grow at the tops of the branches in umbels, and consist of a single petal divided into five segments, that expand in the form of a rose; they are white, small, and have five stamina, with roundish apices; these are succeeded by soft, round, juicy berries, that are green at first, but black when ripe, and there are generally three seeds in each. It grows almost every where, in all parts of Europe, but delights in valleys and moist shady places. It flowers in May and June, and the berries are ripe in autumn. All parts of this tree are in use, and are generally known to have a purging and aperient quality. The dose of the rob of elder berries is from a drachm to half an ounce, in the bloody-flux, and to promote urine and sweat. The use of elder-berries in made wines is universally known.

SANICULA, *Sanicle*, has a thick root above, that is fibrous below, blackish without, and white within. It sends forth several broad roundish leaves, that are a little hard, smooth, dentated on the edges, and of a fine green shining colour; from among these there arises a stalk to the height of a foot, that is smooth, without knots, and reddish towards the root, and on the top there are several small flowers collected into an umbel, consisting of five white or red petals, placed in the form of a rose, with five stamina, and roundish apices. The petals are generally bent back to the calyx, on which they rest, and which turns to a fruit composed of two seeds, convex on one side, flat on the other, and prickly at the points, by which means they stick to the garments of those that pass by. Some of the flowers are always barren. It delights in shady woods, and in a flat moist soil, and

flowers

flowers in June. It has been long noted for its vulnerary virtues, and may be used in the manner of tea; but it is not now depended upon for any such purpose.

SATUREIA HORTENSIS, *garden Savory*, has a small, single, woody root, with stalks that rise to the height of a foot, or a foot and a half, which are round, reddish, and a little hairy and knotty. The leaves are small and oblong, like those of hyssop; they are a little hairy, and seem to have several holes, with a smell like that of thyme, but weaker. The flowers are small and labiated, consisting of a single petal; whose upper lip or crest is divided into two parts, but the lower lip or beard is divided into three, and has the middle part crenated; they proceed from the places where the leaves join to the stalk, somewhat loosely, but not in whorls or spikes, like most of this kind. They are white or purplish, with four silky stamina, that are succeeded by as many brownish round seeds, contained in a capsula, that was the cup of the flower. It is cultivated in gardens, by sowing the seeds on a bed of fresh light earth, in March; and when the plants are come up, they must be moved into other beds, placing them about four or five inches asunder each way. It flowers in the summer. It is aperient, inciding, and strengthening, but it is chiefly cultivated for the use of the kitchen, and is very proper for cold stomachs.

SAXIFRAGA ALBA RADICE GRANULOSA, *white round leaved Saxifrage*, has a root that sends forth several fibres, at the top of which there are several tubercles, somewhat larger than coriander seeds, which are partly purple, and partly white, and of a bitterish taste. The leaves are almost round, crenated on the edges, and pretty much like those of ground-ivy, only they are thicker and whiter. Among these the small stalks rise to the height of a foot, and are tender, hairy, purplish, and branched. The flowers grow on the top, and have five white leaves or petals, placed in the form of a rose, that have six stamina, with roundish apices. The flower-cup is divided into several segments, out of which the pistil arises, that, together with the flower-cup, turns into a roundish fruit, with two horns, and two cells full of small, longish, reddish seeds. This plant is common in moist meadows, in divers parts of England, and flowers in May. It is said to be good in disorders of the breast, and particularly in the moist asthma; but it is now almost neglected.

SAXIFRAGA VULGARIS, *Meadow Saxifrage*, has a perennial, long, thick, wrinkled root, white within, and hairy at the top, with stalks that rise from one foot to two in height, which are thick, round, furrowed, smooth, pithy, reddish towards the bottom, and branched. The leaves are smooth, of a deep green, and divided into longish, narrow-pointed, stiff segments, with an acrid taste. The flowers, which grow on the tops of the branches in umbels, have five leaves or petals in the form of a rose, of a whitish yellow. These are succeeded by fruit, composed of two short furrowed seeds, convex on one side, and flat on the other; they have a strong pleasant smell, and a vinous aromatic taste. It grows almost every where in moist places, and has been looked upon as exceeding good for the gravel, the root being a powerful diuretic; but it is not now much used for that purpose.

SCILLA VULGARIS RADICE RUBRA, *common red Squill*, has a root like an onion, or a bulb, sometimes as large as a child's head, composed of thick, red, juicy, clammy coats, placed one upon another, and underneath there are large fibres. It sends forth leaves a foot in length, and as broad as the hand, that are fleshy, green, and full of a clammy bitter juice. In the middle of these there arises a

stalk to the height of a foot and a half, on the top of which there are flowers, with six white petals, but without a calyx, disposed in a ring, and as many oblong stamina. These are succeeded by roundish fruit, on which are three corners, and they are divided into three cells, full of roundish black seeds. The root only is in use.

SCILLA RADICE ALBA, *the white Squill*, has a large root, but less than the former, and composed of several white coats, full of a clammy juice, and furnished underneath with many pretty thick fibres. It sends forth an upright naked stalk, to the height of a cubit, adorned at the top with several white flowers in the form of a star. The flowers appear before the leaves, and after them six thick, fleshy, large, deep, green leaves, proceed from the root, and lie upon the ground. This, as well as the former, grows in sandy places near the sea, and flowers in August and September. The seeds are ripe in November and December. These roots are brought from the Levant and Spain every year, and deserve to be cultivated in every good garden, for the beauty of their flowers. Those roots should be chosen that are fresh, of a middle size, sound, heavy, firm, and full of a clammy, bitter, acrid juice. They are excellent in disorders of the lungs, caused by a clammy, viscous phlegm; for which reason they perform wonders in the fits of the moist asthma, and in a disposition to a dropsy. However, in swellings arising from the dropsy, and in the inflammation of the kidneys, they are best given with nitre; that is, there should be double the quantity of this to that of the root; and the dose of the latter, in powder, is from four to ten grains. When given in this manner, it almost always operates as a diuretic. There are several preparations of this root kept in the shops.

SCORDIUM ALTERUM, *five SALVIA AGRESTIS*, *wood Sage*, has a woody, flexible, creeping, fibrous, perennial root, that sends forth several square, hairy, purplish, branched, pithy stalks, to the height of two or three feet. The leaves resemble those of sage of virtue, only they are broader and softer, like balm; they are also wrinkled, downy, of a dirty green, dentated on the edges, and have a bitter taste. The flowers grow in spikes, and consist of a single labiated petal, like those of German-der, and have the same shape, but are of a pale white colour, with four purple stamina, that are succeeded by four roundish, blackish seeds, contained in a capsula, that was the cup of the flower. It grows in uncultivated sandy places, and among hedges. It flowers in the summer, and continues a long while in flower. It has somewhat of a garlick smell, and is said to strengthen the stomach, kill worms, and promote urine; but it is now neglected.

SCORSONERA, *five SCORZONERA*, *Viper's Grass*, has a root a foot long, as thick as one's thumb, blackish without, white within, and easy to be broken; it is full of a sweetish milky juice, and some account it good eating. It sends forth a round, furrowed, hollow stalk, to the height of two feet, covered with a little down, and divided into several branches. The leaves are long, pretty broad, smooth, and embrace the stalk by their base; they are sometimes a little sinuated or curled at the edges, terminating in a long narrow point, and are of a dark green colour. The flowers grow on the tops of the branches, and are large, yellow, and composed of semi-florets, with a long, slender, scaly flower-cup; these are succeeded by long white seeds, tufted at the top. It is cultivated in many kitchen gardens about London, and flowers in May and June. The root is accounted good both for food and physic; for it is said to strengthen the stomach, and to promote urine and sweat. Some take the boiled root to be very good food, and affirm it agrees with all ages and sexes.

sexes. The juice of the root, taken to three ounces in a morning fasting, Boerhaave affirms to be good in hypochondriac diseases, and to open obstructions of the viscera.

SCROPHULARIA AQUATICA, *water Betony*, has a thick perennial root, furnished with long fibres, and several stalks, that rise to the height of two or three feet; these are square, thickish, reddish in some places, and green in others, hollow within, pretty tender, full of juice, smooth and branched. The leaves are like those of the former, but more blunt at the end, and twice or thrice as large; they have a disagreeable smell and taste. The flowers are like those of the former, but a little larger, and of a reddish, rusty colour. These are succeeded by round pointed fruit, divided into two cells, that contain very small brown seeds. It is common in all watery places, and flowers in July and August. It is said to be an excellent vulnerary, and to have the same virtues as the former in other respects; but it is not now in much esteem.

SEDUM MAJUS VULGARE, *common great House Leek*, has a small fibrous root, with many oblong, thick, flat, pointed, fleshy, juicy leaves, that grow close to the ground; they are always green, and ranged in a circular order, in the form of a rose, they being convex without, and flattish within, and have a very little down on their edges. A thick, reddish, pithy stalk arises from the middle of these, clothed with the same sort of leaves as the former, only they are more narrow and pointed. It is divided at the top into several branches, on which are flowers, with five petals, placed in the form of a rose, and of a purple colour, with ten stamina, that have roundish apices or summits. The pistil rises from the flower-cup, which afterwards turns to a fruit, composed of many seed vessels, resembling husks, that are collected into a sort of a head, and are full of small seeds. It grows on the top of old walls, and on the roofs of houses; it flowers in July, and the stalk withers away in the autumn, when the seed is ripe. This plant is said to be cooling, cleansing, and astringent, and some give four ounces of the juice, to cure intermitting fevers, when there is no cold fit.

SEDUM PARVUM ACRE FLORE LUTEO, *Wall Pepper, or Stone Crop*, has a small fibrous root, with several low, short, slender stalks. The leaves are very small, somewhat thick, fat, pointed, triangular, and full of juice; the flowers are yellow, and consist of six petals in the form of a star, with many stamina and apices, or summits, of the same colour in the middle, that are succeeded by several sheaths or seed vessels, collected in the form of a head, and full of small seeds. It grows almost every where suspended by its roots, or lying on old walls, and on the tops of cow houses; it flowers in June, and has a pungent, hot, burning taste. It is looked upon by some as an excellent remedy for the scurvy, and is particularly good for ulcerated gums, occasioned by that distemper.

SENECIO MINOR VULGARIS, *common Groundsel*, has a small, whitish, fibrous root, with several round, furrowed, hollow stalks, that rise to the height of a foot; these are sometimes reddish, branched, and hairy in certain places, exposed to the sun. The leaves are oblong, jagged, dentated, placed alternately, fixed to the stalks by a broad base, and terminate in a blunt point; the colour is of a dark green, and the flowers are placed in bunches at the top of the stalks; they consist of many yellow florets, disposed in the form of stars, and contained in a flower-cup, consisting of a single leaf, with five small stamina, that have cylindric apices or summits in the middle; these are succeeded by downy seeds, that altogether form a white head. It grows every where in fields, and by the way sides, in sandy

No. 39.

places exposed to the sun; as soon as the leaves wither, others arise; insomuch that it continues green all the year, and flowers in all seasons. It is accounted emollient and resolvent, and the juice, given to two ounces, kills worms. Some account it good in the jaundice, and even in spitting of blood. Boerhaave recommends the juice, mixed with oxycrate, as a gargle, in inflammations of the throat.

SERPILLUM VULGARE MINUS, *Mother of Thyme*, has a small, woody, perennial, brown root, furnished with capillary fibres, as also several small, square, woody, reddish, and low stalks, that are somewhat hairy. The leaves are small, green, roundish, nervous, a little broader than those of common thyme, and have an acrid, aromatic taste. The flowers grow on the tops of the stalks, disposed like a head, and generally of a purple colour; they consist of a single labiated petal, that has two lips, and is placed in a calyx, made like a horn. These are succeeded by small roundish seeds, contained in a capsula, that was the cup of the flower. It grows in uncultivated, mountainous, dry, sandy, stony places, and flowers in the summer. There are several sorts, but they have all the same virtues, and are accounted cephalic and stomachic, and may be used in the same manner as common thyme, though they are not quite so efficacious.

SILICUASTRUM, *five ARBOR JUDÆ, Judas's tree*, has a thick, hard, woody, perennial root, that sends forth a trunk, which in time becomes a middle sized tree, and is divided into branches at considerable distances from each other; the bark is of a blackish purple colour, on which papilionaceous flowers appear in the spring of a beautiful purple colour, and several of them are placed together; they are composed of five petals or leaves, the two lowermost of which are larger than the upper, which is contrary to other flowers of the leguminous kind. The pistil rises from the center of the flower-cup, is surrounded with stamina, and afterwards becomes a long flat pod, containing several seeds in the shape of kidneys. After these the leaves appear, which are round, and placed alternately on the branches; they are nervous, green above, and whitish below; the pods that contain the seeds are six inches in length, and very flat, purple, membranous, semi-transparent, and made in some sort like the sheath of a knife. This tree grows in hot countries, near rivers and brooks, on mountains and in valleys; it is cultivated in gardens for its beauty, and flowers in April and May. It was formerly preserved in green-houses as a curiosity; but of late years has been transplanted into the open air, where it thrives very well. It may be propagated by sowing the seeds on a bed of light earth, towards the middle of April, and earth should be sifted over them to the thickness of half an inch; if the season proves wet, the bed should be covered with mats. Some few of the plants rise the first year, but the greatest number in the second. About the middle of April following, just before they begin to shoot, they should be taken up carefully without breaking their roots, and planted in fresh ground as soon as possible. After they have continued here two or three years, they may be removed to the places where they design to remain. It is of little or no use in medicine, though the pods are said to be astringent. In the southern parts of France, the flowers are eaten as a salad; but they are best when pickled like capers before they open.

SINAPI SILIQUA LATIUSCULA GLABRA SEMINE RUFO, *five VULGARE, common or red Mustard*, has a white, woody, brittle root, furnished with fibres, that sends forth a stalk to the height of four or five feet, which is pithy, hairy below, and divided into several branches. The leaves are large, and

and much like those of radishes, but smaller and more rough. The small yellow flowers grow at the top of the branches, and consist of four leaves in the form of a cross; the pistil arises out of the flower-cup, which turns to a fruit or pod, divided into two cells by a partition, to which the valves adhere on both sides, and are full of roundish, reddish, or blackish seeds, of an acrid biting taste. This grows wild on the sides of ditches, among stones, and on land newly broken up, particularly in the Isle of Ely, where the land has been flooded for many years, and has afterwards been drained. It is also cultivated in gardens, and flowers in June.

SINAPI ALBUM, *five* **HORTENSE SEMINE ALBO**, *garden, or white Mustard*, has a single, woody, white root, furnished with long fibres, and sends forth a stalk to the height of a foot and a half, or two feet, which is branched, hairy, and hollow. The leaves are like those of radishes, and armed above and below with stiff prickly hair. The flowers are small, yellow, in the form of a cross like those of the former, and are succeeded by hairy pods, that terminate in an empty point, and contain four or five round, whitish or reddish seeds, that seem to be articulated or knotted. It grows wild in fields among the corn, and is cultivated in gardens; it flowers in May and June, and the seeds are ripe in July and August. Both kinds have the same properties, though the former is generally preferred. The seeds are stomachic, diaphoretic, antiscorbutic, and are good in hypochondriac diseases, as well as in sleepy disorders. The common use of mustard is known to every one, and is very proper for people of a cold constitution; because it creates an appetite, helps digestion, and attenuates the food. The powder of mustard seed, taken in white wine, is excellent against the scurvy, and some affirm it will cure a quartan ague, if taken in hot wine two hours before the fit. Some apply mustard outwardly to cure the hypogout, and also lay it to the feet, mixed with other things, in dangerous fevers. The white mustard is used as a salad herb, especially in winter, and in the spring. There are two other sorts of this plant, but these are the most useful.

SISARUM GERMANORUM, *the Skerrit*, has a root composed of several parts, as long as a man's hand, and as thick as the little finger, which are tender, brittle, wrinkled, and fixed to a sort of a neck; they are covered with a thin pale rind, and have a white pulp. The branches rise to the height of two or three feet, and are thick, knotted, and furrowed; the leaves are winged, and placed by pairs opposite to each other, on a rib that terminates in a single leaf, which is longer and broader than the rest; they are greener and softer than those of parsnips, and are slightly crenated on the edges. The flowers grow in umbels on the top of the stalks, and consist of four white leaves, placed in the form of a rose, with as many stamina in the middle. The flower-cup afterwards turns to a fruit, composed of two oblong seeds, which are furrowed on the back, and of a dark colour. It is cultivated in the kitchen garden, and flowers in June. It is thought by some to be the most wholesome and nourishing of all kinds of roots, though it is not very common in the gardens near London, but for what reason it is hard to say. It may be propagated by sowing the seeds about the middle of April, upon a moist, rich, loose soil; the plants will come up in May, and, when the leaves are decayed, the roots may be taken up for use as they are wanted; they will continue good in the ground from October till March, after which they are good for nothing. They are accounted good for all ages and constitutions; Boerhaave looks upon them as one of the best remedies for pissing and spitting of blood, and would have them dressed

several ways, that the patient may feed frequently upon them, especially if inclined to a consumption.

SISYMBRIUM AQUATICUM, *Water-radish*, with *dentated leaves*, has a long flexible root, furnished with fibres, and has a taste like that of radishes. It sends forth several branched, hollow, furrowed stalks, to the height of three feet; the leaves are large, long, sinuated, dentated on the edges, and especially towards the lower part. The flowers grow on the top of the branches, and consist of four yellow petals or leaves, disposed in the form of a cross; the pistil proceeds from the flower-cup, that afterwards turns to a fruit or pod, which is divided into two cells by a partition, to which the valves adhere on both sides, and contain small roundish seeds. It grows in marshes, brooks, rivers, ditches full of water, and flowers in spring. It is observable, that the leaves differ greatly from each other, according to the places in which they grow.

SISYMBRIUM SILVESTRE, *five* **RHAPHANUS AQUATICUS**, *Water-radish*, has an oblong white root, as thick as a man's little finger, that has an acrid pungent taste; the stalks, which rise to the height of three feet, are furrowed, hollow, and sometimes reddish. The leaves are oblong, pointed, cut deeply into jags, dentated on the edges, and are placed alternately on the stalks. The flowers grow on the tops of the stalks and branches, and are small, considering the size of the plant; they consist of four yellow petals or leaves, disposed in the form of a cross, with six stamina; they are succeeded by small short pods, divided into two cells, that contain small roundish seeds. It grows in ditches full of water, and in marshy places; it flowers in June and July. Some account the roots of both kinds good to eat, and use them in the same manner as radishes. They are aperient, cleansing, good against the gravel, scurvy, and dropsy; but they are seldom used either for food or physic.

SISYMBRIUM PALUSTRE REPENS NASTURTI FOLIO, *Water Rocket*, has a creeping, slender, whitish root, with an acrid taste, but not so strong as that of radish; the stalks are short, furrowed, slightly perforated, and are sometime reddish, and like those of the garden cresses. The flowers grow at the top of the branches, and are small, consisting of four yellow leaves or petals, that are succeeded by small cylindric pods, which are longer than those of the former kinds, and are divided into two cells by a partition, containing several small seeds. It grows on the sides of rivers in moist ditches, and in stony brooks; it flowers in July and August. It has the same virtues as the two former, but is now made little or no use of.

SISYMBRIUM ERUCÆ FOLIO GLABRO FLORE LUTEO, *Common winter cresses*, has a long, pretty thick, white, perennial root, with an acrid taste; the stalks are furrowed, firm, branched, pithy, hollow, and rise to the height of a foot and a half. The leaves are smaller than those of radishes, and are somewhat like cresses; they are of a deep, shining green; but have not so acrid a taste as the root. The tops of the stalks and branches are adorned with long spikes of yellow flowers, composed of four petals in the form of a cross; these are succeeded by slender, long, tender, cylindric pods, full of many small reddish seeds. It grows on the sides of ditches and brooks, and sometimes in fields; it is also cultivated in gardens for salads, in some parts of Europe; it flowers in May and June, and continues green all the winter. It is cleansing and vulnerary, and is good in the beginning of a dropsy, made use of in the manner of tea.

SMILAX LÆVIS MAJOR, *greater Bind Weed*, has a long, slender, whitish, perennial root, furnished with

with fibres; and the stalks are long, slender, furrowed, and climb upon trees and bushes, by means of their clasps. The leaves are in the shape of a heart, and are bigger and softer than those of ivy; they are also smooth and green, and the flowers are in the form of a bell, and as white as snow. The calyx is oval, and divided into five parts, with as many stamina, and flattish summits. These are succeeded by round fruits as big as cherries, wrapt up in the calyx, and contain two angular or pointed seeds, of a blackish colour, with a reddish cast. It is milky like other plants of the same kind, and grows almost every where amongst hedges and bushes; it flowers in summer, and the fruit is ripe in autumn. This plant is purgative and vulnerary, and the milky juice is of the same nature as scammony; but it must be given in a larger dose, that is, from twenty grains to thirty.

SMILAX LENIS MINOR, *small Bind Weed*, has a very long, slender, creeping, perennial root, with many small, weak, slender branches, that wind round the neighbouring plants. The leaves are in the shape of a heart, but more rough, nervous and small, than the former. The flowers proceed from the places, where the leaves join to the stalks, like small, whitish bells; but they are sometimes reddish or purplish. These are succeeded by roundish, small fruit, containing pretty large angular seeds. It is an anodyne, cleansing, vulnerary plant, and country people often use it to heal wounds, by applying it after it has been bruised between two stones; many are lavish of their praise of this plant on that account. There is another species of this plant, called the rough Bind Weed, with a red fruit; but it is of no use in medicine.

SOLANUM HORTENSE, *Common Night-shade, of the shops, with black fruit*, has a long, slender, hairy, dirty, whitish root, with a firm, angular stalk, that rises to the height of a foot and a half, is of a blackish green colour, and divided into several branches. The leaves are oblong, pretty large, soft pointed, and blackish; whereof some are angular, others crenated, others whole, smooth, and full of a greenish juice. The flowers grow on the branches, a little under the leaves, and consist of a single petal, divided into five parts, and expanded in the form of a star; there are as many yellow stamina, with oblong summits, and a pistil, which afterwards becomes a berry, like those of the juniper-tree; it is green at first, but when it is ripe it is soft, smooth, black, and full of juice. It grows on the sides of highways, near hedges and houses, and flowers in August and September. Some sorts of this plant have red fruit, and others yellow, which seems to be the principal difference: Some have given the leaves and fruit inwardly, but very rashly; for they are often attended with dangerous consequences, and therefore it is better to abstain from it entirely.

SOLDANELLA MARINA, *Scottish Scuroy-grass, or Soldanella*, has a small fibrous root, with several slender, pliant, reddish stalks, that creep on the ground; the leaves are roundish, smooth, shining, like those of the lesser celandine, but thicker, and full of a milky juice. The flowers consist of a single petal, in the shape of a bell, and are of a purple colour. The pistil, which rises from the lower part of the calyx, turns to a roundish membranous fruit, that contains angular black seeds. It grows frequently on the sandy shores of the sea, and flowers in summer; the whole plant is dried with the root, in which manner it is sent to us. It has a bitter, acrid taste, that is somewhat saltish, and is looked upon by some as very proper to purge off watery humours, particularly in a dropsy, palsy, and the rheumatism. The dose of the powder, when dried, is from half a drachm to a drachm.

SONCHUS LÆVIS, *Smooth Sow Thistle*, has a

small, white, fibrous root, and a hollow, tender, furrowed, purplish stalk, that rises to the height of a foot and a half. The leaves are long, smooth, larger and more tender than those of dandelion, and are dentated on the edges. They are ranged alternately; are full of a milky juice, and some of them embrace the stalks with their broad bases. The flowers grow on the tops of the stalks and branches in bunches, and consist of yellow semi-florets, like those of dandelion, but smaller; these are succeeded by fruit, of a conical shape, that contain oblong, reddish, brown seeds, with a downy tuft. It grows almost every where, and flowers in May and June; rabbits and hares are fond of this plant.

SONCHUS ASPER, *prickly Sow Thistle*, has a root like the former, but the leaves are more entire, resembling those of endive, and they embrace their stalk with their base; they are of a deep shining green, and furnished with long hard prickles. It grows in the same places as the former, and flowers at the same time; it is full of a milky bitter juice. They are both of little or no use in physic.

STACHYS MAJOR GERMANICA, *base Hoarhound*, has a hard, woody, fibrous, yellowish, perennial root, with several stalks that rise to the height of two feet, which are thick, square, knotted, white, downy, and pithy. The leaves are placed opposite to each other at each knot, and are like those of white hoarhound, but longer, and whiter, and as well downy as dentated on the edges. The flowers are verticillated, and disposed like spikes on the top of the stalks, between the leaves; they are downy without, smooth within, and generally of a purple colour, though sometimes white; they consist of a single petal in the form of a tube, cut on the upper part into two lips, the uppermost of which is hollow like a spoon, and erect; but the upper lip is divided into six segments, of which the middlemost is much the largest; the pistil rises from the flower-cup attended by four embryoes, that turn to as many roundish blackish seeds, contained in a capsula that was the cup of the flower. It grows in mountainous uncultivated places, and is cultivated in gardens, where it is propagated by seeds; it flowers in June and July. It is of little use in medicine, though Boerhaave recommends it against the apoplexy and the palsy.

STATICE, *Thrift, or Sea Pink*, has a long, thick, round, reddish, woody, perennial root, with several heads; from whence proceed a great number of long narrow leaves, like those of grass, and of a sea-green colour. From among these several stalks arise, to the height of a foot, that are upright, knotty, hollow, and almost all naked; the bunch of flowers grow at the top, and consist of five small whitish petals, in the form of a pink, and the calyx in the shape of a funnel, besides which there is a general scaly calyx. They are succeeded by seeds, pointed at each end, and contained in a capsula, that was the cup of the flower. It grows wild in Germany, and other inland countries, from whence it has been brought into England, and planted in gardens, to make edgings, and the sides of borders of flower-gardens; but it is now almost neglected, because they require transplanting every year. It continues a long while in flower, even to the very end of autumn. Boerhaave recommends this plant as an astringent vulnerary, and proper to stop internal hæmorrhages; for which purpose the juice is to be drank.

SUBER LATIFOLIUM, **PERPETUO VITENS**, *the Cork tree*, has a long, thick, hard root, that produces a middle sized tree, with a thick trunk, and a few branches. It has a thick, light, spongy bark, of a yellowish grey colour, that cleaves of itself, and parts from the tree; because it is pushed forward by another bark that grows under it. The leaves are like those of the scarlet oak, but they are larger,

larger, longer, green above, and sometimes a little prickly; the catkins and acorns are also like those of the same tree; but they are longer, blunter, and have a more disagreeable taste. The flower-cup is also bigger, and more hairy; it grows in the southern parts of Europe. The inhabitants of the places where they grow cleave the trunk of this tree lengthways, to take off the bark more readily, and then they put it over burning coals, laying stones thereon to render it flat; after which they clean it, and send it to other countries; this is what we call cork, that serves for so many different uses. When cork is burnt, and reduced to a fine powder, it is a very good remedy to ease the pains of the piles, mixed with the white of an egg, and the oil of sweet almonds.

TAMARISCUS GERMANICA, *the German Tamarisk tree*, has a root as thick as a man's thigh, covered with a thick bitter bark, from whence proceed several brittle stems, covered with a reddish bark, divided into several branches, and adorned with leaves, like those of common heath, of a sea-green colour, and an astringent taste. The flowers grow in spikes at the extremities of the branches, and consist of five white, purplish, oval petals, or leaves, with as many stamens and roundish yellow summits; these are succeeded by small oblong pods, which before were the pistils, and are full of small downy seeds. This shrub grows in Hungary, about Strasburg, Landaw, and Geneva, by the sides of running waters, and moist stony places. It flowers in May and June, and does not cease to bear flowers and fruit all the summer. They may be easily propagated in England, by laying down the tender shoots in the spring; but they are not of much value here because they have stragling branches.

TAMARISCUS NARBONENSIS, *the French narrow leaved Tamarisk tree*, has a thick woody root, divided into several branches, that send forth several stems, which together form a bush or shrub, and sometimes a pretty large tree, with a trunk covered with rough grey bark. The leaves are small, long, and round, like those of the cypress tree and common heath; the flowers grow on the tops of the branches in bunches; these are of a whitish purple colour, and consist of five petals or leaves, that are succeeded by pointed fruit, which contain small downy seeds. It grows chiefly in hot countries, but may be propagated here like the former, though it is of no great value. It flowers generally three times a year, namely, spring, summer, and autumn; but the leaves drop off in the winter. The virtues of both these shrubs are much the same, and the root, bark, and leaves, are said to open obstructions of the viscera, and to attenuate gross humours, but they have been long out of use with us.

TANACETUM VULGARE LUTEUM, *common Tansey*, has a long, woody, fibrous, perennial root, which sends forth stalks to the height of two or three feet, which are round, streaked, a little hairy, and pithy. The leaves are large, long, winged, dentated on the edges, and disposed in pairs along a rib, terminating in a single leaf; however, botanists generally reckon all these but one leaf. The flowers grow on the top of the leaves in bunches or umbels, and consist of many florets, divided into several segments, and are of a beautiful yellow. The calyx or flower-cup is scaly, and contains an embryo, that turns to an oblong seed, which is black when ripe. It grows wild on the sides of highways, in fields, and on the edges of ditches; but it is every where planted in gardens, and flowers in July and August. The leaves have an acrid, bitter, aromatic taste, and are looked upon as stomachic, febrifuge, and sudorific, as well as althelminthic; for both the leaves and seeds have always been accounted good to kill worms. Some give the juice to three or four

ounces, in the cachexy, green sickness, and dropsy, in which last case it has succeeded, when other medicines have proved ineffectual. The seed of tansey may be used instead of wormseed; but is not so efficacious.

THALICTRUM LUTEUM, *five RUTA PRATENSIS*, *meadow Rue*, has a yellowish, fibrous, creeping root, with stalks that rise to the height of a man, which are stiff, furrowed, branched, hollow, and generally of a reddish colour. The leaves are large, of a shining green, and indented. The flowers grow on the tops of the branches, and consist of four petals, disposed in the form of a rose, about a cluster of green stamens, or chives, that surround a pistil, which afterwards becomes a fruit, in which the capsules are collected into a small head, that contain each an oblong, yellow, furrowed, small seed of a bitter taste; it has no flower-cup. It grows in meadows, and in moist marshy places, by the sides of brooks, and flowers in the summer. The root purges like rhubarb, for which reason it is called, in Germany, the rhubarb of poor people. It tinges the urine with a yellow colour, and is said to have the same qualities in all respects; but the dose must be three times as much. The juice of the leaves and flowers has been given, from one ounce to two, in all internal bleedings.

THLASPI, *Mitridate Mustard*, has a thick, woody, white root, with round, hairy, stiff, branched stalks, that rise to the height of a foot, which are furnished with leaves without pedicles, that are entire, and as long as the little finger, but broad at the base, and grow narrow by degrees to a point; they are crenated on the edges, and are of a greenish ash colour, or whitish, with an acrid pungent taste. The flowers are small, white, and disposed like those of shepherd's purse; they are composed of four leaves, placed in the form of a cross, with six stamens, that have pointed summits. These are succeeded by round or oval fruit, flattened in the shape of a purse, with a leafy border, slit on the upper side, and divided into two cells by a partition, placed obliquely with regard to the valve, and furnished with smooth, roundish seeds, that have an acrid pungent taste like mustard. It grows in uncultivated places, exposed to the sun, among corn, and on the tops of houses, and walls; it flowers in May, and the seed is ripe in June.

THLASPI ARVENSE, **SILIQUIS LATIS**, *Field Mitridate Mustard*, with broad pods, has a small, oblique, woody root, from whence arise angular, furrowed, winged stalks, that rise to the height of a foot. The leaves have no pedicles, and are long, broad, smooth, dentated, and of a blackish green, with a smell somewhat like garlick. The flowers grow in spikes at the tops of the stalks, and are composed of four white petals, disposed in the form of a cross, that are succeeded by broad, flattish, smooth pods, containing roundish, flattish, reddish brown seeds, of an acrid, hot, biting taste. It flowers in May, and the seed is ripe in June; it grows every where in the fields, and continues from the beginning of the spring to the end of autumn.

THLASPI ALLIUM REDOLENS, *Mitridate Mustard smelling like Garlick*, has a single white root, with a few fibres, that send forth several leaves, of which some are jagged, others are surrounded by small teeth, and others again are without teeth or jaggs; they have generally long pedicles, and are nervous and green. From among these arise small stalks with leaves that embrace each other alternately; the flowers grow at the tops, and are composed of four small white petals, like those of shepherd's purse, and are disposed in the form of a cross. These are succeeded by flat fruit, in the shape of oval purses, which contain roundish flat seeds. All three have the same virtues; but the seeds are only made

made use of. They are said to promote urine, and to dissolve coagulated blood. The dose is from one scruple to two; but it must not be given to women with child, for fear of causing abortion, nor yet to patients of hot constitutions. The seed of the first is an ingredient in mithridate and venice treacle.

THYMUS CAPITATUS DIASCORIDIS, the *true Thyme of the ancients*, has a hard, woody root, furnished with fibres, that sends forth a small shrub to the height of a foot, which is divided into slender, woody, white branches, with leaves placed opposite to each other, that are small, narrow, whitish, and fall off in the winter. The flowers grow in heads at the top of the branches, which are small, purplish, labiated, and consist of a single petal. There are stamina, with slender summits, and the pistil is attended by four embryos, which become so many seeds, inclosed in a husk, which before was the cup of the flower. It is common in Candia, Greece, Spain, and Sicily, and grows on mountainous places, exposed to the sun. With us they are cultivated in gardens, and were formerly set in pots and tubs; but of late they have been found to endure the winter.

Besides this there are common broad leaved thyme, narrow leaved thyme, and broad leaved striped thyme, which have all the same virtues, and may be used indifferently in medicine. They are said to strengthen the brain, and to attenuate and rarify clammy humours. They help digestion, and may be of some service in shortness of breath; but they are chiefly used in the kitchen as a pot-herb.

All these plants may be propagated, either by sowing the seeds or parting the roots; and the proper season for both is at the latter end of March.

THYSSELINUM, *Milky Parsley*, has a long, reddish, brown root, full of a milky fluid, that has a hot, sharp, strong, disagreeable taste. It sends forth a stalk to the height of four feet, which is hollow, channelled, and branched. The leaves are ferulaceous, that is resembling that of the ferula, and have a milky juice like the root. On the tops of the branches there are flowers in umbels, consisting of five yellowish white petals, in the form of a rose, with as many capillary stamina with roundish summits. These are succeeded by oval, large, flattish seeds, placed by pairs, and radiated on the back. It grows in moist, marshy places, on the sides of ponds and brooks, and of ditches full of water. It flowers in June and July, and the seeds are ripe in the beginning of August. The root has been used in decoction, to promote urine, but it is not very safe, on account of its acridity. Boerhaave affirms, that the milk has the same purging quality of scammony, and may be used instead of it.

TILIA, the *Lime*, or *Linden tree*, has a deep spreading root, that sends forth a very large trunk, so full of branches, that it is very proper for shady walks. It is covered with a smooth ash-coloured bark, which is yellowish, or whitish within. It is so tough and flexible, that in some places, where better materials are scarce, they make cords and cables therewith. The leaves are broad, roundish, and terminate in a point, and are a little downy on both sides, as well as dentated on the edges; the flowers consist of five whitish petals, which are placed orbicularly, and expand in the form of a rose. There is a long narrow leaf growing to the foot stalk of every cluster of flowers, each of which has a great number of stamina, with yellow summits, and are sustained by a cup cut into five white thick parts. These are succeeded by a pod of the size of a large pea, which are almost round or oval,

No. 39.

as well as woody, angular, hairy, and contains one or two roundish blackish seeds, of a sweetish taste. Besides this, there are the small leaved lime tree, the red twigged lime tree, the Carolina lime tree, the striped leaved lime tree, and the American black lime tree.

The three first sorts are common in England, and are cultivated in most nurseries; but the *Carolina* and *American* are not yet very common. They are all easily propagated by layers, which in one year will take good root, and then may be taken off and planted in a nursery, at four feet distant, row from row, and two feet asunder in the rows. The best time to lay them down is about Michaelmas, when the leaves begin to fall, that they may take root before the frost comes on; it is likewise much the best to remove them in autumn. They may remain here five years, and the large side shoots must be pruned off, to cause them to advance in height, but the small twigs must not be cut off from the stems, because they are necessary to retain the sap for the augmentation of their trunks. If the soil be a fat loam, they will in that time be large enough to plant where they are to remain. The timber of the lime tree is used by carvers, because it is a light soft wood; as also by architects for framing models of their buildings; not to mention the turners, who make bowls and dishes therewith.

With regard to their medicinal virtues, the flowers are said to be good in all disorders of the head, and may be drank like tea with sugar. Some make a conserve of them for the same purpose, and the dose is from half an ounce to an ounce. Some affirm them to be good in the stone and gravel, and to dissolve coagulated blood. The berries are astringent, and good against all sorts of hemorrhages and loosenesses; the dose is a drachm in powder.

TINCTORIUS FLOS, or **LUTEOLA**, *Dyer's Weed*, or *yellow Weed*, by some called *Weld* or *Wold*, has a root generally as thick as a man's little finger, which is single, woody, white, and has a very few fibres. The leaves are oblong, narrow, smooth, and not dentated, though sometimes they are a little curled. Among these there rise stalks to the height of three feet, which are round, hard, smooth, greenish, branched, and furnished with leaves that are less than those below; and on the tops there are flowers, composed of three unequal petals, of a beautiful yellowish green colour. These are succeeded by almost round capsula, terminated by three points, which contain several roundish, small, blackish seeds. It is very common in England, and grows upon dry banks, and on the tops of walls and buildings, almost every where. It is of great use among the dyers, and will grow on the poorest sort of land, provided it be dry. The seeds should be sown in the middle of August, soon after they are ripe; they will come up the first moist weather, and will grow very strong the same autumn, provided they are sown by themselves. When they are pretty strong, they should be hewed like turneps, to destroy the weeds, and to thin them where too thick. The seed must not be too ripe when gathered, for then it will fall out; nor yet must the stalk be under ripe, for then it will be good for nothing. It must be bound in handfuls, and then set to dry like flax, taking care not to shake out the seed; which is usually sold for ten shillings a bushel, and a gallon will sow an acre. It is used for dying bright, yellow, and lemon colours. A great deal of this is sown in Kent, especially about Canterbury; and they cultivate it in Languedoc and Normandy, in France, where they boil it in water with alum, and then it will colour white wool yellow, and blue stuffs green. It is said to be

5 C

an

an opening medicine, and to be good against the jaundice and cachexy; but it is seldom or never used with us.

TITHYMALUS, *Spurge*, is of three kinds, namely, *German Spurge*, *Garden Spurge*, and *narrow leaved Wood Spurge*.

German SPURGE has a thick, white, woody, creeping root, which sends forth several stalks, to the height of two or three feet, about as thick as a man's little finger; these are reddish, branched, and beset with leaves alternately placed, and these are smooth, oblong, green, and perish in the winter with the stalks. The flowers grow on the tops of the branches, and are disposed in umbels. They consist of one single leaf or petal; in the shape of a slipper, whose pointal afterward becomes a tricapular fruit, divided into three cells, each of which contains a roundish seed full of a white substance. It grows upon the sandy banks of rivers, and other marshy places; it is common in Germany, on the banks of the Rhine, from whence it has its name. It is sometimes in gardens, and flowers in May and June. It is cultivated full of an acrid milky juice, like other plants of this kind.

Garden SPURGE has a single root, with a few capillary fibres, and sends forth a stalk to the height of two feet, as thick as a man's thumb, which is round, solid, reddish, branched at the top, and furnished with many leaves three inches long, in the shape of those of willow; they are of a bluish green, smooth, and soft to the touch. The flowers grow on the tops of the branches, and are each composed of four thick petals, with several slender stamina, and roundish summits; they are encompassed with two pointed yellowish leaves, which seem to be in the room of a cup. They are succeeded by fruits, that are larger than those of the other plants of this kind, which have three corners, divided into three cells, with a seed in each as big as a pepper-corn. The whole plant is full of a milky juice, and is almost every where cultivated in gardens. It flowers in July, and the seed is ripe in August and September. Beggars make use of this milk very frequently to disfigure the skin, in order to move compassion. If the leaves or fruit of this plant are thrown into ponds, it makes the fish rise to the surface of the water, where they lie as if they were dead; but they may be recovered speedily by changing the water.

TORMENTILLA SYLVESTRIS, *wild Tormentil*, or *Septfoil*, has a root about as thick as a man's finger, which is rough, unequal, sometimes strait, and sometimes crooked, of a dark colour without, and reddish within; it is a kind of a tubercle, and is furnished with a few fibres. The stalks are slender, weak, hairy, reddish, and about a foot long; they lie on the ground, and are surrounded with leaves by intervals, like those of six leaved grass; they are hairy, and there are commonly seven leaves at the top of the foot stalk. The flowers consist of four yellow petals, placed like a rose, supported by a calyx or cup, in the form of a basin, divided into eight parts, of which four are large, and four are small; they are placed alternately, with sixteen stamina in the middle. These are succeeded by a globular fruit, which contains many seeds that are small and oblong. It grows almost every where, in dry pastures and commons, in most parts of England; it flowers in May, June, and July, and the root is principally used in medicine; but the Tormentil of the Alps is much more valuable, on account of its superior virtues. The root has a styptic very bitter taste, and is accounted good to stop loosenesses, hæmorrhages, and the like. The dose in decoction is from half an ounce to an ounce, and in powder from half a drachm to a drachm.

TRIFOLIUM PRATENSE PURPUREUM,

common meadow Trefoil, with a purple flower, by many called *Honey-suckle*, has a root as thick as a man's little finger, which is long, round, woody, creeping, and fibrous. The stalks rise to the height of a foot, or a foot and a half, and are slender, channeled, and sometimes a little hairy. The leaves are partly round, and partly oblong, and there are three together on the same pedicle, marked on the middle with a spot, in the shape of a heart, which is sometimes white, and sometimes dark. The flowers grow on the tops of the stalks, and have some resemblance to the papilionaceous kind; are disposed in a head, or short thick spike, of a purplish colour, and have a juice at the bottom, as sweet as honey. They are succeeded by small round capsula, each of which is inclosed in a calyx, and terminated by a long pedicel, containing a seed, in the shape of a kidney. It grows almost every where in meadows and pasture grounds, flowering in April, May, and June. The flowers are greatly sought after by bees, and the whole herb is excellent for feeding cattle.

TRIFOLIUM ARVENSE HUMILE SPICATUM, *Hare's-foot Trefoil*, is the lagopus of the shops, and has a slender, woody, fibrous, crooked, white, annual root. It has several stalks, about six inches high, which are branched, strait, and covered with a whitish down. Three leaves are placed together upon one pedicle, which are smaller than common trefoil, and are downy and whitish, especially upon the back. The flowers are small, whitish, papilionaceous, and fixed on hairy soft spikes, which resemble the feet of a hare; the colour is ash, inclining to purple. These are succeeded by capsulæ, inclosed in a calyx, each of which contain a reddish seed like a small kidney. It grows every where in fields among corn, and flowers towards the latter end of summer, continuing till October. Most physicians affirm it is good to stop loosenesses of every kind, if the decoction be used as common drink. If the seed happens to be mixed with wheat, it turns the bread of a reddish colour, which had like to have caused an insurrection at Paris; for the people affirmed the bakers mixed blood with their flower.

TRIFOLIUM BITUMINOSUM, *Trefoil*, *Smelling of Bitumen*, has a hard, woody, fibrous root, which sends forth a sort of a shrub, about two feet high, and is divided into several stiff channeled branches, which are sometimes whitish, and sometimes blackish. The leaves grow by three's on the same pedicle, which, when they first appear, are round, but grow longer afterwards, and terminate in a sharp point; they are whitish, downy, clammy to the touch, and have the smell of bitumen. The flowers grow on the tops of the stems and branches, are disposed like an oblong head, and are papilionaceous, and of a violet purple colour; they are sustained by an oblong, channeled, hairy calyx. These are succeeded by a capsula inclosed by the calyx, which contains a rough, pointed, blackish seed, of the same smell with the rest of the plant. It grows in Candia, Sicily, Languedoc, and the southern parts of France; on stony hills near the sea, and is planted here in some gardens for the sake of variety, and kept in pots. It flowers in June, July, and August, and will stand the winter, if it is not too severe. The juice of this plant has been accounted a secret against a cancer, and has been given from one spoonful to two, for that purpose.

TRIFOLIUM HÆMORRHOIDALE, *pile Trefoil*, has a long, hard, woody root, with several stalks, which rise to the height of two or three feet, are slender, round, hairy, woody, branched, and make a kind of a shrub, furnished with downy, whitish, and roundish leaves, which grow by three's on the same pedicle, and have two appendages at the base. The flowers grow at the extremities of the stems and branches, and are papilionaceous, whitish, and supported

ported by a hairy calyx. They are succeeded by short thickish pods, of a reddish brown colour, that contain a round small seed, yellowish within. It grows in the southern parts of France, and flowers in the summer. It has been counted an excellent remedy for the piles; and some affirm, a drachm or two of these leaves, given in powder, has been of great service in that disorder.

Bird's-foot Trefoil is the *Trifolium Corniculatum* of the shops, and has a woody, long, black root, divided into several branches, and furnished with fibres. The stalks are slender, branched, and lie upon the earth; and the leaves are placed as in other trefoils, only there are two small flat leaves that grow underneath them, which are sometimes smooth, and sometimes a little hairy. The flowers are papilionaceous, grow in umbels, and are sometimes yellow, and sometimes greenish, like those of broom; the calyx is dentated, and in the shape of a horn; the flowers are succeeded by capsulæ or pods, in the form of a cylinder, which contain several roundish seeds, in the shape of kidneys. It grows almost every where, and flowers in summer; it is exceeding good for cattle, but is of little use in medicine.

TULIPA, *Tulip*, is a lily flower, generally composed of six petals or leaves, in the shape of a pitcher: the pointal, which arises from the middle of the flower, is surrounded with a stamina, which afterwards becomes an oblong fruit, that opens into three parts, and is divided into three cells, full of plain seeds, which rest one upon another, in a double row. The root is coated, bulbous, and there are fibres on the lower part. There are several kinds of tulips, which there is no occasion to enumerate, because they may all be seen in one good garden; but the best have a tall strong stem. The flower consists of six leaves, three within and three without, and the former should be longer than the latter. Their bottoms should be proportioned to the top, and their upper parts should be rounded off, and not terminate in a point. These leaves, when open, should neither turn inward nor bend outward, but rather stand erect; and the flower should be of a middling size, neither too large nor too small; the stripes should be small and regular, arising from the bottom of the flower; and the chives should not be yellow, but of a brown colour. They generally divide tulips into three classes, namely, the early flowers, the middling flowers, and the late flowers; but they are best divided into early and late, of which the last are the best.

TUSSILAGO, *Colt's-foot*, has a long, slender, whitish, tender root, with stalks that rise to the height of a foot, which are hollow within, downy, reddish, and covered with leaves without pedicles. These are long pointed, placed alternately, and at the top of the stalk there is a beautiful, round, radiated flower, resembling that of dandelion, with capillary stamina, that have cylindrick summits. These are succeeded by several oblong, flattish, downy seeds. After the flowers, the other leaves appear, which are very large, a little angular, almost round, green above, and whitish and downy below. It grows in moist places, and on the borders of rivers, brooks, ponds, and ditches. It flowers about the end of February and beginning of March. *Colt's-foot* is an excellent medicine to abate the sharpness of the humours, to cleanse ulcers of the breast, and to facilitate expectoration. There are a great many that are troubled with the asthma, who cut the leaves small, and mix it with tobacco for smoking; and affirm they find great benefit thereby. Both the flowers and leaves are used in pectoral decoctions; and Dr. Hillary, physician to the king of Prussia, cured a great many consumptive children, by feeding them with colt's-foot leaves, boiled and buttered.

VALERIANA HORTENSIS, *Garden Valerian*,

has a wrinkled root, of the thickness of a man's thumb, placed near the surface of the ground, and furnished with thick fibres, of a yellowish or brown colour, that cross each other. The stalks are about three feet high, and are slender, round, smooth, hollow, branched, and furnished with leaves, placed opposite to each other by pairs. Some are smooth and entire, while others are cut deeply on each side; generally terminate in a roundish point. The flowers grow in umbels on the tops of the stalks and branches; and are of a purplish white colour, with a sweet smell, not unlike that of jessamine. Each of these is a sort of tube, cut into five parts, with a few stamina that have roundish summits. They are succeeded by flattish, oblong, tufted seeds. It is cultivated in gardens, and propagated by parting the roots, either in the spring or autumn; they should be planted on beds of fresh, dry earth, about eight or ten inches asunder, and should be watered till they have taken root. The wild sort is now universally preferred for medicinal uses, and therefore no more need be said of this.

VALERIANA SYLVESTRIS MAJOR, *Great wild Valerian*, has a fibrous, whitish, streaked root; with a very strong smell when it is dry, and an aromatic taste; the stalks rise to the height of a man, and are strait, slender, hollow, channeled, knotty, and a little hairy. The leaves resemble those of garden Valerian, but are more divided, greener, and dentated on the edges; they are a little hairy or downy underneath, and have several large veins. The flowers grow on the tops of the stalks and branches in umbels, and are of a purplish white colour, like those of the former; the seeds are tufted or downy, for which reason they are carried about with the wind. It generally grows on dry chalky land, and shady places, in divers parts of England. It flowers in May and June, and the seed is ripe in July. The root is bitter, styptick, and has a disagreeable aromatic smell; it is much cried up against the epilepsy, and is sudorifick as well as hysterick; it is accounted good for the asthma, and all kinds of convulsive disorders. It may be taken in decoction, from two drachms to half an ounce, and, in substance, from one drachm to two. It should be taken up in the spring, before the branches appear, and dried in the shade. Several physicians affirm, they have cured a great number of epileptick patients with the powder of the root of wild Valerian, given to a drachm in a sudorifick decoction, and continued for some time.

VALERIANELLA, *Corn-Sallad, or Lambs Lettuce*, has a slender, fibrous, or white annual root, and a stalk about six inches high, which is weak, round, crooked, channeled, hollowed, knotted, branched, and commonly lies upon the ground. It is generally subdivided into two at each knot, and these last into several branches. The leaves are oblong, pretty thick, soft, tender, and placed by pairs, opposite to each other; the colour is a pale green; some of them are entire, and others crenated, without pedicles. The flowers grow on the tops of the branches, are small, of a purplish white colour, and placed in umbels; they each consist of one leaf or petal, cut into five parts, and are succeeded by roundish, flattish, wrinkled, whitish seeds, which fall off before they come to maturity. It grows almost every where, among corn, and is cultivated in gardens, where it is sown in September for winter use. It is usually mixed with salads, and will continue till April. It is said to have the virtue of lettuce, and to be good in the rheumatism, scurvy, and gout; but it is now never used for these purposes. Young lambs are said to be fond of it.

VERATRUM, *White Hellebore*, is of two sorts, one of which has a greenish flower, and the other a dark red flower. The former of these has been mentioned

mentioned before, in the first chapter; but as nothing was said of the cultivation, we shall take notice of it here, especially as it is accounted a pretty ornament for gardens. They should be set on the open borders of a pleasure garden, and from each head of the root, a flower stem will be produced, about three feet high, with a spike of flowers about a foot long at the top; the red flowers are generally preferred, on account of their colour. They may be propagated by parting the roots, either in autumn or the middle of March, just before they begin to shoot; and should be planted in a light, rich, fresh soil, in which they will thrive exceeding well. They should not be removed above once in three or four years, by which time they will be very strong, and afford many heads to be taken off.

VERBASCUM, *Great white Mullein*, has a single, oblong, thickish, woody, white root, with a few fibres; and the stalk, which rises to the height of four or five feet, is thick, round, hard, woody, and crooked, with a sort of wool or cotton; the leaves are long, broad, woody, white on both sides, partly lying upon the ground, and partly fixed to the stalk alternately, with appendages, which seem to render the stalk winged. The flower consists of one leaf, in a circular form, which is cut into five parts, and joined to each other by a tuft; it is yellow, and surrounds the greatest part of the tops of the stalk and branches. The flowers are succeeded by oval shells, terminating in a point, divided into two cells, which contain a great number of small, angular, blackish seeds. It grows in sandy places, by the side of highways, and sometimes on walls; it flowers in June, July and August.

VERBASCUM FŒMINA FLORE LUTEO MAGNO, *Female Mullein*, with a large yellow flower, has a long, thick, woody, single, white root, like the former, and the stalk, which rises to the height of four or five feet, is thick, round, hard, downy, and a little branched. The leaves are round, long, soft, downy, and white; and the flowers are like the former, having five stamina in the middle, with purple summits. These are succeeded by almost round capsula, pointed at the end, and divided into two cells, which contain several angular brownish seeds. This plant grows in the same places as the former, and flowers the second year after it is come up towards the end of summer, and in August. They both may be cultivated in gardens, by sowing the seeds in August, on a bed of light earth, and in an open situation; but it is seldom done except in botanick gardens for variety. They both have the same virtues, and the leaves and flowers are in use. The decoction has been given in disorders of the throat, in violent coughs, in the bloody-flux, the gripes, and a tenesmus. The flowers are said to be pectoral, proper to abate the acrimony of the humours, to cure itching of the skin, and the outward and inward piles.

VERONICA MAS, *common male Speedwell*, or *Fuellin*, has a slender, fibrous, spreading root, which sends forth several slender, long, round, knotty, hairy stalks, generally lying on the surface of the ground. The leaves grow by pairs opposite to each other, and are like those of a plumb-tree; they are downy, dentated on the edges, and have a bitter acrid taste. The flowers are disposed in spikes, like those of germander, and are small and bluish, and sometimes white, with two stamina of the same colour, with oblong summits. The flower consists of one leaf, which is divided into four parts, and is succeeded by fruit in the shape of a heart, placed in two cells, which contain several round blackish seeds. It grows wild in the woods, and other shady places in divers parts of England. There are some other species of this plant; but this is the only one used in medicine, and is said to have so many virtues, that an entire trea-

tise would scarce contain them; besides which some call it the European tea. In general, it is sudorific, vulnerary, detergent, diuretick, and proper to cleanse the lungs. Hence it is good in a dry cough, the asthma, ulcers of the lungs, and spitting of blood. It opens obstructions of the bowels, promotes the circulation of the blood and humours, and is excellent in the gravel. It is best used in the manner of tea, and is very good in sleepy disorders.

VIOLA MARTIA PURPUREA FLORE SIMPLICE ODORO, *common purple Violet*, with a sweet scented flower, has a fibrous, thick, or tufted root, that sends forth many almost round leaves, as large as mallows, dentated on the edges, green, and having long pedicles. From among these there arise slender pedicles, which have each a small flower, of a purplish blue colour, with a very agreeable smell. It is composed of five small leaves, with as many stamina, that have blunt summits, and a kind of a spur; the calyx or flower-cup is divided at the base into five parts. When the flower is gone, there remains a capsula, or oval shell, which, when ripe, opens into three parts, in which are almost round seeds, connected to the sides of the shell, which are less than those of coriander, and of a whitish colour. It grows in shady places, in ditches, and the sides of hedges, as well as against walls, where they readily multiply with their long creeping filaments, which take root here and there. They flower in March, and do not lose their leaves, nor the verdure, during the winter. Besides this, there are no less than twenty-eight sorts, and about eight of them serve to make agreeable varieties in gardens and wildernesses, by placing them under hedges, and other shady places. They may be easily propagated, by parting the roots; the best time for which is about Michaelmas. The leaves and flowers are used in medicine, and sometimes the roots, by infusion, three ounces of which will purge upwards and downwards. The flowers are a little purgative, and we are assured, that a drachm of their powder, taken in water-gruel, is a good purge; but they are generally used to make a syrup of, which, when well managed, is of a very fine colour.

VISCUM, *Mistletoe*, has a green root, which is a little woody in the middle, and sends forth a shrub about two feet high. The stalks, which are sometimes as thick as one's little finger, are woody, heavy, compact, knotted, and of a brownish-green. There are a great number of flexible woody branches. The leaves are placed by pairs opposite to each other, and are oblong, thick, fleshy, hard, and pretty like those of the great box, but longer, and roundish at the end. The flower consists of one leaf, in the form of a bason, and is generally divided into four parts, and beset with tubercles or warts. The ovary of the female flowers is placed in a remote part of the plant from the male flowers, and consist of four shorter leaves; these turn to a round berry, full of a clammy substance, in which is a plain seed, in the shape of a heart. It grows almost on all kinds of trees, according to some authors, and is always produced from seeds, which will not grow in the ground like other plants. It is supposed that the mistletoe-bird or thrush, which feeds upon the berries of this plant in winter, when they are ripe, often carries the seeds from tree to tree; for the clammy part of the berry, which immediately surrounds the seed, sometimes sticks fast to the outer part of the bill of the bird, which, to disengage himself from, he strikes it against the branches of a neighbouring tree; and by that means leaves the seeds, sticking on the bark, which will grow the succeeding winter. It may be propagated by art in the same manner. The trees it is found commonly upon, are the apple and ash; and it is sometimes, though but seldom, found on the

oak; which perhaps is the reason why that is cried up more than others; but without any sufficient reason. Mistletoe is looked upon as a great anti-epileptic, and the dose of it in powder is from one drachm to two. Simon Pauli cries it up against the pleurisy, and orders one drachm of the powder, in four ounces of barley-water. The berries purge upwards and downwards, with great violence, and therefore are not proper to be given inwardly.

VITIS, *the Vine*, has a long woody root, which sends forth a climbing tree, that has clasps at the joints, by which it fastens itself to whatever plant stands near it. The leaves are large, broad, and almost round, green, shining, cut, a little rough to the touch, and of an astringent taste. The flowers are small, and are each composed of five petals or leaves, disposed in a circular order. They are of a yellowish colour, with as many upright stamina. When the flowers are fallen, they are succeeded by round or oval berries, lying close to each other in clusters, which are green at first, and, as they ripen, become white, red, or black; they are also full of a pleasant juice. This tree is cultivated in most hot and temperate countries, and rises to a great height in a short time, if it be left to itself, and not cut. In some countries it will rise to the top of the highest trees, and have a stem of a prodigious size. It flowers in the summer, and the grapes are ripe in autumn.

All sorts of vines are propagated either from layers or cuttings, the former of which is greatly practised in England, but the latter is preferred by Mr. Millar; and he lays down excellent rules for their cultivation, which we have not room to take notice of here.

The buds of the vine, as well as the leaves, are astringent, and were used by the ancients to cure loosenesses; at present, there are some in France that give the powder of the green leaves, dried in the shade, to a drachm, for the same purposes. The use of the grapes is universally known, they being proper either for eating, or making of wine. When they are green, they produce the liquor which is properly called verjuice; and, in this state, it is a little astringent, serves to abate the heat of the stomach, and to stop a bilious looseness, as well as to recover the appetite. It is made use of in France in the same manner as our common verjuice made with crabs. Of the juice of ripe grapes they make a sapa or rob, by evaporating it over the fire, till a third part remains. This is a little astringent and styptic, which are made use of in France to prepare quinces with; and then it is said to be excellent to stop loosenesses, and to strengthen the stomach. As for wines, they vary greatly, with regard to their colour, smell, taste, and consistence; all which are different, according to the different kinds of grapes of which the wine is made. Good generous wine, of any sort, is an excellent cordial, if properly used, and of late has been found to be of great service in all slow nervous fevers; for they will recover the patient, when other things fail. However, there are some wines that are too astringent for common use, and consequently produce costiveness; for which reason they must be unwholesome, unless drank in small quantities; however, they are proper enough for those whose stomachs are relaxed. Meagre acid wines agree with those of a bilious constitution, to restrain the effervescence of the blood, but with none else. Strong spirituous wines are most proper to raise the spirits, and to restore the exhausted strength, especially when they are not drank too commonly.

VITIS IDÆA, FOLIIS OBLONGIS CRENATIS, *common black Wortle, or Bilberry*, has a slender, woody, hard root, often creeping under the ground, which sends forth a small shrub, about a foot in

height, with several slender branches, that are angular, flexible, and difficult to break, as well as covered with a green bark. The leaves are oblong, and about the size of those of box, but not so thick; they are green, smooth, slightly dentated on the edges, and have an astringent taste. The flowers consist of a single leaf, in the shape of a pitcher, and are connected to short pedicles, of a reddish white. There is a small lasting flower-cup, in which is the germen, attended by eight stamina, with forked summits. The germen afterwards becomes a soft, globular, umbilicated berry, of the size of juniper berries, and of a deep blue, or blackish colour. It grows very common on large wild heaths, in many parts of England; but it is never cultivated in gardens, because it will not thrive therein. In those parts where they are common, the poor people gather them, and bring them to markets to sell, or cry them about the streets. It is common to eat them with milk or cream. Some take the juice of these berries, and boil them to the consistence of a rob, with sugar, which is said to be good against a common looseness, and to temperate the effervescence of the bile. Several vintners in France make use of these berries, to colour their white wines red, as well as to increase the quantity thereof; and it were to be wished, that nothing worse was any where used to adulterate this liquor. Some likewise make use of the juice to colour linen, as well as paper, blue.

ULMARIA, *Meadow-Sweat*, has a pretty thick root, as long as one's finger, which is blackish without, of a reddish brown within, and has a few reddish fibres; it sends forth a stalk, to the height of three feet, which is strait, angular, smooth, reddish, firm, hollow, and branched. The leaves are placed alternately, and are composed of several other oblong leaves, not much unlike those of drop-wort. They are dentated on the edges, wrinkled, and green above, but whitish below. The flowers are small, and grow in bunches on the tops of the stalks and branches; they each consist of several petals or leaves, of a whitish colour, in the form of a rose, and have an agreeable smell. These are succeeded by a fruit, composed of many little membranaceous crooked husks, gathered into a sort of a head, each of which contains a small seed. It grows wild in moist meadows in most parts of England, and the flowers in the middle of June make a fine appearance among the grass. The seeds are ripe in autumn. This plant is said to be sudorific, cordial, and vulnerary, and some recommend its decoction in malignant fevers; others greatly praise it against fluxes, and internal hurts, but it is not to be depended upon on these accounts. A drachm of the extract of the root is sudorific, if it be taken for two or three days together. The tender leaves and flowers of this plant, put into wine, mead or beer, give them an agreeable taste and smell, which some are very fond of.

ULMUS, *the Elm tree*, has a thick, hard, woody root, which spreads greatly in the ground, and sends forth a large branched tree, with a thick trunk, covered with a chapped bark, which is rough, and of a reddish ash colour without, but whitish within. The wood is strong, hard, inclining to yellow, with a reddish cast, and the leaves are broad, wrinkled, veinous, oblong, dentated on the edges, terminating in a point, of a pretty deep green above, with short pedicles, and crossed longways by a nerve, which does not appear so much on one side as the other. The flower, which appears before the leaves at the top of the branches, consists of a single leaf, shaped like a bell, furnished with several dark coloured stamina, and from the bottom arises the pointal, which afterwards turns to a membranaceous and leafy fruit, almost in the shape of a heart. In the middle of which is placed a seed-vesSEL, in the shape of a pear,

containing a single seed of the same shape. This tree grows in plenty all over England, and is propagated by seeds, and suckers that rise from the roots of old trees in such plenty, as hardly to be rooted out, particularly in hedge-rows, which, when left undisturbed, will send forth young plants every year; from whence the people who supply the nurserymen gather them. It flowers in March and April, and the seeds are ripe in May.

Besides the common Elm, there are the witch hazel, or broad leaved Elm; the small leaved or English Elm, the smooth leaved or witch Elm, the Dutch Elm, the English Elm with beautiful striped leaves, the yellow leaved Elm, the Dutch Elm with striped leaves, the smooth narrow leaved Elm, the white barked Elm, and the French Elm. The three first, as well as the former Elm, are common in England, and so is the fourth, which is as hardy as the former. Those sorts with striped leaves are preserved by the curious, who collect variegated plants. The smooth narrow leaved Elm is common in some parts of Hertfordshire, and Cambridgeshire, and is a very handsome upright tree, which retains its leaves late in the autumn. They may be all propagated by layers or suckers taken from the roots of old trees; but the method by layers is best, because they come on faster than the others. The best soil for such a nursery is a fresh hazel loam, neither too light nor too dry, nor yet too moist and heavy.

With regard to the medicinal virtues, we are assured in the German Ephemerides of 1727, that several persons, afflicted with the dropsy ascites, have been cured by the decoction of Elm-bark, used as common drink for five or six weeks. There are sometimes on Elm leaves a sort of bladders, that swell to the bigness of a man's fist, which contain a liquor, in which are greenish insects. This must be strained through a cloth, and then several affirm it will be good for all recent wounds and bruises. Ray tells us, that the decoction of Elm-bark, reduced to the consistence of a syrup, and a third part of brandy added, is good to ease the hyp-gout, if used as a liniment.

UMBILICUS VENERIS, *Navel-wort*, has a tuberose, fleshy, white root, furnished below with small fibres, which send forth round thick leaves, full of juice, that are tender, hollowed like a basin, and fixed to long pedicles, of a sea-green colour; from the middle of these there arises a slender stalk, about half a foot high, which is divided into several branches, covered with small flowers, consisting of a single leaf, expanded in a circular order, and cut into several segments; the colour is white, or a little inclining to purple, with ten stamina, and strait summits. These are succeeded by a fruit, composed of four hollow, umbilicated capsula, somewhat resembling a basket, in the middle of which is contained one seed, that is almost flat. This plant grows naturally among rocks, and on old walls, in stony hot countries, and flowers in April and May, at which time the leaves decay. It begins to appear towards the end of autumn, and keeps its leaves all the winter.

UMBILICUS VENERIS ALTER, *creeping Navel-wort*, has a long creeping root; but the leaves are much the same as those of the former, only they are greater, thicker, open towards the pedicle, crenated on the edges, and from among them there arises a round, firm, reddish stalk, furnished with smaller leaves, divided into several branches, loaded with yellow flowers, in the form of a spike. They each consist of a single leaf, cut into five parts, supported by a long greenish calyx; these are succeeded by five oblong, pointed, greenish capsula, full of very small reddish seeds. This plant grows wild in Portugal, and is cultivated in the gardens of the cu-

rious. It flowers in June, and the leaves are green all the winter, but then entirely disappear in May. The seeds of the former should be sown in autumn, soon after they are ripe, at which time they will come up very well; but if they are sowed in the spring, they seldom succeed. The leaves are said to be very good in external inflammations, and they may be substituted in the room of house-leek. Some bruise this herb between two stones, and apply it to ease the pain of the piles; but there are more certain remedies for these purposes.

UNEDO, *five* ARBUTUS, *the Strawberry tree*, has a pretty thick, woody root, from whence proceeds a shrub or small tree, whose trunk is covered with a rough chapped bark, and there are many reddish branches towards the top. The leaves are oblong, somewhat broad, and almost like those of the laurel tree, for they are thick, smooth, always green, and finely crenated on the edges. The flowers consist of a single leaf, cut into five parts, which are white, beautiful, disposed in bunches, and have an agreeable smell, with ten capillary stamina. These are succeeded by fruits, that have some resemblance to strawberries; but they are larger, of an orbicular shape, with the flesh yellow before they are ripe, and of a fine red when at maturity; it is divided into five cells, which contain several small, oblong, bony seeds. This shrub is very common in Italy, Spain, and the southern parts of France; it flowers in June and July, and the fruit does not grow ripe in less than a year. Blackbirds and thrushes are very fond of these strawberries, as well as women and children. There are some of these shrubs planted in England, and it is very common in Ireland, where the fruit is sold and eaten. With us it has an austere sour taste, which perhaps may be owing to the coldness of the climate, and therefore only the branches are brought to the markets, with bunches of flowers thereon, to be made up into nosegays. They may be propagated by sowing the seeds, which should be preserved in dry sand till March, at which time they may be sown on a moderate hot-bed, covering them with about a quarter of an inch of light earth, screening them from frost, or great rains. About the beginning of May the plants will appear, and then they must be weeded, watered frequently, and shaded in hot weather. In autumn they will be about five or six inches high. The bed must be hooped all over against winter, and should be covered with mats and straw, to keep out the frost. About the middle of April, they may be transplanted into small pots, which should be plunged into another moderate hot-bed, to encourage their taking root, and they should be shaded from the sun in the middle of the day. When they are between three and four feet high, they may be shaken out of the pots into the open ground, where they are to remain; this is best done in September, when the blossoms are beginning to appear, and then, if they be kept moist, they will take root very soon; but in November the roots should be well covered, to keep out the frost.

URTICA, *the Common Nettle*, has a slender, fibrous, creeping root, of a yellowish colour, with stalks that rise to the height of three feet, which are square, furrowed, stiff, covered with a stinging hair, hollow, branched, and furnished with leaves, placed opposite to each other by pairs; these are oblong, broad, pointed, dentated on the edges, and full of small stinging prickles. The flowers grow on the tops of the stalks and branches, under the leaves, and are each composed of several stamina placed in a calyx, with four leaves of the colour of grass; but they leave no seeds behind them; for this reason, they are distinguished into male and female. The male does not flower at all, but forms pointed capsula, that sting when they are touched, and each of these con-

tain

tain an oval, flattish, shining seed. The female bears nothing but flowers without any fruit, according to the vulgar distinction; for the botanists call those male flowers that produce no seeds, and those female flowers that are succeeded by seeds. This plant grows almost every where, in great plenty; it flowers in June, and the seed is ripe in August. The leaves decay every winter, but the roots continue, and send forth fresh leaves in the spring.

URTICA MINOR, the *lesser stinging Nettle*, has a single, pretty large, white root, furnished with small fibres: the stalks are from half a foot to a foot in height, and are pretty thick, square, hard, furrowed, branched, and stinging, but not so strait as the former; the leaves are placed opposite to each other by pairs, and are more short and blunt than those of the common nettle; they are also deeply dentated on the edge, and sting greatly when touched. The flowers consist of stamina, disposed into small bunches, in the form of a cross, and of a grass green colour. Some of these are male, and others female, as in the former. These grow commonly by the sides of houses, and among the ruins of old buildings; both root and branches perish every year, and they are renewed by the seeds in the spring.

URTICA ROMANA, *Roman Nettle*, has a fibrous, yellowish, annual root, that sends forth a stalk to the height of four or five feet, which is round, branched, and furnished with stiff, stinging prickles. The leaves are placed opposite to each other, and are broad, pointed, deeply dentated on the edges, and are covered with a rough stinging, shining hair. The flowers are like those of the former, and are succeeded by small globes of the size of a pea, all rough with prickles, and composed of several capsulæ, that open into two parts, and have each an oval, pointed, flattish, smooth, slippery seed. It grows as well in cold as hot countries, in hedges, meadows, and among coppices. It is not so common as the two former, for which reason there are some that sow the seed in gardens; it flowers in summer, and the seed is ripe in July and August. Some call this the pill-bearing stinging nettle, with seeds like flax. These may be sown at the latter end of March, upon a bed of light rich earth; and when the plants are come up, they should be removed into beds on the borders of the pleasure garden, among other plants; because it is common for persons to gather sprigs of several sorts to smell to, and consequently this among the rest, and this is designed to sting them for the sake of mirth. The juice of nettles is recommended to stop spitting of blood, and other hemorrhages, and the dose is from two ounces to four. Some would have the infusion of the leaves of nettles, made like tea, to be given in the gout, the rheumatism, the stone, and gravel. It is common in many places to make pottage with the young shoots of nettles in the spring, to cleanse the blood. The roots of nettles made into a decoction, are said to be a good remedy against the jaundice, and to promote expectoration in an old cough, as well as in the asthma and pleurisy.

VULNERARIA RUSTICA, *Kidney-Vetch*, or *Ladies Finger*, has a single, long, strait, blackish root, with stalks that arise to the height of a foot, which are slender, round, downy, a little reddish, and lie upon the ground. The leaves are placed by pairs along one side, and are terminated with a single leaf like those of Goats Rue, but a little softer; they are hairy underneath, inclining to white, but of a yellowish green above, with a

sweetish acrid taste. Those which sustain the flowers on the tops of the branches, are broader than the rest. The flowers grow on the tops of the branches, and are yellow, papilionaceous, and have each a calyx like a tube, which are succeeded by short pods filled with roundish seeds, that are contained in a membranous bladder, and was before the cup of the flower. It grows in mountainous, dry, sandy places, or on chalky grounds in divers parts of England. It flowers in May, and June, and the seed is ripe in July and August. It has been accounted good for healing fresh wounds, but it is now out of use.

UVULARIA MAJOR, *Throat-wort*, has a thick, long, branched, white root, that sends forth several branches, to the height of three feet, which are sometimes as thick as a man's little finger, and are angular, furrowed, hollow, reddish and hairy. The leaves are disposed alternately along the branches, and are like those of the common nettle, but they are more pointed, and those below have long pedicles. The flowers are made like a bell, cut on their edges into five parts, and are of a blue or violet colour; but sometimes they are white, hairy within, and supported by a small calyx, cut likewise into five parts, and they have five short capillary stamina in the middle, with flat summits. The calyx is succeeded by a membranous, roundish, angular fruit, which is divided into several cells, with holes on their sides, and contain small, shining, reddish seeds. This plant grows frequently in woods, hedges, meadows, and in shady places; it flowers in summer, and the seed is ripe in autumn. Some cultivate it in gardens for the sake of the variety of the flowers. They are only propagated by parting the roots, for they do not produce seeds in England; the best season for removing them is about Michaelmas, when the roots may be separated and planted on the borders of the flower garden. This plant is astringent, deterfive, and vulnerary, and the decoction of it has been made use of against inflammations of the mouth and throat; but it must be only exhibited in the beginning of the disorder.

XYRIS, *five IRIS FOETIDA*, *stinking Gladden*, or *Flag*, has a round root, pretty much like an onion while it is young. But afterwards it grows crooked, knotted, and is furnished with pretty thick fibres; it sends forth many roots a foot and half or two feet in length, that are more narrow than the common Iris, and as sharp as the end of a sword; they are of a blackish shining green, and have a stinking smell like bugs. Among these leaves several strait smooth stalks arise, on the top of each of which there is a flower like that of the Iris, but smaller, and composed of six petals or leaves of a dirty purple, inclining to blue. These are succeeded by oblong angular fruit, which open like the male piony, and discover round seeds, as large as small peas, of a red colour, and of an acrid burning taste. It grows in moist places, on the sides of hedges, among bushes, and in shady valleys. It flowers in July and August, and the seed is ripe in autumn. It is cultivated in the gardens of the curious, and grows readily every where; however, it does not grow in many places spontaneously in England. The root and seed, taken in decoction, are said to be aperient, to purge off water, and to be good in the rheumatism and dropsy. A dose of the dried root, in powder, given in white wine, is a drachm. Some account it excellent in the king's-evil, and in the moist asthma; but its principal virtue is to purge off water, and to dissolve clammy humours.

OBSERVATIONS on HOT-BEDS,

A N D

WATERING of PLANTS.

HAVING frequently recommended the use of Hot-beds, for the raising of particular Plants mentioned in the preceding part of the Natural History of Vegetables, it may not be improper here to consider that subject more at large, as well as to give the inexperienced some idea of the proper observations to be made previous to watering of plants. Without a perfect knowledge of these subjects, it will be in vain to attempt to rear any tender plant, or, indeed, to make any tolerable progress even in common gardening.

A hot-bed is the common help made use of by gardeners to forward the growth of a plant, and force vegetation, when the season of itself does not afford a sufficient warmth. By the help of this, if it be skilfully managed, the hottest climate of the world may be so nearly imitated, that the seeds of those plants, which are brought from any country, may be here made to vegetate and flourish in England.

In order to have a right understanding of the hot-bed, we must consider what degree of heat is required for the growth of the plant we intend to cultivate; for nature must be imitated as near as possible, and not forced or exceeded, if we hope for success in our undertaking.

Heat and moisture are certainly the rudiments of vegetation; and therefore, whoever would promote the growth of a plant, must contrive how to have them in such due proportion, as that neither one nor the other exceeds those limits, which nature has allotted for the growth of plants. A dry heat, we find from experience, rather scorches and shrinks a plant, than make it grow; and wet, if it is not quickly exhaled from the root of a plant, chills it, and often injures it past recovery. A moderate sweating heat, therefore, is most desirable, such as is raised by the ferment of wet straw or horse litter, which for a time will send forth, from the earth lying upon it, that gentle steam, impregnated with vegetative salts, which we find contributes so much to the growth of plants, besides putting those juices into motion, which are lodged in the root, and circulating them through the proper vessels.

The steam, which is supposed to rise from the root into the wood vessels of plants, to furnish them with sap, will indeed of itself keep a plant alive; but then, at the same time, the bark, leaves, and other spongy part of a plant, which encompass the sap vessels, if they are too dry, will shrink and pinch those vessels so very close, that they then cannot admit the sap to circulate through them in such quantity, as is necessary to support the plant in vigour: on the contrary, when the spongy parts of plants are kept moist by the ascending vapours, which continually rise round about them from the earth, then the sap vessels are also more open, and at liberty to receive the nourishment rising from the roots.

To explain this, let us consider those plants, which are cultivated in pots, and set singly in chambers, and other places of the house, for ornament in summer, though we allow them large pots, fresh earth, and water enough, as well as air, as much as they have in a green-house, yet they sensibly decline in a few days. This happens principally for want of that steam, which is always abroad, more or less, rising from the earth in the day, and condensing and falling upon them at night. Nor can the pots, set singly in a chamber, have this help, as those have, which are set together for shelter during the winter, in a green-house; for the number of pots, in a collection of plants, afford steam enough to nourish one another, which one single pot cannot.

The like is to be observed in a dry season, when we are forced to water plants that stand abroad; they are by that help but just kept alive, because the earth round about them is so dry, that it hardly emits any steam, or at least not enough to support them. However, no sooner does the rain fall, than we find a contrary effect, as the vapours then rise from the earth every where about the plants, and make them flourish. Hence a hot-bed appears to be of use so long only as it can send out such vapours from the earth lying upon it, as are necessary for the support of the plants. When it wants the heat, which is required for that purpose, it must be renewed; otherwise the moisture, which must be maintained to nourish the roots of the plants growing in it, will chill and destroy them. We must not here be supposed to mean the steam, which arises from the dung itself, for that is known to be destructive to all plants; we mean the vapour only, which the heat of the dung evaporates from the earth lying upon it, and which will help the plants; but even this must be tempered and well qualified, lest it should scorch them. It may be moderated according to your desire, by laying on your earth of a thickness proportionable to the heat of the dung below it.

Having now considered the qualities required in a hot-bed, let us proceed to give proper directions for making it. Throw up a load of fresh horse-dung in a heap, mixing it well together, and then let it remain for a week or ten days, by which time it will ferment, and come to a proper heat. The bed then must be marked out, answerable to the size of your frames, the length of it running from east to west, so that it may face the sun. Some gardeners dig a trench a spit deep to make the beds in, and others save that trouble, and make it all above ground. The ingenious Mr. Bradley tried both ways, and found so little difference, that he could not say which was best. However, if the ground be wet and springy, it is best to make the bed quite above ground, otherwise the dung may be chilled. In the spreading of the dung, care must be

be taken to lay it equal in every part, that, when the bed comes to settle, it may not lie uneven; and, besides, that it may heat altogether.

Your bed being thus prepared, set on your frames, and put the earth you design for it upon the dung, laying it ridge-wise, that it may be more conveniently turned over, as you see occasion, if the bed should burn. When you find the extreme heat begin to abate, level the earth upon it, in order to sow your intended seed, always observing to have upon your bed the depth of six or eight inches of earth, to prevent the extreme heat of the dung from spoiling your crop; for, should the roots of whatever you sow or plant touch the dung, they will certainly be spoiled. To these directions should be added a careful observation of those, who make hot-beds; for theory and practice cannot be divided, and the one is indisputably necessary to gain a complete knowledge of the other.

As to the earth, proper to cover the dung of hot-beds, it should always be light, fresh, and well sifted; for you ought to consider how tender the roots of those plants will be, which you there intend to produce. The best composition for this purpose is sandy loam, mixed with an equal part of well-rotted horse dung; let these lie in a heap together, and be screened or sifted when wanted.

From these considerations on hot-beds, let us turn our attention to consider, what kind of water is the most proper to increase the health and vigour of plants. It has been found, from repeated experiments, that the clearest water is not to be preferred, nor such as comes immediately from a cold spring; neither should it be harsh, but rather soft and muddy. A stagnating water, that is well exposed to the sun, seems to be the best for the health of any plant. Pure rain-water, if it can be had without any mixture, is the best of all; for enriched or fattened water, becoming such from dungs or other forcing ingredient, proves always fatal to plants, if not rightly understood: at best, it can only contribute to make a plant grow something the quicker, and such forcing of nature always proves of ill consequence, as well to plants as animals, by shortening their lives.

Indeed, when annual plants are the objects of consideration, it may sometimes be of service to use these provocations, the better to bring them to perfection within the compass of our summer; but then they must be applied considerately, and a right kind of mixture prepared for each respective sort of plant; for we must not imagine, that one sort of mixture, however fattening it may be, will alike contribute to the welfare of every sort of plant. Mr. Bradley found, by experience, that the black water, taken from a dunghill, will make a cabbage, or any of that race, prosper extremely; but having used the same water to other plants that were aromatic, and whose texture of parts was more close, such as myrtles, thyme, and the like, it soon killed them. This shews, that gardeners ought not to confide in the richness of any one particular kind of water for the welfare of every sort of plant, any more than a skilful physician will prescribe always the same medicine for the relief of every kind of complaint.

There is another thing to be considered in preparing water for plants, which as yet seems to be very little regarded; that is, when we mix pigeon's dung, or rather such like ingredients in water, we must allow them due time to ferment before we use them, otherwise they will injure the roots watered with them, and that will distemper the plants, which in the end may kill them, as we find from experience is frequently the case.

Mr. Evelyn very justly observes, speaking of these
No. 40.

mixtures, that they should not be used till they are sufficiently sweetened and purged from their predominant acrimony. That gentleman saw many plants destroyed by the use of unripe mixtures, though the same preparations, when fully matured, performed wonders in forwarding the growth of the same kind of plants. The proportions of every ingredient ought to be reasonably considered, and the quantities not increased too hastily, merely because a moderate quantity has already begun to shew its good effects. However, a few observations, to an ingenious person, who loves a garden, will soon make him a proper judge of these matters.

Let us now return to plain water, which is undoubtedly the most natural to plants. Of this, use only such, if possible, that has stood in the sun some days to soften, either in cisterns, or pits dug in the ground, which last is preferred by Mr. Bradley; but even this should not be used inconsiderately: we should consider the most proper season for using it, and the best method of refreshing plants with it.

In the first place, we ought to water all plants in the morning, in such seasons when the nights are frosty, and in the evening in the warm seasons. The reason of the first is, that too much wet, lying about the roots of plants, chills and pinches them so much, if it happens to freeze, that they often perish; but, if it be given in the morning, where there is likelihood of a warm day, it gives the plant such nourishment as it requires from it, and is dried up before the frost of the evening can have power over it. Morning waterings should therefore be in August, September, and October, March, April, and the greatest part of May. From that time, to the middle of August, chuse the evenings for that work; because then the extreme heat of the sun would over-heat the water given in the morning to the plants, and scald their roots, besides drying it up too quick, before the plants could receive due nourishment from it. Observe never to use evening waterings after the sun is down, without great necessity.

In either of these waterings, care should be taken to do it as near the ground as possible, and not to hold the watering-pot too high; for that would wash the earth from about the roots of the plants, and contribute to make the ground hard, when the sun comes to shine upon it, and so bind the roots too much. Before you water, observe always, that the earth be open, and loose about the roots, and, above all, avoid, as much as can be, wetting the leaves; for, if the frost comes upon them before they are dry, it will pinch and rot them; and, if the sun shines hot upon them while they are wet, it will spot and change their colour.

Besides these simple waterings, cauliflowers, cucumbers, and those plants which have large vessels, should be floated; that is, the alleys between the rows should be dammed up at each end, and filled with water. One of these floatings will do more service than six waterings close to the stems; for they feed and nourish the extreme fibres, which alone want this help, and put the earth in such a condition, that the smallest warmth of the sun will evaporate that steam from it, which is so necessary to plump the principal parts of the leaves and stalks.

It is a rule to be observed in the watering of plants, that, while they are not growing, they should be kept as dry as possible; but, at the time of their growth, they should never want water, giving them frequently a little at a time, and chiefly when they are in blossom: for if, by accident of weather, the water lies long about the roots of plants, it chills them, and checks their growth. It is also to be observed, that such plants as are very succulent or juicy, such as house-leek, &c. must have little

water, as they contain moisture enough in themselves for their nourishment, and feed chiefly upon the air, which they imbibe and condense in their spongy parts, as having fewer sap vessels than any other kind of plants. Mr. Bradley, in his History of Succulent Plants, lays it down as a rule, that the more succulent any plant is, the less water it requires; while those, that have the greatest proportion of sap vessels, and the least spongy parts, require frequent waterings, which we find to be true from common experience in the garden, and by examining the struc-

ture of water plants, such as willows, &c. which are for the most part composed of sap vessels, and are therefore so tough, that they may be wrought into any figure without breaking; but all juicy plants are brittle for want of these vessels.

In short, if we were to examine with the microscope the numbers and sizes of the sap vessels, in every sort of plant we intended to propagate, we might come to a certainty of the proportion of moisture every plant required.

A

NEW, COMPLETE, and UNIVERSAL BODY, or SYSTEM of
NATURAL HISTORY;

Being a Grand, Accurate and Extensive

Display of Animated Nature.

B O O K V.

Containing the Natural History of **WATERS, EARTHS,**
FOSSILS, and MINERALS.

I N T R O D U C T I O N.

THOUGH the great Author of the universe has been pleased to cast a veil over many things, yet we are not to imagine, that he has for that reason forbid our enquiries into them. That veil is not always impenetrable: from whence we may infer, that there is implanted in our nature a thirst after knowledge; and, as we are surrounded with objects of admiration, though we are perfect strangers to their first principles and most secret causes, our gratitude is always increased, and our ideas enlarged, in proportion to the discovery we make of their structure, contrivance and grandeur.

It is to the Earth we are indebted for the conveyance of those particles of Water, which in particular places, by collecting themselves together, form springs and fountains. Let us pursue one of these springs, insignificant as it first appears, through its gradual progression and increase. It is at first nothing more than a vein of water, issuing from some hill upon a bed of sand or clay. The little stones that are dispersed around it are not sufficient to interrupt its current: it turns and winds, and murmurs as it rolls along. At last it clears its way, falls in a torrent down upon the plains, and swells by being united with some other streams. It hollows the ground by the rapidity of its fall, and throws up the earth on each side of it: it insensibly forces its way through every thing that obstructs its passage, and digs a bed or channel for itself. The overflowings of the adjacent ponds, the snow that melts and trickles down the hills, and the additional supplies of brooks and rills that fall into it, fortify and enrich it. Then it assumes a name, and steers its course along the sides of flowery meads, it takes a tour round the hills, and graces, as it turns and winds, the spacious plains. It becomes the general rendez-

vous of almost all kinds of living creatures: a thousand little party-coloured birds, of various notes, divert themselves upon its sandy banks, skim over its surface, and dip their wings in its refreshing streams. This is their favourite place all day, and, when the approach of night compels them to withdraw, they quit it with reluctance. Then the wild beasts enjoy it in their turn; but, at break of day, they leave the plains to man, and the free use of the river to the cattle. The numerous herds forsake their pastures twice a day to pay their usual visits to the streams, in which they quench their thirst, or seek some cool retreat. The river, in short, is as delightful to us as it is to them: for the most part, we reject the hills and woods, and fix our habitations on its banks. When it has enriched the fisherman with a profusion of its stores, and refreshed the farmer's thirsty plains; when it has adorned the pompous seats of the nobility, with the most delightful prospects, and made the country every where agreeable, it pays a visit to those large towns that are indebted to its friendly streams for all their wealth and commerce. It is probable, that the mighty waters of the Danube and the Volga of Europe, the Nile and the Niger of Africa, the Ganges and the Euphrates of Asia, and the Amazons river and Rio de la Plata of America, owe their first source to some such trifling springs.

It may nothere be improper to inform the younger part of our readers, in what manner springs receive their supplies. Hills and mountains contribute not a little to that purpose: At the bottoms of such mountains, whose tops are for ever covered with snow, (and of this kind are the Alps and the Pyrenees) we find springs, for the most part, which begin to flow in May, but run no longer than September, the

the cause whereof may be easily accounted for. As soon as the sun has advanced so near to one of the tropics, as to be able by its genial rays to warm the tops of the mountains, the snow which covers them dissolves, insinuates itself through the pores of the earth, and sinks either absolutely down to the bottom of those hills, or at least into their bowels, where its progress being obstructed by beds of clay or stone, it gathers together in a body, and there forms a variety of fountains; but no sooner does the sun deny its benign influence, than the fountains cease to flow. However, as there are many springs, which are never dry, and which are far distant from any hills or mountains, let us enquire from whence these receive their inexhaustible supply of water: This is undoubtedly from the rains that fall, which insinuate themselves into the bowels of the earth. It is an universal complaint, that moles, worms, field-mice, and a thousand other vermicelli, or little insects, are very pernicious to the earth in hot seasons, by their grubbing it up, and digging an infinite number of little holes in it of various depths; but the injury they do that way is amply recompensed by those numberless inlets, which they open for the rain, at such times when we stand most in need of it: and those crevices or chasms, which gape, as it were, on the surface of the earth in times of excessive droughts, render the passage of the water to the inferior layers more easy and expeditious. Those particles of water, which thus fall in showers, insinuate themselves with ease through beds of sand and porous earth, till they are obstructed in their passage by more compact beds of clay or stone, on which they rest, and there form one large basin or reservoir. The earth is almost every where full of those veins of sand, through which the water is perpetually passing; and some of those veins, having undoubtedly a communication with particular rivers, may either empty their own superfluities therein, or receive a supply in dry seasons. It is probable, that many of those springs, which do not vary in their height with the seasons, may receive their supply from some such source. That spring water should be warmest in the severest weather, seems easily to be accounted for: it is well known, that the earth abounds with particles of a sulphureous nature, which in warm weather escape through its pores, and exhale in vapours; but this is prevented when the ground is frozen so hard, as to form one solid impenetrable mass. The fire, thus confined deep in its bosom, will consequently act with more force on every thing it meets with, and will naturally give a greater degree of heat to the water that passes through it.

Hence we may conclude that those things, which we often look upon with indifference, may sometimes consider as prejudicial, are frequently of the greatest consequence and importance to us: the sea, though the saline particles it contains makes its waters very nauseous, is in reality the first spring which serves to quench our thirst; the wind, though we are very apt to complain of it, brings us our vapours from the sea; the lofty summits of the mountains, though considered by many as useless, help to settle and condense them; the holes, chasms, and crannies, which render the earth so hideous and deformed, serve as so many conduits to convey the waters to their proper stations; and the beds or layers, though sunk so much beneath our sight, are formed to retain them.

Let us now turn our attention from the watry element, and take a slight view of the different soils and moulds, which the Earth produces. In these we see ample provision made for the various plants and vegetables they nourish and support. Some trees, plants, and grains, dwindle and die in some soils, but thrive and flourish in others. If some de-

light in a warm, some in a cold soil, others do best in that which is lax, sandy, or clayish; some in a moist, others in dry places; still we find provision enough for all these purposes. Every country abounds with its proper trees and plants, and every vegetable flourishes and is gay somewhere or other about the globe. To this convenience, which the various soils of the earth are of to vegetables, we may add their great use and benefit to innumerable animals, to many kinds of quadrupedes, fowls, insects, and reptiles, who make in the earth their places of repose and rest, their retreat in winter, their security from their enemies, and their nests wherein to repose their young; some delighting in a lax and pervious mould, admitting them an easy passage, while others seek a more firm and solid earth, that will better secure them from injuries without. In one place we are provided with chalks, okers, and boles, of all sorts, for medicinal uses, and of all colours, proper for drawing the outlines or sketches of any designs we propose to accomplish, or for painting such objects as may contribute either to our profit or delight. In another, we have various kinds of marl, which is so justly admired by our masons for its incomparable chalk, and more particularly by our farmers, who look upon it as an inestimable treasure. In several parts of England, but particularly in the barren regions of the north, there are beds or strata of bituminous earth to be met with, commonly called either Sea or Scotch Coal. Thus Nature provides fuel for the inhabitants of those countries, whose climate requires a more powerful warmth than what is afforded them from the benign rays of the sun, and thus makes amends for the want of those blessings, which are bestowed on more southern countries. Exposed to the severity of the cold northern blasts, they stand more in need of what they dig out of the bowels of the earth, than of what we find on its surface. There, strangers to the delicacies of life, they are contented with humble necessaries.

Mankind, in order to live with decency and pleasure, must be supplied with a vast variety of accommodations: for this purpose they are furnished with an infinite number of Fossils, which are intended by Providence as a treasure that should never be exhausted. These are carefully lodged in spacious repositories under our feet, where we may infallibly find them upon all emergencies. These useful materials do not lie buried in the centre of the earth, nor so deep in the bowels of it, as to be inaccessible; but are planted at a convenient distance from its surface, that the soil may produce its proper fruits, in due season, without interruption. By this wise direction of Nature, our habitations are richly furnished both within and without, and the same spot of ground produces for our service a kind of double harvest.

From these considerations on fossils, let us turn our attention to those immense beds of Stone, which lie buried in the earth. Had all those vast masses, which lie under ground, been lodged up and down on its surface, we should have been much embarrassed, and had but little room left for the erection of our houses: had they proved as hard in the quarry, as they grow afterwards, all the art of man could never have been able to dig or cut them; and had they continued in their original state of softness, when exposed to the open air, our houses would have never been secure. When the descendants of Noah were reduced to the necessity of dispersing into distant countries, in order to seek out commodious settlements for themselves and their families, they found every place over-run with woods, and inhabited by an infinite number of savage beasts. By the help of a few boughs, and the skins of such beasts as they killed in the chase, they erected at first a few huts or tents, which

which served to shelter them from the injuries of the weather. As they were not, however, at that time, always safe and secure from the attacks of those devouring beasts, nor from the merciless insults of their more savage fellow-creatures, what a peculiar providence was it for them, who as yet lived in a restless uneasy state, to find under their feet, and at a moderate distance from the surface of the earth, such immense quantities of matter, that was soft enough to be cut and fashioned according to their pleasure, and yet so solid at the same time, when exposed to the open air, and disposed in a proper manner, as to secure them not only from the most outrageous storms, but from the insults of their private enemies; and, at last, to defend whole kingdoms from any hostile invasions! By this means, in process of time, both villages and cities arose out of the earth, and men attained to the art of lodging and cementing the most unwieldy stones in the closest manner; of building for themselves commodious habitations, impregnable fortresses, and magnificent palaces for the reception of their princes and rulers; and, in fine, those solemn and pompous temples, in which all the families then on earth met together at stated times, to pay their tribute of gratitude and worship to their common Parent, to visit one another without pride or respect of persons; and to lay themselves under the most solemn engagements, inviolably to perform all those good offices one towards another, on which the welfare of an amicable society entirely depends. We shall not here enter into any enquires, how these immense stones are formed, since that matter is fully explained in its proper place; we shall only add, that besides these huge masses, which the earth provides us for building our habitations, there are others, though less in bulk, of infinitely more value, such as diamonds, rubies, carbuncles, and a thousand other precious gems, which adorn the insides of the most sumptuous palaces, and grace the diadems of sovereigns.

We come now to the last point of consideration, that of Metals, of which gold is undoubtedly the first that claims our attention. The preference, which we give to this above all other metals, is by no means the effect of prepossession or caprice: the superior regard we pay to it is grounded on its intrinsic and inherent merit. There is no metal so solid and compact, so weighty, or so capable of being refined to so great a degree of perfection: it is, beyond all contradiction, of the most beautiful colour, and comes nearest to the radiancy of fire: it is the most ductile and obedient to the workman's hands of all metals whatever, and never soils or besmears them, as others will. The least particle of it gives an additional grace to every thing it touches, and has one other excellent quality, which is that of its never rusting, nor will it lose any thing of its weight while refining in the fire. It is therefore not at all surprising, that mankind should unanimously agree to fix upon a metal of so pure, so solid, and durable a nature, in order to pay for and procure such various accommodations as they indispensably wanted. Before the discovery of this precious ore, trade and commerce were carried on by way of barter: wine, for instance, was exchanged for oil, corn for flax, and one commodity was mutually agreed to be accepted for another, as occasion required. This method, however, of negotiating business, was attended with a thousand inconveniencies: two contiguous nations or provinces might possibly be over-charged with the same commodity; or, supposing the products of their grounds to be different, yet it created abundance of trouble to make a just computation of their real and intrinsic worth, insomuch that it was no easy matter to adjust an equivalent in the wholesale trade, though practicable in the retail

way; and men were often obliged, with reluctance, to dispense with many things, for want of such accommodations, as were agreeable to those who were possessed of them. Now, gold being a metal of a pure, ductile, and incorruptible nature, was considered by them as the most agreeable and proper substance, of which to make a general standard, and the most commodious equivalent that could possibly be given in exchange for all the accommodations and conveniencies of life whatever. As this radiant ore was very scarce, they agreed, with one voice, that a small quantity of it should be deemed a sufficient compensation for a large portion of any other merchandize. They wisely considered, how great would be their advantages, to be enabled, by virtue of a small portion of such precious metal, (which is little or no incumbrance to a traveller, and which he can easily conceal from the eyes of those, who might otherwise be disposed to oppress him) to take a tour all round the habitable world, in order to furnish them with whatever conveniencies they might want, and to defray all their necessary expences, without the least dependency, incumbrance, or enquiry. This method of transacting business was found to be so expeditious and convenient, that, in process of time, the practice became universal. There was one little inconvenience, indeed, that at first attended it: every merchant was obliged to carry his scales and weights in his pocket, in order to know the intrinsic value of the gold he received; but an expedient was soon found out to save him the trouble, by making little thin pieces of gold, which afterwards introduced those of silver, with some known and public figure impressed thereon by the authority of government, to settle and determine their real value, that he, who delivered his goods, might be well assured, that he received so much gold or silver, of such a weight and standard, in return. As gold, however, was reserved on account of the great scarcity of it, to discharge and pay off large sums, with the utmost expedition, they had recourse to baser and more common metals for their daily disbursements and their retail business.

The obedience of this metal, under the hands of the gold-beater and wire-drawer, is not only surprising, but a perfect prodigy; and, if we were not eye-witnesses of it, we should never be prevailed on to think it practicable. By the art of the gold-beater, a piece of this metal, of only an inch square, and not thicker than paper, is hammered out into a thousand leaves, each of four inches square. The following operation, though equally common, is much more surprising. A gold wire-drawer takes an ingot or bar of silver, of a cylindrical form, two feet and eight inches in length, and two inches and nine-twelfths of an inch in circumference. Upon this he spreads as many leaves of beaten gold as weigh, in the whole, exactly half an ounce. He then drives the extremity of this cylinder with force through a round hole that is made in a steel plate, the entrance whereof is wider than the other end, which is called the eye. After this the ingot is passed through several holes successively that are one finer than another. Thus, by slow degrees, it is reduced to the thinness of a reed, a coarse thread, and at last, after having passed through upwards of an hundred and forty holes, acquires the minuteness of the finest hair. The most surprising part, however, of this operation is, that the half ounce of leaf gold, which first covered the ingot of silver, should, notwithstanding its former degree of fineness, grow gradually still finer and finer as it passes through the different wire holes, and cover the surface of the silver so very exactly, as that no part of it whatever should be seen: it appears, in short, one entire thread of gold. Thus half an ounce of gold may be made

to extend itself into a surface of about seventy-three leagues in length. Hence we may plainly perceive, that the internal nature of this metal, and, in all probability, that of all other substances whatsoever, is beyond human comprehension.

The uses of copper and tin, for domestic purposes, are well known to every one; and there is not a metal that can be mentioned, but what has some useful property: yet that very metal, which to all outward appearance is the meanest and least polished, which abounds most with allay, is of a dark and gloomy hue, and the most liable to rust—yet that very metal, *iron*, is more beneficial and advantageous to us than all the rest. It has one particular quality, which alone is sufficient, in some measure, to give it the precedence to all others, and that is, it is more hard and tenacious, which renders it every way qualified for the most lasting purposes. By being thus able to resist the strongest efforts, it becomes the guardian, as it were, of our houses, and our most faithful trustee. By linking thus inseparably together the materials of which our habitations are composed, it secures our persons, not only from the injuries of the weather, but from the hands of merciless and violent men. To this metal we are indebted for the greatest part of our utensils, which are made use of, not only in navigation, husbandry, and clock-work, but in all other liberal and mechanical arts. Gold and silver, had we not iron implements to work and fit them for our several purposes, would be in a great measure useless. We are so much indebted to this particular metal, that our daily provisions could not be commodiously dressed, nor should we well know how to divide them for eating, without it: To sum up its superior excellency in a few words: all other metals, indeed, are useful; but this is absolutely necessary, and we can make no tolerable shift without it.

From all these considerations we may conclude, that we can neither look round about us, move one step upon the earth, or dig under our feet, without meeting with a profusion of those treasures, which Providence has provided either for our convenience or delight. The survey of Nature, therefore, when rightly pursued, is a kind of popular theology, where all human kind, even the illiterate, may learn those truths, the knowledge whereof is a concern of the utmost importance.

C H A P. I.

Of Medicated MINERAL WATERS.

AMONG Medicated Mineral Waters some are cold, and others hot; the former are called by physicians *ACIDULÆ*, that is, a little partaking of acid, because some of them have a subacid or vinous taste, especially when taken immediately from the spring. The hot springs are supposed by some to be owing to subterranean fires; because near those places where there are volcanoes they are most frequent; but others think they arise from the fermentation of the different particles of which they partake as they pass through different strata of the earth; as for instance, Iron and Sulphur. But, be this as it will, their virtues are not owing merely to the heat or cold, but to the principles of which they are composed; for which reason it will not be worth while to treat of them as such, but to take notice of their contents, to which their properties are owing. We shall therefore divide them only into four Classes: 1. Mineral Waters containing earthy Particles. 2. Waters impregnated with Salts. 3. Sulphureous Waters. And, 4. Waters impregnated with Metals.

1. There are mineral Waters, which have imbibed earthy particles that have the properties of Soap, particularly the Soapy Water of Plombiers in France, which at the spring head is warm, and tastes a little fat or soapy, with a small degree of roughness. This is supposed to run through a strata of Fuller's earth: it is prescribed in disorders of the stomach, proceeding from acidities, as well as in spitting of blood, excessive bleedings, a consumption of the lungs, and many other disorders, for which they are either drank or used as a bath. A large quantity is to be drank in a morning upon an empty stomach, and some make use of it for common drink.

2. Waters that have imbibed Rock Salt are not very uncommon, but they are not as some imagine of the same nature as those in which common Salt is dissolved; because this latter is not a simple substance, but contains a mixture of Rock Salt and fixed Alcalious Salt, imbibed in the bowels of the Earth; and that which is made with Sea Water partakes of a Volatile Urinous Salt, which is the produce of the putrefaction of fish, sea plants, and other marine substances, together with Bitumen and various Minerals.

It is but lately that Sea Water has been thought of any internal use in medicine, or at least its properties have lain dormant for a great number of years, except for diseases of the skin, for which it has been ordered as a bath; it has been recommended in all disorders of that kind, from the itch to the leprosy, as well as pains in the limbs; and some have thought, and still think, that it is a specific against the bite of a mad dog. It is now prescribed inwardly in all obstructions of the glands, in whatever parts of the body, and the diseases arising therefrom, for which it is both drank and used as a bath. It is also good against obstructions of the kidneys, when there is no inflammation, or the stone is not too large to pass; and likewise against recent obstructions of the liver, and consequently the yellow jaundice, when given with medicines proper for that disease. A person of twelve years of age may drink half a pint every morning, and an adult a pint.

The Waters of mineral springs, impregnated with Sal Gem, when given inwardly, open the body and promote urine; besides which they are drying, binding, and discutient, whence they are good in cachexies, and the dropsy.

Those Waters are said to be nitrous, which abound with a Salt like the Natrum of the ancients, which some have mistaken for Saltpetre; whereas it is a kind of Alcalious Salt. Those springs that abound with it, are good for dissolving thick clammy humours, for opening obstructions of the bowels, as well as in a decayed appetite. When used as a bath, they help to resolve swellings and obstructions of the nerves.

3. There are many mineral Waters that partake of Sulphur, which may be easily known by the smell, as also by the sediment that is left after it has been evaporated over the fire. These are commended in disorders of the breast, and foulnesses of the skin, whether drank, or used as a bath; as also in trembling of the limbs, contractions of the tendons, the rickets, and some kinds of palsies.

Our *Bath* Waters are thought chiefly to partake of Sulphur, mixed with an exalted Vitriolic Steel. They are good in all weaknesses and decays of the constitution, as well as for a debauched stomach. They likewise dissolve viscid and saline particles in the blood and humours, and sweeten the fluids in general. Hence they are good in dropsies and consumptions before they are too far gone; as also in catarrhs, cachexies, jaundice, scurvy, scorbutic rheumatisms, asthmas, and all diseases of the skin, as well

well as old pains and aches; nor are they less effectual in many womens disorders.

4. These in general partake of iron or steel, though there may be possibly some of other kinds which have not been taken notice of by naturalists. There are many of these in Hungary, Germany, France, and other parts of the world; but the Pyrmont and Spa Waters are the most famous we have from abroad; and in England we have the Tunbridge, Scarborough, Hampstead, and Islington. These in general dissolve gross humours, sweeten those that are salt and acid, and open obstructions. They are accounted good in all diseases of the head; whether they arise from the consent with the stomach, or not; they are also good in many diseases of the breast, particularly shortness of breath, coughs, and spitting of blood. In short, they are efficacious against all those distempers wherein iron or steel is of any use; and they must be much better, because the particles of the metal are become so volatile that they do not change the colour of the water; but then they are apt to fly off after they have been exposed to the air for a few days. Besides, as it is necessary to drink a pretty large quantity of these waters, the solution of gross thick humours is much better performed hereby, than by administering the metal in any other form.

CHAP. II.

OF MINERAL WATERS peculiar to ENGLAND.

HAVING taken a general survey of medicated Mineral Waters, in the preceding Chapter, we shall in this confine ourselves to those only, which are peculiar to England: We shall relate the chemical trials, which have been made to find out their virtues, and the good effects which they have been experienced to produce in the constitution.

It is usual to give an account of their contents, after the evaporation of the water; but this is not sufficient in all cases, because there is often a volatility, when just taken from the spring, wherein the principal strength of the water resides, and which is lost if not immediately drank. Hence it follows, that the nature of the contents will not always ascertain the virtues of the waters. However, in recounting the effects and properties of these waters, all the circumstances will be taken notice of, that may tend to give an insight into their operations; and that each spring may be more readily found, we shall place the counties in which they arise in an alphabetical order.

BERKSHIRE. In this county we meet with but two Mineral Waters, one at Sunning-hill in Windsor-Forest, which is of the same nature as the Tunbridge waters; and the other at Comner, or Cumer, three miles west of Oxford. This last water is always of a whitish colour, especially in the summer time when the well is low; the reason of which appearance is said to be owing to its proceeding from lime-stone. Oil of Tarter being dropt therein, causes it to let fall a white sediment; and Spirit of Hartshorn turns it to a pearl-colour; but with the Solution of Silver it turns to a purplish pearl-colour, and with Syrup of Violets, green. A gallon of this water will yield 296 grains of sediment, whereof 76 grains are lime-stone, and the remainder a calcareous nitre. The sediment is dark brown, with a saltish and very bitter taste; will ferment with Vinegar, as well as with Oil of Vitriol, and will turn green immediately with Syrup of Violets. The salt itself is of a yellowish brown, and has a saltish, nauseous, bitter taste. It is a kind of calcareous nitre, but inclines more to an alkali than

most others of this class. A quart of it will purge a robust country fellow.

CORNWALL. The mineral springs in this county have never been taken notice of till very lately; and that by Mr. Borlace, in his Survey of Cornwall. Madern Well is only a spring of pure water, which rises in the parish of Madern, four miles west of Penzance: However, it is resorted to by many people that are afflicted with pains, aches, and stiffness of the limbs; and it has done many cures, which may be only owing to the coldness and purity of the spring. Euny Well, once so famous, still preserves its reputation for drying up humours, and healing wounds and sores. However, as this has no evident mineral impregnation, these effects may be owing merely to the coldness of the water, which braces up the nerves and muscles, and strengthens the glands: Here is another well of this sort, called the Holy Well, which is about a mile and a half to the north-west of St. Cuthbert's church, in a cave that lies in a small sandy bay. In this cave, there are stones like icicles, that hang from the roof, and the floor of the rock is covered with the same substance. This water will not change the colour of green tea, nor curdle milk; from whence it is concluded, that it has neither alum nor steel in its composition. When this water is evaporated, it will deposit a small sediment, of the same colour and substance with the incrustations: it will neither melt nor flame, nor has it any particular taste or smell, and yet is in great use for fluxes and disorders of the bowels.

The most remarkable Chalybeate Spring in Cornwall rises in the tenement of Colurian, in the parish of Ludgvan. The bed through which this water runs is full of an ochreous, iron mineral, from which its taste and smell proceeds. It turns to a deep reddish purple with Galls, and with Oak-leaves it becomes of a bluish black, but has a purplish cast. When a thimbleful of Oil of Tarter was dropped into this water, it fell immediately to the bottom of the glass, which held about half a pint: but it precipitated no sediment, nor made any change in the water; only the colour was more inclinable to that of a bright oker, but was scarcely discernible. It will not turn silver black, and therefore it is concluded there is no sulphur in it; but in the morning, before the water is stirred, there is a film on the surface with all the colours of the rainbow, shooting to and fro, which occasions some to think, there is a naphtha in the water. It will mix with milk, and lathers readily with soap; and after it has stood 24 hours in the open air, it undergoes no alteration from Galls, which is owing to the flying off of the volatile spirit. The virtues of this water are very great; for persons have been cured of the King's Evil, by drinking it, and washing the parts affected, whom Mr. Borlace knew; and he heard of many others that were cured in the same manner. It is very diuretic, promotes perspiration, opens obstructions of the bowels, and restores a lost appetite. It also cures sores of every kind, and is a very good eye-water.

CUMBERLAND. At Stanger in this county, two miles south of Cockermouth, and three west of Keswick, there is a spring of clear saltish water, with the taste and smell of iron; it turns white with Spirit of Hartshorn, and lets fall a great sediment with Oil of Tartar: a gallon of this water will yield 1170 grains of sediment, whereof 1080 are sea-salt, and the rest lime-stone. It is white, hot on the tongue, and grows very moist in a damp air. There is a little mixture of nitre with the sea-salt, but this last predominates, and is joined to a considerable quantity of iron. Four or five pints will purge upwards and downwards; but it is an excellent remedy in surfeits, pains in the stomach and breast, the green-

green-sicknefs, fcurvy, fores, and breaking out of the skin.

DERBYSHIRE. Buxton Well lies at the bottom of a dirty village of the same name, and there is a large commodious house, to which much good company resort in the summer time. The water is neither so hot as that of Bath, nor so cold as that of Bristol. It has a sweet, pleasant taste, and a gallon will yield about 20 grains of a sediment, which consists chiefly of lime-stone, sea-salt, and a little calcarious nitre. It deposits a white sediment with Oil of Tartar; but it will not turn silver black, nor does it discover any signs of sulphur. It will not ferment with Spirit of Vitriol, nor turn green with Galls, till they have soaked four days therein. It is a temperate bath, and a very light water. It is of a relaxing, diluting, sweetening and attenuating nature, and will open obstructions of the smallest vessels. It is good in consumptions, for hot scorbutic humours, and all fluxions and bleedings, as well as in hypocondriacal and hysterical cases. It is of great use in the regular gout, in rheumatic and scorbutic pains, in vomiting of blood, and in all kinds of fluxes. It is good in internal inflammations, consumptions, the diabetes, and a bloody urine; as also in a bilious cholic, want of appetite, and in cold stomachs from hard drinking. To these may be added, contractions, cramps, convulsions, St. Anthony's fire, and all breakings out of the skin.

Matlock Bath is also in Derbyshire, near Warkworth, and ten miles north by west of Derby. The village is seated on the very edge of the river Derwent, is a very beautiful place, and is frequented by very polite company. The water of the bath is not so hot as that of Bristol, and it curdles with soap. It deposits a white sediment with Oil of Tartar, and the same experiments give the same appearances as in Buxton water. A gallon of water yields 40 grains of sediment, whereof 13 are salt, consisting of nitre and sea-salt; and the remainder is a rough, white, alkaline earth. The virtues of these waters are nearly the same as those of Buxton and Bristol, used either internally or externally. Both drinking and bathing are generally thought good for the cancer and the king's evil. Bathing is proper for rheumatisms, scurvy, and defecations of the skin. It is also used successfully in all sorts of bleedings, as well as hectic fevers and inward ulcers, with a milk diet. It also cures the diabetes, and the bilious cholic.

Westwood is another village in this county, near Tandersley, where there is a spring, which seems to be a solution of the pyrites, that generally attends pit-coal. It turns blue with Galls, and the salt separated from the earthy part of the sediment will shoot into beautiful crystals of vitriol, without any other salt. The water will cure stubborn ulcers, and particularly healed one in a maid-servant that was very frightful: it was washed twice a day with this water, and was cured in three months.

DORSETSHIRE has only one mineral water hitherto taken notice of, and this is at Nottinton, a village near Weymouth. The water has a strong sulphureous smell, with a flavour resembling that of boiled eggs, and the colour in a tin vessel is blue. At the fountain head a shilling put into this water, becomes of a gold colour in two or three minutes; and from various experiments it appears to be impregnated with sulphur and natron. It is remarkable for curing foulnesses of the skin, by internal use.

DURHAM. Hartlepool is a market-town in this Bishopric, 15 miles south-west of Durham. The water found here is a chalybeate, though as it rises it discovers a little steel and sulphur, which soon flies off after it is taken up. It lets fall a white sediment with Salt of Tartar, becomes whitish with

Spirit of Hartshorn, and turns of a pink-colour with Galls; but green with Syrup of Violets. A gallon yields 120 grains of sediment, whereof two parts are nitre, one sea-salt, and the rest lime-stone. The water is an excellent antiscorbutic, and cures habitual cholics. It is good in pains of the stomach, in indigestion, in the gravel, in women's obstructions, in hypocondriac melancholy, in the cachexy, in weaknesses of the back, hectic heats, and recent ulcers.

ESSEX. Here are several mineral waters in this county, of which one is at Upminster, seven miles south of Burntwood, and eight east of Barking. The water is bitter, and will curdle with Oil of Tartar, but more strongly with Spirit of Hartshorn, and will not lather with Soap. A solution of Alum causes it to let fall a large grumous sediment, and the solution of Copperas changes it to a dark dun colour. It appears to be a sulphureous water, of a considerable strength, and a gallon will yield 332 grains of sediment, which is of a nauseous bitter taste. It is chiefly a calcarious nitre, mixed with a little natron and sea-salt. The water is purgative and diuretic, absorbs acidities, strengthens the stomach, and checks vomiting.

Witham Water, when fresh, is perfectly clear, and has a very strong chalybeate smell and taste. It has a remarkable freshness when just taken from the spring, which renders it agreeable to the taste and stomach; but, after it had stood awhile, it loses that quality, and deposits a brownish sediment. A gallon, by evaporation, will yield 30 grains of sediment, which will grow damp in a moist air. However, this water is of no use, unless it be drank immediately at the spring, and then it is diuretic, and is good in hectic fevers, lowness of spirits, weakness of the nerves, and want of appetite. Witham is a market-town, which lies in the road between Chelmsford and Colchester.

Tilbury is a village, seated over-against Gravesend in Kent; the water here is somewhat of a straw-colour, and has a soft smooth taste. With Oil of Tartar, it will cause no immediate precipitation, though it will curdle with Soap, but not with Milk. A gallon will yield 180 grains of sediment, of a yellowish brown colour, with a sharp taste, like that of a fixed alkali. A quart of this is a middling dose; it generally passes off by urine and perspiration. It warms the blood, is good in lowness of spirits, and is a specific in loosenesses. It also cures almost all fluxes of blood, and is particularly good in an acidity of the stomach, and for some kinds of scurvies.

FLINTSHIRE is in North Wales, and Caergile, in this county, is about seven or eight miles south by west of Chester. The water found here is as clear as crystal, and yet it will turn whitish with Oil of Tartar; it also turns green with Syrup of Violets, and red with Logwood. A gallon will yield 220 grains of sediment, of which 66 are earth, and 154 are sea-salt and lime-stone. It appears to be impregnated with calcarious nitre and sea-salt, and, if drank to a quart or two, will purge pretty well. It has cured a woman that had a loathsome scurf all over her body, by drinking three pints of this water in a day. Likewise several children afflicted with scorbutic disorders, and the leprosy, have been cured by drinking and washing.

GLOUCESTERSHIRE has but one remarkable water, which is at Cheltenham, a town which lies in the road from Gloucester to Warwick. It was not much taken notice of before the year 1740, and then it was said to be the best purging water in England; but it begins now to be neglected. It is limpid, a little brackish, and nauseously bitter. It will curdle with Soap, and lets fall a white, grumous sediment with the solution of Salt of Tartar, and

and with the Spirit of Sal Ammoniac. It will ferment with Oil of Vitriol, Spirit of Salt, and Vinegar: beef and mutton boiled therein will become of a pale red, and it turns a deep green with Syrup of Violets. A gallon will yield 688 grains of sediment; which contains a little impalpable earth; mixed with a little salt, which is chiefly calcarious, and has a nauseous bitter taste. The dose is from one pint to three or four, nor is it ever attended with gripes; but creates a keen appetite. It has been used with success in the gravel; and will cure old scorbutic humours, St. Anthony's fire, and strumous inflammations of the eyes.

GLAMORGANSHIRE is in North Wales, and at Swansey, a sea-port town, there is a spring that has an acid stiptic taste like alum, though the predominant salt is a martial vitriol. It turns blue with Vinegar, and will not curdle with Milk. A gallon of this water yields 40 grains of sediment, of a highly acid, stiptic, vitriolic taste, and a light brown colour, which will ferment with Spirit of Hartshorn and Oil of Tartar. It is good in loosenesses, and will stop the bleeding of external wounds.

HERTFORDSHIRE has two medicinal springs, at Barnet and Northall. The first is called East Barnet, and is situated two miles south-east of High Barnet. Northall lies three miles north of High Barnet, and receives its name from Northaw, which is the same as North-grove, there having been a wood here belonging to the monastery of St. Alban. Both the waters seem to be of the same nature; that at Northall is a little brackish and bitterish in the throat; but is not so nauseous as that at Epsom. Barnet water is bitterer than the former, but they will both curdle with Soap, and let fall a grumous sediment with Oil of Tartar. With a solution of Alum they will let fall white grumes; which experiment shows they are not aluminous; but with Galls they turn of a wheyish colour, and with Logwood of a deep red. A gallon of Northall water will yield four drachms and twelve grains of very white sediment; and a gallon of that at Barnet, 20 grains of a brackish, bitter sediment. From other experiments it appears, that both these waters contain calcarious nitre, with a small mixture of sea-salt, and a little lime-stone. They have both a purging quality; but they are not half so strong as that at Epsom.

KENT has a remarkable mineral water, commonly known by the name of Tunbridge Wells, which is 34 miles south-east of London. In a warm season a gas of vitriol may be perfectly distinguished in this water; and it is generally allowed to be impregnated with volatile and spirituous exhalations. It turns of a blackish purple colour at the fountain-head with Galls, Oak-leaves, and Green Tea; but if a few drops of Spirit of Vitriol be added thereto, it will become clear again. In a rainy season in January, a gallon will yield nine grains of sediment; but in August no more than six grains. It is a light, and comparative pure chalybeate, and its virtues are most powerful at the fountain-head. It causes a blackish perspiration, which in time will change the linen of the drinkers to the same colour. It purges most by stool and urine; but if the stomach be foul, by vomit. In general, it is an effectual remedy in obstructions of the glands of the mesentery, as well as in recent dropsies, as also in phlegmatic patients, whose blood is very poor. It is good in all pains, and swellings at the pit of the stomach, though of many months standing. It is excellent in ulcers of the kidneys and bladder, and cures the cholic, vomiting, and the hiccough; it likewise kills worms. It strengthens the brain and nerves, and is good in convulsions, the head-ach, and vertigo; besides, it cures long and tedious agues, and is good in the

dropsy, black and yellow jaundice; hard swellings of the spleen, the scurvy, and green sickness, as well as helps sore eyes and red pimples.

Sydenham Wells are in the parish of Lewisham; and are seated upon a common near Dulwich in Surry. The water is a little bitterish, will curdle with Soap, and, with the solution of Pot-ashes, it will let fall a white grumous sediment. From these, and other experiments, it appears to be impregnated with a calcarious nitre and sea-salt; joined to a little natron and calcarious earth. A quart will yield above a drachm of a palish yellow sediment; with a nauseous, bitter taste; and the salt separated therefrom has the same taste, with a little brackishness. It produces much the same effects as Epsom water, though it is not half so strong.

Dulwich water has its name from rising in the hills nearly adjoining to that village in Surry; but in reality it is in the parish of Lewisham, in the county of Kent. The water is generally clear, has a brackish taste, with a little bitterness in the throat; and will curdle with Soap; but with Oil of Tartar it will let fall a white grumous sediment. A gallon will yield three drachms of sediment of a greyish colour, and a brackish taste, which will ferment greatly with Oil of Vitriol. This water is chiefly impregnated with sea-salt, calcarious nitre, and a little calcarious earth. It is a brisk purge, and will cure ulcers of every kind, by bathing therein, all defecations of the skin, and even leprosy itself. It is good in obstructions of the bowels, in the green-sickness, black and yellow jaundice, the cholic, gravel, piles, cachexy, scurvy, and removes difficulty and sharpness of urine, as well as strengthens the brain and nerves. The dose is three pints a day at first; but should be increased every day till it come to eight or nine pints.

LANCASHIRE has several mineral springs, among which is Carlton Water, so called from Carlton, a village ten miles south-west of Preston. This water is somewhat of a chalybeate, and when just taken up has a faint smell of sulphur. It will curdle with Soap and Milk, turns white with Oil of Tartar, has a pink sediment with Galls, and changes to a deep blue with Logwood. A gallon contains 236 grains of a white sediment; whereof one third part is earth. The sediment is of a brackish taste, and bitterish in the throat, and will ferment with acids. The salt is also brackish, very bitter in the throat, and emits an acid fume with Oil of Vitriol; but will not ferment nor change with Vinegar. It is a more powerful absorbent than many other nitrous waters, and three or four pints will purge briskly.

Rougham Water, so called from Rougham, a village in Lancashire, two or three miles from Cartmel. The spring rises from the bottom of a rocky mountain, and the taste of the water is a little brackish: it turns white with Oil of Vitriol, green with Syrup of Violets, and brown with Logwood; but it continues clear with Galls. A gallon of this water yields 300 grains of sediment, of a saltish taste, will ferment with Oil of Vitriol, and emit an acid fume. The water purges briskly by stool and urine, and the common people drink it from three to eight quarts. It is of great use in bad digestions, loss of appetite, and the scurvy. It has cured the jaundice, and a quartan ague, and is excellent in the green-sickness.

Crickle Spa rises in a village of that name, a mile from Broughton. It has a strong foetid smell, and will turn silver black in a minute. The earth it runs over is of a shining black, and yet it will turn rags, leaves, and grass, white. A gallon contains 320 grains of sediment, 12 of which are earth, and the rest are sea-salt and nitre. It is a purging, sulphureous water.

Heigh is a village not far from Wigan, where there is a water, which will ferment strongly with any alkali, will turn inky with Galls, and has likewise a vitriolic taste; a gallon yields four ounces of sediment, which consists of a variegation of white and green, with ochre, sulphur, and a little copper. It works plentifully by vomit and stool, and will stop any internal bleeding.

Burnly is a town also in Lancashire, whose waters will turn Galls of a deep red in a moment, and with Syrup of Violets to a very deep green. It works powerfully by urine, and is good in scorbutic cases.

Handbridge is seated between Burnly and Townly, which has a spring that changes Galls to a faint orange colour. The salt obtained therefrom yields a foetid, penetrating smell with salt of tartar. These two last Waters agree with the Pohun at Spa, in containing iron and natron as their principal ingredients. It purges by stool and urine, and is of great use in the gravel, scurvy, obstructions, and diseases from an acid.

At Ancliff, a village three miles from Wigan, there is a Spring called the Burning Well, which will take fire by holding a lighted candle near it. It will continue a whole day, and eggs and flesh may be boiled therein; but the water itself is cold. It is but a few yards distant from a rich coal mine, which renders it probable, that the inflammable vapour is rock oil.

There is a Spring two miles from Whaley, seven miles west of Burnly, whose stream renders Gold brighter; but turns all white metals black. The channel this water runs in is lined with a bituminous, stinking substance, and it is strongly impregnated with sulphur, combined with a little calcareous nitre, a mixture of sea-salt, and of absorbent earth; but we have no account of its virtues.

Inglewhite is a village in Lancashire, where there is a strong, sulphureous and chalybeate water, which is the product of marle. This partly resembles slate, will moulder, when exposed to the air, into exceeding thin flakes, like leaves of fine paper, and will afterwards turn to a black powder. A gallon contains 24 grains of sediment, of which 19 are earth and ochre, and 5 nitre; but it will not purge unless drank with salt.

LEICESTERSHIRE has one remarkable mineral Spring at Nevil Holt, a village seated to the south of Market Harborough: the water is exceeding fine and clear, and it has a styptic, bitter, sweetish and subacid taste, leaving the mouth somewhat dry. It is uncommonly brisk and sharp, when drank at the Spring-head; and then also it passes quicker than elsewhere: it curdles with Soap, and lets fall a gross, white sediment with oil of Tartar; but with a solution of Alum and Copperas, it will continue clear. Hence, and from other experiments, it appears to contain a calcareous nitre and alum, with a fat clay, a latent sulphur, and sometimes a little ochre. It will cure externally fresh wounds, and all sorts of ulcers; and is excellent for the eyes: used outwardly, and taken inwardly, it will cure hectic ulcers. When taken inwardly, as an alternative, an ounce or two may be taken five or six times a day, or four ounces night and morning; but when designed as a purge, it must be taken from one pint to three. If the constitution is cold and phlegmatick, it will be necessary to add four spoonfuls of brandy, and an ounce of sugar to each bottle of water. It is excellent in bloated, dropical constitutions: it has no parallel in all sorts of hæmorrhages, as well as in all great and natural secretions, of what kind soever. It also cures an inflammation of the lungs, attended with a cough and spitting of blood. It is very successful in the King's Evil, hidden cancers, as well as scrophulous inflammations of the eyes of many years standing. It also cures all dif-

eases of the skin, and has had surprizing success against rheumatisms; but it must not be drank in the increase and height of any internal inflammation.

LINCOLNSHIRE has several mineral springs, whereof one is at Cawthorp, a village seven miles north-east of Stamford, where the spring rises up in a large basin, in the middle of the street. It will turn very white with Oil of Tartar, and afterwards let fall a yellow sediment; but it will turn green with Spirit of Hartshorn. A pint will yield a scruple of a white sediment, whereof near one half is salt, and the other earth. It is a purging chalybeate, and is probably a great corrector of acidity.

In the parish of Strenfield, ten miles east of Lincoln, there is a water that is pleasant and sweet to the taste; but will curdle with Soap, and turns to a pearl colour with Oil of Tartar. A gallon of it contains four scruples of a white sediment, whereof 44 grains are earth, 30 nitre, and 8 sea-salt. It is found effectual in curing obstinate fluxes, and the diabetes; as also all internal hæmorrhages, and profuse night sweats.

Gainsborough is a market-town in Lincolnshire, seated on the river Trent, 14 miles north-west of Lincoln. The spring rises to the south-east of the town, and smells and tastes like steel and sulphur. A gallon yields 192 grains of sediment, whereof 120 are earth, and 72 calcareous nitre: it has somewhat of a purgative quality.

MIDDLESEX contains several mineral waters, of which one is at Acton, a large village, eight miles west of London, which is a purging water, though it is very clear and without smell. The taste is a little nauseous, like a weak solution of Epsom salt: it will curdle with Soap, and with Salt of Tartar it produces a white grumous cloud. Oil of Vitriol and Spirit of Salt will excite a small fermentation, and with Syrup of Violets it will turn to a light green. A gallon will yield 344 grains of sediment; it is very white, and of a nauseous bitter taste; it will ferment very briskly with Spirit of Salt, and the proportion of the salt to the earthy matter is as 73 to 4: from other experiments it appears, that this water is chiefly impregnated with a calcareous nitre, and a small proportion of absorbent earth. It is accounted one of the strongest purging waters near London, and is noted for causing a great foreness in *Ano*.

Pancras lies on the north-west side of London, and in the road to Kentish-town; the water here has scarce any taste, till one half is evaporated, and then it becomes bitter; with Oil of Tartar it will deposit a copious white sediment; but with the solution of Alum there will be a small grumosity. Acid spirits will produce a small fermentation; and with Syrup of Violets it will turn green. A gallon will yield five drachms of whitish sediment, which has a saltish and strongly bitter taste in the throat: from hence it is concluded, that the impregnating salt is a calcareous nitre, and it is considerably diuretick, and somewhat purgative.

Shadwell Water is found in the Sun Tavern Fields, about two miles eastward of the Tower of London, and about half a mile from the river Thames. It is of an amber colour, with a strongly acid and styptic taste. It ferments for some time with Oil of Tartar, and lets fall a large ochreous sediment; but with the solution of Alum it continues clear. It will turn a copper half-penny black on the surface, and a knife black, blue, and rusty. A gallon contains 1320 grains of a white and yellowish sediment, which has a highly acid and austere taste. The predominant salt of this water is highly acid and vitriolic, with a combination of sulphur. This water has been chiefly used externally; but if a pint of it

be used at twice, in the space of an hour, it will produce a gentle vomiting, and two or three stools: it has done a great deal of good in all diseases of the skin; and some say it will cure fistulas, stubborn ulcers in the legs, and sore eyes, by dipping linen rags in the water, and applying them to the parts affected: taken inwardly, it stopped internal bleedings, and has perfected the recovery from camp dysenteries.

Hampstead is well known to be a large village, or rather town, five miles north of London; and the water that is found there was formerly in as great reputation, as that at Tunbridge. It will lather with Soap, but undergoes no alteration with Spirit of Hartshorn; and yet it will ferment with Oil of Vitriol, and grow warm and smoky. It will keep milk sweet for four days, and will turn purple with Syrup of Violets; likewise with half a grain of Galls grated, it will turn of a fine deep purple. A gallon will yield about five or six grains of a kind of saline concretion, mixed with a yellowish earth, that will taste somewhat like vitriol of steel. It works chiefly by urine, and has been found good in want of appetite and indigestion: it is also good in vomitings, cholicks, nervous, and hysterical disorders, raising the spirits greatly. It is serviceable in the fluor albus, in weakness from miscarriages, and in the scurvy and all diseases in the skin: it is proper in obstructions of the mesentery, bladder and skin; and also in some paralytic disorders.

New Tunbridge-Wells are near the New-River-Head, at the entrance of Islington, on the side next London. The water has the taste of iron, and is a little styptic, with some degree of quickness both in smell and taste, especially in the summer season. It will lather with Soap, and turn a little milky with a large proportion of Oil of Tartar; but it will not let fall any sediment with volatile alcalies. A gallon will yield from 10 to 30 grains of a reddish earth, which will ferment with Oil of Vitriol. It is a light and comparatively pure chalybeate, of considerable strength at the fountain head; where it ought to be drunk. It is of great efficacy in all nervous disorders, and restores the strength after violent acute diseases: it opens all obstructions in women, and is excellent in a dropsy; in which case the dose is from half a pint to a pint, and no more. It opens obstructions of the glands, and is of some service in reducing corpulent habits.

NORFOLK has but one remarkable mineral Spring, which is at Thetford, a market town of great antiquity: the water appears to have somewhat of iron; for Galls will turn it first purple, and then black. It will let fall spontaneously a drachm of an earthy substance of the colour of ochre, which being calcined in a crucible, some of its particles may be attracted by a loadstone. From other experiments, it appeared to be impregnated with iron, sulphur and natron; it works gently by stool and urine, and sharpens the appetite: it restores lost strength, and cures pains of the stomach, and of the head, as well as fainting, vomiting, convulsions, and indigestions, difficulty of breathing, and the beginning of a consumption; it also kills worms.

NORTHAMPTONSHIRE has three mineral Springs, whereof one is at King's-cliff, eight miles south of Stamford, and it both smells and tastes of iron. It will let fall a white sediment with Oil of Tartar, and with Galls it precipitates a purple sediment; but turns of an opaque red with Logwood, and of a deep green with Syrup of Violets. A gallon yields 140 grains of sediment, 75 of which are limestone and ochre, and 65 a calcareous nitre. From various experiments it appears, that this water is of a chalybeate, laxative nature, impregnated with iron and calcareous nitre, with a small quantity of sea-salt, and a calcareous earthy substance. It will not purge a strong person, unless he drinks from three

to five quarts; but it has been used with great success, in disorders from obstructions, and in eruptions of the skin; it has also cured several lame persons.

Astrop is a village in this county, four miles south-east from Banbury in Oxfordshire; and the mineral water here is a brisk, spirituous, clear and well-tasted chalybeate. It lets fall a white sediment with Oil of Tartar; and a gallon, after evaporation, yields 17 grains of sediment, containing nitre and calcareous earth. Drank at the fountain head, it is a certain cure for all female obstructions, and in the first and second stages of consumptions. It seldom fails in the jaundice and beginning of a dropsy, and restores a constitution weakened by hard drinking: the dose is very large, that is, from three quarts to five in the forenoon; and some affirm it will cure madness and melancholy.

In the parish of King's-Sutton four miles south by east of Banbury in Oxfordshire, there is a mineral Spring, that has an intolerable strong smell like rotten eggs; but the taste is saltish, warm and pungent, like Salt of Tartar. A gallon yields 166 grains of sediment, of which 9 are earthy, and the rest salt, of a pungent, brackish and bitter taste, with all the characteristics of an Alkali. It is a purging water, strongly impregnated with sulphur, and an alkaline salt mixed with sea-salt. It is famous for discharging and healing of tumours, ulcers, and all diseases of the skin.

NOTTINGHAMSHIRE has a mineral Water at Kinalton, nine miles south-east of Nottingham. It is clear, pleasant, cooling, and a little saltish; it grows white and curdles with Oil of Tartar; but undergoes no alteration with acid spirits, and will turn of a beautiful light red with Tincture of Logwood. A gallon will yield 280 grains of a beautiful white sediment, the fourth part of which is a fine alkaline earth; and in the remainder is a remarkable pure, clear nitre. This is a purging water, that has not above half the portion of contents as Epsom water, nor will it work unless drunk plentifully.

At Orston, 12 miles east of Nottingham, there is a mineral Water, which, as it rises out of the spring, has a sweetish chalybeate, and a little roughish taste; but, when it has stood for some time, it becomes rough and harsh. A gallon yields 128 grains of sediment, of which the portion of the earth to the salt is as 27 to 9. The Water is a rich chalybeate, with a considerable quantity of sulphur, if drunk as it springs up; but the predominating salt is a calcareous nitre, mixed with a small quantity of sea-salt. It will purge those of a gross habit of body, and will turn the throat, tongue, and stools of the drinkers, perfectly black. It is good in the hypochondriac melancholy, scurvy, want of appetite, indigestion, pain of the stomach, costiveness and stoppage of urine. It is also good in the beginning of obstructions of the bowels, and likewise in ulcers of the lungs, and spitting of blood.

In OXFORDSHIRE is Chadlington Water, in a village of that name, three miles south of Chipping Norton. It smells like the washings of a foul gun, and a gallon yields 90 grains of sediment, of which 7 are earth, and the rest a peculiar sort of nitre. From other experiments it is found impregnated with sulphur, and an alkaline salt mixed with sea-salt: it is accounted a purging water.

Clifton is a village two miles east of Doddington, where there is a clear water that affords a sediment, which yields a peculiar kind of nitre, inclinable to an alkali. It is laxative, and is used to cure diseases of the skin in men and cattle, by bathing therein.

Doddington is a small market-town 16 miles north of Oxford, where there is a strong sulphureous water,

ter, that smells like the washings of a foul gun. A gallon yields 87 grains of sediment, whereof 44 are earth, and 43 salt. It is impregnated with sulphur and iron, both of which are very volatile; besides which, it has salt enough to give it a purgative quality.

RADNORSHIRE, in South Wales, has very remarkable mineral Waters at Llandridod, which is 24 miles west of Lempster in Herefordshire. Here there is a common six miles long and three quarters broad, and in that part of it lying in the above parish are the mineral Springs. These are the saline pump-water, the sulphureous water, and the chalybeate rock-water. The air is exceeding healthy, insomuch that weak and consumptive people, that come here to drink the waters, soon revive and gather strength. These Springs are now frequented by very genteel company, and in the summer time the common people resort here in crowds.

The Rock-water is so called, because it issues out of a rock, and a glass of it taken up in a clear warm day, is as bright as crystal; but after it has stood some time, it changes to a pearl colour. While it continues clear it has a strong chalybeate taste and smell, but they forsake it as it changes colour: at the spring head, it turns to a deep purple with powder of Galls, and becomes hot with Oil of Vitriol. However, it will not curdle Milk; but with Oil of Tartar it becomes as white as milk, which afterwards changes to a yellowish green. It preserves its transparency with acid spirits; but with Sugar of Lead it turns first milk white, and at length lets fall a yellowish grey sediment, from a quart of water, which after it has been analysed, is found to contain about 15 grains of crocus of iron, and about 5 of the bituminous mucilage of iron. From hence, and various other experiments, it is concluded, that this water contains iron, salt, sulphur and vitriol. It is good in all chronick distempers proceeding from a laxity of the fibres; particularly in scorbutic eruptions and weakness of the nerves, and disorders proceeding from the brain. It is also efficacious in obstinate agues, obstructions of the bowels, slow nervous fevers, and in all female disorders.

The saline purging water is called upon the spot the Pump-water, and from various experiments it appears to contain a neutral salt like native borax, a small quantity of bitumen, and an ethereal, elastick, volatile mineral spirit, and a mineral oil. It is excellent in all diseases of the skin, and in such disorders as proceed from corrupt humours: but if the disease is obstinate, it requires some time to cure it radically. Persons troubled with the scurvy, must use the water both as a purgative and alterative; and, for the last, a pint and a half should be taken at three doses, in the morning before breakfast. As a purge, half a pint must be drank at a time, till it begins to work. In diseases of the skin the patient must bathe frequently, and wash the parts affected with the water, and particularly in the leprosy, so much water must be drank, as to cause two or three motions every day; to which must be joined bathing twice a week in a warm bath, made with equal quantities of the pump and sulphureous waters. In the gravel, the patient must drink so much as will give him two or three stools, and when the gravel is discharged by this means, the patient must drink every morning half a pint of the rock water, and half a pint of the pump-water; also half the quantity going to bed.

The Sulphureous Water, commonly called the Black stinking Water, has its name from the strong smell, and the blackness of the channel through which it passes. It smells like the washings of a foul gun, and has the strongest smell in rainy weather. From various experiments, it appears to con-

tain ethereal, volatile, mineral spirits, a small quantity of a vitriolic acid, a mineral, unctuous mucus, a fine mineral oil, a subtle crocus, a perfect sulphur, and a neutral salt, of a briny, calcareous nature. It is of great use in all cases, where bathing is proper, made into a luke-warm bath. It is excellent in benumbed limbs, in wasting of the flesh, and in nervous disorders; as also in old sores, tetters, and in all diseases of the skin; as well as in the stone, gravel, rheumatism, and gouty distempers. Drank inwardly, and used outwardly, it cures the King's Evil, and is an excellent absorbent, insomuch that it is efficacious in soreness of the stomach, obstructions of the liver, and in the jaundice: it is also good in contractions and weaknesses of the limbs, and in broken constitutions from hard drinking. The dose cannot be determined, and therefore it is best to begin with drinking from a pint to a quart in a morning, that is, about half a pint at a time, with short intervals between the draughts: the quantity may be increased to as much as the constitution will well bear, that is, as much as will sit easy on the stomach, and pass off well.

SOMERSETSHIRE is remarkable for having two of the most noted mineral Waters in the kingdom, those of Bristol and Bath, besides others of different kinds: that at Bristol issues out of a rock, and in that city is called the Hot-well Water. It is seated on the north side of the river Avon, where there is a romantic and beautiful prospect. When first drawn off, it is of a whitish colour, at least sometimes, which it loses gradually as it grows cold, and many small bubbles arise in it when taken from the pump. The taste is exceeding soft; pleasant and milky, at the spring head, and is very agreeable to the stomach; but it leaves a sort of stypticity on the palate. It is entirely without smell, and is only lukewarm to the touch. It keeps well in bottles that are properly stopped, losing only a part of the elastick air, which flies off before the corks can be put in.

With regard to chemical experiments, if a glass of water is poured upon a few grains of Sal Ammoniac, it immediately dissolves it, with a very sensible effervescence. Oil of Tartar not only produces the same effect, but renders the water milky, which after it has stood a-while goes off, and lets fall a light earthy precipitate. Dissolved Soap, dropped into a glass of water, immediately curdles, and in a short time the surface is covered with a greasy substance, and the water below becomes turbid. Twenty drops of the Solution of Silver, mixed with three ounces of the fresh water, in three hours made it appear as if a small quantity of ink had been dropped therein.

These, and other experiments, seem to declare there is some degree of an acid in the Bristol water, though not discoverable by the taste; there is also a small portion of sulphur, because when bottles filled with this water happen to be broken, it will stink very much. A gallon contains about 34 grains of sediment, which is of a light grey colour, of a brackish taste, and bitter in the throat. This will ferment with acids, and turn green, after some time, with Syrup of Violets. The salt is white, but will not ferment with distilled vinegar; and in the air it will grow damp.

Bristol water is generally allowed to be cooling, cleansing and balsamick, with a considerable degree of astringency, which renders it excellent in the diabetes: it will also open the urinary passages, obstructed by gravel. It is useful in many chronic diseases, that will not yield to a common course of medicine, and it is serviceable in many internal inflammations. It strengthens the stomach, promotes an appetite, assists digestion, and will cure the first stages of a consumption. It is good in disorders of

the eyes, and will cure ulcers therein, if taken warm from the pump, and applied with a soft rag: it has also cured many scrophulous ulcers, by washing them in this water, others say those of the cancerous kind, drinking the water at the same time: it has also been found successful in the bloody-flux, all internal ulcers, preternatural discharges, and bleedings of every kind.

The method of drinking the water, when the patient first comes down, is to go to the pump-room in the morning, and drink a glass or two before breakfast, as also about five in the afternoon; the next day the patient takes three glasses before breakfast, and three in the afternoon: and this course is continued during his stay at the Hot Wells.

Bath water, when viewed by itself in a small quantity, appears clear and transparent; but when beheld in the Bath, the surface is of a sea-green colour. The smell is not very agreeable, especially in the Hot Bath; but when quite fresh it has a soft and milky taste. There are four Baths in this city, which differ from each other, chiefly in their degree of heat: namely, the Cross-Bath, the Hot-Bath, the King's-Bath, and the Queen's-Bath.

With regard to the experiments made with it, it is observable that when carried at a distance from Bath, it will precipitate Silver out of Spirit of Nitre into a hardish curd; but not so much as common salt: however, it is concluded from hence by some, that sea-salt predominates in Bath water. The King's-Bath, and Hot-Bath, will turn the solution of Silver white, with a bluish cast, which becomes gradually more dusk-coloured, and then deposits a dark grey sediment. The solution of English Vitriol, mixed with this water, turns to a pearl colour; that is, with the King's-Bath and Hot-Bath, and both will be covered with a thin variegated pellicle. With Oil of Vitriol, and other acids, the Bath waters will excite some intestine motion, and greatly blunt the acidity. If one part of boiling Milk be mixed with two parts of Bath water, a thin whey and curd will appear, if the water be just taken up. A drachm of Syrup of Violets will give a grass-green colour to an ounce of the King's-Bath water, as well as of the Hot-Bath in 24 hours time.

Some experiments shew there is a vitriolic principle in the Bath waters; for if they be taken fresh from the pump, in clear frosty weather, Galls will tinge them of a purple colour; but when cold, they scarce make any alteration at all. It is generally thought to be owing to the ferruginous principle of Bath water, that it will make better and blacker ink than common water. Likewise the sand of the Baths, exposed to the air for some time, will become vitriolic, and make ink with infusion of Galls. That there is an ochre in this water, appears from the yellow colour of the stones in the bottom of the Bath, and from the yellow matter like thin cream floating on the surface of the water, in the winter time.

From these and other experiments it is concluded, that there is a mixture of calcarious substance with the ochre; and the mud is found to consist of a bluish clay, with some testaceous particles; when it has been used as a cataplasm, it has somewhat of the smell of sulphur, and when rubbed on silver it changes it black. The sand, thrown on a red hot iron, emits a blue flame with a sulphureous smell, and being exposed to the air becomes vitriolic, as before observed.

A gallon of the Queen's-Bath water will yield 155 grains of sediment, the Hot-Bath 139, and the Cross-Bath 130. The quantity of a calcarious and argillaceous substance is double to that of the saline; the quantity of salt in each gallon scarce exceeds 43 grains, and the rest of the matter is a grit, with a blue sulphureous earth or marl. The gross remainder

No. 41.

emits a strong sulphureous smell, with a blue flame upon calcination, and by this operation a fourth part of the weight is lost, by burning away. The result of all the observations of different Physicians plainly shew, that the minerals in Bath water consist of a calcarious and marly earth and ochre, a marine or sea-salt, a little calcarious nitre, a glass of vitriol, a little bitumen, and a very small quantity of sulphur, which last can be made to appear no otherwise, than by consequences.

The Bath Physicians are agreed, that the Bath waters are useful in all diseases of the head and nerves, such as convulsions, palsies and epilepsies; in all diseases of the skin, obstructions of the bowels; in scirrhoties of the liver, spleen and mesentery; in most diseases of women, and in the scurvy and stone. The Bath waters are certainly a most powerful deobstruent, and their energy is so great, and their operation so sudden, that a very exact preparation of the body is required, and a stricter regimen than in drinking other waters. Likewise, a regard must be had to the habit of body, the season of the year, the symptoms of the disease, the changes of the weather, and the different degrees of heat in the several Baths. As for instance, the heat of the King's-Bath, without due precautions, is apt to inflame the blood, heat the bowels, and sometimes cause a fit of the gout. As to the manner of the operation of Bath waters, whether by bathing or drinking, or both, their effects are thus enumerated. Externally, they will heat, dry, attenuate, resolve and strengthen, and have a singular virtue in diseases from a cold and moist cause. They ease pains, disperse cold tumours, dry up moist ulcers, and are very advantageous in phlegmatic diseases. It is also remarkable, that nothing more effectually prevents too great a corpulency than the frequent use of these Baths. Bathing cures contractions and relaxations of the limbs, restoring lost sense and motion; but it is not proper in a fit of the gout, except in the decline of that distemper. It is also highly serviceable to those, whose sinews are impaired and crippled by the severe fits, and their frequent returns.

The Bath waters taken inwardly, to two or three quarts, commonly give two or three stools extraordinary; and it is remarked of the Hot-Bath, that it generally keeps the body open, while the King's-Bath has a contrary effect. When they are used as an alterative, they dilute, attenuate, sweeten, strengthen and heal, correcting the acrimony of the first passages, and curing the many disorders of those parts. They supply a want of spirits, and are good in diseases, where the secretions are diminished, as well as in all cachectic and scorbutic habits of body. They are very successful in hypochondriac disorders, and melancholy, as well as in disorders of the urinary passages, particularly sharpness of urine, the strangury, gravel, and ulcers of the bladder. The usual time of bathing and drinking these waters is generally five or six weeks, and, in obstinate cases, they must be repeated every year. The common quantity drank is from a pint to a quart and half a pint a day; but some have been allowed to drink a gallon every day, and then the patient must begin with small doses.

Alford is a village 24 miles south of Bath, and is remarkable for its mineral water, which has a nauseous bitter taste, and will curdle with soap, as well as yield a white grumous sediment with the solution of Pot-ashes. It turns of a dilute green with Syrup of Violets, and Galls will produce a greenish cloud on the surface, which descends deeper in two or three days. A gallon will yield six drachms of sediment, consisting of calcarious nitre and sea-salt, with a little lime-stone. It is cooling, cleansing, and penetrating; will attenuate gross humours, de-

stroy acrimony and temperate ebullitions of the blood; hence it is good in the scurvy, jaundice, and all sorts of obstructions. It cleanses the urinary passages, purges briskly, and promotes urine and sweat.

Lincomb Water is seated near Bath, and the water is by some called Lincomb Spa. When first taken up, it has a light, brisk, sulphureous smell, which it loses in six or eight minutes time; but its taste of iron is more lasting, that is, for the space of eight hours. It is transparent at first, but becomes bluish with standing, and throws up to the surface a thin, variegated unctuous scum. From various experiments it appears, that this water is impregnated with iron and a little sulphur, as also with bitumen, and a small quantity of alkaline salt. It passes off quickly by urine, mends the appetite, and raises the spirits. It is serviceable in disorders of the first passages, and is good in cachexies, the jaundice, and recent obstructions of the liver: it also deterges and heals ulcers of the kidneys, and removes the strangury. Outwardly, it cleanses and heals scrophulous ulcers, dries up sharp humours, and cures foulnesses of the skin.

Queen's-camel is a village five miles north of Sherborne, where there is a spring that proceeds from a hard rocky bank, and is called the Black-Well. It smells like the washings of a foul gun, and, from the trials made with it, appears to contain a considerable quantity of sulphur, some natron, and a calcarious earth. It cures, by bathing, scorbutic, leprous and scrophulous disorders; and it has been observed to cure dogs of the mange, by dipping them therein.

STAFFORDSHIRE has only three mineral waters, whose virtues are ascertained, one of which is at Codfall, a village 12 miles south-west of Stafford, that is in the wood adjoining thereto, which is a sulphureous spring, and the sulphur is mixed with salt, but not sufficient to restrain the volatility of the sulphur, so that in the winter, before rain, it may be smelled twenty yards off. It will lather with Soap, will not curdle Milk, and with Syrup of Violets will turn green; but neither Galls, Oak-leaves, nor a solution of Sublimated Tartar, would throw down the sulphur: however, Spirit of Urine did, and turned it of a faintish red. When leprosy was more frequent, this water was famous for curing them; but at present it is only used in scrophulous cases, and it operates both by stool and urine. They brew their beer with this water, and in Dr. Plot's time there was a house, called the Brimstone-Alehouse, where no one that lived there was troubled with diseases of the skin.

St. Erasmus's-Well is in the grounds belonging to the Lord Chetwynd, near Ingestre, two miles from Stafford. The water is clear, and of the colour of Sack, but has no remarkable taste, nor smell. A gallon of this water will yield 300 grains of sediment, whereof 272 are salt, and the rest moss. We are not told what diseases it is used for, nor indeed that it is used at all.

Willoughbridge is six miles north-east of Drayton in Shropshire, and in the park near it there is a well, whose water is as clear as crystal; but it renders the sides of the glasses, after they have been used awhile, a little oily, and of a bright yellow colour. If a few drops of a solution of Sublimate be let fall into this water, it presently becomes of a deep sack-colour, which seems to shew it has somewhat of a lixivial salt. It will lather with Soap, but will not curdle with Milk, nor change colour with Syrup of Violets. Contrary to most other waters, it leaves nothing behind it, after the evaporation of several gallons. Its oil or sulphur is so very volatile, that when distilled in a glass body and head, the Oil of Sulphur comes over the helm, upon the first heat, and is

always in the receiver, before the least drop of water appears. There is such plenty of this water, that at least 60 springs have been counted, that send forth plentiful streams. Dr. Plot informs us, that these waters have performed many wonderful cures, which he attributes to its balsamic virtue, and its great subtilty and volatility; and he farther adds, if we were to judge of the waters, from the many attested cures, it bids as fair for an universal medicine, as any thing else in the world.

SHROPSHIRE has a mineral water at Moreton, a village two miles west of Market Drayton, which will not lather with Soap, but curdles Milk, and yields a white sediment with Oil of Tartar; it turns green with Syrup of Violets, and scarlet with Log-wood. A gallon of this water will yield 277 grains of sediment, whereof 76 are earth, and the rest a calcarious nitre. It is an excellent cooling diuretic and cathartic, and purges very briskly. It bears a great resemblance to Holt water, only the taste is more pungent, and consequently it is very likely to have the same virtues.

Pitchford is a village six miles south by east of Shrewsbury, which takes its name from the pitchy spring that is found there, on the top of which there floats a liquid bitumen, though it is scummed off every day. It is found to be excellent for wounds, and will cure inveterate scrophulous ulcers.

Broseley is a village four miles north-east of Wenlock, and has a burning Well, which was discovered about the year 1711. A candle being put down into the well, it will take fire at the distance of a quarter of a yard, darting and flashing in a violent manner, to the height of 1820 inches. It is hotter than common fire, and boils any thing much sooner. It appears to be impregnated with a sort of liquid bitumen.

In SURRY there are several mineral waters, the most famous of which is at Epsom, a town about 15 miles south-west of London. The water is pretty clear and without smell; but if it be kept in covered vessels for some weeks in summer, it will stink, and acquire a nauseous bitter taste, with somewhat of a maukish saltness. It will curdle with Soap and Salt of Tartar, and with Spirit of Sal Ammoniac it will let fall a grumous sediment; but if mixed with lime-water, it will continue clear. A gallon will yield an ounce, sometimes an ounce and a half, of a sort of cream and sediment, which is of a greyish colour, almost impalpable, of a brackish, nauseously bitter taste, and an odd strong flavour. There are about eight parts of salt to one of earth, the former of which is of a whitish yellow colour, and of a singular strong smell, with a nauseous bitter taste. All authors agree, that the crystals of this salt will require but a small proportion of water to dissolve them, for an equal weight has been found sufficient. The salt has a purging quality, for half an ounce, dissolved in spring water, will work like other physic. The water itself is a diluent, and a mild absorbent: it is also diuretic and cathartic. Poor people formerly used to wash old sores with the water, with a good effect. A dose of the water, in summer, is two thirds of a pint, and in the winter, half a pint.

Stoke is a village two miles south of Cobham, where there is a spring commonly called Jessop's-Well. This water is thought to contain more salt than any purging water in England, and it has a taste much like that of Epsom-Wells. A gallon of this water yields an ounce and a half, with 22 grains of sediment, that is, 742 grains in all. It is very white, and has somewhat of a brackish taste, with a nauseous bitterness. The earthy matter bears but a small proportion to the salt, which, as Dr. Hales informs us, will shoot into very bitter, irregular oblong crystals, some of which have retained

tained their former firmness, for five years at least. Half an ounce of distilled water will dissolve only 10 grains of salt, though standing by the fire-side, in which it greatly differs from that at Epsom. From the experiments made with it, it appears, that this water contains a large proportion of calcareous nitre, a little salt and calcareous earth, and very probably a little natron. A less quantity will suffice for a dose than of any other; for which reason it fits better on the stomach, and enlivens the spirits of those that drink it. It has been long noted as a good purging water; for a single quart will purge pretty briskly, and promote plenty of urine without gripes. It cures obstinate scorbutic cases; and, as some think, there is a fine volatile spirit in the water; it may be drank for a considerable time, as an alterative, with happy consequences.

Stretham is a village six miles south of London, that has been long remarkable for its medicinal spring. The water has somewhat of a yellowish tinge, and throws up a scum variegated with copper, blue and green colours. At the spring head it has a saline nauseous taste, and a gallon will yield 200 grains of sediment, the salt of which has a penetrating, brackish taste, with a strong flavour, and in the air it will almost melt. This is partly marine, and partly nitre, enveloped with a little sulphur, and a greater proportion of absorbent earth. When it was most in vogue, three pints boiled to a pint and a half were given as a purge; for it operates both by stool and urine, and it has been found good in disorders of the eyes.

The Dog-and-Duck is a noted public house in St. George's-Fields, in the parish of Lambeth near London. The water is clear, and has very little taste; but a gallon will yield 200 grains of sediment, of a dirty colour, and a pungent, brackish taste. The earthy matter is as one to twelve, in proportion to the salt, and it will ferment strongly with Spirit of Salt and Spirit of Vitriol; but will not turn to perfect lime by calcination. This water has been noted for curing leprous disorders; and some have affirmed, that it cured an ulcerated cancer in the breast by drinking the water, and keeping a cloth, wet therein, always over it. Being drank from one pint to three, it generally purges easily and briskly, without affecting the strength, unless in very tender constitutions. It may be taken as an alterative, instead of common drink, for the cure of scorbutic pimples, tetters, the leprosy, and the king's evil. It is also a palliative cure in cancerous disorders, and has been the means of prolonging the lives of several. The only fault of this water is, its being too cooling, for which reason it is prejudicial to persons of phlegmatic constitutions, and of weak habits of body.

Cobham is a town seated in the road between London and Guildford, and is seven miles south-west of Kingston. The water has a sensible taste of iron; and a gallon will yield seven grains of a substance like ochre, which a loadstone will attract, without calcination. It is a strong chalybeate, and deserves to be more known.

WARWICKSHIRE has two mineral springs, one of which is at Lemington, three miles south-west of Dunchurch, and is of a saline nature. A gallon yields 960 grains of sediment, 30 whereof are calcareous nitre, and the rest sea-salt. It is a strong purge and vomit, and is drank by labouring people from two quarts to three. It is noted for curing sore legs, and diseases of the skin.

Ilmington is a village seven miles south of Stratford upon Avon, and the water found here, though it has a brackish taste, is one of the strongest chalybeates in England. It sparkles at the spring head like bottled cyder; but it will not curdle with Milk, and yet Oil of Tartar will procure a small coagulum.

It will turn purple or black with Galls, according to the quantity; but with Syrup of Violets it changes to a green. A quart of water will yield near a spoonful of a reddish white powder, that will ferment and fume with acids. Those that drink this water have their stools tinged blackish, and though it generally operates by urine, it will sometimes purge. Internally, it is good in the scurvy, obstructions of the bowels, the jaundice, and beginning of the dropsy; it is also good in the strangury, and difficulty of making water.

WESTMORELAND has a mineral water at Kirkby-Thower, a village eight miles east of Penrith, which is a weak purging chalybeate. It is exceeding clear, sweetish, and has a little taste of tea. It grows whitish with alkalies, and turns to a clear purple with the Solution of Silver; but it becomes of a pink purple with Galls, a red purple with Logwood, and a deep green with Syrup of Violets. A gallon contains 190 grains of sediment, of which 140 are lime-stone, and 50 a calcareous nitre. The salt will not dissolve entirely in 48 times its own weight of distilled water; but it will turn of a pale green with Syrup of Violets. This water is a more powerful absorbent than any other of this kind, and it will purge well, if drank to the quantity of three or four quarts.

Shapmore is a marshy heath, lying between the mountains to the north of Shap. The water here seems to be of a sulphureous nature, for it has a strong foetid smell, and a sensible bitterness; but this soon goes off when it evaporates over the fire. It will curdle with Soap, and let fall a large white sediment, with the Solution of Pot-ashes. A gallon will yield 376 grains of a saline sediment, with a small proportion of very white earth. It is very white, and has a salt, pungent, bitter taste, growing moist when exposed to the air. This water has been casually found to work by stool and urine, and three pints have proved a very strong purge. It will cure inveterate piles, and is used by the common people to cure rheumatic pains in the joints, by rubbing it warm on the parts affected.

Wisherlake is a village seven miles south-west of Kendal, where the mineral spring has a saltish taste, and in summer smells a little like sulphur, throwing up a whitish scum. With Oil of Tartar it lets fall a pearl-coloured sediment, and with Galls it precipitates one that is purple. A gallon yields 547 grains of sediment, consisting chiefly of sea-salt and a calcareous earth, with a little mixture of a bitter, purging salt. From experiments made with it, it appears that it is chiefly impregnated with sea-salt, combined with a kind of calcareous nitre, a little iron, and a small quantity of sulphur. It has been found of great use in the stone, gravel, worms, want of appetite, the cachexy, jaundice and dropsy.

WILTSHIRE has a mineral spring at Chippenham, lately taken notice of, and was found in a garden near the river. At the spring head it has a brisk ferruginous taste, and turns of a claret colour with Galls. A gallon will yield 39 grains of a sediment of the colour of ochre, which has a very brackish taste. It contains a strong sea-salt, and a natron combined with iron. It has cured scorbutic disorders, besides others that are not particularly taken notice of.

West Ashton is a hamlet in the parish of Steeple-Ashton, four miles east of Trowbridge, which has a spring that yields plenty of water all the year round. It is clear, and will deposit a small quantity of sediment, after it has been kept several months in bottles. It will curdle with Soap, and lets fall a white grumous sediment with the Solution of Pot-ashes. A gallon will yield two drachms and two scruples of a whitish sediment, with a saline bitter taste.

taste and warmth on the tongue. It is chiefly impregnated with sea-salt, nitre, and a little iron, with a small matter of sulphur. The water is best drank at the fountain head, and three pints is purging and diuretic.

Road is a village eight miles north of Bath, where there is a mineral Spring, whose water has a chalybeate and sulphureous taste and smell. A gallon will yield near a drachm of a yellow coloured sediment, that has a salt and pungent taste. The water appears to be impregnated with iron, sulphur, and a strong, native alkali or natron. It is a very gentle purge, and is good in scrophulous cases and diseases of the skin; it will also cure scorbutic ulcers.

Holt is six miles east of Bath, and is of note for its medicinal spring, first taken notice of in the year 1713. It will let fall a gross, grumous sediment with Oil of Tartar, and when mixed with Spirit of Sal Ammoniac, a white crusty substance adheres to the sides of the glass. It will not lather with Soap, but will ferment with Oil of Vitriol. With Syrup of Violets it will become greenish, and with Galls change to a green. Logwood turns it to a deep red, Brazil Wood to a scarlet, and Rhubarb to a pale amber colour. A gallon will yield 176 grains of very white sediment, which has a saltish, bitter taste, and will grow moist in a damp air; but the earthy part is nearly equal to the salt. This water principally contains a calcareous nitre, and the operation is more mild than other springs of this kind, on account of a large quantity of earthy matter contained therein. In small doses it is an alterative and diuretic; but two quarts will purge pretty briskly. It will dilute, cool, absorb and strengthen, and is used both externally and internally. Rags, or a sponge, dipped therein, will cure scrophulous ulcers, attended with carious bones; but then it must be taken inwardly at the same time. It will also cure inveterate running ulcers of the legs and other parts, and diseases of the skin, attended with great heat and corrosive humours. It is good for sore eyes, the piles, and ulcers of a cancerous nature, used outwardly and drank inwardly. It never fails of procuring an appetite, and will strengthen the relaxation of any part.

YORKSHIRE has several mineral Springs, of which the principal one is at Malton, otherwise called New Malton, that lies in the road from York to Scarborough. The spring lies at the west end of the town, and is so strongly impregnated with iron, that it is called the Malton Spa. Seven pints contain three drachms and a half of a reddish brown sediment, which has an austere bitterish taste, and a salt of a calcareous nitre, though different in some sense from others; for it will not ferment with Oil of Vitriol, nor Spirit of Salt; but it will turn greenish with Syrup of Violets. The mud and scum of this water will dry up and heal old ulcers, scabs and tetter to a wonder. Internally, the water works agreeably by stool and urine, unless the stomach be foul, and then it will vomit the first day or two. The common dose is from three pints to six; but some think smaller doses would be more proper. It is good in the hypochondriac melancholy, in an asthma with spitting of blood, and in internal ulcers and bleedings. It is also recommended in obstructions of the bowels, and in a relaxation, weakness, and languidness of the body, it being a strengthener and a deobstruent as well as a purge.

Croft is a village in the North-Riding of Yorkshire, on the confines of the bishoprick of Durham, where there is a spring of fine, clear, sparkling water, with a strong smell of sulphur. A gallon yields 177 grains of a very white sediment, which has a strong smell like that of hawthorn flowers. It consists of lime-stone, nitre, and sea-salt; but the nitre is double or treble to the latter. It is a purging wa-

ter, if drank from four pints to nine, and is said to have performed many eminent cures, both by drinking and bathing.

Harrowgate is two miles north-west of Knaresborough, in the West-Riding; it is supposed to be the strongest sulphureous water in Great Britain. A gallon of that commonly drank, for there are three wells, contains two ounces of pure sea-salt, and near two scruples of earth; therefore the predominating salt must needs be marine. A warm bath made with this water cures aches, bruises, strains, lameness, weakness of the back, beginning of the dropsy, and paralytic pains and weaknesses. It also dissolves hard swellings, cures old ulcers, and all diseases of the skin; it has also great power in easing the gout and sciatica. Internally, drank from three to four pints, it purges briskly, and raises the spirits. It powerfully cleanses the stomach and intestines, killing all sorts of worms; besides which it will cure the cold scurvy, and help the jaundice of many years standing. It also cures disorders of the spleen, the green sickness, cramp, the head-ach, and the king's evil.

Broughton water proceeds from a spring, in the road from Skipton in Yorkshire, to Coln in Lancashire, the village being in the mid-way between those two places. It is of a whitish colour, and colder than common water, as is observable in others of the sulphureous kind. A gallon contains four drachms of sediment, the fourth part of which is earth, and the rest sea-salt and nitre. The virtues are much the same as those of Harrowgate water, but weaker.

Wigglesworth is a village in the West-Riding, four miles south of Settle, where there is a spring remarkable for yielding an alkaline nitrous salt. It is very black, and has a strong smell of sulphur, with a saltish taste, and lathers with Soap; but will not curdle Milk. Three gallons yield seven drachms of sediment, of which six scruples and a half are black earth, and the rest salt. The country people drink four or five pints of this water as a vomit, and six or seven as a purge; but it seems strange that more should be required for the latter than the former.

Newton-dale is in the North-Riding, 12 miles west by north of Whitby. The water here is cold and very astringent; and it petrifies every thing in its course, producing various and beautiful incrustations and figures. It effectually cures loosenesses and bleedings of every kind, both in men and beast; and it quickly and wonderfully restores weakened joints, that are even beginning to be distorted, by bathing therein.

Knaresborough is noted for a dropping Well, so called, and is a market-town in the West-Riding. The water is very cold, extremely limpid and sweet, and it will let fall a white sediment with Oil of Tartar. It has a petrifying quality, and its particles consist chiefly of spar and some sulphur. A gallon of the water, that fell from the petrifying rock, yielded 185 grains of sediment, of which seven scruples and four grains left five scruples and four grains of earth, which would ferment with acids; and there were two scruples of salt, which shot into nitrous crystals. It cures inveterate fluxes of the belly, bloody fluxes, and the diabetes, as well as all preternatural discharges of blood; also colliquative sweats, as well as ulcers of the bowels, and hectic fevers. Three half pints are a dose.

Scarborough Water is the most noted in all Yorkshire, and was discovered about 160 years ago. It has been much used of late years, not only at the fountain head, but at distant places. The taste is bitterish and ferruginous; it curdles with Soap, and yields a large white grumous sediment with Oil of Tartar. A gallon yields about 284 grains of a red-

dish white colour, with a bitter, saltish and roughish taste. It destroys the sourness of acids, ferments strongly therewith, and turns of a light green with Syrup of Violets. The proportion of earth to the saline parts is as 66 to 150. The water has been found good in hectic fevers, the rheumatism, scurvy, preternatural thirst, recent and partial inflammations, and diseases of the skin. It is also good in disorders of the stomach from intemperance, as well as in hypochondriac and hysteric disorders; in asthma, in habitual costiveness, the heart-burn, and in all cases where purging is indicated.

CHAP. III.

Of EARTHS and CLAYS.

THAT sort of Earth, which we call SOIL, proceeds from the putrefaction of animal and vegetable substances, and will burn in the fire and swim in the water. Linnæus has nine sorts of these, whereof one does not properly belong to this class: the others are, the Marshy Soil interwoven with roots, and this is the same that we call Turf, which in many parts of England is used for such. The Vegetable Watery Soil is nothing else but Mud, and is to be met with every where in and about standing waters. The Spungy Soil of heaths will ferment with some sort of fluids, particularly acids. The Vegetable Soil of the Alps is to be met with every where among those mountains, and is a little reddish, or rather of a blackish brown. The Vegetable Common Black Soil is met with in various places, particularly in meadows, fields, and pastures. The Vegetable reddish Soil, partaking of Ochre, is particularly found in West Gothland. The Animal Soil of brute beasts may be met with in places where several of those animals have been laid in heaps, and have putrified and turned to Dust; that of human bodies may be seen in every church-yard.

A CLAY is a heavy, thick, fat, tenacious, smooth Earth, which when held in the mouth becomes like soap or suet; it is either soft or hard, in proportion to the quantity of Water that is mixed with it, for it readily dissolves in that fluid. When it is soft, it may easily be shaped into any form; but, when it is baked in the fire, it turns into a stony substance. There are a prodigious number of different sorts of Clay, and of different colours.

The Clay that is perfectly pure and white is of a very fine texture, and when cut, leaves a polished shining substance; when examined by a microscope, it appears to be of a close, even, regular texture, unless mixed with particles of a different kind. It will ferment pretty briskly with Aqua Fortis, as will most other kinds; for Linnæus makes it a characteristic of Clay. Whether we have here any of this sort is uncertain.

The CIMOLIAN EARTH of the shops is a sort of Fullers-earth, and is of a dull white colour, though the surface is tolerably smooth. When burnt in the fire, it becomes very white and hard, and in a violent fire will turn to a dirty sort of Glass. It is to be met with in several parts of England, particularly at Wedensbury in Staffordshire, where they use it for making tobacco-pipes, as they do another sort, which is hard, heavy, and of a greyish white, which is said to be the best of all Tobacco-pipe Clays. Besides these, there are the White Tough Clay, the Smooth Greyish White Clay, the Heavy Grey Clay, the Soft Grey Alkaline Clay, a Hard Grey Alkaline Clay, a Soft Ash-coloured Heavy Clay, and several other kinds, whose differences are not so considerable as to be particularly insisted upon. They are used for making tobacco-pipes, Dutch tiles, and several sorts of earthen ware.

The EARTH of MALTA, so called from the Island from whence it is brought, is a sort of Clay of a whitish ash colour, and is imported in small cakes, marked with various characters.

There are four sorts of YELLOW CLAY, all which will ferment with Aqua Fortis; one of these is entirely yellow, another yellow with blue spots; the third is a sandy Clay, and consequently brittle, as well as the fourth, which is of a brownish yellow. They are all of use for making some sorts of earthen ware.

The Hard Brown Spotted CLAY is in some degree transparent, and is of a fine shining pale brown, variegated and spotted with deep black. It does not stain the hands when touched, and yet it adheres firmly to the tongue, having a sort of an astringent taste, but without grittiness. This is what is usually called Lemnian Earth, or The True Sealed Earth, and is brought over in small cakes, weighing above four drachms each, and marked with several characters. The island on which it is dug was formerly called Lemnos, but now Stalimene. The virtues of this Earth, or Clay, were formerly much celebrated, and it was given as an antidote against poisons. It was supposed to be of an alkaline substance, but this is found to be a mistake; for it will not ferment or effervesce with Aqua Fortis, nor indeed several others, notwithstanding what Linnæus has said to the contrary. When analysed, it is found to contain a small quantity of an urinous volatile Salt, a small matter of bituminous oil, and a little Salt like common Salt. It may be easily dissolved in Water, and has been given in some disorders; but it is now not used with us.

There are three ENGLISH CLAYS of the brown sort, as the Brown Heavy Tough Clay, with which they floor barns in some places, and in others make earthen vessels. The Dusky Bluish Brown Tough Clay, which when burnt in the fire turns to a red colour, and in a violent fire to a deep grass green; however, it is most useful for making of tiles. The Hard Pale Brown Clay is generally full of shining particles, and is of a rough kind; but being mixed with tougher Clay in Staffordshire, it serves to make strong vessels of several kinds.

The Bluish Brittle Soft CLAY has somewhat of the nature of Marl, and when dry it appears to be full of shining particles. It burns to a darker colour, and is used in several parts of England for making a very strong sort of earthen ware. The Tough Bluish Clay has an even smooth shining surface, and when burnt in the fire becomes as hard as stone, and of a fine red colour. It is to be met with in Northamptonshire, but at present is made no use of. The Hard Tough Pale Blue Clay is extremely heavy, and of a close, even texture; being burnt it turns to a pale yellow, but it will not well endure the fire. It is used to make gally-pots, and the like. The Light Soft Blue Clay is of a loose texture, and burns to a pale reddish brown; there are but small quantities found of it at a time, and therefore it cannot be supposed to be much in use in making any sort of vessels. The Hard Tough Whitish Blue Clay is supposed to be that with which they make China ware here in England when mixed with other things; however, this is not certain.

The Green Heavy Turf CLAY is a fine smooth compact Earth of a dull dusky green, and very heavy. It has hitherto been put to no use. The Pale-Smooth Green Hard Clay is of a smooth, even, regular texture, very heavy, of a shining surface, and almost as hard as Stone. When a thin piece of it is held up to the light it is almost transparent; but in the fire it loses its green colour, and turns to a pale grey. It has been brought from Saxony in Germany.

VERDITER is a sort of bluish green hard Clay, and is usually dug out of the Earth in lumps of different

ferent sizes, that is, from half a pound to six pounds and upwards. It is a fine even glossy surface, and very smooth to the touch: it does not colour the hand: but when it is drawn along a rough surface it leaves a dusky green line. When burnt it is of a dusky brown colour, being entirely divested of its green or blue. It has been brought from several parts; but that from Italy is the best, and is much used by painters.

The ENGLISH VERDITER is got out of Mendip Hills in Somersetshire, and is a hard, heavy, firm earth, of a deep dusky green colour; when burnt it becomes as hard as stone, and of a very pale whitish brown colour. There is another Greyish Green Brittle Clay, that is met with in Mendip Hills, which bursts and crackles in the fire, though the change of the colour is very small; but it acquires a considerable hardness.

The Soft Pale Red CLAY is very clammy while soft, but when dry it is compact and hard, and of a very beautiful pale red, variegated with grey, at least sometimes. In the fire it grows as hard as stone, but the colour is much the same. It is brought to London from the Isle of Wight, and is said to be of some use to the workers in mahogany wood. The Pale Brownish Red Smooth Clay has somewhat of a Brownish cast, and is commonly veined with Pale Bluish Grey Clay; it is considerably heavy, and of a very close even texture. It crackles at first in the fire, but becomes pretty hard. In Staffordshire it is part of the composition of their finest earthen ware. The Dusky Brown Reddish Blue Clay is found in several parts of England, particularly in Staffordshire, where it is a principal ingredient in their fine earthen ware.

The Light Brittle Black CLAY is more dry than the generality of this sort, and not quite so tough; but it is seldom met with except in small quantities at a time. In the fire it emits a pale blue flame, with a sulphureous smell, and burns to a very deep red. It is common in many parts of England. The Tough Heavy Black Clay; while in the bed, is of a shining jet black, extremely heavy, and pretty moist, with a fine glossy smooth surface when cut with a spade; when dry, it becomes extremely heavy and compact, and will not dissolve easily in water. In the fire it becomes as hard as stone, and of a pale red colour; it was formerly unknown in England, but has been lately met with in Staffordshire and elsewhere. The Heavy Brittle Black Clay is very fine, heavy, and of a smooth compact texture. When burnt, it becomes perfectly white, for which reason in Northamptonshire it is used for making tobacco-pipes.

There are sealed EARTHS in Germany, so called, because they are marked with particular seals; the principal of which are at Gran in Hungary, and Goldberg in Silesia. That of Gran is called the Marrow of Gold; it is of a yellow colour and fat, seeming to be of a soapy substance, and melting in the mouth. It is got out of the gold mines near Gran, and is under the care of the magistrates, who have it made into round balls, and marked with the city seal. They suppose it to be impregnated with a golden Sulphur. The Goldberg Sealed Earth has the name of the Marrow of Silver, and is of a whitish grey colour. It is supposed to be derived from silver, from whence it has its name. It is not brought into medicinal practice.

CHAP. IV.

Of MARLS.

MARL is an earthy, brittle, light substance, between Clay and Chalk; for it is not so soft

and fat as Clay, nor so hard as Chalk, nor will it very easily dissolve in water.

CIMOLIAN EARTH is heavy, but loose and apt to crumble, for which reason, being thrown on the surface of the earth, it soon moulders away. It has not the least effervescence when put in water; for it only melts away, and turns to a sort of fizy liquor of a greyish colour. It is not at all affected with the oil of tartar, but spirit of salt poured on it causes it to ferment. It is pretty fat and soapy.

SAMIAN EARTH is very fine, pure, of a close equal texture, and yet remarkably light; when dry, it is of a fine bright white, with a smooth polished surface; it is very soft to the touch, and adheres firmly to the tongue; when burnt in the fire it becomes of a snowy white, and is found in the Isle of Samos; but this, as well as the former, is not at present used in medicine.

The SAMIAN ASTER is by some called Samian Earth, but it differs greatly from the former, it being of a loose texture, and will not cut into regular pieces. It is of a pale brownish white, and seems rough, dry, and dusty to the touch, but adheres firmly to the tongue. It turns to a pale ash colour in the fire, and is found between clefts of stone in the Island of Samos.

CHIAN EARTH is a dense compact substance, but of a soft texture, and easily broken in pieces. When dry it has an irregular surface of a pale greyish white, and seems to consist of numerous flakes. It is very fine and soft to the touch, adheres firmly to the tongue, and melts freely in the mouth. Thrown into the water, it causes it to bubble with a hissing noise, and melts into a substance like cream; in the fire it becomes perfectly white, and is found in the island of Chio; but it is of no use in medicine.

CELENEUSIAN EARTH, by some called Mineral Agarick, is found in the perpendicular clefts of the strata of stone, in irregular masses of a fine pure white colour. It is spongy, brittle, whites the fingers, and adheres firmly to the tongue. When thrown into water, it sends up a great number of bubbles with a hissing noise, and turns it white. It comes to a snowy whiteness in the fire, and is found in stone quarries almost all the world over.

The White Spongy Dense MARL is not so white as the former, but is of a more dense texture. It is frequently found in the cavities of stones, and, if alone, generally near the surface of the earth. When it is dry, it becomes of an uneven compact texture, moderately heavy, and of a dull dead white. It bubbles in the water like the former, with a hissing noise, and is found in many parts of England.

Hard Spongy Alkaline White MARL, called by some Native Lime, is a hard, dry, coarse earth found in the clefts of stone, and sometimes lying loose upon, or immediately under them. It is of a dull whitish colour, with a small mixture of greyish brown, and is of a more firm texture than the former earths. It bubbles and hisses like the former, and will cement like Lime. It is found in some parts of England.

MELIAN EARTH, found in the island formerly called Melos now Milo in the Archipelago, is not unlike the Cimolian, and is made use of there for washing of linen.

CRETAN EARTH, or CHALK, was so called by the antients, because it was found in the island of Crete, now Candia; but it is now to be met with in most parts of the world, and particularly in England, in very great plenty, where there are many large hills of it consisting of nothing else. It is an Alkali, and therefore is given in acidities of the stomach, and the heartburn, when properly prepared; though some take it as it is for that purpose without any preparation. It is likewise good in coughs that proceed from an acrid phlegm. It is commonly given from

from ten grains to a drachm, but there is no danger in taking larger doses.

Bluish Chalk MARL when dry, after it is taken out of the earth, is of a hard texture, of a bluish colour, generally veined or spotted with red. It is very soft and smooth to the touch, and will not adhere to the tongue, at least very little. Burnt in the fire, it turns to a palish brown, streaked with dark red. It is found in some parts of England, and in some places serves to manure land.

Bluish Brown Brittle MARL is of a loose texture, and very light. It is soft to the touch, and adheres a little to the tongue, melting freely in the mouth, it being a pure fine earth. It is somewhat alkalious, and when burnt turns to a dirty reddish brown colour. It has sometimes a great many sea shells found in it, and is a good manure for land.

Stony Bluish MARL is the hardest of this class, and is of a rough compact texture, with an unequal surface. It bubbles in water, but will not ferment with aqua fortis, and in the fire turns to a dull dusky red. This and the former are found in several parts of England.

Yellow Brittle Sandy MARL breaks into small pieces, when dug out of the earth, and when dry is of a brighter yellow than before it was dug up, which is the property of all colours; for a little water will turn them darker. It is spangled all over with small, flat, glittering particles, and is rough and dusty to the touch. When burnt in the fire, it turns to a fine deep red, and is a good manure for heavy stiff Clay lands.

Pale Red Brittle MARL is always found in the cavities of Stone, or in perpendicular clefts of the Earth, and has a fine, compact, close texture, with an even, smooth, soft surface. It is common in Germany, Italy, and France.

Red Brittle Heavy MARL is very common in England, and is a good manure for poor hungry land. It is of a crumbly texture, and commonly very dry; it becomes of a deeper red in the fire, and much harder.

Deep Dusky Red Sandy MARL is frequently found variegated with whitish, greyish, or bluish Earths, and is of a loose crumbly texture. It melts very readily in the mouth, but leaves a great deal of harsh, sandy matter between the teeth; when burnt it becomes of a deeper red, but not much more hard, and is found in our North American Plantations.

Stony Red MARL is greatly valued by the farmers for making a good manure: for, though it is almost as hard as a stone when laid upon the surface of the earth, it will crumble to bits, which perhaps is owing to the rain, as it will break to pieces in about ten hours time in water. Fire makes little alteration in it, and it is found in several parts of England.

RUDDLE, by some called Red Ochre, and by others Marking Stone, is a sort of Marl of a thin texture, and very brittle. It is of a red colour, and has a smooth soft surface. When burnt it becomes pretty hard, but does not change the colour. It is used in the country for marking of sheep, and by the painters for colouring of pales, window shutters, and the like. The best is said to be brought from Derbyshire.

Red Heavy Hard MARL is firmer and drier than the former, it being of a regular close texture, and composed of several thin plates lying close upon each other. In the fire it burns to a darker red, and grows much harder. It is used by the furriers to mark with.

Brown Brittle MARL is of a loose texture, and easily crumbles, but makes a very good manure. It is sometimes variegated with grey, and sometimes with black, and is a little dry and dusty to the touch. When burnt it becomes of a pale red, and somewhat more hard. It is used to manure grass land in Suffex.

Fullers EARTH is well known almost to every one, being commonly used for getting greasy spots out of cloaths. It is soft, and of a greyish colour; but sometimes paler, and sometimes of so deep a colour as to be almost black; though it has always a greenish cast. It melts freely in the mouth, and for its softness and smoothness is sometimes called Soapy Earth.

Green Fullers EARTH is the most dense and compact of all kinds of Marl, and is of an even smooth texture, being extremely soft and oily to the touch. It melts freely in the mouth, and in the fire turns to a very pale brown. It is found in Germany, where it is used as common Fullers Earth.

Green Sandy Brittle MARL, though very heavy, is of a loose texture, and easily crumbles in pieces. It is found in many parts of England, and is used in Suffex to manure clay lands.

Black Brittle MARL is of a loose texture, easily crumbles, and is very heavy; though it is of a brownish black, it does not stain the hands. It is found in Mendip Hills in Somersetshire, above twenty feet deep in the earth.

CHAPTER V.

Of LOAMS or EARTHS found in Strata or Beds.

THE WHITISH LOAM is coarse, loose, soft, and moist, while in the stratum; and though it is easily cut with a spade, it will not stick thereto. When dry it is of a loose crumbly texture, considerably heavy, hard, harsh, and gritty to the touch. It does not at all stick to the hand, but will melt freely in the mouth, and makes a slight hissing noise when thrown into the water, where it almost immediately falls into a loose powder. It is composed of a large coarse white sand, united to a greyish marly clay, and will burn to a pale brownish red. It is sometimes mixed with stiff clays in making of bricks.

The Brownish White LOAM is of a fine even texture, and consists of very fine white sand joined to a pale brown clay. When it is cut with a spade it leaves an even surface, and when dry it is of a whitish brown colour, but very pale. It does not break very easily between the fingers, nor does it stick to the hands; but it will melt in the mouth, though slowly, and makes a violent effervescence with aqua fortis. It is used for making bricks mixed with clay, and then turns to a pale red colour.

The Pale Yellow LOAM is of a spongy texture, and consists of white sand united to a yellow clay. When it is cut with a spade, it leaves irregular masses, with a rough uneven surface behind it, and when dry it is loose and spongy, and seems mixed with a great number of shining particles. It is harsh and dry to the touch, and crumbles readily between the fingers, but does not stick to the hand. It makes an effervescence with aqua fortis, and turns red in the fire; but it is never used alone for bricks.

The Rough Yellow LOAM consists of a coarse yellowish sand, joined to a pale yellow clay, which in a few places is white. It is smooth when cut with a spade, and when dry is extremely hard. It makes no effervescence with aqua fortis; but when thrown into the water it makes a little hissing noise, and soon falls into a loose powder. It turns to a deep red in the fire, makes excellent bricks for building furnaces for melting iron, and even endures the fires of the glass-houses; it also makes fine lutes for chemical vessels. It is met with near Hedgerly, five miles from Windsor, and bears a considerable price.

The Deep Dusky Yellow LOAM consists of a deep yellow and a whitish sand, with a very little clay, and is very harsh and coarse. It is moist in the stratum, and

and when dried is of a loose texture, readily crumbling between the fingers without sticking to the hands. It makes no effervescence with aqua fortis, nor does it hiss when thrown into water. It is used for making bricks when mixed with good clay.

The Hard Brown LOAM consists of large white sand and deep brown clay; it is very hard, but not tough, though it cannot be got up without pick-axes: when dry, it is very hard and heavy, and will not break between the fingers. It will not hiss when thrown into water, nor make an effervescence with aqua fortis. It is often full of small sea-shells; and in Northamptonshire it is so full of them that they make floors for barns therewith; it likewise serves to make roofs for ovens and other purposes.

The Light Pale Brown LOAM is the lightest and most spongy of any of this kind, and is composed of fine pale yellow sand, mixed with light brown clay. When dry, it crumbles easily between the fingers, and sticks a little to the hand. It will not effervesce with aqua fortis, but when thrown into water makes a little hissing, and almost immediately falls into a loose powder.

The Yellowish Brown LOAM consists of a white and yellow sand, together with a small quantity of fine brown clay. It is moist in the stratum, and when dry is of a loose crumbly texture, with a rough and somewhat dusty surface. It makes an effervescence with aqua fortis, and hisses a little when thrown into water. This sort alone will make fine red bricks.

The Greyish White LOAM is composed of a fine white sand and a pale bluish clay, spangled with a great number of small plates of talc. While in the earth it is moist and soft, but when dry is very heavy and compact, with an even smooth surface; but it will not break between the fingers, nor stick to the hands. It raises a great effervescence with aqua fortis, when thrown into water makes a slight hissing, and after a little time breaks into small lumps. When burnt it becomes very hard, is of an agreeable reddish colour, and will make good bricks when mixed with a proper clay.

The Pale Yellow LOAM is of a loose spongy texture, and consists of small whitish sand with a pale yellow clay. It is pretty tough in the stratum, as well as moist; but when dry it becomes firm and hard, and is spangled with talc. It will not break readily between the fingers, nor stick to the hands, nor yet make any effervescence with aqua fortis: when thrown into water it makes a very little hissing, and soon falls into a loose powder. It is proper for making fine red bricks.

The Yellowish Brown LOAM has a very loose texture, and is composed of yellowish sand with fine brown clay. It will not effervesce with aqua fortis, but it makes a very small hissing when thrown into water, where it moulders into powder after some time. Mixed with ashes it is greatly used near London for making bricks.

The Reddish Brown LOAM consists of a hard whitish sand, and a reddish brown clay. It is pretty firm in the stratum, and when dry becomes very hard and heavy. It will not effervesce with aqua fortis, and it hisses but little when thrown into water, where it falls into powder after some time. This Loam serves for making bricks in many parts of England.

The Red Sandy LOAM consists of fine pale yellow sand, and a bright red clay, mingled with fragments of a very red iron ore, and a great deal of reddish dusky spar. While it is moist it is quite loose, and of a very deep red; but when dry it is of a pale red, and of a very loose texture, for which reason it crumbles to powder between the fingers. It will effervesce with aqua fortis, and burns to a fine florid red. The land composed of it is very proper for rye, barley and pease.

The Brittle Brown Sandy LOAM is an earth partly sandy and partly stony, and when dry will not keep together in a lump, the texture being so loose and spongy. It makes a brisk effervescence with aqua fortis, and hisses pretty much when thrown into water. Those lands that consist of this are accounted poor and barren.

The Greyish Brown Sandy LOAM is composed of small white sand mixed with pebbles, and is full of cavities which are smooth and glossy at the bottom. It is pretty tough and very heavy, and has a rough rugged appearance, without any dust on the surface. It does not readily crumble to powder, nor does it stain the hands. It makes little or no hissing when thrown into water, nor does it effervesce with aqua fortis. Land consisting of this is very good for barley.

The Heavy Yellowish Brown Sandy LOAM is composed of a great number of different hard particles; a brown gritty stone, a yellow sand, pieces of spar, and a very glittering bright white sand, with a brownish spongy earth. It is hard, heavy and somewhat tough, and in dry seasons breaks into very large masses, though it is of a very brittle loose texture. It is very dusty and hard when dry, and very sticky in wet seasons, which renders the walking on it very slippery and troublesome. It makes a considerable effervescence with aqua fortis, and burns to a pale red with very little hardness. Some of these last are more properly called Moulds than Loams; though they are placed in the same class.

CHAP. VI.

Of OCHRES.

LIGHT Brittle Pale Yellow OCHRE is between the colour of brimstone and what is called a cream colour, and is of a loose crumbly texture, it being composed of very thin fine plates. It is extremely light, and separates into flakes, in the fire, of a dull reddish brown colour. It is found in Pennsylvania and Virginia, and with water makes a straw colour, but with oil a pleasant yellow.

Hard Heavy Pale Yellow OCHRE is well known to the painters, and is of a close, compact, firm texture, with a smooth even surface; when burnt in the fire it turns of a dull pale red, and becomes considerably hard. It is found in several parts of Europe; and particularly in Somersetshire.

Light Crumbly Yellow OCHRE is commonly seen at the mouths of the springs of the Spa kind, and at present is made very little use of; nor can it be expected in any large quantities. In the fire it turns to a pretty good red.

Light Brittle Gold Coloured OCHRE is found in small lumps in the earth, and is very light, being of a crumbly texture, and stains the hands of a true gold colour. It turns to a bright red in the fire, and becomes a little more hard. It is common among gravel in several parts of the kingdom, particularly on Mendip Hills, where it lies in the clefts of the strata. It is also in a gravel pit on the right hand of Oxford Street, about a mile from London. When burnt it turns to a red, and might probably be of use to painters.

Light Plated Saffron Coloured OCHRE is sometimes found making a stratum, and sometimes in the perpendicular clefts of other strata, and is of a soft crumbly texture, with a rough and even surface, but colours the hands with a very beautiful yellow. It burns to a dusky red, and is common in Northamptonshire and Staffordshire.

Common Yellow OCHRE is a dense heavy earth, of a dull yellow colour. It ferments pretty much

with aqua fortis, and burns to a pretty good red. It is greatly used for house painting.

Hard Heavy Clayey Yellow OCHRE is very compact, and when dry is of a very fine bright yellow, with a smooth glossy surface. It burns to a red, but crackles in the fire. It is found in Buckinghamshire and Yorkshire, and is sometimes used by the painters.

Stony Hard Heavy Yellow OCHRE is in great plenty about Oxford, but it is so hard that it is not to be cut with a spade, and therefore they are forced to use pick-axes. It crackles a little in the fire, and turns to a fine red. It is used by the painters.

Dull Dusky Yellow Clayey OCHRE is found in several parts of England, and is dense, compact, and heavy. It is of a dusky unpleasant colour, though it burns to a very fine pale red, and becomes almost as hard as stone.

Light Clayey OCHRE, of a brownish yellow, is sometimes found among other strata, and in their perpendicular clefts. The surface is smooth and glossy, and the texture very fine; it burns to a dead dusky brownish red. It is found in several parts of England, and being of a good body is used by the painters.

NAPLES YELLOW is of a bright beautiful colour, between that of gold and saffron; but it is very loose, spongy, brittle, and porous, and ferments pretty briskly with aqua fortis. When burnt it turns to a deeper yellow, and is found in Italy, particularly about Naples. It is generally esteemed a pretty good colour.

Brittle Heavy Red OCHRE is common in several parts of England, and is of great use among the painters. It crackles a little in the fire, where it becomes more hard, and of a paler colour. It is used by painters for priming the coarser sort of works.

Brittle Purple OCHRE is common in Spain, of a very fine colour, and, though of a loose texture, weighs very heavy. It is of a fine deep purple before it is dug up, and when dry it turns red. It is a strong Alkali, and therefore ferments greatly with aqua fortis; in the fire it turns to a paler colour.

INDIA RED is a very fine purple earth, of a firm, compact, and hard texture, it being heavy, and almost as hard as a stone. Before it is dug up it is of a blood colour, but when dry of a fine glowing red, and is full of bright glittering particles of a whitish colour. In the fire it burns to a greater hardness without much changing the colour. It is found in the Island of Ormus in the Gulph of Persia, from whence it is by some called the Persian Earth.

Bright Red Brittle OCHRE is found in Bengal in the East Indies, and though used in France is not much known in England. It is of a fine, bright, florid red, and pretty heavy, though it crumbles between the fingers, and stains the hands. It ferments with aqua fortis, but undergoes little alteration in the fire.

VENETIAN BOLE is a sort of an Ochre, and is well known among painters, it being of a fine bright pale red, being pretty nearly of the colour of Red Lead. It grows harder when burnt, but the colour is worse. It is brought hither from Venice.

Pale Red OCHRE is light, brittle, and of an alkalious nature, for it ferments very briskly with aqua fortis. It somewhat resembles the Venetian Ochre, only it is brighter, and of a little paler colour. It is found in Florida, and is very probably in other parts of America, though it is not much known in England.

Pale Red Clay OCHRE is found in North America, and, though pretty heavy, is of a loose, brittle texture. It is nearly of a flesh colour, and burns to a good red in the fire. It is at present made no use of.

No. 42.

EARTH of Sinope is so called from a town of that name in Natolia, and is a sort of a Bole, sometimes of a deeper, and sometimes of a paler colour. It has been sometimes used in medicine, on account of its being of a drying nature, and particularly in fluxes of the belly.

Red CHALK is of a very dense compact substance, and is of a dull red colour. Some use it in the manner of crayons, or rather like black lead pencils. It is very well known to painters, and therefore needs no farther description. It is found in several parts of Europe, and particularly in Flanders.

Red Stony Ochre is the hardest and driest of any of this kind, and is found in regular strata in the earth, but is so hard that it cannot be got up without pick-axes. It is of a fine purplish red, and is very heavy, being mixed with fragments of Lead Ore, of a bright bluish colour; as also a small quantity of pure native Cinnabar. It burns to a fine red, and becomes more hard in the fire. The painters call it Indian Stone Red, it being brought from China; but it is very scarce.

Brown UMBER is a sort of Ochre, and is greatly used by painters. It is found loose in small lumps among gravel, and sometimes in the perpendicular clefts of other strata. It is very light, though of a close compact texture, and burns to a deep brown in the fire. It is generally brought from abroad, there being very little of it in England, though it is thought to be in Mendip Hills in Somersetshire.

COLOGN EARTH, commonly called Cullens Earth, is well known among the painters, and is of a dusky brown, with a close, compact, fine texture, but extremely light. It is not at all gritty, and has the taste of oak bark. Being thrown into the water, it swims on the surface till it is quite wet, and soon breaks into a very fine powder. It is easily set on fire, and never goes out till it is reduced to pale yellow ashes; from whence it appears to be of a vegetable nature, owing its origin to wood long buried in the earth. It is brought to us from the city of Cologne.

The ARMENIAN STONE is very opaque, and mixed with green, blue, and black spots, somewhat in the manner of Lapis Lazuli. It is of an even, regular texture, and the general colour is a beautiful blue. Some think it differs in nothing from Lapis Lazuli but in hardness, and is like that very scarce. It was formerly used in medicine as a purge and vomit, and the dose was from six grains to a scruple; but it is now out of use, except among the painters, for when it is prepared it yields a fine blue colour, with a greenish cast.

Green OCHRE, or TINCAL, is of a dense, compact substance, though of a coarse irregular texture, the surface being rough and uneven, and the colour of a pale green. It is found in many parts of Germany in and near the copper mines, and it partakes very evidently of copper. By burning it turns to a hard dusky brown Ochre, and therefore is only used in its natural state, it being reckoned a very good paint.

Heavy Brittle Black OCHRE is found in masses of different sizes, in the perpendicular clefts of stone. It is of a fine deep black, and of a compact, even, close texture, though it breaks very readily into small pieces between the fingers, and slightly stains the hands. It is common about Mount Sorrel in Leicestershire.

Black CHALK is found in broad flat pieces from two to ten feet long in the earth, and from four to twenty inches in breadth. It is moist and flaky when just taken out of the ground, but soon becomes pretty hard, and very light. It will cleave very easily one way, and seems to be the offspring of wood buried in the earth; for it will burn, but not

so long as Cologn Earth. It is much used in painting, and is to be met with in Spain, Italy, and Germany.

C H A P. VII.
Of B O L E S.

A BOLE is a heavy fat earth, which readily adheres to the tongue, and colours the fingers. It is of various kinds.

ARMENIAN BOLE, or **BOLE ARMENICK**, is sometimes white, and moderately heavy, being of a close compact texture, and having a very smooth surface. It is very scarce, and therefore being quite unknown to the shops it need not be insisted upon.

White Brittle BOLE is moderately heavy, with a smooth surface, though it will crumble between the fingers. It will ferment with aqua fortis, and in the fire may be burnt to a sort of Lime. It is brought from Germany.

NOCERIAN EARTH is very heavy, and of a greyish white, but not so brittle as some of this kind. It has no taste, nor does it ferment with aqua fortis. It is met with in Italy, and some think it good for the bite of mad dogs, and in malignant fevers.

ERETRIAN EARTH is a fine kind of Bole of a greyish white colour, and pretty heavy, with a smooth surface, though it crumbles very easily between the fingers. It ferments very briskly with aqua fortis, and in the fire it turns perfectly white and as hard as stone. When a little wetted and drawn over a copper-plate, it will leave a line behind it, which in a short time turns bluish. It is dug up in Negropont, near the antient Eretria, from whence it has its name.

Whitish ALKALINE BOLE is hard, of a close compact texture, and like other Boles melts gradually in the mouth. It ferments but slightly with aqua fortis, but in the fire turns to a pure white. It is found in the East Indies.

The **Yellow ARMENIAN BOLE** is of a saffron colour, and of an earthy, heavy, fat, brittle substance, with an astringent taste, it is of a close compact texture, with an extremely smooth surface and very hard; but it melts on the tongue, though very slowly. It ferments briskly with aqua fortis, and in the fire becomes more hard, and of a deeper colour.

BOLE of Blois is of a pale yellow, and of a compact texture, but very light, and readily crumbles between the fingers. It ferments violently with aqua fortis, and becomes almost as hard as stone in the fire, turning to a much darker colour.

BOLE of Tokay is of a yellow colour and brittle, but very fine, and considerably heavier than the former. It melts easily in the mouth, and ferments violently with aqua fortis; in the fire it becomes considerably hard, but does not change the colour.

SILESIAN SEALED EARTH is a sort of Bole which is pretty heavy, and of a compact texture, with a smooth surface. It turns to a kind of chocolate colour, in the fire, and becomes considerably hard; but is a stranger to our shops.

LIVONIAN EARTH is a very fine Bole, and very brittle; it is of a dully dusky yellow with a reddish cast, and its surface is smooth and glossy. It becomes of a harder texture and a darker colour in the fire, and is usually sealed with the figure of a church, an escutcheon, and two cross keys. It is not only found in Livonia, but in Spain and Portugal, wherewith they make a sort of earthen ware.

BOHEMIAN BOLE is of a deeper yellow than that of Tokay, it having a small mixture of red. The surface is very smooth and shining, and it melts readily in the mouth.

Red BOLE ARMENICK is the hardest of all

Boles, and is of a reddish yellow colour, not unlike that of saffron. It melts readily in the mouth, and has an astringent taste. That is the best which will most readily beat to powder with a pestle, or dissolve in water, without the least sandy sediment. Its virtues have been greatly cried up in various disorders; but it is now seldom met with in the shops.

FRENCH BOLE is of an earthy substance, and of a pale yellowish red; it is heavy, brittle, and of an astringent taste. It ferments very slightly with aqua fortis, and in the fire becomes of a somewhat redder colour. It is often mixed with sand or small stones, and therefore it should be mixed with water before it is used, and poured off, after the grosser parts are sunk to the bottom. It is reckoned a good astringent, and is now used in the room of all other Boles, but seldom alone.

The **Sealed EARTH of Striga** is of a deep dull red, and has a tolerable smooth surface. It will crumble between the fingers, and melts readily in the mouth. It ferments a little with aqua fortis, and becomes harder in the fire, without any change of colour.

Red Sealed EARTH of Livonia is considerably heavy, though of a loose texture, and of a paler colour than the red Silesian Bole. It dissolves readily in water, and has a strong astringent taste. The fire makes little or no alteration in it.

TUSCAN Sealed EARTH is a heavy pale red Bole, with a smooth surface, and easily breaks between the fingers. It grows hard in the fire, and the colour becomes somewhat more dark. It is dug up near Florence, and is said to be good in loosenesses and excessive bleedings.

PORTUGAL EARTH is a brittle, heavy, fine red Bole of a close texture, with a smooth shining surface. It becomes a little harder in the fire without change of colour, and is very common in the northern parts of Portugal.

TURKEY Sealed EARTH is of a greyish red colour, and of a looser texture than some other Boles. The surface is soft and smooth, and it breaks easily between the fingers; in the fire it becomes considerably hard, and of a dusky yellow colour. It is said to be good in the plague, and to promote sweat. The hard pale red Bole is moderately heavy, and remarkably hard. It is of a beautiful pale red, or rather of a flesh colour, with a very smooth glossy surface. In the fire it becomes as hard as stone, and the colour acquires somewhat of a blue. This is found in North America among our plantations.

Pale Brown Hard BOLE is very pure, of a compact texture, and moderately heavy. It consists of thin plates laid closely upon each other, and has a smooth shining surface. It cracks and bursts in the fire, flying off in small flakes at first; but afterwards becomes considerably hard, and of a pale red colour. It is met with in Germany, as well as in America, and in some parts of England.

Pale Brown Heavy Dense BOLE is very compact, and speckled with white and yellow. The surface is a little rough, but it may be polished by rubbing; It burns to a dusky red, but does not acquire a much greater hardness; it is found in many parts of Germany.

Light Brittle Round Bole is of a looser texture than others of this kind, and is less weighty. It has a smooth equal surface, but readily crumbles between the fingers. It easily dissolves in water, and is a little astringent to the taste. It becomes considerably hard in the fire, and turns to a dark dusky red colour. It is found in several parts of England.

Greenish BOLE is very fine and beautiful, and considerably heavy. It is compact, and of a pale dusky greenish colour, with a smooth glossy surface. It has a brackish disagreeable taste, without any remarkable

markable astringency. It becomes considerably hard in the fire, and turns to a dusky brownish red. It is found in the West of England.

C H A P. VIII.
O F T R I P O L I E S.

SILVER CHALK of the antients is of a snow white, and its texture is somewhat loose and spongy; for it is very light, and has a rough uneven surface. It easily breaks between the fingers, and has a taste like that of Pumice stone, but with no sandy grittiness. It grows hard in the fire without changing colour, and is found in Prussia, where it is used for cleaning and polishing silver vessels, from whence it has its name.

The **Yellow TRIPOLI** is of a firm texture, moderately heavy, and is only yellowish in the Earth; for when it is dry it becomes white, and almost as hard as stone. In the fire it turns to a beautiful pale red: it is found in several parts of Europe; but the greatest quantity is met with in Africa. It is called Tripoli from a city of that name in that part of the world. This and the former, as well as all of this kind, are composed of harder particles than Ochre, for which reason they are of greater use in polishing metals.

Reddish White TRIPOLI never makes a stratum in the earth of itself, but is found in distinct masses among other strata. It is pretty hard; though of a loose texture, and consists of a multitude of plates or flakes lying upon each other. It is met with in Germany, and on Mendip Hills in England. It is used in polishing brass.

The **Melian EARTH** of Dioscorides is a hard, heavy, ash coloured Tripoli, and is of a loose, open, spongy texture, very readily falling into powder, it being very brittle. It consists of very harsh particles, and is extremely rough to the touch. It has a disagreeable styptic taste, somewhat like Alum; but the fire makes no great alteration in it. It is found in the islands of the Archipelago; but it is not much known in England, and consequently not used by workmen.

Light Brittle Greenish Red TRIPOLI is of a loose spongy texture, and remarkably light, with a rough uneven surface. It easily breaks between the fingers, but does not colour the hands, and undergoes no alteration in the fire. It is found in several parts of the world, as well as in Somersetshire.

ROTTEN STONE is a sort of Tripoli of a brown colour, and is very soft and light while in the earth; but out of it becomes more hard. Its texture is light and spongy, and it is dry, hard, and rough to the touch. It becomes a little more hard in the fire, and acquires a reddish cast. It is found in Derbyshire, Shropshire, and Somersetshire, and is of great use in polishing brass.

Hard Pale Brown TRIPOLI has sometimes a little cast of red, and is somewhat heavy, it being of a close compact texture, and almost as hard as stone; but it is more smooth than other Tripolies. In the fire it becomes more reddish. It is found in Wiltshire, and serves for the same purposes as the former.

Sparkling Brown TRIPOLI is the heaviest of this kind, though it is of a loose texture. It seems to abound with a sort of spangles that glitter pretty much, though the surface is rough and irregular. It ferments briskly with aqua fortis, and in the fire becomes of a fine red, and pretty hard. It is not very uncommon in England, but has never been put to any use.

Brownish Red Sparkling TRIPOLI is very light, it being of a looser texture than any of this tribe;

but it is full of a great number of large glittering particles, and has a rough irregular surface. In the fire it undergoes little alteration. It is found in Wiltshire, Suffex, and other parts of England. It is not fine enough to be used for any thing else but polishing Brass.

C H A P. IX.
O F I S I N G - G L A S S , M O S C O V Y - G L A S S , a n d
T A L C .

I S I N G - G L A S S consists of shining scaly particles, or flat plates, and that called Moscovy Glass is of the same nature; or rather, both these names are given to the same substances.

White Shining I S I N G - G L A S S is usually found in masses of a smooth and even surface, except at the edges; it is sometimes from eight to twelve inches broad, and from half an inch to three thick. It will cleave into innumerable thin plates or flakes, and is as transparent as the finest glass, instead of which it is used for putting before small prints generally designed for children, as also by some miniature painters for covering their pictures. They may be split, with care, so as not to be thicker than leaf gold, and yet still have a sort of springiness or elasticity, for which it is very remarkable. In the fire it becomes as white as silver, but then it ceases to be transparent. It is found in various parts of the world, particularly in Russia or Moscovy.

Bright Brown I S I N G - G L A S S is not so beautiful as the former; but it has much the same texture, and, like that, will cleave into plates or flakes; but the surface is not quite so even. It is very bright, though not so transparent as the former, and is more subject to flaws and cracks. It soon becomes white and opaque in the fire, and then readily breaks to pieces, though it seems to be adorned with silver spangles. It is found in Germany; and it is said, there have been small pieces of it met with in England.

Bright Purple I S I N G - G L A S S is as even and regular as the first kind, and may be cloven into as many flakes as that. While the flakes are pretty thick they are of a fine beautiful colour like an amethyst; but when split into thinner plates it becomes paler, and in the thinnest of all, the colour is wholly lost. It also loses its colour and transparency in the fire, becoming entirely white. It is found in Moscovy and Persia, and by some it is called Red Talc.

TALC is a shining stone, and will split into very thin plates, which are transparent and a little flexible. It will not melt in the fire, nor will it admit calcination, nor lose its colour. It is of various kinds.

VENETIAN TALC is well known for the several attempts that have been made to reduce it into a sort of paint to beautify ladies' faces. Linnæus calls it Whitish Talc, consisting of plates almost transparent, which feel like suet to the touch. The masses of Venetian Talc are from one to five or six inches in diameter, with a very rude irregular surface, full of prominences and cavities. It is of very little use in medicine, it being employed only as a cosmetic to render the skin more white and shining. The best way is to reduce it into an impalpable powder, the shortest way of doing which is to heat it red hot in the fire, and then quench it in cold water; this must be done several times, after which it may be ground upon a porphyry into an exceeding fine powder shining like silver. This, when mixed with pomatum, is what the ladies call cold cream. The chemists have endeavoured to get the oil of Talc, but without success; though they suppose it would

would turn brass into silver. If any thing of this kind has ever been procured, it has been owing to the additions, and not to the Talc itself.

Shining Black TALC, with small leaves, is of an irregular complicated texture, like the former, and is found in masses, which have a rugged surface from one to four inches in diameter. They are composed of a prodigious number of irregular scales very closely but unevenly laid together, which will easily split into irregular flakes. None of the Talcs, nor yet the Ising-Glasses, can be made to strike fire with steel, for which reason they are called by Linnæus, *Apyri*, that is, without fire. They likewise remain unchanged in the fire, and cannot be dissolved by acids.

Shining Gold Coloured TALC, with small spangles, is called by some writers *Mica aurea*, from its shining like gold. It is found in small masses of a loose, irregular, brittle texture, with an uneven surface, but never exceeding an inch and a half in diameter. It is composed of a multitude of small flakes or spangles, with sometimes a mixture of a sort of crystal. These flakes are very small, being seldom above a quarter of an inch broad; but they are extremely smooth and soft to the touch. It is found in several parts of Europe, particularly in England.

Shining TALC, with the appearance of silver, has spangles of various sizes, is known to some by the name of Glimmer or Cat-silver, and is very brittle, readily parting into flakes of which it consists. The masses are very small, being seldom above the fifth part of an inch in length. It is found in several parts of Italy, as well as in England, and in some places looks like shining sand.

Greenish Shining TALC, with very small spangles, is of a very pure kind, though it does not shine so much as the two former; but it is very brittle, and of an irregular shape, with a rough scaly surface. Its masses are found from one inch to eight or ten in diameter, which seem to be composed of very small spangles, which will readily stick to the fingers in handling. It is found in great plenty on the shores of Italy, and there has been some found in England, on Mendip hills, but in no great quantity.

Greyish Green TALC, with small scales, is of a very dull colour, and has a distant resemblance to the Venetian Talc, though the structure is very different. The flakes are of different sizes, but usually small, and lie in various directions, being of no determinate shape, and they are not so transparent as the other kinds. It is found on the shores of Yorkshire and Lincolnshire.

Grey Shining TALC, with very thin scales, is rather brighter than any of the former kinds, and consists of a vast number of plates or flakes, lying in a very confused and irregular manner, and of various sizes and shapes, the larger not being above half an inch in breadth. In the fire it turns as yellow as gold, and shines like it, it being the only Talc that changes in the fire. It is very common on the English shore.

Bright Green Shining TALC, with broad spangles, is found in masses that are composed of others that are smaller, and these consist of very fine thin plates, which are generally wrinkled and turned several ways. The colour is very beautiful when unbroken; but, when the flakes are separated from each other, it is quite lost. It is considerably heavy, and loses its greenness and transparency in the fire. It is found in the beds of rivers in Italy.

Shining Greyish Yellow TALC, with small scales, makes a very splendid appearance, and is found in masses of eight or ten inches in diameter, which are composed of a great number of very broad, thin, light flakes. The surface is bright and glossy, but never even. In the fire it loses all its

yellowness. It is found very frequently on the shores of Italy.

White Sweet-Scented TALC, with undulated scales, is by some authors called the Violet stone, on account of its smell. It is found in masses of a very compact and firm texture, though rough and irregular on the out-side; these are from an inch to twelve in diameter; they consist of a prodigious number of thin snow-white flakes adhering very closely to each other. These are of various sizes, without any regularity, and lie in all directions, being as soft to the touch as those of the Venetian Talc. In the fire it turns to a dusky brown red. It is common on the shores of Italy, and on the mountains of Germany.

Besides these, there are other TALCS not so easily cloven as the former, which consist of small plates in the form of spangles, and consequently are very distinct from the former.

The Shining Bluish Brown TALC is usually found in masses of a pretty firm compact texture, with rugged unequal surfaces, and in the shape of pebble stones, from the size of a horse-bean to five or six inches in diameter. It consists of small, but generally thick spangles cohering firmly to each other, and, though irregular, nearly of the same shape. They are very hard and harsh, feeling more like stone than common TALC, and consequently are hard to be separated from each other. They are very heavy, and yet will not strike fire with steel; but the fire will bring them to a pale reddish grey without transparency.

Dull Pale Red TALC, with scales of various sizes, is usually found in masses from two to eight inches in breadth. It is composed of a vast number of scales that lie closely together in a very agreeable order; but they are mixed with an opaque substance of the same nature with the scales, only they are not of the same shape, nor well disposed: They seem to have very smooth and even surfaces, and are as smooth to the touch as Venetian Talc, to which they seem to have some distant relation. Though this Talc is considerably heavy, it will not strike fire with steel, but will turn in the fire to a pale whitish grey. It is very common on the shores of Lincolnshire.

The East-Indians have a Heavy, Shining, Orange-Coloured TALC, which has a smaller number of plates than any of the other kinds. They have likewise another bright purple Talc, which is so clear and elegant, that it might not improperly be placed among gems.

There are other TALCS that seem to be chiefly composed of fibres or filaments, and are, therefore, by authors called fibrous Talcs.

ENGLISH TALC, so called in the shops, is of a coarse, harsh, rough kind; with an unequal surface, and of a loose brittle texture. It is found in masses from one to eighteen inches broad, and seldom more than two inches thick. It has a rough, irregular, wrinkled surface, and consists of considerably long coarse fibres, that run pretty regularly through the whole mass. It may be easily cloven according to the directions of the fibres, which, however, are so brittle that they seldom come off whole. It is of a dull, dead, whitish colour, and the filaments, when separated, appear a little glossy. It will not strike fire with steel, but when calcined it turns to a perfect white. It is found in clay and marl pits, as well as among the strata of gravel; and the fissures of stone, and it will burn into a very good plaster, for which reason it is called the plaster stone; when burned it is used for cleaning silver lace.

Glossy Yellowish White TALC, with broad straight fibres, is of a very close texture, and is found in thick flat masses of a very beautiful straw colour, but is seldom three inches over either way. It is composed

composed of filaments that are perfectly straight, and may be very easily cloven; but the fibres cannot be divided singly from each other, being so very brittle. It turns in the fire to a pure white, and is found in the stone pits of Northamptonshire.

Bright white TALC, with broad filaments, is of a loose brittle texture, and is found in large broad and pretty thick white masses, and where fresh broken it is very glossy and bright. The filaments are much broader at the top than at the bottom of the mass, it being above an inch upwards, and very even and glossy; they may be cloven very thin, but they will not bend, having no spring. It calcines in the fire to a white plaster, and is very plentiful in the alum pits of Derbyshire.

Flesh-coloured Fibrous TALC, with narrow filaments, is not so bright as others of this class; but it is of a fine smooth close and compact texture. Its horizontal surfaces, formed by the ends of the fibres, are smooth and even, but not glossy. The masses are from three to twelve inches broad, and sometimes five inches thick. It consists of single fibres, which run throughout the whole length of the mass without interruption; but they are very brittle, though smooth and glossy. It will easily calcine in the fire, and will turn into very good plaster. It is chiefly found in Yorkshire.

Dull White TALC, with very sharp narrow filaments, is of a very compact firm texture, though it is only found like white veins in other substances, particularly red marl. The fibres are of various lengths, but they are all continued without interruption through the veins, and are from the breadth of a horse hair to half an inch. It will not easily cleave, and when it does, it is not perfectly straight, because the filaments run a little obliquely.

The Greenish White Glossy TALC, with straight narrow filaments, is of a perfectly even and regular texture, being very firm, compact and hard. It is found in broad thin masses of a fine glossy white, with a greenish cast, from two to fourteen inches broad, and to an inch and a half thick. When held up to a good light it is pretty transparent, and in the fire turns perfectly white.

CHAP. X.

Of FOSSILE SUBSTANCES that are not elastick, and composed of short Fibres.

SOME authors call these Lachnides, from *Lachne*, a Greek word, signifying hair or down.

The Flesh-coloured Pale Glossy LACHNIS, with short, broad, and crooked filaments, is found in very broad flat masses of a whitish flesh colour, which have a very smooth, even, and somewhat glossy surface at the top and bottom; some of them are eight or ten inches broad, and from one to four thick; and they are composed of flat broad filaments, irregularly placed, and lying in oblique angles. These masses will cleave perpendicularly according to the direction of the filaments, though they adhere pretty closely together at their sides, and have very smooth glossy surfaces. They will neither ferment with aqua fortis, nor strike fire with steel; but in the fire they will turn to a perfect whiteness. It is found in the marl pits of Derbyshire, but is of little use.

Greenish-White Glossy LACHNIS, with broad oblique filaments, is found in large, broad, thick masses, with its horizontal surfaces very uneven, rough, and rugged. It is sometimes seen near two feet broad, and six or seven inches thick. It consists of pretty bright glossy filaments that are very broad, but placed in no regular order, nor continued through the whole thickness of the mass, which

separate it transversely into several rows, separated by narrow veins of greenish white marl. The whole mass is easily cloven and separated into transparent filaments that will not bend. When in the fire it soon calcines to a white plaster.

Dull Greyish White LACHNIS, with thick oblique filaments, is of an extremely compact and firm texture, and is found in very large, thick masses, from two to eighteen inches in diameter, and nearly as thick the other way. It is composed of eight or twelve rows of filaments, sometimes making angles with each other. It is not easily cloven, the filaments being so harsh and brittle, that they are separated with difficulty to any tolerable length. It is very heavy, and yet it will not strike fire with steel, nor will it very easily calcine into plaster.

Dull White LACHNIS, with straight broad filaments, is of a pretty close texture, and extremely brittle. It is found in short thick masses, from two to six inches in breadth, and sometimes four inches thick. It is only composed of two rows of filaments that are pretty broad and very irregularly placed, meeting each other at the centre; they are so extremely brittle that they can never be cloven directly. It will turn to a very good plaster very soon in the fire, and is found in the marl pits of Derbyshire.

The White Glossy LACHNIS, with broad oblique filaments, is of a very irregular texture, but very glossy. It is found in large flat masses, from two to ten inches broad, and from half an inch to above an inch thick. It consists of several rows of very broad glittering filaments, confusedly woven with each other at their ends, and they are all very short and broad, though bent and waved in different manners, making all sorts of angles with each other. It is hard to be cloven, nor can the filaments be easily separated, they have so firm a consistence. They are soon turned by fire into a fine white plaster. It is very common in Yorkshire in the blue clay pits.

Dull Flesh-coloured LACHNIS, with broad, short filaments, is very brittle, and of a coarse, harsh, irregular structure. It is often found from eight to twelve inches broad, and six inches thick. It consists of broad, short, and very obliquely ranged filaments, divided into three or four beds, by the thick horizontal earth it is lodged in. The filaments are short and crooked, and adhere slightly to each other on the sides, which render the mass very brittle and easily cloven. It is easily burnt into plaster, and is found in the alabaster pits in Derbyshire.

The beautiful Flesh-coloured glossy LACHNIS, with slender filaments, interwoven with each other, is of a very short, fine, smooth, equal texture, and is extremely firm, compact, and hard. It is found in flat masses, from four to six inches broad, and seldom above an inch thick. There are four or five rows of fibres that go to the making up less than an inch in thickness. It is difficult to cleave, the filaments being not easily separated from each other. It may be calcined very soon to a fine white plaster. It is found in Somersetshire and other places.

The Bluish-White LACHNIS, with very narrow straight fibres, is of a fine smooth texture, and pretty compact; it is found in flat masses from ten to fourteen inches in breadth, though seldom above an inch thick. It is composed of three or four rows of orders or filaments standing perpendicularly on each other; these filaments being straight render the mass easy to be cloven or split, and they have pretty smooth glossy substances. They soon calcine to a very white plaster. It is found in the marl pits of Staffordshire.

The Glossy Greenish-Grey LACHNIS, with broad and very thin filaments, is found in masses

four or five feet in breadth, being seldom above four or five inches thick. They consist of two rows or orders of filaments that are interwoven with each other at their internal ends; but they are always bent, and often placed obliquely. It will calcine, though but slowly, to a very white plaster.

The Glossy Greenish-White LACHNIS, with narrow bent filaments, is found in masses frequently as thick as broad, being sometimes no more than an inch in diameter, and at other times twelve inches. It is composed of many rows of interrupted filaments, variously bending and intersecting each other, which have very smooth unequal surfaces; though they are very hard and heavy, they will not strike fire with steel, and they calcine very slowly in the fire. It is found in the marl pits of Derbyshire. All these Lachnides may be accounted a sort of Talc, or at least akin thereto.

CHAP. XI.

Of FOSSILS, called ASBESTOS and AMIANTHUS.

MOST authors that have treated upon fossils make Asbestos and Amianthus to mean the same thing; that is, what some call Earth-flax, and others Plumous Alum; but this last name has been very improperly applied: for the Plumous Alum is a real salt, which is found in an island in the Archipelago, called Melo. However, Linnæus makes a distinction between Asbestos and Amianthus; for he would have the latter to consist of longitudinal fibres, and the former of those that are interwoven.

Incombustible flax is a sort of Amianthus, and consists of flexible fibres, like thread, lying parallel to each other, and easily separated. The ancients spun these fibres, and made a sort of cloth thereof, in which they wrapped up the dead bodies they intended to burn, that they might preserve the ashes; for, when the body was burnt, the cloth remained entire. The Germans call it mountain flax; and it is found in Lapland, Siberia, and in the vallies of the Pyrenean mountains; but the largest quantity is brought to us from Negropont. When handled it causes an itching in the skin, and sometimes blisters, which is owing to the fibres or down, of which it is composed, getting into the skin; however, it is easily cured, by rubbing the part with oil, which will soon blunt the points of the down.

There is another Amianthus, with angular, rigid, and opaque fibres, which some call Asbestos, with hard parallel fibres, not to be separated from each other. These are of an ash colour, and the whole has pretty much the appearance of wood. It is found in Lapland, Sahlberg, and other places. There is another Amianthus, consisting of stiff fibres that are easily separated from each other; but they are as brittle and transparent as glass, and of a greenish colour. A fourth sort is known in the shops by the name of Plumous Alum, and consists of exceeding brittle parallel fibres, that can hardly be separated from each other. It is found in Sweden.

Linnæus has also three sorts of Asbestos; namely, that which is heavy, and consists of hard fibres, formed into a sort of flakes or plates. It will readily cleave, and is of a pale colour; but is so heavy it will not swim in water. The Swedes call it mountain flax. Another Asbestos is membranous; that is, it consists of fibres so interwoven, that it resembles old leather. It will swim upon water, and the surface of it is hard, smooth, light and white. The third sort consists of flexible fibres that cross each other irregularly, and is so light that it is called by the Swedes mountain-cork; indeed, it looks like the

inward bark of cork, and is so porous a stone that it will swim in water.

Other authors have the Greenish Asbestos, which is extremely smooth, firm, compact, and exceeding soft to the touch. It is found in the form of veins in a sort of marble, and its filaments are slender and bent. It is met with in the isle of Anglesea, and other parts of Wales, in lumps, seldom larger than a nut.

Whitish-Brown Silky ASBESTOS is called in America petrified wood, its texture being even, regular and close. It is extremely soft and silky to the touch, and of a whitish-brown colour. It consists of long continued flat filaments, and is found from one to three inches long.

Greyish Silky ASBESTOS, with very long continued and roundish fibres, which run in straight lines the length of the whole mass, is found in lumps from two to nine inches long, and the fibres are so placed as to make it look like a piece of wood. It is found in the Highlands of Scotland.

Greyish-Green Silky ASBESTOS, with long continued and very slender fibres, is found in the isle of Cyprus, in bits not exceeding a quarter of an ounce in weight, though sometimes three inches long, and half an inch broad.

White, Loose, Thready ASBESTOS, with broad fibres, is found in length from two inches to twelve; and sometimes the fibres seem to be bundled up like the threads of cotton in the wicks of lamps. This is found in the Highlands of Scotland.

Soft, Reddish-Black AMIANTHUS, with short, abrupt filaments, is found in the strata of iron ore; sometimes forming veins of an inch in diameter, but seldom so large. In the fire it turns to a very pale red. It is common in Germany among iron mines.

Greyish-Green, rigid AMIANTHUS, with short, abrupt, and interwoven fibres, is said to be the Plumous Alum of the shops; though Linnæus affirms it is an Asbestos.

CHAP. XII.

Of the FOSSILS called GYPSUMS.

AUTHORS are not well agreed what Gypsum properly signifies; for some would have it to be the lime of alabaster, others a sort of plumous alum, others Ising-glass, and others again the lime of the stone called Selenites; but it is more generally taken for the lime of certain whitish stones, which when burnt, contain some shining particles like Talc, and which are required to be but a short time in the fire before they turn to lime. But the Gypsum that is meant here includes those sort of fossils that are composed of small flat particles, which are ranged irregularly, and give the whole masses somewhat of the appearance of softer marble, they being bright, glossy, and in some degree transparent. They will very easily turn to lime in the fire.

Hard white GYPSUM, or plaster of Paris stone, has somewhat the appearance of loaf sugar, it being pretty fine, and of a very close, firm, compact texture. It is found in masses from four inches to four feet in diameter, and, when broken, shines like crystal. In the fire it readily turns to a very fine plaster. It is chiefly found in France.

Hard Shining red and white GYPSUM, that has the appearance of marble, is found in masses four or five feet in breadth, and three in thickness, with a rough, dusky, dark surface; but when broken it is bright and glossy. It does not turn into plaster, when calcined, so soon as the former. It is common in Yorkshire and Derbyshire.

Handwritten text at the top of the page, possibly a title or header, including the word "Lectura".

Hard Greyish-white GYPSUM is found in masses about six or seven inches broad, and three thick, with very rough, rugged, uneven surface, and a coarse, dull, dead look; when broken it does not sparkle like the other kinds. It is common in Germany and Derbyshire.

Soft, Shining, Green GYPSUM is found in lumps four inches broad, and more than one thick. It is of a very dull, dusky brownish colour on the outside, but when broken is very glossy, though it seems to be a little spongy. It is very soft and brittle, and loses its fine colour before it is quite calcined in the fire. It is found on the shores of rivers in the East-Indies.

Soft White GYPSUM, commonly called Derbyshire plaster stone, is found in lumps from the size of an egg to two or three feet in diameter, which are opaque, and of a dusky brownish-white; but, when broken, pretty bright and glossy. It is of so soft and brittle a texture, that it will break with a small force. It becomes very white when calcined, and makes a very valuable plaster. It is found in many parts of Derbyshire.

Soft, Pale-brown, Glossy GYPSUM, is generally found in thin masses, seldom above a foot broad, and three inches thick, with a rough unequal surface; but, when broken, it has the appearance of marble, being extremely bright and glossy, and composed of very large broad particles. It is very soft and brittle, as most of this kind are, and readily calcines into a pure white plaster. It is found in some parts of Germany as well as in Derbyshire.

Soft Red GYPSUM is sometimes met with in small lumps, not much bigger than a walnut, at other times in masses of ten pounds weight, with a very rough, dull, unequal surface; when broken, it sparkles, but not very much. The texture seems to consist of different rows of short lines or streaks, variously intersecting each other. It is very brittle, and calcines very easily in the fire, making an excellent plaster. None of these Gypsums will ferment with aqua fortis, or strike fire with steel.

CHAP. XIII.

Of the SELENITES.

THE Selenites are stones consisting of slender fibres, ranged in fine even flakes of different forms, according to their kinds. They will cleave like Talc, not only horizontally but perpendicularly; and though they will bend a little, they have no spring. They will not ferment with aqua fortis, nor readily calcine in the fire.

The Thin, Fine, Transparent SELENITE, with transverse streaks, is a common sort, and is met with from one tenth of an inch to five or six inches long. It consists of fine thin plates irregularly disposed through the whole breadth of the mass. These plates or flakes easily separate from each other in an horizontal direction, being almost as apt to cleave as Talc. It is pretty soft, and as void of colour as crystal; in the fire it turns to a pure opaque white. It is formed in the strata of clay in several parts of England.

The Thin, Dull, Opaque, Slender, Streaked SELENITE, is found from half an inch to three inches in length, and consists of a great number of even flat plates or flakes, each of which is of the same size as the horizontal surface. It is formed pretty much like the former, but not quite so regular, nor is the appearance so beautiful.

The Thin, Fine, Streaked SELENITE, with longitudinal streaks, is seldom broader than an inch, and above a seventh of an inch thick. It consists, like the former, of parallel horizontal plates; but

the fibres of which they consist, are slender, straight and exceeding regular, running in an oblique longitudinal direction, from one end of the stone to the other. It cleaves very easily, parting into flakes like Talc, and readily calcines to a fine white in the fire. It is found in the clay pit at Richmond, but at a considerable depth.

The Thick SELENITE, with transverse streaks and a rough surface, is usually met with of the size of about an inch and a half in breadth, and the plates and flakes, of which it consists, are remarkable for the largeness of the fibres that compose them, as well as the regular order in which they are laid. It calcines in the fire to a perfect whiteness, and is common in Yorkshire and Leicestershire.

The Short SELENITE, with thick plates, is of various sizes, but the most common is two inches in diameter. It consists of a smaller number of plates than others of this kind, because they are considerably thick, and are composed of bundles of fibres running longitudinally, and they are intersected with four or five transverse streaks. The whole stone is pretty bright and transparent. In the fire it turns to an opaque white, and is very common in the clay pits of Northamptonshire.

The Transparent SELENITE, with narrow transverse streaks, is generally between two and three inches long, and consists of very numerous horizontal plates, irregularly disposed, and of different thicknesses. They are composed of fine parallel straight fibres, running obliquely across the stone from side to side. It very easily cleaves into very fine flakes, and calcines in the fire to the whiteness of snow.

The Thick, Dull SELENITE, with very fine transverse fibres, is generally about two inches long, and consists of fine thin plates, evenly disposed, without the mass; these are made of exceeding fine slender filaments, running transversely in an oblique direction through the stone. The plates do not separate very easily, and the whole mass is dusky, being very little transparent. It is found in the clay pits in most parts of England.

The SELENITE, with fine longitudinal filaments, is composed, as well as the two former, of two horizontal, and two oblique planes. It is of various sizes, from a quarter of an inch to three inches in length. It calcines in the fire to a snow white substance, and is very common all over England.

The Brown Transparent SELENITE is generally three inches long, and consists of a greater number of fine, transparent, firm, parallel plates, joining exactly to each other. The plates consist of many fine filaments, all ranged in the same order, and not collected into separate bundles. It may be very readily cloven into horizontal plates that are very thin, and it calcines to a fine white in the fire. It is common in Germany.

The Thin Transparent SELENITE, with transverse fibres, is commonly about an inch long, and consists of many thin horizontal plates or flakes, made up of parallel fibres running obliquely across. It cleaves very easily, both horizontally and perpendicularly, and readily calcines into a white mass. It is common in Northamptonshire, and other parts of England.

The Dull, Thick SELENITE, with very thin transverse fibres, is generally between two and three inches long, and is composed of many extremely thin plates, that consist of an infinite number of parallel fibres that are connected into bundles, and run transversely in an oblique direction. It is very brittle; but it easily cleaves, according to the horizontal direction; and though it is as bright as the rest, it is not so transparent; but it calcines more readily to a perfect whiteness. It is found in Leicestershire in the yellow clay pits.

The Long Scaly SELENITE is commonly about three inches long, and has its horizontal plains very rough and scaly, it being composed of a vast number of oblong narrow plates, falling very irregularly one over another; it turns in the fire to a pure white.

The SELENITE, with thin flakes and transverse filaments, is generally about an inch in length, and is composed of six planes that are nearly equal; that is, a top, a bottom, and four sides. It is considerably long, in proportion to its thickness, and is composed of parallel plates lying evenly over each other in an horizontal direction, each making one whole surface of the stone. These consist of very fine slender fibres, laid obliquely across the flakes. It may be cloven very easily, according to the direction of the flakes; and in the fire it turns soon into a very pure white. It is sometimes found in Northamptonshire.

The Dull SELENITE, with thick plates and longitudinal fibres, is exactly of the same shape as the former, and is usually about two inches long, and a little more than a quarter of an inch in diameter. It is of an opaque whitish colour; but calcines very slowly to a fine white. It is common in clayey grounds in Yorkshire, lying near the surface.

The SELENITE, in the shape of a column, with very fine fibres, has six angles, and looks as if there was a part broken off at each end. There is no distinction of top and bottom, and all the planes are nearly alike. It is usually about an inch and a half long, and half an inch in diameter, consisting of a great number of very bright, and fine parallel filaments. It will cleave every way, but not into flakes, and the filaments are very flexible, but not elastick. It turns in the fire to a very pure white, and is found, but not commonly, in the clay pits of Northamptonshire.

The SELENITE, shaped like a column, with thick fibres, may be easily separated into filaments, for they will split off from many of its surfaces; but they will not bend readily, for they will easily break. They are neither bright nor transparent, but of a chalky whiteness, and turn to a pure white in the fire. It is found in the cliffs in the isle of Sheppy.

The Colourless Transparent SELENITE is of no regular shape, it being found in thin flat masses of different sizes and forms, that is, from one inch to a foot in length. It is composed of a vast number of minute and thin parallel flakes, not unlike Ising-glass. They are formed of a multitude of parallel fibres, ranged in a beautiful order. They are extremely bright and transparent, and the substance is very soft. It turns in the fire to fine pure white. It is found in several counties in England.

There is another SELENITE of this kind that is whitish and dull, but not so pure as the former; but it seems to be made up of plain even flakes, like those of Ising-glass. It is commonly long, in proportion to its breadth, but is a little thicker than the former. The sides are uneven and ridged, like the tiling of a house; and it is of various sizes, being from one inch to six or eight long. It calcines slowly, but at length attains a perfect whiteness. It is common in Germany, and is sometimes met with in the strata of clay in Northamptonshire and Leicestershire.

The SELENITE, with eight sides, is always short and thick in proportion to its breadth, and is from one sixth of an inch to two inches long; but when it is only an inch, which is the common size, it is about half an inch thick and broad. It is composed of a vast number of pretty thin plates, laid evenly and regularly in a transverse order, and these consist of moderately large fibres. The flakes are very flexible, but not elastick, and they are all

opaque and whitish while together. It is found in the clay pits of Staffordshire.

The SELENITE, composed of filaments that are ranged toward the surface of the body, into broader plates, which are notched at the edges, and seem to be radiated in the form of a star, is bright, and of a brownish white, and seems to be composed of fine thin plates, propagated from a single point, which is seldom placed in the centre of the mass, and the whole variously jagged. The stars are usually broad and flat, having but little thickness in proportion to their extent. This stone is of various sizes, namely, from that of a barley-corn to two inches in diameter. When broken it seems to be composed of straight, even, and very fine slender longitudinal fibres, proceeding from the centre, and form a mass of a very beautiful streaked texture. In the fire it turns perfectly white, and is found in the isle of Sheppy.

There are other species of the Selenite; but those we have already mentioned are fully sufficient.

CHAP. XIV.

Of CRYSTAL.

CRYSTAL is a soft transparent gem, that has somewhat the appearance of frozen water, and is sometimes like an hexagon column pointed at each end; or rather seems to be composed of two hexagon pyramids with a column placed between them.

It is the softest of all gems, and when it is coloured goes by another name, though it ought not to be substituted in the room of the more precious sorts of stones. When it imitates a Beryl, it is called a bastard Topaz, and the like.

Crystals, with a long intermediate column, are, the very bright CRYSTAL without any colour, which seems to be the most perfect kind, and is generally free from all kinds of blemish. It is pointed, as mentioned above, and consequently consists of sixteen planes or sides in all; but those on the pyramids are not of an equal breadth, two of them being narrower than the rest. It is found from the size of a barley-corn to three inches long, but the common size is an inch. It does not depend upon any other body; but where one is met with there are generally more. It is moderately heavy, will strike fire with steel, and when calcined, is of an opaque white. It is commonly met with in the mountains of Germany, but is very rare in England.

Blackish Bright CRYSTAL, with short pyramids, is always pure and without clouds. It is of various sizes, and is most commonly three quarters of an inch in length. The number of sides is the same as in the former. It is harder than common Crystal, and cannot be broken without difficulty. It is remarkably bright and transparent, and has what they call a black water. It is very uncommon, though it is sometimes found among other sorts in some parts of Italy.

Dull Whitish CRYSTAL, with irregular pyramids, has a longish and pretty thick column, and the pyramids are longer in some parts than in others. It is seldom quite an inch long, and is near half an inch in diameter. It will strike fire with steel, and calcines easily into a pure white. It is common in Germany, and is sometimes found in Yorkshire and Cornwall.

British colourless CRYSTAL, with long pyramids, and a short column, is very bright and transparent, and the thick short column has long pyramids tapering at the ends. It is usually about an inch and a half long, and three quarters of an inch thick.

thick. The planes are seldom regular, but four on the column and pyramid are frequently broader than the other two. It is so hard as not to be scratched, and is not easily broken: When calcined, which it is with difficulty, it is as white as snow. It is found in Bohemia.

Bright Brown CRYSTAL, with short pyramids, and a very short column, is always thicker than it is long, and is seldom or never either cloudy or foul; it is of various lengths, from the third part of an inch to three inches, and the diameter is always greater than the length. It is generally found in large parcels in the same place, and is extremely hard, breaking with difficulty, and in any direction; when calcined, it becomes perfectly white.

Yellow Bright CRYSTAL, with regular pyramids, and a short column, is seldom pure, there being cloudy spots, films and streaks therein; it is composed of eighteen sides or planes, like the rest; that is, six on each pyramid, and six on the column, and is found from a quarter of an inch to two in length. It is considerably hard, strikes fire with steel, and when calcined is entirely white. It is common in Silesia and Bohemia, and has been sometimes found in Yorkshire.

Bright Colourless CRYSTAL, with a short column gibbous in the middle, is a very fine sort, and has moderately long and sharp pyramids at the end; it is three quarters of an inch long, and a quarter and a half in diameter, and is found single, though sometimes it is met with among the strata of stones. It is very hard, strikes fire with steel, and calcines to the whiteness of snow.

Dull CRYSTAL, with large pyramids, and an extremely short depressed column, is a very foul opaque sort, and of a coarse texture, with a continual cloud throughout its whole substance. It almost entirely consists of pyramids without a column, and is found detached from all other bodies, but commonly in considerable numbers. It is not so hard as common Crystal, but will strike fire with steel, though not easily; and is very white when calcined. It is seldom or never found in England.

Small, Bright, Blackish CRYSTAL, with regular pyramids, is extremely clear and regularly formed; it is of various sizes, the largest among them not exceeding a sixth of an inch in length, but many are extremely small. It is very hard, and is calcined with difficulty. It is found in Germany in the cavities of a black fissile stone.

White CRYSTAL, consisting only of two pyramids, which are short, and joined base to base, is generally very pure, and is always found independent of all other bodies. It is not perfectly colourless, it being a little whitish; but it strikes fire with steel very freely, and calcines very slowly.

Brown CRYSTAL, consisting of two long pyramids, without a column, is perfectly pure, and regularly formed, and is of different sizes, from the eighth of an inch to three inches in length, and one third of its length in diameter. It is seldom found single, many of them being usually joined together in an irregular manner; and, when not joined, they are always pretty numerous. It is of a very fine water, and extremely hard, striking fire with steel, and calcining slowly to a perfect whiteness. It is found in Scotland on the sides of hills, and sometimes on the banks of rivers.

Crooked or Slanting CRYSTAL, consisting of two pyramids, without a column, is perfectly pure and transparent, and consists of an oblique, or slanting double pointed body, besides the pyramids being irregular. It is from a quarter of an inch to two inches long, and about three fourths of its length in diameter. It is of a very fine water, and is extremely hard, striking fire readily with steel. It is

found in the East and West Indies, and is common in New Spain, where it is highly valued.

Bright Blackish CRYSTAL, consisting of two very short pyramids, without a column, is a very fine sort, and appears as bright as any stone of this kind. The two pyramids join evenly base to base, though sometimes one is a little larger than the other. It is commonly found in lumps, consisting of several of these Crystals pretty close together; however, at other times, they are loose and independent of each other. It has a fine blackish hue, and is very bright, with a fine water. It is extremely hard, strikes fire with steel, and after a long calcination becomes white. It is found in Italy, Germany and France.

CRYSTAL, consisting of two pyramids only, with eight sides each, that is, having sixteen planes in all, and of a brownish colour, is of a very uncommon kind; it is fine and clear, though often spotted with large blotches of black. The pyramids are much of the same length, and the planes are extremely smooth; sometimes a hundred, or upwards, are found together, but detached from each other. It is considerably hard, strikes fire with steel, and calcines to a pure white. It is found in Virginia, on the sides of hills, among a sort of iron ore.

CRYSTAL without colour, consisting of two longish pyramids, with eight sides each, is a very pure sort, and very fine and clear; it is usually near an inch long, and a third of an inch in diameter, with the planes entirely smooth polished and even. It is usually found single, is very transparent, and of a very fine water, as well as extremely hard. It is exceedingly scarce, and, as yet, has been found only at Gosslear in Saxony.

CHAPTER XV.

Of Imperfect CRYSTALS.

SPRIG CRYSTAL is whitish and transparent, and has only one pyramid with six angles, besides the column; it is an exceeding common sort, and is very regularly formed, though it is subject to variety of blemishes. The column is always long and slender, and fixed at one end to some solid Fossil, consequently the hexangular pyramid must be at the other end. The length is from a tenth of an inch to ten inches and longer; the planes are irregular, as to length and breadth, and they differ so much from each other, that scarce any two of these Crystals are found exactly alike. They are, almost always, found in clusters, are very hard, strike fire with steel, and calcine after some time, to a pure white.

Bright imperfect CRYSTAL, without a tinge of any colour, is, by many, confounded with the former; but it is different from it, and is often sold by dealers for a white sapphire, because it is somewhat like it; it is perfectly clear, generally pretty regular, and has a long slender column with six angles, terminated by a pretty long hexangular pyramid; it is from one tenth of an inch to three or four inches long; but it is most commonly about an inch and a half. It is not found in such large clusters as the former, but is extremely hard, strikes fire with steel, and calcines very slowly to a pure white. It is found in the East and West Indies, as well as in Germany; sometimes it is so tinged as to imitate gems, and may be readily mistaken for them.

Dull Whitish imperfect CRYSTAL, with a very short pyramid, is remarkably coarse and impure, not with having films or clouds, but by being whitish throughout its whole substance; it consists of the same planes as the former, and is usually long in proportion

proportion to its thickness in the column; but the pyramid is always short. It is met with from a quarter of an inch to four inches long, and is generally found in large clusters; but it is not so hard as most of the rest; for it will not readily strike fire with steel, and yet it calcines slowly to a pure white. It is found in most parts of Europe, and particularly in Cornwall.

Bright Brown imperfect CRYSTAL, with a long pyramid, is generally known by the name of brown Crystal, and has a very fine clear texture. The form is generally regular, it having a long and pretty thick column, and is found from the size of an inch to an inch and a half in length, though some have been met with ten inches long. It is extremely hard, strikes fire with steel, and calcines, at length, to a pure white. It is found in the East and West Indies, as also in Silesia and Bohemia, as well as in the islands of Scotland.

Dull Brown imperfect CRYSTAL, with a short pyramid, is sometimes mistaken for the former, though it is not near so good, it having a dull and dead aspect. The column is regular, but always slender in proportion to its length, and is from half an inch to fourteen inches long. It is commonly found in clusters, but the columns do not adhere to each other, as in the former; and its brown colour is of various degrees, for some are pale, and others almost black. It is tolerably hard, strikes fire with steel, but will not readily calcine. It is very common in Germany, and is found in the cliffs of rocks.

Bright Brown imperfect CRYSTAL, with a short pyramid, is often tinged with various colours, but most frequently with a pale yellow; it is extremely pure, and of a bright fine texture, though often covered with a rough coat. The column is long and slender, and it is generally met with about two inches long, and not quite half an inch in diameter, but the planes are irregular; it is commonly found single, though sometimes in large clusters, and is extremely hard; it strikes fire with steel, and, after a considerable time, calcines to a pure white. It is found in the great mine at Gosslear in Saxony; as also in Virginia.

Bright Brown imperfect CRYSTAL, with a very long irregular pyramid, is called the Beryl by some jewellers, and has the greatest lustre of all the brown Crystals; but it is not very large, being only from half an inch to four inches long, and has a thinner column than others of the same length. The planes are the same in number as in others; it is very hard, strikes fire readily with steel, and calcines very slowly. It is found in Italy and Germany, and is commonly called by the jewellers, the Beryl Crystal.

Whitish imperfect CRYSTAL, with a very long pyramid, is, by some authors, called the Iris or Rainbow Crystal; it is remarkable for reflecting different colours, whence it has its name. It is not very pure, for sometimes there are large white flaky blemishes, but the form is perfect and regular; it is usually long and slender, and most commonly about three inches long. It is often met with in clusters of forty or fifty together; but the columns singly touch each other; it is pretty heavy, strikes fire with steel, and in the fire readily calcines and turns white.

Bright Yellow imperfect CRYSTAL, with a short pyramid, called Citrino by the jewellers, is very clear, pure, and of a fine texture, it being generally free from blemishes, and is from one to five inches in length; but commonly much thinner at the top than near the root. It is mostly found single, and is of a very beautiful yellow; it is not extremely hard, but it will strike fire readily with steel, and calcines slowly to a whiteness in the fire. It is found in Bohemia and the West Indies, and is made use of for stones to set in rings.

Short, Bright imperfect CRYSTAL, without any colour, may be distinguished from all others, by being very short in proportion to its thickness; it is almost always extremely pure and without blemish, and its figure has little variation. It is always fixed to some body or other, and is found of various sizes, from half an inch to three inches long, and the diameter is commonly two thirds of the length. A cluster of eight or ten of these is generally found together, but the columns seldom touch, and never adhere. It is remarkably hard, and will admit of a fine polish. It is found in New Spain, and other parts of America.

Brown imperfect CRYSTAL, with a rough coat, and five planes on the pyramid, as well as on the column, has a coarse and opaque coat, but the inside is never subject to any foulness. The column is thick and short, and the pyramid pretty long and slender; the most common size is three inches long, and near an inch and an half in diameter, and there are two broad planes on the pyramid, as well as on the column. The root is very small and inconsiderable; and it is usually found single, of a very beautiful brown, extremely transparent; and of a fine deep water. It is very hard, and calcines slowly to a pure white. It is found in the East Indies, and is in high esteem among the jewellers, it being the finest of all brown Crystals.

Brownish-white imperfect CRYSTAL, with a long pyramid, has twenty-four planes; that is, twelve on the pyramid, and twelve on the column. The texture is pretty fine, pure, and clear, though sometimes subject to foulness from flakes. It has a regular, pretty long and slender column, and is about three inches long, and little more than half an inch thick. The planes are all irregular with regard to breadth, and sometimes there is a part of them wanting. The root of this kind is long, large and whitish, and is usually found single. It is very hard, and calcines slowly into a perfect whiteness. It is found in the mountains of Silesia and Bohemia, as well as on the shores of rivers, and is in high esteem.

Yellowish-Brown imperfect CRYSTAL, with a short pyramid, having twelve planes on the pyramid, and as many on the column, is of a pure, perfectly fine sort, and is seldom subject to blemishes; though there are sometimes found very small flakes of a whiter substance. The column is long and slender, and the usual size is about an inch in length. The planes are very irregular, with regard to breadth; and the pyramidal planes differ greatly in length as well as in breadth. It is extremely hard, and will calcine at length to a pure white. It is usually brought over with the Saxon topazes.

Clear Colourless imperfect CRYSTAL, with a very short pyramid, and twelve planes on the pyramid, as well as on the column, is extremely clear, pure, and of a very fine texture, without the least spot or blemish. It is from one to two inches long; and some of the planes are broader than the rest. The surfaces of those on the pyramid are perfectly smooth, and those on the columns have deep ridges. It is commonly found single, is perfectly transparent, and has a fine bright water. It is remarkably hard, and is found in the East Indies.

Colourless, very Bright, imperfect CRYSTAL, with a pretty long pyramid, which has twelve planes, and the column as many, is generally found in clusters, and is a pure, elegant, regularly formed Crystal, though generally very small, it being not above an eighth part of an inch in length, though it has been found half an inch long or upwards. The planes seem to be nearly all of a breadth, and of the same length, and the top of the pyramid stands over the centre of the column; the planes of the pyramid are always smooth, having a high natural polish, and a

fine lively dark water. It is extremely hard, and is found in all parts of this kingdom, sometimes surrounding a single or double round ball, and at other times in the cracks, cavities, and clefts of flints, and other stones.

Blackish imperfect CRYSTAL, with very short pyramids, with twelve planes thereon, and as many on the base, is thought to be the hardest and brightest of all the class. The column is somewhat longer, and the pyramid shorter, than in others of this kind. It is so extremely small as sometimes not to be discovered, unless by its glittering, though there are some the tenth part of an inch in length, and a few the third of an inch. It is shaped like the former, and has naturally a very fine polish; it is extremely hard, and is found in great plenty in the forest of Dean in Gloucestershire.

Imperfect CRYSTAL, with a blunt pyramid, and a very short column, each of which has twelve planes, is pretty pure and clean, though sometimes subject to spots and white opaque flakes. The pyramid is blunt, broad, and fixed to a broad short column, that sometimes seems to the naked eye to be wanting. It is extremely small, the usual size being not above the twelfth of an inch in length, and nearly of the same diameter. There are various sizes in the same mass, there being small ones between the larger; but the surfaces are very smooth and pretty glossy. It is found together in large quantities, and is sometimes tinged with red or yellow. It is considerably hard and heavy, and found in Cornwall, Yorkshire, and other counties of England.

Whitish Transparent imperfect CRYSTAL is somewhat like the common Crystal, and, at first sight, seems to have the same number of planes. It is pretty fine and pure, and is of a perfect regular form, being in the shape of a pyramid with four sides, and is pretty broad at the bottom. It is generally about half an inch high, and almost as much in diameter; but there are some two inches high. However, it is often met with in large clusters, and the largest single Crystal is no bigger than a grain of barley. When it is found single, it always adheres to some fossile body at the base, and is principally met with in Devonshire and Cornwall.

Colourless, Transparent, imperfect CRYSTAL, consisting of six planes, is perfectly pure, fine, clear, and broad in proportion to its length. It is very small, being generally of the size of a grain of Wheat, and the largest is seldom more than the third of an inch in length. It is but thin in proportion to the size, and sometimes all the planes are perfectly smooth, and sometimes with ridges, appearing streaked near the extremities. It is sometimes found single and loose, and at other times in clusters that hurt each other. It is extremely heavy, very hard, and is found in pretty large quantities among the iron ores of the forest of Dean.

Black, Glossy, imperfect CRYSTAL, of a rhomboidal form, is extremely pure, and of a very regular shape. It is from a third of an inch to an inch in length, and is bright, smooth and glossy. The larger sort is usually single, and the small are in larger masses, of a fine blackish colour, and calcines to a fine purplish red. It is met with on the surfaces of the perpendicular cliffs, in the iron mines of Gloucestershire. There are many other sorts of crystals; but to enumerate them all would be tedious and useless.

C H A P. XVI.

Of SPARS, of various Figures and Shapes.

SPAR, with a narrow oblong pyramid, is very like Crystal with eight sides, and is of a pure

fine texture, it being the most perfect of all the whole class, having a column with single angles, with a pyramid, consisting of the same number. The column is pretty long, but not thick, and the pyramids are remarkably slender and pointed. The common size is the twelfth of an inch long, though some have been seen of three quarters of an inch. The larger specimens are generally found loose; but they are most commonly among the coarser strata of stones, and is sometimes tinged with a faint purple colour. It will not strike fire with steel, but will dissolve in aqua fortis, and will calcine easily in a moderate fire. It is found in the mountains of Germany, and in North Wales.

SPAR, with very short pyramids and a long column, is perfectly pure, and a regularly formed body, consisting of a pretty long and thick hexangular column, terminated by a very short pyramid with the same number of sides. It is commonly about an inch long, and the third of an inch in diameter. It will not strike fire with steel, but will ferment with aqua fortis, as will indeed every kind of Spar, and therefore this needs not be repeated. It is found in Saxony, and sometimes in Hartz forest.

SPAR, with short pyramids, and a very short column, may easily be distinguished from others by its shape, and is of a pretty pure and fine texture, but not so clear as the former. It is generally found in clusters of eight, ten, and twelve together, and has a dusky hue, with very little transparency.

SPAR, with very short and broad pyramids, is extremely pure, and of a perfect fine texture, having a pretty long and thick column, with a depressed pyramid at each end, each of which has five sides. It is sometimes met with an inch long, but the commonest sort is exceeding small, and is lodged in the strata of clay. It is found in Derbyshire, Yorkshire, and Cornwall.

SPAR, with long pyramids and a long column, which consist each of three sides, is pretty pure, but has a whitish cast and a dullish look. It is commonly about an inch in length, and half an inch in diameter. It is considerably heavy, but very soft and easily scratched. It is found in Germany, and sometimes in Cornwall and Devonshire.

Slender SPAR, with very short pyramids, consisting of three sides as well as the column, is generally pretty pure, and of a fine texture, though sometimes subject to blemishes. The common size is three quarters of an inch in length, and is of a bluish white, but sometimes approaching to a lead colour, or a yellowish brown. It is very soft, and is found in England, Ireland, and Germany.

SPAR, consisting of two long pyramids without a column, each having eight sides, is very pure and fine, and commonly about three quarters of an inch long. It is very transparent, though it is somewhat of a whitish colour.

SPAR, with short and sharp pointed pyramids, each consisting of eight sides and without a column, is very pure, and is remarkable for its short points and broad basis, and is often found half an inch thick, but never longer than two thirds of its thickness. This, as well as the former, is found in Hartz forest, in Germany.

SPAR, with long narrow sharp pointed pyramids, consisting of six sides each, and without a column, is generally fine, clear and pure, though sometimes cloudy. It is often an inch in length, but not a third of an inch in diameter, and is very soft. It is found in the mines of Mendip hills.

SPAR, with short broad pyramids consisting of three sides each, and without a column, is very pure, fine, and clear, and is very short in proportion to its thickness. It is from half an inch to an inch and a half long, with very smooth glossy planes. It is pretty transparent, and brighter than most other Spars,

Spars, as well as harder, though it will not strike fire with steel. It is found in Hartz forest.

Slender SPAR, with a long pyramid, consisting of six sides, has often been mistaken for a Crystal, it having a long slender hexangular column. The texture is extremely fine, though it is sometimes subject to flaky flaws, and is commonly two inches long, and a third of an inch in diameter. It is not so bright as Crystal, and is sometimes of other colours, which are very lively and beautiful like gems; but it is soft, and found in Mendip hills.

SPAR, with a very short pyramid, consisting of six sides as well as the column, is generally very pure and clear, though sometimes blemished, and the common size is about an inch and a half. It is naturally of a greyish white, very transparent, and pretty bright; however, it is sometimes tinged with other colours. It is very soft, and found in the mines of Derbyshire.

SPAR, with a very long pyramid, consisting of five sides as well as the column, always adheres to some solid body, and is of a clear fine texture. It is seldom more than a quarter of an inch thick, and the third part of its length high. It appears very smooth and glossy, and looks like Crystal, though it is sometimes tinged with other colours. It is pretty hard, and is found in Mendip hills.

Hard transparent SPAR, of the shape of a parallelepiped, commonly called Iceland Crystal, is extremely pure, clear and fine, and is found of various sizes from a quarter of an inch to three inches in diameter; but its usual size is two inches and a half. It seems to be smooth and even at first sight, though if nicely examined ridges will be found upon it; it is almost as transparent as fine Crystal, but is very soft, and generally found single. It is found in Iceland, as also in Germany and France; it consists of plates laid one upon another, and will cleave in the manner of Talc; and when it is reduced to powder it still retains its rhomboidal figure, which may be discovered by a microscope. It has this singular property, that all objects appear double through it, which is owing to the double refraction of the rays of light.

Milk-White Opaque Shattery SPAR has a pretty fine and perfectly equal texture; but has no determinate shape, and is found from an inch to a foot in diameter, with a rough irregular ragged surface; it is sometimes a little brownish, and sometimes inclining to a dusky red, and is pretty hard. It is found in France and Germany, and in some of the cliffs of the Welch coasts, as well as in Yorkshire and Scotland.

Hard, Grey, Transparent SPAR, is of a pure equal texture, and has the appearance of Crystal, though it is sometimes tinged with the colour of gems. It has usually the figure of common flints with very uneven surfaces, and the size is from two inches to six or eight in diameter; it is frequently tinged with green, and sometimes with yellow. It is pretty hard, and is found in the lead mines of Scotland, and in other places.

Transparent, Colourless, Shattery SPAR, is nearly like Crystal, and is of a pure, fine, regular texture; but it has no determinate figure, being found of various shapes and sizes, that is, from half an inch to five inches in diameter; it is dark on the outside, but when broken is extremely bright and glossy, and with a small blow it will fall into many rhomboidal thick masses. It is not very hard, and is found in Hartz forest.

Naturalists divide Spar into innumerable other classes; but, after the Reader is well acquainted with such as we have here mentioned, he will easily distinguish those of an inferior sort, without being burthened with a long account of them in print.

C H A P. XVII.

Of Crustated SPARS debased with Earth.

HARD, Semi-Transparent, Yellowish-Brown SPAR, has an equal regular texture; though not very fine, and the earth is regularly diffused throughout. It always conforms to the shape of the substance to which it is joined, and consists of a thin crust extended over flat, round, and irregular surfaces. It is from the twentieth part, to the third part of an inch thick, and is from a few inches, to many feet in breadth. It is very soft, and is found in many parts of England.

Brittle, Transparent, Whitish SPAR, is of a pretty pure fine texture, though sometimes transversely streaked with earth, rendering it red, yellow, brown or black; it is formed like a crust, and is sometimes flat. It is found on the sides of the perpendicular clefts of the mines in Germany, and the caverns of Mendip hills.

Hard, Whitish-Brown, Dusky SPAR, is foul and impure, though of a regular texture: it is extended over various bodies in the form of a crust, and is from an inch and a half broad to five or six feet. It is pretty hard, and is found in Hartz forest, as well as in the lead mines on Mendip hills.

Dull, Pale-Brown, Brittle, Coarse SPAR, is the most common of all the crustaceous Spars, and is very coarse, impure and earthy, being often tinged with various colours, by the different earths it is blended with. It is of no certain size, and it conforms to the shape of the mass to which it gives a coat. It has a pretty even surface, the wrinkles being never deep; and, when broken, it is of an irregular texture. It will readily crumble between the fingers, and is found as well on the inside of pipes for water, as in tea-kettles.

White, Light, Brittle, Earthy SPAR, is the coarsest of any of this kind, and the whole mass is light, loose and brittle; for some of this kind will not bear touching without crumbling to pieces. It has very luxuriant efflorescences on its surface, and more than any of these bodies. It is met with in various places.

Light, Hard, Pale-Brown, Earthy SPAR, with a smooth surface, often incrusts round moss, for which reason some have taken it for petrified moss. It is of an equal uniform structure, but foul, and always assumes the shape of the body it is formed upon. It is pretty hard for an earthy Spar, and is found in all parts of the world.

Whitish, Brittle, Crustaceous Earthy SPAR, with a rough surface, is of a very coarse, foul, impure texture, and of an earthy colour. It is always of the shape of the thing it incrusts, being sometimes met with on small stones, branches of moss and the like. It is of a dull whitish colour, without the least brightness, and is very soft and brittle. It is found in the subterraneous caves of various countries.

Hard, Pale-Brown, Thick, Rough, Earthy SPAR, which is the osteocolla of the shops, is of a very coarse, foul and impure texture, having the appearance of hardened marl. It is always found in long, thick, irregular, cylindrical pieces, usually hollow, and sometimes filled up with a softer substance. The surface is always rough and deeply wrinkled, being without the least brightness. It is very hard, and is found in many parts of Germany. It has formerly been much esteemed as a medicine, though it is now out of use.

Whitish-Grey, Brittle, Earthy SPAR, with a smooth surface, by some called the Fossile Unicorn, and by others Stone Marl, is of a stony substance, and in colour, smoothness, and form, represents the horns, teeth or bones of animals; but sometimes it is softer, with a hard yellowish, blackish, or ash coloured

coloured crust, while it is soft and brittle in the inside. This has an astringent taste, and adheres firmly to the tongue. It is frequently dug up in pieces resembling bones that are petrified; among which are the teeth called grinders and incisors, which are extremely large, to which there is a root plainly connected. Sometimes they look like the fragments of bones of the arms and legs; and sometimes they appear like the branches and trunks of trees turned into stone. They are found in various parts of Germany, as also in a hill near Paris, where they appeared to be real bones, covered over with a stony substance. It is commended by the Germans for being an astringent, promoting sweat, and for stopping bleedings and loosenesses. It is given in the epilepsy from half a scruple to a drachm.

Whitish-Brown, Tuberosé, Unequal SPAR, in the shape of coral, is of a pretty fine texture, and contains less earth than others of this kind. It is commonly in the shape of a small oblong cylinder, with a pretty even surface, though it has often several branches like the coarser white fossile corals. It is about two inches and a half long, and the third of an inch in diameter; when broken, it is firm, solid and compact. It is found lodged in the strata of yellow clay, and is very common in France and Germany; it is also met with near London.

Hard, White, Oblong, Conical SPAR, is extremely pure, and is as crystalline as any Spar whatever. It has the appearance of an icicle, broad at the base, and tapering towards the point; and its natural place is the arched roof of a subterraneous cavern. It is found from an inch to fifteen inches in length, and is sometimes perfectly round. These Spars are formed by water dropping from the roof of these caverns; and consequently it is often met with in a petrified state on the ground formed into various shapes; we have a remarkable instance of this in Pool's-Hole in Derbyshire, which is considered as one of the wonders of the Peak.

There are also other Spars of various colours, which are found hanging to the roofs of caverns; but which, in reality, differ very little in their nature from the former.

C H A P. XVIII.
Of S A L T S.

FOSSILE SALT, commonly called Sal-Gem, is of several kinds; it is almost as transparent as Crystal, and is sometimes as white as snow, at others grey, red or yellow. When dissolved in water and crystalized, by evaporating the moisture, it becomes of a perfect cubical shape. It is called Sal-Gem, because it has some resemblance to stones of that kind; but it may be readily distinguished from them, by applying it to the tongue. There are large rocks of this kind in different parts of the world, particularly in Spain near the river Ebro, and there is one of a purple colour in Portugal, and in Poland and Russia there are several. It is pretended in Spain, that it grows as fast as it is taken away; however, it is certain, the mine has been opened five hundred years. In Poland, six miles from Cracow, they hew the Salt out of the mountain, in the same manner as they do stone, in very large pieces. It has the same virtues as common Salt, and is used as well for clysters as suppositories to evacuate the hard excrements. But this must never be used where there is an inflammation of the intestines.

Common SALT is either made with sea-water, salt springs, or wells, by the heat of the sun, or by boiling. In some places they dig pits near the sea, and line them with clay; they afterwards fill them with sea-water at high tides, and the water being

exhaled by the heat of the sun, there is left plenty of Salt at the bottom. In Neustria, that is, in the western parts of France, they heap up the sand on the sea-shore, on which they pour sea-water often, and after the moisture has been exhaled by the heat of the sun, the salt is left behind. When there is a sufficient quantity, they boil it in fresh water, and then strain it off into leaden vessels, when they boil it again till it is become of a proper thickness; after which they remove the fire, and suffer it to coagulate into whitish crystals of Salt. They make Salt from salt springs much in the same manner, though there is a particular art in causing it to granulate; for some mix bullocks blood therewith, to cause a quicker separation of the Salt from the bitter. This likewise frees it from the bituminous and earthy particles mixed with the Salt, which are either carried off in froth, or remain in the bottom of the pans. But that is the best Salt which is made with lakes of sea-water, by the heat of the sun, because that which is made by fire has generally somewhat of bitterness. That made with the water of salt springs or wells is most pungent, on account of the alkalious mineral Salt mixed therewith; and is more apt to dissolve than the former, even with a moist air; therefore, that made with sea-water by the heat of the sun is more fit for medicinal purposes, and is commonly called Bay Salt. This Salt also, when dissolved and crystalized, is of a cubical form; but that made either with salt springs, or sea-water, by the assistance of fire, cannot be brought into exact cubes, on account of its mixture with other Salts. Bay salt dissolved in water, which being evaporated till a cuticle appears, will shoot to cubical crystals when cold; but that which is left, being of an alkaline nature, cannot be crystalized into any regular figure; however, there is a Salt made therewith, which is now generally known by the name of Epfom Salt. The spirit of Salt, when mixed with an alkaline Salt, as long as they will ferment together, will turn to common Salt, which in its taste, and its cubical shape, resembles Bay Salt; whence it appears, that sea Salt is an acid perfectly saturated with an alkaline Salt. The use of sea Salt is well known for its preventing flesh from putrefaction; and therefore is necessary to hinder the fermentation of victuals, and their corruption; it likewise restrains the heat of the fluids in the body. Besides, when volatile urinous salts are mixed with it, it turns into a Sal-Ammoniac, which is proper to temperate the sharpness of the humours, and to cleanse them by urine. People are in doubt whether it prevents or breeds stones in the kidneys, for many affirm, that the latter is true; but then it must be understood of meats that are rendered hard by being over salted. The spirit of Salt is proper to promote urine, to prevent the stone, to cure the dropsy, and to quench thirst in burning fevers. It is excellent against the scurvy, and is given from three drops to twenty or upwards; or as much as will make any liquor agreeably acid. Dulcified spirit of Salt is given from fifteen to twenty drops every morning, in a decoction of juniper berries.

NATRUM, or NITRUM, of the ancients, is vastly different from the Nitre of the moderns. By old authors, it is said to be an acrid Salt of an alkalious nature, brought from Egypt and other places, which would ferment with acid liquors, and was used for washing of cloaths and for making glass. Natrum is now found in Lesser-Asia, in little hills, like mole-hills, in the spring and summer, of which they make a lye for washing their linen. It is at present seldom seen in Europe, though it was of frequent use with the ancients, not only for medicine, but various other purposes. The natrum of the ancients was a native Salt of a whitish colour and a bitterish taste, which did not crackle in the

fire like common Salt, nor flash like Saltpetre; but it would melt and swell like alum and borax, as well as ferment with acids; whence it appears to be much of the same nature as pot-ashes.

NITRE of the moderns, commonly called SALT-PETRE, is a white crystalline substance, of an acrid bitterish taste, and seemingly a little cold. Its crystals are in the shape of prisms, with six sides, which are slender, long, equally thick, and terminate at each end, like a pyramid with a point. It dissolves readily in water, melts over the fire, and will not flash, unless mixed with sulphur or charcoal; and then it will with great violence. Saltpetre is often seen on old walls that are not washed by the rain, from whence it is taken off with brushes. Artificial Saltpetre is made with earth saturated with common or pigeons dung, whose salts will, in time, be converted into Saltpetre. As Saltpetre cannot be obtained, except from earth impregnated with urinous, animal, or vegetable Salt, some are in doubt whether it is a mineral or animal production; but it is generally reckoned among those that are mineral, because it may be extracted immediately from the earth, and not from any excrements themselves, unless they be mixed with earth.

The spirit of nitre will dissolve silver, whence it is called aqua fortis; and it will communicate the same power to spirit of vitriol and spirit of sulphur. However, aqua fortis will not dissolve gold; for that is only to be done with aqua regia.

NITRE is used in medicine to cool the blood, and to restrain the heat of a fever, to allay thirst, and to hinder putrefaction; for which reason it is commended in malignant cases. It is given from three grains to a scruple, three or four times a day. A drachm given every morning, dissolved in a draught of ale, has been found to cure the dropsy. When Nitre is put into a crucible, and placed over the fire, it will melt like water; and then, if powdered charcoal be thrown into it, it will deflagrate with a noise, which being over more powder must be thrown in, and this must be repeated till the Nitre will flame no longer. By this method, the Nitre will turn into an alkalious salt, which has the same virtue as salt of tartar. Every one knows, that Nitre mixed with due proportions of sulphur and charcoal will make gun-powder.

VITRIOL is either native or factitious, and, with regard to the colour, is distinguished into white, blue and green. White Vitriol is brought from Germany in large lumps, which look almost like loaf-sugar, and has a sweetish astringent taste. It is found in mines at Gloslaer in Saxony, where it springs forth from the sides, under the appearance of a woolly substance, which being dissolved in water, must be boiled to a due thickness; and at last, it will turn into a white mass like sugar. Sometimes there are found in the same mines pieces of Vitriol, which are already crystalized and appear transparent.

Blue VITRIOL is dry to the touch, and is formed into blue crystals, like sapphires, of a rhomboidal form, but flat, and with ten sides. It is prepared in various places, but more particularly in Cyprus and Hungary; whence it is commonly called Hungarian and Cyprian Vitriol. It obtains its fine colour from copper, and has an austere taste, with great sharpness.

Green VITRIOL is of an herbaceous colour, and has various names, according to the different places from whence it is got. It abounds with iron from whence it has its colour, and is either in large crystals of a rhomboidal form, or in bits composed of crystalline grains united together, which feel a little oily to the touch; it has a sharp styptic taste.

VITRIOL is nothing else but an acid vitriolic salt, which by corroding zinc, copper, or iron, co-

gulates with them, and so concretes into a transparent body, which takes its colour from the metal. Blue Vitriol is now got in Hungary from water in the copper mines, near Smolnik and Newfol, by evaporation; and green Vitriol is obtained in Germany after the same manner. But in England, at Deptford, near London, green Vitriol is obtained from a stone, called Pyrites, which is heavy and brown on the outside; and, when broken, there are rays that appear to run from the center to the circumference; and consist of particles that shine like brass, and yet are without any taste. These stones, after they have been exposed to the air for some time, undergo a sort of fermentation, and then crack into clefts, out of which a kind of white down of a saltish nature springs forth, which has an acid styptic taste; at length the whole substance dissolves, and turns into a fine saltish powder, of a vitriolic taste and sulphureous smell. If these stones are calcined in the fire, a copious smoke will exhale from them, with a sulphureous smell, and a red calx will remain behind, containing a little iron and copper.

White VITRIOL is extremely good for making an eye-water, which is, perhaps, the best hitherto known for abating inflammations of the eyes, and to repel fluxions thereon. It is made by dissolving a scruple of vitriol in hot rose water, and then passing it through a linen cloth: a few drops of this is to be put into the eyes. When blue vitriol is calcined, it is very proper for stopping hæmorrhages, by cauterizing the vessels, and condensing the blood therein. Spirit of Vitriol, like other acid spirits, restrains the heat of the humours, stops hæmorrhages, and promotes urine.

ALUM is either native or factitious; but the former sort is now little or not at all known. The factitious is distinguished by the name of the country it comes from, it being of several kinds; for there is scarce a country in which it is not made. One sort is called Roch, or Rock Alum, because it is sometimes got out of a rock, where it is often met with in very large pieces.

In Yorkshire and Lancashire they get their Alum out of a bluish stone, like slate, that is full of sulphur. It is a sort of Pyrites, which will kindle in the fire, and being exposed to the open air will break of itself. The fragments of these stones are laid in heaps, where they are burnt in the open air; and when the sulphur is quite exhausted, the fire will go out of itself, after which they steep the calcined stones for twenty-four hours in water, when it is drawn off into leaden cauldrons with the lye made with the ashes of a sea-weed. After the liquor begins to boil, they pour urine therein, which causes the sulphur, vitriol, and earthy matter to sink to the bottom. This done they take the liquor and pour it into vessels made with deal boards, where, in time, the Alum concretes to the sides, in white transparent crystals, which, after washing, are melted in iron cauldrons; after this it is poured into a tub, and forms a mass of the same size. However, in different countries, they have different methods of making Alum, which would be tedious, as well as useless, to relate.

Alum is of a very binding nature, and has always been looked upon as a great styptic. That of the ancients had a smell like aqua-fortis, but the factitious has none at all; and, when placed over the fire in an iron pan, it bubbles up and melts like water. When Alum is set to crystalize, it concretes into a figure with eight sides, which looks like a triangular pyramid, with the angles cut off; inasmuch that it is composed of four hexagon surfaces, and four that are triangular. From a chemical analysis it appears, that Alum consists of an acid vitriolic salt, and an astringent earth or bole intimately united. Alum is recommended for swellings of the gums, and against the fluxions upon the tonsils. When burnt,

it will take down proud flesh in wounds and ulcers; it is of no use internally, only it is sometimes given with a large portion of nutmeg for the cure of the ague.

SAL-AMMONIAC, of the ancients, was a sort of fossile Salt or Sal-gem, though Dioscorides would have it to be a kind of common Salt, which is dense, transparent, white, easily cloven, and dug out of the earth; all which have the properties of Sal-Gem; for it will readily cleave into plates.

Factitious SAL-AMMONIAC is of two sorts, one of which is brought from the East Indies in conical pieces like sugar loaves, of an ash colour; but this is very scarce. The other and common sort is brought from Egypt and Syria in flat cakes, convex on the upper part with a sort of a navel, and a little hollow on the other; they are about a palm in breadth, and three or four inches thick, of an ash colour without, and whitish within.

SAL-AMMONIAC is a very useful medicine, for it dissolves thick clammy humours, and carries them off by sweat and urine. Some commend it in agues, given to the quantity of half a drachm, with a scruple of crabs eyes before the fit. The Volatile Salt and spirit of Sal-Ammoniac are good in a lethargy, apoplexy, fainting, giddiness of the head, and hysteric fits, being held to the nose. Internally, the spirit promotes a diaphoresis, sweat and urine; it blunts acid humours in the body, promotes the circulation of the blood, refreshes the spirits, excites the oscillations of the nerves, and opens obstructions. Whence it is good in the apoplexy, epilepsy, lethargy, sleepy diseases, and in hysteric fits. It may be given from six drops to a drachm in any proper liquor.

BORAX is of two sorts, the one native, and the other refined. Native Borax is brought to us in bits of the size of large hazel nuts, and of a dark green colour, covered with a sort of earthy fat matter. It is found in various places, and is brought from the empire of the great mogul, and from Persia, where it is found in mines of metal, especially those of copper, from whence proceeds a saltish, muddy, greenish water, which is carefully caught, and being evaporated into a proper thickness, is afterwards poured into pits lined with a paste, made with the mud of these springs, and the fat of animals, which are also covered with the same paste. After some months they are opened, and find the water concreted into stones. When Borax is purified, it appears clean, white and transparent, somewhat like the crystals of Alum, with a slight saltish taste, and a lixivious sharpness. It is of the same substance with the native, and was formerly brought from Venice. It is imported to us from the East Indies, and principally from Bengal. When Borax is placed over the fire, it swells like Alum, and at length melts into a hard transparent mass, resembling glass, which, however, will dissolve in water. After examination, it appears that Borax is a sort of a fixed Salt not unlike that of Tartar; but differs from it in joining with acid Salts, without any effervescence. Borax is used by goldsmiths for soldering gold, and to render the melting of metals more easy; likewise, it is employed by some dyers to give a gloss to their silks.

C H A P. XIX.

Of SULPHURS, BITUMENS and COALS.

COMMON SULPHUR, or BRIMSTONE, is either native or factitious, or rather depurated. Native Sulphur, commonly called Sulphur Vivum, is either transparent or opaque; the transparent appears like a gem of a gold colour, though some is

met with that is yellowish or greenish. It is found in the gold mines of Peru, particularly in Quito, on the island of Milo, in the Archipelago, and in the canton of Bern, in Swisserland. The opaque is usually met with in hard solid masses of a greenish shining colour, or under the form of an ash coloured clayey glebe, inclining to yellow. It is in the greatest plenty at the feet of the mountains that throw out fire and smoke, such as Vesuvius, Etna, Hecla, and the like; as also in some parts of Europe and America, where there are sulphureous earths or fountains.

Factitious SULPHUR is prepared several ways; for in some places it is boiled in water, as at Buda in Lower-Hungary. At Aix la Chapelle, in the hot baths, Sulphur is raised in vapours from the water, and sticks to the cover of the spring in hardish lumps, that have the appearance of flower of Sulphur, and a great quantity of this is gathered every year. Sometimes it is extracted from a whitish clayey earth; and is as often obtained from the stone called the Pyrites, particularly in the diocese of Liege, where they are found like lead ore.

ORPIMENT is an arsenical juice, compacted into glebes, consisting of thin scales or leaves, almost like fling-glass, which may be easily separated from each other. There are three kinds, one of which shines like gold, another is reddish mixed with a citrine colour; the third is greenish and mixed with earth; but the first is best. They are found in mines of gold, silver, and copper.

ORPIMENT has a sharpish taste, will dissolve in oil, readily take fire, and emit a copious fume; between the smell of sulphur and garlick. By the heat of the fire it will dispense in plentiful fumes, which if collected, concrete in yellowish flowers, like sulphur; and at the bottom of the vessel there will remain a blood-coloured melted mass, which, when cold, becomes thick and solid, like cinnabar. This, by some, is called red Orpiment, or Realgar. If this mass be kept longer over the fire, in a sublimating vessel, it will rise to the upper part, and there concrete into a transparent, red, elegant substance, like a ruby; but at the bottom there will remain a little metallick earth.

Hence it is plain, that Orpiment consists of the same principles as common Sulphur, only it is mixed with some mercurial particles. Some take it to be of a very poisonous nature; but Hoffman, after many experiments, by giving it to dogs, has found that it is intirely innocent. It is made use of by some barbers, mixed with lime, to take off the hair where it is superfluous; but if it lies on long, it will corrode the skin, which doubtless is owing to the lime.

REALGAR, called ZARNICK by some, is, by others, named Red Orpiment. It is of two kinds; that is, native and factitious. The native, which is got out of mines, is of the colour of cinnabar, and smells like a mixture of sulphur and garlick when it is burnt. The factitious is made with Orpiment in sublimating vessels; for the yellow part will rise towards the top, and the mass that remains at the bottom is the Realgar. However, we are not to confound this with the red factitious Arsenick hereafter described.

Realgar is brought into Europe from China, in several shapes, which they call Pagods, these seem to be made by melting, not carving. Some ancient physicians have given this inwardly; the natives of the East Indies make cups herewith, and the water poured therein, after some time, is used as an excellent remedy against several diseases. Some think that it would not have the like effect on European bodies; for they suppose the nature of man in the East Indies and ours to be greatly different; but this is a mistake. However, it is uncertain whether
Realgar

Realgar be as innocent as Orpiment, or not; but that it is not poison is certain, for Hoffman gave two scruples of it to a dog, without the least bad consequence, and he was as well afterwards, as if he had taken nothing; but this is not the case with the flowers of Orpiment, for a scruple of these being given, it excited enormous vomiting; however, it did not kill, but if the flowers are obtained another way, that is, by mixing four ounces of Orpiment with three ounces of oil of Vitriol, they will yield an ounce of the flowers adhering to the neck of the retort, which are entirely innocent; for they are almost tasteless and promote sweat more powerfully, perhaps, than any other medicine.

ARSENICK, properly so called, is in Bohemia and Saxony extracted from a mineral called cobalt. If this be mixed with calcined flints and pot-ashes, the mixture, in a very strong fire, will turn into a glass of a bluish colour, that when reduced to powder is called smalt. In the preparation of this glass a copious smoke is exhaled, or rather flowers, which sticking to the sides of the furnace, and collected together, appear in the form of a white powder, which put into a crucible, and melted in an exceeding strong fire, turns into a white, heavy, hard, glassy mass; and this is named white Arsenick, which is a most dangerous poison. But when to ten parts of the former powder, one of sulphur is added, and melted, as before, then yellow Arsenick will be produced. Again, if two parts of the sulphur are added to ten of the powder and melted, as before, it will turn to a reddish mass, which goes by the name of red Arsenick.

COBALT itself is a fossile body, which is heavy, hard, and almost black, not very unlike antimony; it has a sulphureous, nauseous smell, when kindled in the fire, and is commonly mixed with a portion of brass, and sometimes of a little silver. Cobalt is found in some parts of England, and particularly in Mendip hills in Somersetshire; but some think it is not so good as that of Saxony.

NAPHTHA, or PETROLEUM, is a mineral oil of a bituminous nature, which is inflammable, and has a fragrant smell. It is of several colours, as white, yellow, red, and blackish. There is scarce any country where this bitumen is not to be found; but in the island of Sumatra there is an excellent sort, which by the inhabitants is called *miniac tanna*, which signifies oil of earth; and this is in high esteem in the East Indies. The Italians are lavish in their praises of the Petroleum found in Modena, and obtained from certain springs and wells. The earth of this dutchy abounds therewith; but that is most remarkable which is met with in the place called Il Fumento, where there is a well near forty yards deep, whose water is mixed with this oil. Twelve miles from Modena there is a noted rock, where there is a spring, on whose water a yellowish oil is seen swimming; and this will produce about twelve pounds of this oil in a week.

Petroleum readily flames, for which reason, in many places, it is used for lamp oil. It consists of fine volatile parts, upon which account, if a candle be held over the wells or fountains that yield this oil, the vapours will readily take fire. It is difficult to unite spirit of wine with Petroleum, it being of such a fat consistence. That Petroleum is generally counted best which is fresh, white, transparent, and has a subtle bituminous smell; the next in esteem is the yellow, then the red, but the black is worst of all. A few drops of this oil is given to children to kill worms; and it is used outwardly in the palsy, and for cold pains of the nervous parts.

Mineral PITCH is a kind of reddish or blackish bitumen, having a fragrant bituminous smell. It is of a middle consistence between petroleum and bitumen, and is not unlike tar. It grows more fluid

in heat, and thicker with cold; and it emits a flame when kindled. It is by some authors called Pissasphaltum, and springs out of the earth in several places between the chinks of stones. That at Castro near Rome rises through the clefts of stones, chiefly in the summer time, of the consistence of honey, and is of a black colour and a most subtle smell. In Auvergne in France there is a plentiful spring of this bitumen, which has the appearance of tar, it being black; but if it be kept a considerable time, it will grow harder, but not so hard as pitch. That most common in England is Barbadoes tar, which is a liquid bitumen, and is used externally, for all pains proceeding from a cold cause; as well as numbness, cramps, and palsies. It is given, inwardly, in pretty large doses, for the dry belly ach.

Jews PITCH is a sort of bitumen, which is solid, brittle, heavy, of a reddish black, shining, and inflammable, with a strong bituminous smell, especially when it is melted over the fire. It is found in several places, and particularly in Judea, from whence it has its name. It is found swimming on the top of the Dead-Sea, and is, at first, soft, thick, and may be readily pulled in pieces; but, by length of time, it becomes harder than common pitch; it is known in the shops by the name of Asphaltum. The true sort is seldom brought to us; for what we have is entirely black; only when it is broken, it has a saffron colour cast.

AMBERGREASE is of an ash colour, or grey, and is a fat solid substance, like suet, but light. It is variegated like marble, and is sometimes speckled with white; it springs from the bowels of the earth, is condensed in the sea, and is found floating on the water, though sometimes it has been met with on the sea shore, where it has been thrown by the waves. It is sometimes black as well as grey; but the grey is accounted best. There is little room to doubt that this is a sort of bitumen, which proceeds from the earth near the bottom of the sea; for it sometimes contains stones, shells, the bones of animals, and the bills and claws of birds, as well as honey-combs, from which the honey has not been all lost. Hence it appears, that this bitumen must have been first in a liquid state; it has been sometimes found in lumps of above two hundred pounds weight. A great deal of this is got in the Indian ocean, about the Molucca islands; though it has also been found near Africa, and sometimes near the northern parts of England, Scotland, and Norway.

Ambergrease will readily melt in the fire into a sort of gold coloured rosin, which will kindle and burn when held to a candle. It will not dissolve entirely in spirit of wine, but leaves a black pitchy matter behind it. The solution, after some time, will deposit a white cloudy sediment, which will coagulate by little and little, and grow thick, especially by the evaporation of the finer parts of the spirits of wine; this being dried becomes a shining sort of earth, not much unlike sperma-ceti. It consists of oily greyish particles, which are very fine and volatile, with others that are thicker, saline, and bituminous. Ambergrease is of great use among perfumers, and is recommended by physicians for raising languishing spirits, and increasing their motion; whence it is given for disorders of the brain and heart, as well as in fainting fits. The dose in substance is a pill of the size of a small pea, or from one grain to eight in a poached egg or wine.

AMBER is a hard bituminous substance, brittle, somewhat transparent, and of a yellow or citrine colour, though sometimes it is whitish and sometimes brown. The taste is somewhat acrid and bituminous, with a little astringency; the smell, when warm, is fragrant and bituminous; and when rubbed it will attract straws and bits of sticks by its electrical

electrical virtue. It is found in large quantities in Prussia, which is the country where it is chiefly got, particularly in the Baltick sea near the shore of Sudavia, where it is found swimming upon the water, and is taken in nets. However, this bitumen is not a production of the sea; for its water only serves to wash it off from the bowels of the earth, and remove it to places near the shore. The veins of this bitumen have been found, by the order of the king of Prussia. In digging for them they first met with sand, which being taken away, a stratum of clay appeared, and still deeper there was another like old wood, under which there was the mineral of vitriol, which being exposed to the open air, it was covered with an efflorescence of green vitriol. Still deeper there was a sandy mineral, out of which, with proper instruments, they got Amber in various places. By this means, in the March near Kustrin, as also in the Tract of Stolpen and Dantzick, it was met with among sand; and found collected in heaps; whence it appears they were greatly mistaken, who took it for the resin of trees that dropt from them into the sea. It seems to proceed from the bituminous fossile wood, just mentioned, by the assistance of the subterranean heat; which, at first, is probably like Petroleum, and after passing through the mineral of vitriol, by the mixing therewith, becomes coagulated into a hard body. There is no doubt that it has been liquid, because it is often found in a round form, containing several sorts of insects therein; besides, the oil which is obtained from Amber, is, for virtue and smell, like Petroleum. Charlton, who was a very great naturalist, has sometimes found real Petroleum included in pieces of Amber, which is a farther reason to prove what is asserted. The greatest plenty of this bitumen is found near the shore of Sudavia, after a violent north wind, attended with a tempest. Sometimes Amber is so transparent, as to serve to make burning glasses, one of which is kept in the cabinet of the Landgrave of Hesse-Cassel. Amber, properly prepared, becomes a medicine for opening the obstructions of the bowels, and promoting all sorts of excretions; and consequently is a very useful remedy in chronical diseases. It is likewise said to be very efficacious in curing cold disorders of the brain, and particularly in pains of the head, sleepy and convulsive diseases, as well as in hysteric and hypochondriac fits. The dose is from a scruple to a drachm in a poached egg, or any other proper vehicle. The volatile salt of Amber is diuretick, and accounted a specific in hysteric and convulsive diseases. The dose is from ten grains to thrity. The oil is commended in nervous disorders, particularly in the gout, palsy, and catarrhs, by anointing the parts therewith. It is given inwardly from two to twenty drops.

JET, called by some Black Amber, is a bituminous substance, dry, hard, black, smooth and shining, and being set on fire turns almost like pitch, emitting a thick smoke, with a bituminous smell. It differs very little from pit-coal, especially the finer sort, which we call Kannel coal, if it be not the very same. It differs from a bitumen in not melting as that will do, and when distilled it yields a sharpish acid phlegm, and then a black oil; but last of all a substance like butter, or thick oil. It leaves behind it a very black caput mortuum.

PIT-COAL is universally known in these parts, and when distilled in a retort, first yields a phlegm, then a sulphureous spirit that is a little acrid, which is afterwards succeeded by a subtil oil, and then one that is thick, which sinks to the bottom. With the greatest degree of fire there is produced a sort of an acid salt, like that of Amber, leaving behind it a light black earth. When the spirit is thrown on quick lime, it becomes volatile, and strikes the nose

No. 43.

with a strong smell; spirit of nitre being added to this, a white smoke will arise, which yield a very pleasant sight. The foetid oil being mixed with salt of tartar, has the smell of volatile salt, and when this mixture is distilled, it yields an alkaline, volatile, oleous spirit, which will turn syrup of violets green; but if it be mixed with an acid, it will immediately ferment, and become of a bright red colour. The thick oil of coals has a sulphureous smell, and being put into a silver spoon, with a gentle heat, will turn it blackish, which is a certain sign there is a true mineral sulphur contained therein, for common sulphur, dissolved in oil of turpentine, will do the same. Hence it is plain, that coals contain nothing that is unwholesome; nor is there any arsenick at all in them, though some have supposed the contrary. Nor yet is the mineral sulphur which they contain so hurtful as some have imagined; for those that are employed in the melting and preparing sulphur are as well, and in as good case as other people, and much better than miners of other kinds. Coals are so far from doing any harm, that they are rather beneficial, by drying up the too great humidity of the blood, and preserving the body from putrefaction; for it has been observed by Galen, that all bitumens, being kindled, mend the disorders of the air, by dispersing their too great humidity; which opinion has been hitherto followed by all phisicians. Where the atmosphere is very moist, and full of watery vapours, so hurtful to human bodies, the burning of Coals is certainly very proper. In former times, when the plague and other infectious diseases were common, they used to burn bitumen to purify the air; and this is certain, that in London, since the burning of Pit-Coal has been almost universal, no plague has ever affected that city; nor any disease of that kind; and therefore there is no reason to be afraid of it, unless it be brought from other countries.

There are mines of Coals dug in various parts of England, which generally differ, in some respect, from each other; those brought from Newcastle, improperly called Sea-Coal, are remarkable for their being generally small, and caking on the fire. These are the best for boiling flesh, which others, in various parts of the kingdom, will not do, particularly in Staffordshire. Kannel Coal, which is dug up in Derbyshire and other places, is famous for its fineness, as well as hardness, though it will burn like a candle; there are now several things made with it, such as the tops of snuff-boxes, salt-cellars, and the like. It is also found in Staffordshire, and it is remarkable, that the choir of the cathedral church of Litchfield is paved therewith; that is, the black part with Coal, and the white with alabaster, which look like black and white marble. It will turn like ivory, into ink-pots and candlesticks; and some have their coats of arms carved thereon. The other Coals most used in London are brought from Wales and Scotland, and are valued for burning clear without a great deal of smoke.

CH A P. XX.

Of METALS and SEMI-METALS.

ANTIMONY is a mineral, consisting of sulphur and a mercurial arsenical substance, as is universally allowed by the chemists. It is solid, heavy, brittle, of the colour of lead, consisting of long shining streaks, and will melt in the fire, but is not malleable, in which it differs from a metal properly so called. There are several kinds of it, one of which looks like polished lead; but it is brittle, and mixed with a sort of crystalline stone. Another consists of slender shining lines, that look like needles placed

placed in rows, in some places, and in others without any order. A third kind is made up of broader shining plates; and a fourth of small lead coloured rods, which melts in the fire as readily as sulphur, on account of the large quantity of that substance contained therein: this is found in Italy, near Massa in Tuscany. There is still another kind, which may be distinguished by saffron coloured, or reddish spots dispersed here and there; and this is met with in the gold mines of Hungary. In short, there is scarce any part of the world where this mineral is not to be found, and though they seem to be of so many different sorts, yet their natures are nearly the same.

The Glebe of Antimony is generally mixed with a stony substance, which it is freed from by melting. They first break it into bits, and place it over the fire in earthen vessels, with holes at the bottom, under which there is another earthen vessel in the form of a cone, and when it is in fusion it runs through the holes, and leaves the dross behind. That which is hard, heavy, of a lead colour, with shining streaks, placed like rays, is accounted the best, and the Hungarian Antimony, for this reason, is chosen for medicinal purposes. The sulphur in Antimony may be readily perceived, not only from the smell, but from the bluish flame it emits while it is melting. Besides, when nitre is thrown into the crucible, containing red hot Antimony, it flashes in the same manner as with common sulphur.

It was formerly thought, that the sulphur of Antimony partook of the nature of gold; for which reason they employed themselves to little purpose in making experiments to extract the fine sulphur therefrom. Notwithstanding this, it is now generally acknowledged, that the sulphur of Antimony is exactly of the same nature as common sulphur, though all the reguline parts are seldom extracted from it; nor yet can that be called the pure sulphur that rises in flowers, when sublimed; for, though it takes fire like sulphur, yet the fume is of a whitish-yellow like that of orpiment. Besides, that it is not pure, may be known by its effects; for it will occasion violent vomiting, which is a certain sign that it is not entirely freed from the reguline particles. If you take white arsenick and mix it with half sulphur vivum, and afterwards sublime the mass, there will arise reddish flowers, which, when taken inwardly, have a very violent operation, and when they are set on fire emit a reddish fume; for there is such a force in mineral sulphur, that it will readily join with the arsenical particles, and carry them up therewith, when sublimed.

There is no substance in the world that yields so powerful a poison, and such efficacious medicines, as Antimony; however, when crude, it has no violent operation, and yet, taken in a proper quantity, may be given very advantageously in many cases, both to men and cattle. But if crude Antimony be melted in the fire, and mixed with the like quantity of nitre, by little and little it turns to a poison; and yet, if Antimony is mixed with one part of common salt, and calcined over a gentle fire for some hours, continually stirring it with a spatula, and afterwardsedulcorating with water, there will remain an ash-coloured powder, which has no violent operation, but will promote a gentle sweat. Moreover, if you take four parts of Antimony, and four of salt of tartar, and melt them, and then pour them into a cone proper for that purpose, you will have the medicinal regulus of Antimony, which may be beaten into a reddish powder of extraordinary virtue. But if, instead of one part of the salt of tartar, two or three be made use of, and then melted, the regulus will be changed to a poison, which is occasioned by its being deprived of too much of its sulphur.

Crude Antimony, reduced to a fine powder, and taken inwardly, is very useful in several diseases; for it will dissolve the clamminess of the fluids, open obstructions, and is a good remedy in diseases of the skin. It is also excellent against the rheumatism, and will take away numbness of the limbs. The dose is about half a drachm. Antimony is also useful to various artificers; for pewterers mix it with tin and lead to make their pewter shine, and to give it the sound of silver; bell-founders mix it with other metals in making their bells; likewise the letter-founders constantly employ it in making their types. Add to this, that goldsmiths make use of it in purifying gold; for, when melted therewith, it will destroy all other metals, not excepting silver, and turn them into dross.

BISMUTH is a semi-metal, which will melt in the fire, but is not ductile; it is heavy, brittle, and differs from lead and tin in its colour and hardness; for it sometimes looks like silver, and sometimes is of a faint purple colour, not unlike regulus of antimony, though it consists of broader plates. Bismuth is sometimes found in so very pure an ore, that it stands in need of no other operation to fetch it out, than by breaking it in pieces. In the Museum of the Royal Society there are pieces of Bismuth sent from Cornwall under various names, which are so very rich, that, if a piece of it be only held with a pair of tongs against a clear fire, the Bismuth will run down in the form of melted tin, almost as soon as cheese will drop in toasting. Some call the ore of Bismuth the cobalt of Bismuth; because it contains the same principles as real cobalt, only in a different proportion. It is by some called tin-glass; and, when broken, appears to consist of small cubic particles, and these again of minute plates applied to each other. It is more brittle than zinc, though it differs little from it in external appearance, except in colour. It will cause metals, that will not easily melt, to be more fusible by a much less fire than they otherwise would. It mixes easily with any metal, and, according to the greater or less quantity added thereto, it renders them more or less white and brittle. But as Bismuth is easily destroyed, its mixture with metals, difficult to be melted, should be made in close vessels. It is very observable, that Bismuth melted with lead, tin, or silver, and afterwards amalgamated with Mercury, will pass through leather in much greater quantities, than they otherwise would. When this powder is washed it is very white, and used by the ladies as a beautifier of the skin. It is of little use in medicine.

ZINC is a semi-metal, of a blueish-white colour, brittle, and yet somewhat ductile and malleable, though much less so than metals. It melts in a gentle fire, after which it smokes, and then sticks to the furnace in the form of exceeding white flowers. In a greater fire it burns, and emits a flame of a most beautiful green colour. All the Zinc that is prepared in Germany, especially at Goslaer, is obtained by sublimation, and not by melting; nor is it got out of any single ore, but out of such a confused mixture of different ores, that several other metals and semi-metals may be separated therefrom at the same time. There is no particular kind of sublimation for the extracting of Zinc; for it is collected during the melting of other metals, especially lead. The ores that yield Zinc are, by long and repeated roastings, freed from sulphur, and in a manner from arsenic, by the same operation.

There are certain substances that may be more properly called ores of Zinc, such as lapis calaminaris, or calamine; as also native cadmia. This is of a very irregular figure, sometimes spongy, and now and then solid. It is sometimes of a gold colour, sometimes red, and at other times grey; or of
the

the mixture of them all. It is not very heavy nor hard; and, when broken in pieces, it immediately emits a flame of a greenish colour, and exhales a white, thick, copious fume, of a smell peculiar to itself, which condenses into very light flowers, at first bluish, and then of a greyish white. But care must be taken that the calamine be not mixed with a yellow sulphureous pyrites, or the white arsenical one, nor yet with lead ore.

Zinc, by some called Spelter, and by others Tuttenag, mixes readily with lead and tin, rendering them more brittle and less malleable. When it is by fusion mixed with four times the quantity of copper, it becomes a brittle metal of a gold colour, which is well known by the name of Prince's or Bath metal. The white flowers of Zinc, taken internally, promote sweating, and sometimes they will work upward and downward. The dose is from four grains to twelve. The making of Prince's metal is by melting three ounces of copper with half an ounce of Zinc, and when the mass is cold, it will appear of a fine gold colour, remaining ductile with a hammer.

COBALT is a ponderous mineral finely streaked, or sometimes granulated. It is often smooth on the outside, of a light greyish, and almost semi-metallick colour, and sometimes of a dark blackish dye. It contains a great deal of arsenick, as well as a certain fixed earth, which being melted with flints, and fixed salts, turns into a glass of a fine blue, called Smalt, which has been taken notice of before. Cobalt commonly contains bismuth; however, there are several minerals which go by the name of Cobalt, that have different properties from the former. That called the flower-of Cobalt is finely streaked, lighter than the foregoing, and of a fine red purple colour, and belongs to this class; for it is a very arsenical mineral, and loses one half of its weight in the fire; but a great deal of bismuth may afterwards be melted out of what remains. This will likewise give a blue colour to glass, like the other Cobalt.

Native CINNABAR is a fossile metallick substance, heavy, but not very hard, which is either found pure, or mixed with stones. One of the sorts, when pure, is of a purple colour, inclining to red, and when ground, becomes of a beautiful red. There is another of a blackish, or of a liver colour, like blood-stone, and another yellowish. That sort of Cinnabar, which is mixed with stones, is often found in a fissile ash coloured stone, and sometimes in a very white metallick stone. It is sometimes met with under the form of pyrites, of a gold or silver colour. It is found in various places, as in Carinthia, Hungary, Bohemia, Italy, Spain and France.

It is known almost to every one, that it contains plenty of quick-silver, which is got from it by distillation, with the assistance of quick-lime or filings of iron. Sulphur may be extracted from it, though in a small quantity, if it be boiled in a strong lye, and separated from the quick-silver by pouring distilled vinegar thereon. Besides, Cinnabar may be made by art, not much unlike the native, as will be taken notice of hereafter. It is recommended by some physicians for internal use against the epilepsy, vertigo, madness, and disorders of the head; but the native Cinnabar is now very little used, the factitious sort being preferred.

QUICK-SILVER, or MERCURY, is a metallick fluid substance, cold to the touch, of a shining silver colour, very heavy and volatile, and readily mixes with most other metals. It is either found fluid in the bowels of the earth, in the chinks and veins of mines from whence it is collected, and washed with plenty of water to separate it from the earth, or it is dug up in glebes, consisting of a red mineral, sulphu-

reous, mercurial substance, called cinnabar. It is also found in the form of a slimy or stony glebe of divers colours, it being sometimes red, yellowish, brown, or of a lead colour. From this last, Quick-silver may be obtained by simple distillation, without the addition of any other matter, either by ascent in a retort, with a proper fire; or by descent, which is the common way, and is done in the following manner: They pound the mineral, and throw it into earthen vessels with a narrow neck, stopping it up with fresh moss from trees; then they place another over it, with a wider mouth, and bury them in the earth, with one of the mouths against the other, coating them all round with clay, and luting the mouths together, in such a manner, that the empty vessel is entirely hid under the earth, and that which is full placed above it. This is done in an open place, and many of them ranged in rows, after which they make fires all round them, by which means the minerals are heated, and the Quick-silver falls by drops into the lower vessel; but if the mineral abounds with sulphur, the Quick-silver cannot be extracted without the addition of some other substance, such as quick-lime and filings of iron, already taken notice of, as also wood-ashes.

Quick-silver exceeds all other metals in weight, except gold; for that will sink therein, while others swim at the top. The weight of gold, compared with Quick-silver, is a little more than four to three. It will mix with all metals, or semi-metals, though not without difficulty, with antimony, iron, and copper. It penetrates the metals, renders them brittle, and dissolves them; for which reason it is accounted by some the first matter of metals; but this opinion cannot be supported by experiments. It may be made to put on various appearances, which are all reducible to running Quick-silver again. It joins very readily with sea-salt, and turns therewith, by a gentle heat, into a white crystalline mass, called corrosive Mercury sublimated; but it will not do the same with nitre and vitriol. It will readily dissolve in spirit of nitre; but not without great difficulty with the oil of vitriol. It undergoes no change with alkaline salts; but it may be killed and fixed with salin-sulphureous bodies. Being ground some time with sulphur, it will turn into a very black powder, called Æthiops mineral; which, by the assistance of fire, may be sublimated into a very red radiated shining mass. Quick-silver being dissolved in spirit of nitre, and the acid spirit exhaled by fire, a red powder will remain at the bottom, called red precipitate; but if it be precipitated with salt of tartar, a brown powder will fall to the bottom, named precipitate of Wurtz; but with sea salt it will be white, and with lime water yellow.

The analysis of Quick-silver is very difficult; because it frequently flies away with the heat of the fire; however, if it be exposed to that heat in a glass vessel, with a long neck, it will, at length, become a grey powder, then yellow, and, at last, red; at which time it is somewhat more heavy than when fluid. But if this be exposed to a more violent heat, it will fly away, leaving only a little brown earth behind it.

Quick-silver, by the ancients, was accounted a poison, and Avicenna was the first who ventured to use it externally; but upwards of two hundred years ago some had the courage to use it internally, because they observed that it did sheep no harm, when it was given them by their shepherds to kill their worms. But Quick-silver cannot be said to have no bad effects; for those that are employed in digging for it, seldom continue four years without being affected with a trembling of the limbs and a palsy, of which they die.

However, Quick-silver has a remarkable virtue in opening all obstructions of the vessels and glands,

and of dissolving the thick gross matter contained therein, for which reason it is given in schirrosities of the liver, spleen, and mesentery, as well as in obstructions of the glands, and will also temperate the acrimony of the blood and humours. Quick-silver, not only taken inwardly, but applied outwardly in an ointment, will purge the body by stool, sweat and insensible perspiration; but its most remarkable effect is that of salivation.

That Quick-silver is counted best that is of a shining silver colour, very fluid, and, when held over the fire in a silver spoon, will fly away, without leaving any thing behind it. That which is of a livid colour, and does not separate into drops that are exactly round, is naught, and shews that it has been adulterated with lead or bismuth. However, it ought always to be cleansed, which may be done by squeezing it through shammy leather; but the best way is to distil it in a retort with quick-lime, pot-ashes, or iron filings. Crude Quick-silver may be given to kill worms, from a scruple to a drachm; and it may be rubbed on glass with sugar till it is dissolved, if a drop or two of oil of sweet almonds be added thereto. A pound of Quick-silver may be also boiled in pure water for an hour, and some of the clear liquor given to children for common drink. It will kill worms taken inwardly and lice when applied outwardly with an ointment. Crude Quick-silver is sometimes given to the quantity of two or three pounds, with oil, to force a passage through the guts in the iliack passion.

LEAD is of the least value of all metals, it being heavy, livid, and fouls the hand with a blackish colour; it yields little or no sound, and melts quickly in the fire before it turns red. Pure Lead is seldom found in the mines, but is extracted from ores of different kinds; for it is sometimes black, blue, yellow, or of an ash colour. It is sometimes full of shining minute particles, and sometimes again it is like a stone of a leaden shining colour, consisting of squares like dice, that lie in a white or reddish stone. The ore of Lead almost always contains a small quantity of silver; and particularly that of Cardiganshire in Wales has so much of it, that from two thousand pounds weight of ore, there has sometimes been extracted twenty pounds of silver.

When flints and the like are mixed with an ash or black colour, or are only marked here and there with veins and spots of the same, it is a sign that they contain either Iron or Lead. The green Lead ore is very rare; but when it is found it is variegated with a yellowish green colour and semi-transparent. It is likewise heavy but not hard, and one hundred weight of it yields from seventy to eighty pounds of Lead. There is also white and ash coloured Lead ore, but it is as uncommon as this.

There are several mines of Lead in Spain, Italy and Germany; nor is France without, though the metal be extracted with difficulty; but the best and richest are in England and Scotland. The method of obtaining the metal, is by placing the ore between strata of coals, and then when the fire is kindled the metal will flow; or pieces of wood may be used instead of coals or mixed therewith, according to the degree of fire that is required; for coals yield a more violent fire than wood.

The weight of Lead compared to Gold is as three to five. Lead is easily calcined and reduced to an ash coloured calx, which in a more violent fire turns yellow, and at length red, when it is called minium, or red lead, which may be easily reduced to Lead again, when mixed with combustible matter and melted. Lead mixed with nitre in a crucible will flash a little, and if the filings of Lead be thrown into the flame of a candle, it will tinge it with a bluish colour. From whence it appears, that there is a sulphureous principle in Lead, though in a small

quantity. When Lead is exposed to the focus of a large burning-glass, it will immediately smoke, and by little and little change into an ash coloured calx, then yellow and red, afterwards turning to a saffron coloured fluid, like oil, which in time will fly away in smoke; but if this fluid, before it is quite dissipated, be taken away from the focus, after it is cold, it will turn into a red, or reddish yellow mass, consisting of thin plates like orpiment, which are transparent and look like Talc. But if this be applied to the focus of a large burning-glass on coals, it will immediately melt, and turn to Lead again. From hence it appears, that Lead consists of a glassy earth, not much unlike Talc with a sulphureous principle, that is inflammable, and not mixed intimately with the earth.

Lead will dissolve all other metals, except gold and silver, and carry them off along with it, or turn into litharge or fly off in smoke; for this reason it is used for the purifying gold and silver. It will not rust in water like iron or copper, but will dissolve in vinegar, spirit of vitriol, and spirit of nitre; and the salt which is obtained therefrom, when the spirits are evaporated, will have a sweetish taste; whence it is called sugar of Lead. It will also dissolve in oil and all fat substances. When Lead is reduced into a calx, though it emits a copious smoke, and loses much of its substance, it will increase in weight, in so much, that an hundred pounds of Lead will increase to an hundred and ten, when it is converted into red Lead; but if this afterwards be reduced to Lead again, it will not yield near an hundred pounds. When red Lead is melted with sand, it obtains a yellow gloss, not much unlike amber. Several preparations of Lead have formerly been used as medicines; but, as it is an enemy to the nerves, it is in a great measure left off, and ought to be entirely abandoned.

Litharge is generally made in the furnaces of metals, when Lead is separated from silver, or when Lead is made use of to cleanse silver from other metals mixed therewith; and it sometimes is of a silver, and sometimes of a gold colour, whence it is called litharge of gold or silver, though it does not receive its colour from those metals. Litharge is of great use in making plaisters of which it is the basis, being mixed with oil. It is a moderate drier, cleanses with a little astringency, and is proper to bring ulcers to a cicatrix.

Cerufs, or white Lead, is a sort of rust of Lead prepared in the following manner: The sharpest vinegar must be put into wide mouthed vessels in the summer-time, over which a plate of Lead is to be placed so closely, that nothing can escape out of the vessel: In about ten days the plate will be dissolved, and fall to the bottom of the vessel, from whence it is to be taken and dried, and afterwards ground in a mill. It is also made from the filings of Lead put into very sharp vinegar for ten days together; or a plate of Lead may be put therein, and taken out from time to time to scrape off the white part; and so again and again, till the whole plate is dissolved; then all the scraplings may be collected, ground, and made into masses with vinegar.

TIN is one of the softer and more ignoble metals; and is white, shining, brittle, sonorous, and crackles when bent. It is the lightest of all metals, and never existed naturally in a true metallick form. The richest Tin ore is of a black or dark colour, with many sides of an irregular figure, and a glossy surface. It is heavier than the ores of all other metals, which is somewhat strange, because Tin is lighter than all the rest. It is indifferently hard, and bears a quick fire without melting or growing clammy. But the most common Tin ore is of a dark, yellowish, rusty colour, and is very like the ore of iron; it is like the former in shape, and seems only to differ from

from it in its degree of purity. The garnet is a sort of precious stone, and now and then contains Tin; so that, upon this account, it is reckoned among the ores of this metal.

Tin, in Cornwall, is extracted from its ore, after it is separated from the stone to which it is connected, by pounding it with iron pestles, and in the mean while it is continually washed with water, that the earthy parts may be carried away therewith, and that the metallick particles may sink to the bottom. This gross powder, after it is dried, is ground with stone mills, and then washed, till it is quite freed from all foreign matter. Then it is dried and thrown into a furnace, mixed with charcoal, which being lighted and blown with bellows, the Tin will melt and fall to the bottom of the furnace; when the workmen, opening the small door of the furnace, suffer the metal to run into sand prepared for that purpose, where it forms large masses. The upper part of the Tin is so soft, that it is not fit for use without copper; and therefore they mix three pounds of that metal with an hundred of Tin. The middle part only requires two pounds of copper; but the lowest is so brittle, and so unfit for use that they mix eighteen pounds of Lead with an hundred of Tin.

There is often an arsenical substance mixed therewith, which they call mundick, that is of a shining dark colour, and blackens the hands; but by the help of fire, it flies away in smoke. There is also another white saponaceous substance, which is soft, and may be dissolved in water at first; but soon after turns very hard. It is a kind of marl. The weight of Tin, with regard to gold, is as three to eight; and is easily melted and reduced into a whitish calx.

Tin will melt sooner than other metals, and will adhere to them very readily; for which reason copper and iron vessels are often tinned on the inside, to hinder them from rusting, and to prevent the bad effects of the copper. If it be mixed with these metals, it renders them more hard and brittle, and cannot be separated from them without great difficulty. Tin will not dissolve in any spirit, unless it be aqua regia; and its solution will tinge gold with an elegant purple colour.

The virtues of Tin are now well known as a vermifuge; for it will kill worms, taken either in powder or filings, from a scruple to a drachm for several days. Salt of Tin is made of that metal reduced to a calx, by exposing it to a reverberatory fire for two or three hours, and then throwing it into very strong distilled vinegar. This is recommended in hysterick fits, and is given from two grains to six. Mosaic, or musive gold is made in the following manner: take of fine Tin one ounce, of Mercury revived from cinnabar ten drachms, and make an amalgama, which must be mixed with ten drachms of common sulphur, and an ounce of sal-ammoniack. All these, being finely ground together, must be sublimed in a strong fire for four hours, and a sort of cinnabarine substance will be raised to the upper part of the vessel; but at the bottom a kind of spongy substance of a gold colour will remain, which being washed in several waters, is called musive gold. It is of great use to painters, and in medicine has a diaphoretic quality. It is accounted good in hysterick and hypochondriack disorders, as well as for killing of worms. The dose is from ten grains to thirty. Some have supposed this to be a mercurial preparation; but falsely; for all the mercury is raised from it in sublimation.

IRON is an ignoble metal, remarkable for its hardness; and is of a whitish livid colour when polished; but before that it is blackish. When it is cleansed it is called steel. The ore of common Iron is of no certain form; but is most commonly of

a rusty colour. There is also an ore which is very heavy, and of a red bluish colour when broken. It is very rich in the best kind of Iron, and usually yields at the first melting, from sixty to eighty pounds out of an hundred weight. There is also a singular kind of Iron ore, of a pale yellowish colour, though sometimes grey; and sometimes of a kind of semi-transparent white. It will yield, when melted, about thirty pounds of Iron out of an hundred weight.

The HÆMATITES, or Blood-stone, is also a sort of Iron ore, and is very smooth on the outside, when the rust is taken off; but the inside is composed of convergent streaks. It is of a dark red colour, very heavy and hard, and is one of the purest of the Iron ores, with a small mixture of arsenick. Smiris, called in English emery, is the hardest of all the Iron ores hitherto known, and is almost as heavy as the blood-stone. It is of a brown colour, and certainly contains Iron, though it is not worth while to employ it for that purpose; and therefore it is used by workmen, when pounded, to polish steel and other things. Magnesia, or Magnanese, has no certain figure, is of a greyish black colour, and contains Iron; but it is not worth while to make use of it on that account, because it will not answer the charges. It is used in glass-houses to take away the green or blue colour of glass.

When iron is melted, it is formed into large masses, which are long and thick, and commonly called pigs. These are melted over again, and stirred with an Iron rod, in order to render them malleable. While they are yet red hot, they are placed under hammers, and by that means the heterogeneous particles are forced away by the repeated strokes. One sort of Iron differs greatly from another; but that which is toughest is best; and that which is most brittle is worst of all. However, all sorts of Iron are of the same nature; and they are only more or less tough in proportion to the earthy, vitriolic, and sulphureous particles mixed therewith. Iron being often melted and cleansed is turned into steel; though, in some, little labour is required for that purpose, and in others a great deal. When Iron is very good, they melt it in a furnace, and throw in gradually a mixture of equal parts of an alkalious salt, and filings of lead, with the raspings of oxes horns; then they stir the melted metal, and at length place it on the anvil, where they beat it into rods. Some iron will not melt over again, and then they take Iron rods as thick as a man's finger, and place them in a proper earthen vessel, alternately with strata composed of equal parts of foot, powder of charcoal, and raspings of oxes horns. When the vessel is full, they put a cover over it, and lute the joints, placing it in a reverberatory furnace; the fire is kindled, and increased by degrees, till the vessel is hot, and after six or seven hours, they let it go out of itself, in which time the rods will be turned into steel. When this operation is not perfectly performed, and only the outside of the Iron is turned into steel, in some parts of England, it is called case-hardening, and this is commonly done with the leather of old shoes.

Iron is the hardest of all metals; but it will become harder still, if heated red hot, and quenched immediately in cold water. The weight of Iron when compared with gold is as three to seven. Iron may be converted into rust, by moistening it with water, letting it dry, and often repeating the same operation; but it may be preserved from rust by being smeared with fat. Iron, calcined in a reverberatory fire, will turn into a darkish red, or purple calx; but being heated so hot as to be ready to melt, it will turn into scales under the hammer, which is nothing else but Iron half turned into glass. That part of the Iron, which in furnaces is turned into a

fort of glossy froth, is called the dross of Iron. This metal will dissolve in all sorts of acids; but alkalious Salts will not touch it.

Iron is a most useful metal, not only on account of the various mechanical uses it is put to, but on account of the many medicines it yields. Iron has two remarkable effects, namely, that of opening and binding; for it opens the obstructions of the liver, spleen, and bowels, stops loosenesses and hæmorrhages, and restores relaxed fibres to their due tone. For medicinal purposes, Iron is better than steel; and the filings of Iron alone, when ground small, is better than any other preparation of this metal whatever. The dose is from twelve grains to half a drachm, once or twice a day, in the form of a bolus, pills, or lozenges.

COPPER is one of the more hard ignoble metals, is softer than iron, and, when polished, is of a shining reddish colour. It will melt in the fire, and is so ductile that it may be beaten into exceeding thin leaves. It is more frequently found in its metallic form than iron, in various shapes; but its ore never distinguishes itself by any certain figure, for it is almost always irregular. But the finest colours of any kind, except the red and transparent, most commonly betray the presence of Copper; for this reason there is hardly any Copper-ore that is not mixed with Iron in a larger quantity than the ores of other metals commonly are. However, there is not so much in some as in others, and those that contain the least Iron are naturally more easily melted than the rest. The vitrious Copper-ore is of a darkish violet sky-colour, like that of a piece of steel that has touched a red hot iron. It is very heavy, and of a moderate hardness; but it is commonly variegated here and there with spots and grey veins. One hundred weight of this contains from fifty to eighty pounds of Copper. The Azure Copper-ore is of a most beautiful blue colour, and is not soft, but very heavy, and when broken shines like blue glass. This is most free from iron, arsenick, and sulphur; and a great quantity of excellent Copper may be extracted out of it with very great ease. The Green Copper-ore is like green crystals, and sometimes very prettily streaked; but in other things it has the properties of the former. The light dusky blue concretes, as well as the green, called by some Copper-ochres, yield a great deal of very good Copper when they are pure, which may be known from their colour and weight; but those that are more light are mixed with unmetallic earth, and those that are yellow contain iron ochre; on which account they are the more difficult to be met with, and yield less Copper of an inferior sort.

The white Copper-ore has been hitherto found only in one single mine of Misnia, and is distinguished from the white pyrites by a somewhat yellowish colour.

The Sulphureous Copper pyrites is of a yellowish gold colour, with a light tinge of green, both within and without. When broken, the inside has a kind of granulated surface, and is easily beaten into powder. It contains sulphur and Copper in many different proportions; on which account its specific weight varies very much. If it is very rich in Copper, and at the same time is mixed with any quantity of arsenic, its gold colour becomes more yellow, and when it is broken, the surfaces are more smooth, neat and even. It is very often of a fine bright green, and blue on the outside, and between the chinks, though when broken, it appears of a different colour. When the Copper pyrites is mixed with a considerable quantity of arsenic, it will then look pale like the sulphureous Copper pyrites, and still whiter when there is more arsenic. However, it may be easily distinguished from the iron pyrites in being more heavy, and in

not sparkling so easily when struck with a steel. The yellow sulphureous iron pyrites belongs to this class, because it often contains a great deal of Copper, which may be known from its not being of a globular figure; for, when it is in that form, it is always destitute of Copper. There is likewise an unusual yellowish colour throughout its whole substance.

Copper is seldom found alone in its ore, for there are other metals along with it, as silver, iron, and lead; there is also a large quantity, generally speaking, of a combustible sulphur, not easily separated from it. That which abounds with most sulphur, must undergo different calcinations till all the sulphur is exhaled, and this the workmen call roasting. After this, the roasted ore is beaten into smaller pieces and calcined again, then it is beaten very small, and must undergo a third roasting, after which it will melt into a stoney red substance, which is called the stone of Copper. This done it must be roasted again, and then melted, when it will yield a black Copper. It must yet be roasted eight times, and then it will be thoroughly cleansed from all the sulphur.

There is a sort of Copper springs, out of which vitriol is made by boiling, and Copper may be extracted by precipitation, with the assistance of iron. There is one of this kind found near the town, called Smalnick, not far from mount Krapac in Hungary; in which there is Copper that will stick to iron when thrown into it; thus for instance, if you throw a horse-shoe into this spring, after a few days it may be taken out covered all over with Copper. There are Copper mines in various parts of the world, but the best and richest are in Sweden and Germany.

The weight of copper, with respect to gold, is a little more than four to nine; and if it be exposed to a moist air, it will contract a green rust. It has a disagreeable smell, and an austere acrid nauseous taste; it will, in time, dissolve in water, as well as in oil, and salts of all kinds will corrode it. Copper contains a portion of combustible sulphur, though not so much as iron, with a metallic red earth that will turn into glass. Copper will turn white with the fumes of arsenick or quicksilver; but it will not continue long. Being melted with lapis calimnaris, or zinc, it will turn of a yellow or gold colour, which is called Brass. Copper, on account of its ductility, is formed into various household utensils, and is melted into mortars, great guns, and the like; but it is seldom used in physic, especially internally, because it is of a poisonous nature; for which reason it is not safe to use it in pots, kettles, and the like, without tinning.

Verdigrease is the principal preparation, and is of great use to painters and dyers; but it is seldom or never given inwardly by physicians, though it is frequently used externally.

SILVER is a noble and perfect metal, of a white shining colour, sonorous and ductile, but not so perfect as gold. It is sometimes found in small masses of many different shapes, but most commonly like filaments and scales in several sorts of stones and earths, and in many sorts of land.

The Vitrean silver ore is of an irregular and uncertain form, is very weighty, and may be easily flatted with a hammer; for it is not much harder than lead, and is much of the same colour; for which reason it is often mistaken for lead. It melts presently, and soon grows red-hot. It consists of sulphur, and pure Silver, and above three quarters of it is Silver. The Horny Silver ore is half transparent, and is of a deeper yellow or brown colour, according as it consists of larger or smaller lumps. It looks like rosin, and is of an irregular shape. When carefully examined, it appears to consist of very thin plates; it is not very weighty or hard, for it may be easily ground; and when brought suddenly

to the fire, it crackles, bursts, and exhales a sulphureous smell, and sometimes burns lightly. This hard sort contains two thirds of Silver. The red Silver ore is sometimes of a lighter, and sometimes of a deeper scarlet colour; the first case is transparent like a garnet, and has been mistaken for transparent cinnabar; and in the second case it is of a deeper dye. It is heavier than the former horny ore, but bursts when brought near a candle or a mild fire, and the remaining part melts before it grows red-hot; then it emits a disagreeable smell of arsenic, together, with a thick smoke. It contains the same quantity of Silver as the horny ore just mentioned.

The White Silver ore is of a light grey colour of an irregular figure, pretty weighty, and very brittle. It has not only copper in it, but sometimes more of it than of Silver; for it differs from the white copper ore in nothing but in the quantity of Silver it contains. These are the principal Silver ores hitherto known, though many others are looked upon, by some, as such, because they contain a considerable quantity of Silver; but then there is always more of other metals along with them, and therefore they cannot properly be called Silver ores.

There are mines of Silver in many countries, as in Italy, Germany, Hungary, Norway and England; but the most remarkable are those of Peru and Mexico. In England the veins of lead always contain a small quantity of silver, particularly that in Cardiganshire. Silver may be easily extracted from lead, by melting it in channels, made with ashes in the furnace, and then blowing up the fire with bellows; till it turns into glass, sinks into the channels, and leaves the pure Silver behind.

Silver is harder than gold, but not so ductile, and is lighter than gold or lead, the weight, with regard to gold, being little less than five to nine. It will not rust, but will grow black by sulphureous vapours, and will dissolve in aqua fortis, but not in aqua regia. When it is mixed with common salt, and melted, it turns into a half transparent mass like horn, which is hard to be brought back to Silver again, because it is volatile, and in a violent fire will all fly away. When Silver is dissolved in aqua fortis it may be crystalized; and the crystals are very corrosive, and of an exceeding bitter taste; when applied to the skin, they leave an impression like that of a burning coal, and make an eschar of a black colour. The solution of Silver will turn any thing black, and therefore, when properly diluted, is often used to colour the hair. These crystals will melt in a very moderate heat before they grow red, and form a blackish mass; it is then proper for the use of surgeons, and is called the Silver caustic.

GOLD, the heaviest and most noble of all metals, is extremely ductile, and of a shining yellow. It is often found native, as it is called, but of no distinct figure, consisting only of small irregular masses. But there is a flint, in which Gold is commonly contained in very large solid masses. It is likewise concealed, but not so often, nor in so large a quantity, in a yellow and blue sort of stone, which some call the horny stone. Lapis Lazuli is a blue stone, and is often very elegantly variegated with very small specks of Gold; however, the quantity is not so large as in the former. Many sorts of gravels and earths often contain Gold; but they are seldom rich enough to pay the charges of extracting it. However, that kind of gravel, which is found in the channels of rivers and brooks, especially when they wind and turn very much, is richer in Gold than the rest. It has been found in the rivers of Scotland, of which medals have been made, especially at the time of the coronation of king Charles I.

Native Gold is not always found pure, for it is

often mixed with silver; and there has been no ore hitherto found, in which Gold constituted the greatest metallic part; so that no ore whatever can be properly called gold ore. However, there are Gold mines in Norway, Hungary and Guinea; but the richest of all are in Mexico and Peru. It is extracted from the substances in which it is contained; by roasting, pounding, washing, and mixing them with quick-silver.

Gold is not only the heaviest of all metals, but of all other substances yet known. It will not change with common fire, nor will it fly away in the focus of a large burning-glass, till it has continued there a long while. It will not rust, nor will it dissolve in any other menstruum, except aqua regia. It will mix readily with quick-silver, and turn into a soft amalgama. It may be calcined with common sulphur when it is made glowing hot, and held thereto. When gold is dissolved in aqua regia, and oil of tartar poured thereon, it will precipitate into a brown powder, which if heated at the fire, or lightly ground, will fly up with a great explosion and noise, from whence it is called fulminating Gold. All attempts to analyze this metal have hitherto been in vain. As for the use of gold in physic, notwithstanding the boasting of former chemists, it is little or none at all; for all its preparations have been hitherto found rather noxious than otherwise.

CHAP. XXI.

Of GEMS of all Kinds.

OF all the Transparent Gems, the DIAMOND is the hardest, the most beautiful and valuable. The best are those that are void of all colour; for if they are tinged with white, yellow or black, they are in some degree faulty, and considerably lower in price. It may be readily distinguished from all other Gems by its extreme lustre and sparkling, as well as the brightness of its reflections. If a little burnt ivory be laid upon mastic, in such a manner as to render it black, and the diamond be laid upon it, it will then reflect the most lively colours every way, which is a property belonging to this Gem, as all others will not bear the like trial; for, when they are laid upon the mastic in this manner, they either reflect no colours at all, or, if they do, they seem to be seen through a mist. There have been jewelers, who, designing to make other stones appear like diamonds, have taken a grain of wheat, and have pressed the oil out of it with a hot iron, and then have mixed it with lamp-black, or burnt ivory; then put it under the stone, but so as to leave a little room between it and the black tincture. Then the transparency, which is partly owing to the stone, and partly to the air, causes it in some degree to resemble a true diamond, inasmuch that some, though skilful in these matters, have been deceived thereby.

Those Gems that are most proper to counterfeit diamonds are the sapphire, the oriental amethyst, the topaz, and the chrysolite, because they are all hard, transparent, and may be deprived of their colour by means of fire; but this is most commonly done with quick lime, or the filings of steel; for when the Gem is buried in these, and put into a crucible with charcoal, it is put over the fire, and gently heated at first, and when the heat is increased the colour will vanish. When it has been in a sufficient time, they let the fire out by degrees, and do not take the stone out till it becomes lukewarm. If it is not entirely deprived of its colour, they repeat the operation as before; for if it was to be heated suddenly, or, when hot, immediately exposed to the cold air, it would certainly crack, or perhaps break entirely.

entirely. A topaz is more fit for this purpose than an amethyst, for this has been managed so artfully, that it could scarcely be distinguished from a Diamond by the best judges.

Diamonds sometimes receive their names from the places where they are found, as the Hungarian, Bohemian, and the like. Among these there are two differences worth observation; for some are found in the form of hexagons, and others almost round; but they differ greatly in hardness: those that have angles are softer, and are little better than crystal, as the Hungarian; those that are round, and in some sense resembling flints, are by much the hardest, and come pretty near the lustre and sparkling of oriental diamonds; but as they will not stand the trial of the maffick above mentioned, they cannot properly be called diamonds. The oriental diamonds are distinguished by the name of the places where they are found, for some of these are denominated from the old mines, and others from the new. However, they are not all equally hard, nor of the same colour, but they will stand the test of the maffick; and the harder they are the more they sparkle. Diamonds are not weighed like gold, but by carats, each carat consisting of four grains; and it has been said, that there was one found in Bijnagar that weighed an hundred and forty carats, that is, five hundred and sixty grains; it has also been reported, that there was one met with that weighed two hundred and fifty carats, and was of the size of a pullet's egg: However, the largest now known in Europe, is one that belongs to the great duke of Tuscany, which weighs an hundred thirty nine carats and a half; and that in the possession of the French king, which is equal to an hundred and six carats.

Diamonds are of such a nature that no fire will injure them, for when they have remained in one for several days, they rather come out with a more perfect lustre than otherwise.

The value of a Diamond arises partly from its sparkling and reflections, for it will imitate all the colours of the rainbow: and partly from its hardness, from whence it may be said to be almost incorruptible. Diamonds were formerly worn by kings, and other great persons only; but now they are very common, and may be easily purchased by people in moderate circumstances. A well polished Diamond formerly, of the weight of a pepper-corn, was sold for fifty shillings, but now it is not worth above two. A cut Diamond, weighing a carat, or four grains, has been valued at upwards of ten pounds; but now the price is extremely fallen.

With regard to the use of a Diamond, it not only serves for ornament, but, when reduced to powder, is extremely serviceable for polishing and cutting all other Gems whatever; and it is well known, that Diamonds themselves cannot be properly polished without it.

A Diamond seems to consist of several plates, laid one against another; for which reason, a skilful lapidary, with the point of a knife, can divide one into two or more tables. If one be placed in the focus of a burning-glass, with its plates perpendicular to the rays of the sun, it will receive no detriment; but if it be turned the other way, the rays will get between the plates, divide them, and afterwards turn them into a glassy substance, leaving not the least sign of the splendor of a Diamond.

The places from which Diamonds are brought, are the island of Borneo, and the kingdoms of Visapour, Golconda, and Bengal, in the East Indies, as well as from Brasil, in South America.

Tavernier, who travelled to the East Indies, chiefly for the sake of Diamonds, visited the places where they are chiefly to be found, in order to get the best knowledge of them he could. The first mine that he saw, was at a place called Carnatica, in the do-

minions of the king of Visapour, and at a place called Raolconda, five days journey from Golconda. This was found out above three hundred years ago; and about the place where the Diamonds are met with, the ground is sandy, and full of rocks and low trees. In these rocks there are several veins, sometimes half an inch, and sometimes an inch broad. The miners have small pieces of iron, crooked at the end, which they thrust into the veins to draw out the sand or the earth, which they put into vessels; and it is among this earth they find the Diamonds. But as these veins are not always straight, but sometimes ascend, and sometimes descend, they are obliged to break the rock to follow the course of the veins. After they have opened, and gathered as much sand as they can out of the veins, they wash it two or three times, in order to discover whether there are any Diamonds among it or not. This mine yields Diamonds of a very fine water; but they are often flawed by the bad management of their hammers in breaking the rocks to pieces. If the Diamond is good, they only polish the surface a little, because they are afraid of bringing it to a proper form that would lessen its weight. But if there be the least flaw or foulness, they give it variety of faces, or sides, in order to hide the defect. However, it is observable, that they would rather see a black speck in a stone than a red; and therefore, when there is one that is red, they put it into the fire, and then it becomes black. There are several men here, whose employment is to polish the Diamonds, and they have each but one wheel, which is made of steel, and about the diameter of a pewter plate. They apply but one stone at a time to the wheel, and sprinkle it constantly with water, till they have found out the way in which it will best work. This being found, they take oil and the powder of Diamond, which they never spare, because it is cheap here, that they may polish the Diamond the sooner. There is always a little boy, who continually supplies the wheel with oil and powder of Diamonds. However, they cannot polish the stones so well as the lapidaries in Europe, because as it is necessary to keep the steel rough by applying emery, or by filing it, and they are too lazy to do it so often as they ought, consequently the wheel will not perform the work so well, nor so soon, as those in this part of the world, where they take more pains.

The CARBUNCLE is a stone of a very deep red, with a mixture of scarlet, and has been formerly thought to shine in the dark like a lighted coal; but this is now known to be otherwise. It is said to be as hard as a sapphire, and to be found naturally of an angular figure, or smaller at one end than the other. However, as it is very uncommon, there needs no more to be said about it.

The RUBY is a transparent gem, of a reddish colour, with a small portion of blue, and cannot be touched by a file. The redness is not like that of vermilion, but of blood, or rather of cochineal, or kermes; but the less blue it has in it, the better it is. There are commonly said to be four kinds, the Ruby-cell, the Balas, and Spinel Ruby, which with the true Ruby make up the number; and the best are found in the island of Ceylon. In Pegu they are found in a river of that name, and the inhabitants try their goodness with their teeth and tongue; for they judge those that are coldest and hardest to be the best. They are said to mend the colour by the assistance of fire. They are usually met with in a stony matrix of a rose colour, and if they meet with one that is transparent, they then call it a Balas Ruby; but if it is otherwise, and has no resemblance of a gem, it is then the true matrix of Rubies, because it is formed, nourished, and increased therein. At first it is whitish, and assumes a red colour; as it ripens. It is generally found in the same mines with sapphires,

sapphires, and some of them are pretty large; for the Emperor Rodolphus had one that was as large as a small pullet's egg, and this was thought to be the largest that ever was seen in Europe.

When the value of a Ruby exceeds ten carats, it is thought to be very great, and is not exceeded by a Diamond. When a Ruby is deficient in its colour, that is, when it is not so red as it ought to be, some lapidaries endeavour to mend it, by putting a red foil under it, or glass of a beautiful red colour. Some have attempted to counterfeit a Ruby, with stones of a whitish colour, as a white sapphire, topaz, or crystal, by the assistance of a red foil, for then it will sparkle and seem to differ very little from a true Ruby; however, those that have judgment in stones will very easily distinguish it. There are other methods of counterfeiting this Gem, which we shall here omit.

The **BALAS RUBY** is the matrix of the true Ruby before described, and is supposed to have its name, from its being the house or palace thereof, for by some authors it is called palas on that account. This Ruby is of the colour of crimson, for it has a very little mixture of blue, and when it is polished, it is a very agreeable gem, and will sparkle almost as much as a true Ruby. It is found in veins of sapphire, and is to be met with in the same places as the other; though it is not so valuable by far. It may be adulterated like the true Ruby, and the fraud will not be so easily discovered.

The **SPINEL RUBY** is of a deeper colour than the true, but it has not the splendor, for which reason it is more easily adulterated. However, there are some so good as to come very near the value of the true Ruby, especially those that are said to be of the old rock, and are about half the value of Diamonds.

The **RUBYCELL** is a gem that seems to be between the Spinel and the Hyacinth, inasmuch that it is hard to say to which class it properly belongs. Likewise, they are sometimes exceedingly like Bohemian Garnets, and are not known from them till an experiment is made in the fire; for these will bear it without the least loss of colour, whereas the Ruby-cell will either lose or change it. They are not near so valuable as the Balas or Spinel.

The **GARNETS** have by some been taken to be carbuncles; for, when exposed to the sun, they will shine like a lighted coal, and much better than a ruby. They are brought from the East and West Indies, and from Ethiopia, where they are of three kinds; for some are darker than the rest, being of a blackish blood colour, and yet they will sparkle indifferently well. When a white foil is placed under them, they are of such a fiery colour, that some have mistaken them for true carbuncles. Many of these are large, some having been found bigger than a hen's egg. Another sort is of the colour of a hyacinth, and, if it was not for being redder, might be taken for a true gem of that kind. When it has a yellowish tinge, it may be placed among the class of hyacinths, and will be that stone called in Italy *Jacintha la Bella*. These sometimes resemble other gems so much, that even the lapidaries themselves are not certain what they are. Another sort of Garnets are of a violet colour mixed with red, and these are better than the former, inasmuch that they are called by the Italians *Rock-Rubies*.

The **OCCIDENTAL GARNETS** are often of a fainter colour, and particularly the Spanish, inasmuch that they appear like a pomegranate seed, and are pretty large. Some are of a yellowish red, and will not change in the fire, particularly the Bohemian, and they are all free from flaws. These are more valuable than the oriental, on account of their resisting fire, and resemble real carbuncles. These are found in the fields almost every where by the

country people, without any matrix; they are generally of the size of peas, and are carried to Prague to be sold. At first they are so black on the outside, that no redness can be perceived, till they are held up to the light. Others are found in Silesia, but these are rough, and generally full of flaws, inasmuch that they are seldom transparent. If a Garnet be exposed to the focus of a large burning-glass, upon charcoal, it will be reduced to a metallick mass of the nature of iron, for it may be attracted by a loadstone.

The **HYACINTH** is so called, from its being of the colour of a flower of that name, which is of a yellowish red. There are four kinds, as being of so many different colours; the first is as red as vermilion, and pretty nearly resembles Bohemian Garnets, but without any mixture of blackness. These are more valuable than the rest, and may be placed in the class of carbuncles. The second sort are of a reddish saffron colour; the third are like yellow amber, and could not be distinguished from it, unless by their hardness, and their want of electricity. These are of little value, no more than the fourth sort, which look like white amber, and are worst of all. The Hyacinth is found in the East and West Indies, as well as in Silesia and Bohemia.

The **AMETHIST** is a transparent gem, of a violet colour, arising from a mixture of red and blue. However, they are of different colours, for some, as the oriental, have a mixture of yellow, and some are purplish like red wine; but the best sort are those that shine most like a carbuncle, and are so hard that they may be turned into a sort of diamonds, so as to deceive the most skilful lapidaries. They are found in India, Arabia, Armenia, Ethiopia, Cyprus, Germany, Bohemia, and Misnia; but they are generally as soft as crystal, and are not in very great esteem. The oriental are hardest; if they are without spots they are of the greatest value. They are found of various sizes, and in various shapes, from the bigness of a small pea, to an inch and a half in diameter. They are adulterated with mastick tinged of a violet colour, placed between two crystals; but the Germans do not think it worth while to counterfeit them, because they are pretty common.

The **SAPPHIRE**, which is a hard gem of a blue or sky colour, is very transparent and sparkles very much; but some of them are whitish, and others of a deeper blue; and when they are destitute of all colours, they are called white sapphires, and are so like diamonds they may very well supply their place. They are either oriental or occidental; the former are brought from Calicut, Cananor, Bissnagor, and Ceylon; but the best are found in the kingdom of Pegu. It is very subject to flaws, and yet is so hard that a file will not touch it. The colour may readily be taken away by fire, and then it will be converted to a sort of a diamond, inasmuch that when it is set in a ring, it can hardly be known from one by a skilful lapidary. The value of a Sapphire is derived from its colour, purity, and magnitude; for if it has no flaw, and is of a deep colour, continuing transparent at the same time, it is then the best. It has been common to counterfeit Sapphires with a bit of blue glass placed between two Bohemian diamonds. Some tinge glass of a blue colour, and sell it to ignorant people for a Sapphire. They are found in various sizes; but seldom so small as other gems, and yet never more than three quarters of an inch in diameter; but the usual size is between the sixth and the tenth of an inch. The shape is very uncertain; for it is sometimes in one form, and sometimes in another.

The **OPAL** is a most beautiful gem, for in different lights it shews all sorts of colours, which is occasioned by the different refraction of the rays of light.

light. There are four kinds of this stone, the first of which is transparent, without any opacity, and yet reflects all the colours of the rainbow. Another sort is black, and yet sparkles so much that it appears like a carbuncle; but this is exceeding scarce and consequently highly valuable. The third species reflects various colours; but the yellow is predominant, and consequently this is not so valuable as the first sort. Almost all these are brought from Hungary, and are in very good esteem. The fourth sort is a bastard Opal, and is of the colour of the crystalline humour of the eyes of fish; for it is a little transparent, and is nearly of a bluish milk colour or yellowish; and when it is turned to the light, it seems to shine at the farther edge, by means of the reflection of the light. It is by some called an asterites, or the star stone, because within it may be seen a sort of star, which changes its place as it is turned differently to the light.

The CATS-EYE, by most jewellers, is not placed among the opal kind; but is thought to be a peculiar gem, and therefore will require a more distinct consideration. The opals of the first and second kind are seldom to be met with very large; but they are of very great value; for one in the possession of a Roman senator was said to be worth twenty thousand ducats. Those of the third and fourth kind are sometimes met with pretty large; for one of these that reflected various colours was of the size of a walnut, and was valued at two hundred crowns. All sorts of opals are found in the East-Indies; but those of the ordinary sort are to be met with in Cyprus, Egypt, Arabia, Natolia and Hungary; and in this last place some of the first sort have been found in opal stones, though very seldom. There have been also some lately found in Denmark, and they are all contained in a soft stone full of black, yellow, and fallow coloured veins. With regard to the value, it has been generally thought to equal that of sapphires. They cannot be counterfeited like other gems with a double glass, nor yet any other way.

The EMERALD is a green, shining, transparent gem, and has a very agreeable appearance. It is of two kinds, the oriental and occidental; the oriental are very hard, and of a meadow green colour, which never changes in any light. They are quite transparent, and are in very great esteem, they being of the very best kind. They are brought from the East Indies, as well as Tartary, Egypt, and other countries at a great distance from thence; however, they are very scarce, and there are very few of this kind seen in England. But the American Emeralds are more common, and are found principally in Peru in the earth of the mountains. These are of a very pleasant green, though they are but dull in comparison of the former; for they are neither so transparent, nor so sparkling, nor yet so hard; and comparatively the value is but small, with regard to the former. The European come principally from Silesia, and there are coloured crystals found in Germany, that commonly go under the name of occidental Emeralds. The oriental are seldom met with above the size of a hazel nut. When an Emerald is put in the fire it kindles like brimstone, and the green colour flies off in a flame, after which it looks like a bit of crystal. Hence it appears, that gems in general consist of two parts; namely the crystalline, which is fixed, and the sulphureous, that is volatile. An Emerald is not quite destitute of medicinal virtues; for what is done in the fire, may, in some measure, be performed by the heat of the stomach, and by the digesting fluid. However, it must be acknowledged, that the virtue of any sort of gem is not sufficiently apparent hitherto. The best kind of Emeralds have always been in high esteem; but these are exceeding scarce, as has been

observed: the occidental being more common, and by far not so good, are of little value with respect to the former. An Emerald may be counterfeited various ways, but the best is by melted crystal glass, with a small addition of red lead. By this method, practised judiciously, counterfeit emeralds may be produced as good as those of America.

The PRASIUS, or PRASSITE, is by many thought to be the matrix of an Emerald, and perhaps not improperly, because it is sometimes found within it: for the greener parts that are transparent, and without any mixture of yellow, may be properly called Emeralds; and those that are of a golden yellow, may have the name of Chrysoprasites. The colour of this gem is like that of leek, or a mixture of yellow and green. It is but semi-transparent, on account of the clouds that are visible in it; and sometimes it has a mixture of red, white, or black; according to the various stones to which it has been formed, such as jasper, crystal, and the like. There is one sort altogether green, another more yellow like dried fern, and a third is very little green, with a great deal of whitish yellow. This last kind is semi-transparent, and ought rather to be placed among the nephritic stones. This gem is very common, and so large, that statues have been made therewith, and therefore it can be of little value. The Chrysoprasius is nothing more than a Prassite, that has the colour of gold mixed with the greenness of a leek, and it looks very prettily, though it is not of much value.

The SMARAGDOPRASIUS is a gem between a Prassite and an Emerald, and is of a grass green colour, without the least yellowness in it; but it is not so green as an emerald. It is sometimes, though very seldom, almost transparent, and is called by some a bastard emerald. These stones are found in Bohemia and the West Indies. The Bohemian is generally opaque, and nearly resembles Roman vitriol. These are said to be the stones that the native Americans near the river of the Amazons wear in holes of their lips, in pieces about the length of a man's finger. Some take this to be the true nephritic stone; but this is doubtful, as well as its virtues.

The CHRYSOLITE is the topaz of the ancients, and is a transparent gem, shining with the colour of gold. It is of a fainter green than the emerald, and has somewhat of a yellowish tinge. Some take it to be the matrix of the emerald, and by many it is confounded with a chrysoprasius. This stone will not stand the test of the file, and sometimes there are such large pieces of it that statues may be made therewith. The topaz of the shops is the Chrysolite of the ancients, and is a transparent stone of a shining gold colour without any mixture. It is of two kinds, the oriental and the European; the first of which shines like pure gold. The European are as soft as crystal, and have a mixture of blackness with the gold colour; and there is sometimes so much of it, and so little of the yellow, that if it was not for the blackness, it could not be distinguished from crystal. Sometimes pieces of these have been found to weigh twelve pounds, and there was one brought from Bohemia that was two ells in length, and near half an ell broad. These stones may be counterfeited in the same manner as the rest; but the best way is to put a quarter of an ounce of saffron of iron, and a little red lead into a pound of melted crystal glass, or if one part of calcined crystal be added to three of lead, and then kept for a whole day in a furnace, a topaz will be formed without any other addition.

The BERILL is a gem of a bluish green like sea water, for which reason it is called by the Italians Aqua Marina. When it has rays of a gold colour, or the sparkles are of that colour, it is called a Chrysoberill,

Chrysoberill, and some place it in the same class as the chrysoprasius. All these stones are transparent, and have but a faintish colour, for when this is more deep, they are taken for other gems. It is found of various sizes and of different shapes, that are seldom more than a third of an inch in diameter; and the value is always in proportion to the fineness of the colour. It may be counterfeited by reducing burnt copper to an impalpable powder, and melting it with crystalline glass, or calcined crystal, in the proportion of one drachm to a pound of glass.

The ASTERIA, called by the Italians Girasole, is a sort of opal; only it is harder, and consequently may be placed by itself; especially as it may be distinguished from an opal very easily. The harder it is, the better it reflects the image of the sun, and so agreeably, that it is by some called the gem of the sun. This stone is transparent like crystal, but much harder. It has been named by some the cats eye, because the sparkling is sometimes greater and sometimes less. It differs from the eyes of Belus termed by the Italians Bellocchio, because it exactly imitates the iris of the eye and pupil. Specimens of this have been taken from the matrix of opal, and when exposed to the sun, they emit sparkles like so many small stars.

We now come to the semi-transparent stones, among which the SARDIUS, or CORNELIAN, is reckoned the chief. By some it is called the Carnelian, because it is of the colour of raw flesh, for *Caro* is Latin for flesh. However, it is more of the colour of bilious blood. It is semi-transparent like the washings of flesh, and is called by Pliny Sarda. It was in common use among the ancients, especially for seals, as it is at present. It was first found by the inhabitants of Sardis, a town of Lydia in Asia Minor, and from thence was carried to Rome; but there was a very good kind found near Babylon in the heart of a stone. There are three kinds of it; namely, the red, the demium (which looks duller or fatter than the former) and that which seems to have a mixture of silver films. Those of the East Indies are most transparent; and the thicker or fatter sort is brought from Arabia. It is also found in the West Indies, as well as Silesia, Bohemia, and many other places. There are three kinds of Cornelians, the first of which is the red, now taken notice of. The second is of a faint blood-colour, and semi-transparent; and the third is of a yellowish red. It is usually found in other stones. It was formerly in high esteem; but since other and better gems are more common, it is of little value, being chiefly made use of for seals, as was above hinted.

The SARDONYX seems to be of a middle nature, between the cornelian and the onyx, which its name seems plainly to imply. It is generally tinged with white, black, and blood-colour, which are distinguished from each other by circles or rows, so distinct that they appear to be the effect of art. There are many kinds, and great diversity in the colour of these stones; but the greater variety there is of these last, the more they are valued. They have sometimes purple, blue, rose-coloured, and yellow circles, whose ground is black, especially the Arabian; for in the East Indies it is of the colour of horn. When the circles are not distinct, but as it were separated, and of the colour of honey, they are of no great value. The best sort is brought from the East Indies, and the next to that is the Arabian. It is found also in Germany, Bohemia, Silesia, and the neighbouring countries; but it is seldom clear, nor are the circles distinct like those of the East-Indies. There are pieces of the Sardonyx found so large, that drinking vessels may be made therewith.

The CHALCEDONY is placed by Pliny in the

class of rubies of a darker aspect, and yet paler than a carbuncle; but this is evidently the characteristic of a garnet. This gem is generally of the same colour throughout; though it is sometimes a little clouded. It is semi-transparent, and so hard, that it is seldom or never made into seals. It was formerly placed in the class of onyx's, of which it is a species, and was called the White Onyx. It is either Oriental or European; and those that have a mixture of a faint colour are hard and beautiful, and are taken for the oriental. Such as these have a purplish or bluish mixture, or a redness like that of lac. Those that are earthy, or of a dusky whitish colour, are of little value, and are met with in all parts of Germany. There are always some found in the Netherlands. Those that are tinged with a disagreeable reddish or yellowish colour, though they are not of the oriental kind, are in higher esteem than the last. Some of these have been seen in Lorrain of a surprising magnitude, and when they have been struck with a hammer have yielded a ringing sound. Those are accounted best of all, in which there is blue, white, yellow, and red confusedly mixed together, and which exposed to the sun shew all the colours of the rainbow. This also served to make the Myrrhine vessels of the Romans, which were so highly valued, and at this day they are wrought into cups, heads of great men, and the like; but its chief use is for seals, because the wax will not stick thereto. Some of these stones, brought from the East Indies, are almost transparent, and of a whitish pale colour, and some are tinged with white circles or zones. They are now of little value, except when the pieces are large and fit for the making of figures.

The ONYX, which in Greek signifies a nail, is so called from its likeness to the colour of the nail of a man's hand. It is seldom transparent, and generally consists of a mixture of black and white colours, which are quite distinct from each other. The horny colour is often marked with whitish veins or zones, somewhat resembling an eye. The kinds of Onyx are distinguished, either from the places where they are found, or from their different colours. The Arabian Onyx is black with white zones, and a variety of other colours. When the white zone in carving any figure is placed on the top, and the black serves for a ground, it is called Camehuia by the jewellers, as if it was a distinct gem. When it is white, it is called a Chalcedony, before described. Some Onyx's are quite black, others are tinged with fallow colour, yellow, whitish, bluish, and horn colours, mixed in an agreeable manner. They have all zones or streaks, which distinguish one colour from another. The Onyx has been sometimes found so large, that columns have been made therewith; and there are now six of this kind in St. Peter's church at Rome. This likewise served to make the Myrrhine vessels before taken notice of, and is now made use of for cups, statues, and the like. It is of greater value than the sardonix; those are the best which are bluish at the top, and blackish at the bottom; and these are much sought after by the Jews. This stone does not stick to wax, and therefore is as often now, as formerly, made into seals.

The AGATE is very like an onyx, with regard to colour, but it differs from it in being adorned with zones, whereas the Agate has none; but instead thereof there are lines or spots of various colours, in such a manner as to represent the pictures of different things, as woods, rivers, fruits, flowers, herbs, and clouds, though not very distinctly. An Agate differs from a Jasper in hardness and smoothness; for though the jasper has all the same colours, it is softer, and consists of rougher particles.

The.

The White-veined AGATE, with delineations of trees and mosses, is most commonly known by the name of the Mocha stone. It is of a very firm compact and fine texture, though it is found in the shape of a flinty pebble-stone. The sizes are various, being sometimes only one, and sometimes eight inches in diameter. The veins of this stone are very beautifully disposed in different figures; but generally there are many concentric irregular circles drawn round from one to three points in various places. They are commonly a little whiter than the ground, though sometimes they can scarcely be seen. Those of this kind are of the highest value, and contain the figures of trees, mosses, sea-plants, and the like, which were just taken notice of. Some have supposed that these are only petrifications, and that real mosses and sea plants were included therein; but this is a mistake, which is evident from hence, namely, that the real things which they represent were never met with so diminutive as their images in these stones: for none can be so foolish as to imagine, that there ever was a perfect tree no more than half an inch high. These figures are generally black, or of a dusky colour, and appear with great advantage from the whiteness of the stone. This kind of Agate, when it is perfect, is only found in the East Indies; but there are some of an inferior sort to be met with in Germany. They are called Mocha stones, because they have been brought from the East Indies to Mocha in Arabia, and from thence transported into Europe. However, there are some that will not allow them to be found in the East Indies; which if true, they may as well have the name from the place near which they are found; or at least they may be brought to Mocha from other parts of Arabia, or even Asia.

The Dull Milky AGATE is not so valuable as the former, though it is of a very firm texture. It is found in the shape of common flint stones, and is from one inch to ten in diameter. It is of the colour of milk, or rather like that of cream; and, when it is broken, has a smooth, glossy surface. It is more opaque than the former, and yet it will bear a very fine polish. This species is common on the shores of the rivers in the East Indies, and there are some of less value met with in Germany and Bohemia.

The Lead-coloured AGATE, with black and white veins, is of a very fine, firm, compact texture, though it is found, like the former, in the shape of common flint stones, and of as rugged a surface. The ground is of a pale bluish grey, or rather of a dove-colour, and is often without variation, though it has sometimes black and sometimes white veins, which are generally towards the centre of the stone. This resembles an onyx very much, but is certainly distinct from it. It is very hard, and will bear a fine polish. It is found in the East Indies, as well as in Germany, where they make cups and snuff-boxes therewith.

The Flesh-coloured AGATE is not so valuable as any of the former, though within it has a pretty firm compact texture, and is from one to ten inches in diameter. The flesh colour is very faint, and almost whitish; but yet it is never entirely wanting. Sometimes it has no veins at all, and at other times it abounds in veins, spots, or clouds. The spots are generally very small, about the size of a pin's head, notched at the edges; though sometimes they are much less. When broken in pieces it is very smooth and glossy, though it is not always of the same transparency. It is found in Germany, Bohemia, and Italy, and is worked into various sorts of vessels: it is also often made use of instead of gun-flints.

The Blood-coloured AGATE is more beautiful than most of this class. It is always of a deep blood-

red colour, sometimes throughout, but more frequently variegated with a pale blue and brown. The blue always surrounds the red, and inclines to the colour of whey; but it is in no other part of the stone. The brown is of the colour of horn, and generally appears in irregular veins, sometimes in such plenty as to make the ground to the stone, and the red with its blue edges only the variegation. It is not very common, though it is found in the East Indies, America, and some parts of Germany. It is chiefly used for the tops of snuff-boxes.

The Clouded and Spotted Flesh-coloured AGATE is of a very fine close texture, though it is subject to flaws and cracks when the pieces are large; for which reason the lesser stones are most esteemed; but, in general, it is in very little esteem with us.

The Red AGATE, variegated with Yellow, is of the colour of red lead, has a fine pure equal texture, with a smooth regular surface, and is commonly found in the shape of a pebble stone. It is from one inch to four or five in diameter, and its ground is of a paler red with one that is deeper, disposed in concentric veins round from one to three points; but this does not appear without close examination. Besides these it has irregular bright yellow blotches, that are never intersected by the veins, but are either within or on the outside thereof; and they are always extremely short, being never above a sixth part of an inch in length. It is very hard, and will bear a very fine polish; it is found in the East Indies, though it is not very common there.

The Yellow AGATE has been found from one to seven inches in diameter in various shapes and sizes; but they are all of a very firm compact texture. It is sometimes of the same colour throughout; sometimes consists of irregular veins, and at others has a pale and almost white ground, veined and spotted with a strong yellow, exactly resembling that of a fine yellow bees-wax. It is very hard and capable of a fine polish; but the degree of transparency differs greatly, for sometimes it is as much so as any of the rest, and at others it is almost entirely opaque. It is found in the East Indies and America, as also in Germany, though not very good. In some places it serves to make knife-handles and the like.

The Pale Yellow AGATE, variegated with white, black, and green, is called the Leonina, from its likeness to a Lion's skin. It is more variegated than the rest of the stones of this kind; and has a fine compact close texture, though it is found in very irregular shapes, with a rugged outside. It sometimes seems to consist of an irregular mass, made up of the above-mentioned colours, and at other times is distinctly clouded therewith, and sometimes again it has black and green veins in the form of concentric circles running round a point. The ground is always of a pale yellow, but very differently disposed; sometimes more, sometimes less. Likewise in some, one or more of these colours are wanting, while others contain them all. The green is like that of Jasper, and the black is inclinable to brown. It breaks with some difficulty into pieces, with fine smooth surfaces, and is brought from the East Indies; but it is not commonly known, because it is very scarce.

The Blackish Veined Brown AGATE is found in stones that have a pretty smooth surface, though of an irregular shape, and from two to seven inches in diameter. The brown is pretty deep, and is finely clouded, spotted, and veined with a colour that is almost black, and the veins are generally paler and browner than the other variegations. The veins are disposed in irregular concentric circles, and the innermost are generally broadest. There have sometimes been vegetable substances found in the middle of it, such as the slender roots of moss, or of crow silk.

filk. It is capable of a very high and beautiful polish, and is commonly cut into seals, buttons; heads of canes, knife-handles, and the tops of snuff-boxes. It is frequently adorned with factitious colours, which sink into the substance so much, that they appear like the natural veins of the stone; and then it is of great value.

The Greenish Brown Variegated AGATE seems to be of a middle nature between Agate and Jasper. It is a beautiful species, and is found in roundish stones with a smooth even surface, from two to six inches in diameter. Its texture is very firm, and it is sometimes of the same colour throughout, being only distinguishable from the true Jasper by its hardness. But it has most frequently a brownish green ground, variegated with irregular concentric circles, of a red, or of a finer green; it is also found irregularly clouded and spotted, with the same or other colours, as white, flesh colour and yellow. It is never entirely transparent in those that are clearest; and it is found in different parts of the world, but not equally good; for the European are the worst, they being more coarse, soft, and opaque than those of the East or West Indies.

The JASPER differs little from an Agate, only it is softer, and will not bear so fine a polish, because it consists of grosser particles; besides, it is not so transparent, and is most commonly green; and the nearer it comes to an Emerald, the higher is the value. However it is of other colours, and on that account is divided into different species, among which are included the Nephritic Stones.

The White NEPHRITIC STONE has a very fine, compact, firm texture, with a smooth glossy surface, and is of various sizes; but the common sort are two inches in diameter. The shape is very irregular like a common flint, and it is naturally of a fine white, with great brightness and transparency. It has sometimes a bluish tinge, which makes it appear of a deep pearl colour, and upon that account is more valued by some; but when it is yellowish, it is not in great esteem. It looks pretty much like marble, but breaks into fine glossy bits, and is considerably heavy, as well as very hard. It is found in many parts of America, particularly near the river of the Amazons. It is often cut into small cups and other toys, which are extremely bright.

The Green JASPER is a bright semi-transparent stone, and of a close, very hard, irregular texture. It has been found in masses of many feet in diameter, sometimes no bigger than a horse-bean. It is of a deep beautiful green, and almost always of the same colour throughout; though it has been sometimes met with clouded with white. It is externally pretty, bright and glossy, and breaks into smooth pieces, seeming to be of a texture between flint and marble. It is considerably heavy, and its very great hardness renders it capable of a fine polish.

The Soft Dusky Green JASPER is not so heavy nor so valuable as the former, and is generally found in stones of a flat shape, from two to five inches in diameter. The surface is pretty full of superficial cracks, and the colour is always dull, with sometimes a bluish and sometimes a brownish cast. It is so common in Guernsey, that it is frequently brought over with other things, and is often made use of to pave the streets of London.

Hard Bluish Green JASPER, variegated with red, is called Oriental Jasper. It may be easily distinguished from all others by its blood-red spots, and it has a very firm and compact texture. It is found from two to six inches in diameter, and has a roughish irregular surface, but has no determinate shape. It is not at all transparent, except in very thin pieces, and is sometimes veined and clouded as well as spotted with red. It is most commonly

No. 44.

known by the name of Blood Stone, and will take a very fine polish. It is common in Egypt, Africa; and the West Indies, and is by some termed the matrix of the Emerald. It serves for various purposes, particularly cups, snuff-boxes, and seals.

The Hard Whitish Green JASPER is the nephritic stone of the ancients, and is generally of the same colour throughout. It is harder than a Jasper, and the surface seems as though it was smeared with oil. It is sometimes of a whitish green, which last colour is sometimes yellowish, and sometimes bluish; but generally it seems to be composed of greenish white, yellow, bluish and black colours; but not all at the same time. The common sort are from two to five inches in diameter, and the shape is very irregular like common flints. It is found on the surface of the earth, and in the beds of rivers in many parts of America, where they form them into the figures of birds, beasts and fishes.

The very hard Yellowish Green JASPER is more dull and opaque than the former, though the texture is very firm and close. The colour is properly a mixture of green and yellow, in which it differs chiefly from the former, and in its transparency.

The Bluish Green JASPER, variegated with blue and black, is a kind of nephritic stone, it being of a middle nature, between the oriental green Jasper, the green nephritic stone, and the marble Ophites. The texture is firm and compact, and is found from four to six inches in diameter, and generally of a flatish oval shape, with a rough surface. The colour is usually very agreeable, and is always made up of a mixture of green, grey and blue, which are sometimes paler and sometimes deeper, as well as inclining to other colours. Sometimes they are so blended, as to render it of one colour throughout, and sometimes they are disposed in clouds, spots and veins; and then the colours are as distinct as in the blood-stone. It is found on the banks of the great river of the Amazons in America.

The Hard Greyish Green JASPER is a very hard stone of a greyish green colour, approaching to that of an olive; but the green is of three different kinds. The finest sort is brought from the East Indies, and the Turks and Poles make handles of it for their sabres and cutlasses. It is capable of a very elegant polish, and is found from six to ten inches long, of an unequal shape with a rough surface. It has little or no degrees of transparency, but it is remarkably heavy, and is found only in the East Indies.

The Dull Deep Green JASPER is of a green colour like mallows, from whence it has its name, for *Malache* in Greek signifies Mallows. It is generally adorned with white veins, and the bluish colour that is intermixed is very ornamental; but when there is any black therein it debases the value. It is pretty heavy, and will take an excellent polish. It is brought from the East Indies and America, and is also found in Germany, and some other parts of Europe but is not so good as the former.

The Dusky Green JASPER, variegated with white and flesh-colour, is a rough, coarse and rugged stone, which is found from thirteen to eighteen inches in diameter, is generally of a roundish or oval shape, and always flatted more or less. The texture is firm and compact, and it is often mixed with a variety of colours disposed in a different manner. It is always green in part, and has often thin transverse veins of flesh-colour and white, with spots and clouds of black. The green is not always the same, for it is sometimes deep, and at other times light; but generally the variety is very agreeable. It is very hard, and for that reason will bear a good polish. It is common in the island of Jersey, from whence it is brought among other stones to pave the streets of London; but it might be put to a much better use.

5 R

Hard

Hard Variegated Purple JASPER has been called the rose coloured Jasper by Pliny. It has a smooth, fine, hard texture, though the surface is rough and unequal like a flint stone; it is sometimes fifteen inches in diameter, and is variously tinged with colours, in which the red and blue are always predominant, which when uniformly mixed render it purple; but where it is blue, it is always most bright and transparent. It is brought from various parts of the world, as the East and West Indies, Egypt, Germany, Bohemia and Spain; in which last place it is cut into vessels and images, because it will bear a very fine polish.

Bright Red JASPER, variegated with white, is not so hard as the former, nor of so fine a texture, and is found from the size of a hazle-nut to that of a man's head. The colour is that of red lead, and the most certain colour of the variegation is white, which is almost always disposed in regular narrow veins, though sometimes in spots. That which comes from America is generally accounted best.

Dull Purple and White JASPER is of a coarse and irregular, though of a very firm texture. The purple colour sometimes insensibly changes into a pale red, and the white to a yellowish or bluish colour; it is hard to say which of the two is predominant. It is considerably heavy, and so very hard as to be capable of a good polish. It is brought from Italy and Germany, as well as found in England, and serves to make the handles of knives and tops of snuff-boxes.

Pale Brown Hard JASPER, with purple veins, has much the same texture as the former, but is more beautiful. It is usually found from two to four inches in diameter, and is commonly of an oblong flattish shape. Its ground is an agreeable pale whitish brown, and its variegations consist of regular horizontal and fine deep purple veins, or of a pretty pure white. It is common in Yorkshire and Suffex, and is sometimes met with in gravel pits near London.

Yellowish Hard Variegated JASPER has a very close, hard, and compact texture, though the surface is very rough and irregular. It is generally met with from three to seven inches in diameter, and the predominant colour is a pale dusky yellow, not unlike honey. It is variegated with white, brown, lead colour, and a very pale red, with which is mixed a cloudy crystalline substance. These colours are blended in the form of clouds; but sometimes one and sometimes another is wanting. It is extremely hard, will take a very fine polish, is common in the East Indies, and is also met with in several parts of Europe. The only use of it at present is to make handles for knives.

The Pale Bluish JASPER, with black veins and clouds, has a very close firm texture, and its size is from four to six inches in diameter. It is always of a dusky blue or lead colour, and the black clouds appear like curling smoke. It is but of little value, and consequently not much in use.

The Bluish Marbled JASPER, variegated with white, is of very little value. The colour is of a pale disagreeable grey, and a pretty clear white; but the former colour is the ground, and the other appears in veins or irregular clouds. It is pretty heavy, hard, and will bear a good polish. It is common in the gravel pits about London, and is generally taken for a bit of blue and white marble that seems to be worn by the collision of other stones, for it is rounded at the edges. There is also a black marbled Jasper, variegated with white, and another marbled with yellow.

The Hard Dull Flesh-coloured JASPER is extremely hard, of a very close texture, and is found from eight to eighteen inches in diameter. It is of an extremely pale whitish red or flesh-colour, which

is generally the same throughout, though there are sometimes horizontal veins of a darker red. It is found on the sea shore, and is commonly made use of in pavements. It must be observed, that all these Jaspers strike fire with steel, and will not effervesce with aqua fortis.

The TURKY STONE, called by some the Turquoise, is of two kinds, the oriental and the occidental; the first is rather blue than green, and the other is more inclinable to the latter colour, though it sometimes inclines to a whiteness. They are found in the East Indies, Persia, Spain, Germany and Bohemia. In Persia it adheres to blackish stones, and is very common; but it seldom exceeds the size of a hazle-nut. Those of the East Indies differ in their colour, for such as are said to be of the old rock, always preserve the same colour, but those of the new, are greener. This stone is in so high esteem among the Turks, that those of the better sort are seldom without one; but it is never worn by the women. It is generally valued in proportion to the brightness of the colour. Those that are of the size of a hazle-nut, are of a fine sky blue without any blackish veins; but the lesser sort are not so good. Those that have blackish veins, or are inclinable to greenish, or to the colour of milk, are of no value. There is another Turkey stone, which is nothing but ivory, a tooth, or a bone, which have lain in the neighbourhood of copper ore till they have been tinged with deep blue spots and veins; but when they are put into a gentle fire the colour diffuses itself throughout the whole substance, and becomes of a very fine pale blue. There are several mines of these stones in France; but they may be perfectly counterfeited by art with a tincture of copper in an alkaly.

The LAPIS LAZULI is an opaque stone of a sapphire colour, with golden spots or streaks. It differs from an Armenian stone in being harder, for this may be easily reduced into powder; and, besides, it is without veins of gold. This is the stone with which they make the colour called Ultramarine. It is of two kinds, one of which will remain unchanged in the fire, and the other not. It is found in various countries, and the Armenian stone is said to be its matrix, which is met with in gold mines. It is found in very large pieces; but the common sort are only big enough to make knife-handles and the tops of snuff-boxes. The best sort, which will not in the least change its colour in the fire, is brought from the East Indies; and this is the test whether it is right or not; for that in Germany, which is of a middle nature between an Armenian stone and the true Lapis Lazuli, alters in the fire, and is much more brittle than the true. However, they both will serve very well for the use of painters. Lapis Lazuli has the property of purging upwards and downwards, and therefore has been accounted good for melancholy disorders, quartan agues, apoplexies, and the falling sickness. There is no room to doubt that the blue colour arises from particles of copper, for which reason it is taken by some to be a copper ore.

The ARMENIAN STONE has a smooth surface, and is of a sky blue colour; but it is brittle, by which it may be distinguished from Lapis Lazuli; besides which it has no gold spangles, nor will it keep its colour in the fire. The blue colour has a greenish cast, and when it is made use of in painting, by length of time it changes to green. It is found in various places in Germany, as in the county of Tyrol, and in other silver mines. It is also met with in Hungary and Transilvania. Whenever it is used as a paint, it must be mixed with petroleum, or rock oil, and then it will keep its colour.

The ASTROITES, or STAR STONE, seems to be a kind of opal, and by some is called a Cat's Eye, or Gem of the Sun; but that which is properly so

called has been treated of before. It is a very beautiful stone, and is usually set in rings; it contains the figure of stars so exactly, that no painter can imitate them better. It is an opaque gem, sometimes of a white, ash, dusky, or grey colour. In this sort of stones are sometimes seen roses, sometimes waves, and at other times they contain all three together; which may serve as so many different distinctions of this stone. It is found in various places, particularly in Tyrol, as large as a man's head.

The TOAD STONE seems to be a kind of an astroites; for it is of the colour of that stone, and marked with dark spots, only the ash or grey colour has a reddish cast. It is convex like an eye on one side, and flat on the other. There are two kinds of these stones, the first of which is called by some Brontia and Ombria, and is of a dusky, reddish, yellowish, or greenish colour; sometimes of the size of an egg, and like one, only it is flat on one side. Some take these to be serpent stones or thunderbolts; but the common name is that of a Toad Stone. All these stones differ among themselves: however, that properly so called has the name of Batrachites, but the Brontia and Ombria are called Chelonites. It is now taken to be a petrified substance, and some suppose it to be the tooth of a fish; but this does not seem to agree with its shape. Indeed there may be some in the form of teeth comprehended in this general name; but that resembling an egg is the most common sort. They are all hollow more or less, only some are filled up with the stratum in which they lay, and some of them resemble the cup of an acorn. Another sort are of an oblong figure, but round at the top, and others swell a little in the middle. Many of them have an outward circle of a different colour from the rest, and this is sometimes streaked with very fine lines: some are also found very long in proportion to their breadth, and others perfectly round. They are all naturally of a very fine polish, and are worn in rings without alteration. They are of different sizes, from a pin's head to two or three inches in circumference; and are of a great variety of colours, as above taken notice of.

CHAPTER XXII.

Of the more ignoble STONES.

THE EAGLE STONE seems to consist of several shells or crusts laid one over another; but that which distinguishes it from all others is its being hollow on the inside, in which cavity there is another stone that is smaller: this, when it is shook, may be heard to rattle. It is of various colours, as white, grey, dun, or brown. Modern authors have only three sorts of this stone, the first of which is rough on the outside, and is of different colours, but commonly of a black dun: this makes a very distinct noise when rattled. The second is of an ash colour, and contains a sort of marl in the inside, which is sometimes white, yellow, red, or blue. The outside is rough and sandy, and seems to consist of the particles of flint. A third is of several colours; but has the like contents as the former. The first kind is no bigger than a peach-stone, but the other two are often as large as a man's fist. These sort of stones are found almost every where.

The GEODES is a sort of an Eagle Stone of a round shape, and contains sand or earth, which makes no noise when shook; for when it rattles it may be properly placed in the former class. It is found in Misnia, and near Pelsna in Bohemia. It is of a reddish colour, and of the size of a man's fist; but it is of no manner of use.

The ENORCHUS is another species of an Eagle

stone, and is generally of the size of a pigeon's egg. This contains one stone within another, as the yolk of an egg is contained in the white. It is not smooth on the inside, but is tinged with various dirty colours, and on the outside is of an ash colour.

Authors mention many other species of this Stone, such as the rough purplish, the red and dusky yellow, the yellow, brown, and black crufted, the purplish red, the coarse yellow and brown, and the coarse Eagle Stones.

There are also five kinds of the Geodes, which are distinguished by the names of the Cracked GEODES with ferruginous brown and yellow crusts. This is always hollow, heavy, and of a regular shape; it being oblong, and larger in the middle than at the ends. It is generally about two inches long, an inch and a quarter broad, and three quarters of an inch thick. The outer shell or crust is of a yellow colour, with a mixture of reddish brown, and is smooth to the touch, though it is all over cracked in different directions. However, it is very hard, and will not break without a strong blow; and, when broken, it is found to contain a yellow earth, with a little mixture of sand. It usually consists of three crusts, the innermost of which is of a bluish black colour, the middle of a deep brown, and the outermost yellow as above. It is met with among gravel.

The Wrinkled GEODES, with ferruginous, reddish brown, and gold-coloured crusts, is very heavy when pieces of it are considered apart; but when unbroken it is light, because it consists of a large hollow case. It is about three inches long, and two and a half in diameter, and has no distinct coat different from the general substance. It is of a fine gold colour, with a small mixture of brownish red, and is full of wrinkles or superficial cracks. The cavity is usually divided into several cells, and contains a small quantity of fine bright yellow earth. The shell, when perfect, consists of a great number of coats, some of which are of a ferruginous colour, others of a reddish brown, and others as yellow as gold.

The Sparkling GEODES, with ferruginous, purple, and orange-coloured crusts, is subject to great varieties, excepting the internal structure. However, it is generally oblong and flattish, and sometimes it is full of protuberances, sometimes branched, and sometimes again tapering to one or both ends. It is bred among gravel, and consequently has a very rough outside, it being covered with pebbles of different sizes. It is generally four inches long, two broad, and an inch and a half thick; though sometimes it is twelve inches long. Different stones contain earths of different kinds; and the shell is composed of eight or ten coats, which are all bright and sparkling. Some are of a dark iron grey colour, others of a dusky purple, and others of a saffron or orange colour.

The Long Rough GEODES, with a single purplish crust, is always of an oblong shape, of a firm substance, and considerably heavy and hard. It is yellowish on the outside, and is about four inches long, and three quarters of an inch in diameter; but the surface is strangely rugged and uneven. It has only a single coat of a mixed purplish iron-grey colour, and is a little sparkling.

The Long GEODES, with a single blackish crust, is always of an oblong irregular form, it appearing frequently twisted, and of a different thickness in the different parts of the same mass. The outside is generally so invested with a stratum in which it was formed, as to appear of a brownish yellow. It is sometimes two inches long, three quarters of an inch broad, and above half an inch thick; but it varies in size. It is very brittle, and when broken is of a blackish colour, a little sparkling; and the cavity

cavity is filled with very fine bright red earth, though sometimes it is not without mixture.

The stone called ENHYDRUS is a-kin to the Eagle stone, but it contains nothing but water. The first of these is the thick-shelled Enhydrus with black, reddish brown, and yellow crusts. It is of a close, even, compact texture, pretty heavy, and very hard; and always is of an irregular roundish shape, but very flat, rising in the middle, and thinner towards the edges. It is about four inches in diameter, and two thick where thickest. The surface is rough, and of a mixed yellow and brownish red colour. When broken it is found to be a very thick shell or case, containing a small quantity of water, which is generally muddy. The shell usually consists of three thick coats, of which the innermost is blackish and shining, but that in the middle is of a dusky brownish red, and the outermost of a bright yellow. The cavity is large, and generally divided into different cells.

There are still other stones of the Eagle kind, which may be referred to the Enorchus, of which the first is the very Hard Smooth ENORCHUS, with brown, yellow, and red coats. The texture is fine and compact, with a pretty smooth even surface, and is remarkably heavy. It is always of a roundish oblong figure, and is found from a quarter of an inch to four inches in length; but its usual size is that of a pigeon's egg. It is sometimes met with smooth and glossy, and sometimes covered with a whitish crust. It consists of only five or six coats, inclosing a firm, hard, and solid nucleus of the same nature and texture. This is of a deep dusky brown colour, sometimes of a strong red, and sometimes has a mixture of both. The coats are alternately dark brown and reddish.

The Hard Glittering Rough ENORCHUS, with brown, purple, and deep yellow coats, is much more rugged than the former, and of a coarse unequal texture. It is always of an oblong shape, and is found of several sizes, from half an inch to eight inches long. The surface is made up of small prominences and cavities, less than the heads of the smallest pins, which give it the appearance of shagreen. The nucleus is but small, and is surrounded with eight or ten coats, irregular in thickness and of several colours, as pale brown, deep brown, dusky and reddish yellow; and the nucleus is sometimes purple, but more generally of an orange colour. The substance is pretty bright and sparkling, not only within, but on the surface of the stone.

The Soft Brownish Yellow ENORCHUS is quite of a different nature from the former two; for this is only a composition of soft earth, though the texture is close and smooth. It is always of a flattish oblong shape, and is commonly four inches in length, two in breadth, and one in thickness. It is of the same colour throughout, and the nucleus is of the same shape as the stone, but of a very agreeable brownish yellow, as well as the coats themselves, which are almost innumerable. It has no manner of brightness, but looks like clay. There are two other sorts of the soft Enorchus, the one with a shining brown and dusky green coat, and the other with a shining whitish, yellowish, and red coat.

The HÆMATITES, or BLOOD-STONE, is so called from its colour, which is that of darkish blood; though it is sometimes black, sometimes yellow, and sometimes of the colour of iron; but its streaks always resemble antimony, and when it is calcined it turns to a reddish colour. It was formerly divided into several kinds, but now there is only one treated of by authors. It is found in various parts of Germany, in marl-pits and iron mines. It is now known to be a rich iron ore; for, when melted, a great deal of that metal may be extracted.

It is of various degrees of purity and hardness; for sometimes it is of a coarse texture, and seems to be composed of large filaments. With regard to its medicinal qualities, it is now generally used in some disorders of the eyes, especially to remove spots and films.

The SMIRIS, in English Emery, may be placed in the class of the Hæmatites. It is of an iron grey colour tending to blackness, and so hard that it is used by jewellers, glass-grinders, and smiths, for polishing their work. It will cut glass almost as well as a diamond, and is reckoned a sort of an iron ore. It is found in large masses, bespangled all over with shining specks.

The PUMICE STONE is spongy and full of small holes and cavities. It is of several colours, as ash-coloured or white, which are so soft that they may be crumbled to pieces between the fingers; but some are more hard, though they are all so light that they will swim on the surface of the water. It is found in divers places, but especially near burning mountains, from whence it is thrown out. It is used by various artists for different purposes; and in some places they use it in the baths to clean the skin.

The MAGNET or LOAD-STONE is well known for its property of attracting iron, and for its polarity; for, when suspended, one end always points to the north, and the other to the south. It is found in various places, and often in iron mines; which is no wonder, for it is a kind of iron ore. It is generally of an iron grey colour, with a bluish cast, and sometimes reddish without, and blackish within; but that which is bluest is best. When a needle is touched with a Load-stone, the Magnet will not attract both ends equally, but will repel the one, and draw the other, which is known almost to every one.

C H A P. XXIII.

Of SAND-STONES, ROCK-STONES, MARBLE and ALABASTER.

THE Bright White Brittle SAND-STONE is coarse, harsh and rough, and of a loose porous texture. The surface is of a dusky, dead white; but immediately after it is broken it glitters pretty much. It is composed of a large angular crystalline grit, which is very hard and firm in the mass; but when in small pieces as soft as loaf-sugar, and falls into a white sand like powder. Water, when poured thereon, will immediately sink through it, though it will strike fire with steel, and will soon blunt the workmens tools. It makes no effervescence with aqua fortis; but it burns to a beautiful pale red. It is used in building, and will bear the weather pretty well; but it will not take a polish. They build houses with it in Northamptonshire without mortar.

The Dull Greyish White Brittle SAND-STONE is coarse, rough, and of a loose texture. It is pretty heavy, without splendor, and is composed of a large irregular grit, mixed with a soft loose substance in the form of powder. When examined with a microscope, it appears to consist of an angular oblong transparent large grit, which adhere together in very few places; but the pores are filled up with a whitish powder, and while in the earth it is very moist and crumbly. It is much used in building, because it cuts very easily. When water is poured thereon it will become wet through; but it will hardly strike fire with steel, and yet it will make a violent effervescence with aqua fortis. It burns to an almost white flesh colour.

The Hard White Dull SAND-STONE consists of

of crystalline grits that are not very pure; but they are cemented together by a finer crystalline substance. It is very coarse and rough, and of a close, compact, dense texture, it being very hard and pretty heavy. It is penetrated by water very slowly, and will not readily strike fire with steel; but it ferments very strongly with aqua fortis, and burns to a pure white. It is common in Dorsetshire, and does not lie so deep in the earth as many others. It is a very good stone for building.

The Loose Dull Whitish SAND-STONE is very coarse and pretty heavy; it is composed of a very hard roundish grit, cemented by an earthy spar. It is not very hard in the mass, and when in small pieces it will crumble into powder between the fingers, and when water is poured on it, it will readily penetrate its surface. It will not strike fire with steel, but will effervesce violently with aqua fortis, and burn to a reddish white. This is known in London by the name of Portland Stone, where it is much used in building. It is so soft while in the earth, that it is usually cut into a proper form on the spot, for afterwards it becomes considerably hard.

The Hard Greyish SAND-STONE is composed of grit of an oblong angular shape, many of which are purely crystalline, and very bright and glittering when viewed through a microscope; but to the naked eye they appear like shining specks scattered here and there. The grits themselves do not at all cohere, but are cemented together by an earthy spar. It will not crumble when broken into small pieces, nor is it at all dusty; likewise water poured on it penetrates its substance very slowly. It will not strike fire with steel, though it is cut with some difficulty; but it will make a violent effervescence with aqua fortis, and burn to a white. This is what is called in London Purbeck Stone, and there are often shells contained therein. It is a good stone for building, but will take no great polish.

The Brittle Brownish White SAND-STONE is very coarse, rough and of a loose texture, being somewhat porous. It consists of a large angular grit, slightly cemented together by an earthy spar; when reduced to small pieces it readily crumbles between the fingers, and sticks to the hands. Water will penetrate it very freely, and therefore it is no wonder it will not strike fire with steel; but it makes a violent effervescence with aqua fortis, and burns to a pale reddish white. It is common in many parts of the kingdom; but it is chiefly brought to London from Portland, where it is much made use of in building, because it will stand the weather, though it cuts very easily.

The Brittle SAND-STONE, with a round grit, is known by the name of the Kettering Stone, though it is not only found about that town in Northamptonshire, but at Kerton in Rutlandshire. It is of a loose texture, and seems to be porous when broken, which is occasioned by the falling out of the inner part of its grit. It is pretty heavy, with but a little brightness, and consists of a roundish grit laid very closely together, as well as cemented by an earthy spar. In small bits it will crumble between the fingers, but not stick to the hand. It will not strike fire with steel, but it ferments violently with aqua fortis, and burns to a pale whitish colour. It is used in many places for building.

The Greenish White Brittle SAND-STONE is coarse and dusty, and its particles cohere so slightly, that they are continually falling off in powder. It is of a loose texture, though moderately heavy, and is full of glittering spangles of talc. The grit is pretty large and angular, cemented by a very loose coarse earthy spar. Water poured thereon will readily penetrate through it, and it cuts very easily. It will not strike fire with steel, but it ferments violently with aqua fortis, and burns to a reddish white. It

is common in all parts of England, and will bear fire better than many harder stones.

Hard Greenish White SAND-STONE is very hard, coarse and rough, though of a firm texture, and is spangled all over with broad glittering flakes of talc. In some places it is variegated with brown spots, and consists of large grit with irregular angles, lodged in a sort of crystalline cement. It is considerably hard in the mass; but small bits may be reduced to powder between the fingers, and it sticks to the hands. It will not strike fire with steel, nor make any great fermentation with aqua fortis. It burns to a pale reddish white, cuts easily, and takes a pretty good polish. It is sometimes brought to London, where it is used in building.

The Brittle Yellowish Brown Glittering SAND-STONE is very coarse, and of a loose texture; but it is considerably heavy, and very full of fragments of talc. It consists of large angular grit, lodged in a dusty cementitious substance, is soft and brittle in the mass, and will crumble between the fingers in small pieces. It will hardly strike fire with steel, and makes but a slight fermentation with aqua fortis. It is used in building, being cheap and easily cut.

The Brittle Pale Brown SAND-STONE is extremely coarse, rugged and rough. It is somewhat spongy and pretty heavy; but it has not so much talc as the former. It consists of oblong grits with obtuse angles, and is cemented by a sort of crystalline substance mixed with earth. It is soft and brittle in the mass, and is easily penetrated by water. It will not strike fire with steel, nor ferment with aqua fortis. It is common in the northern counties, where they make whet-stones of it, which are brought up to London, and much used by shoemakers; it also serves for grinding stones.

The Hard Red Glittering SAND-STONE is coarse and rough, though of a very close firm texture, and will bear a pretty good polish. It is remarkably hard and heavy, and of a deep reddish brown colour, with glittering spangles of talc. It consists of large oblong angular grits cemented with a sparry substance. It cannot be rubbed to pieces between the fingers, nor will water so much as penetrate its surface. It is cut with difficulty, and therefore it is no wonder it strikes fire with steel. It makes but a slight fermentation with aqua fortis, and undergoes little or no change in the fire. This is brought to England in large quantities from Norway.

The Hard Glittering SAND-STONE, of the colour of rusty iron, but sometimes more yellow and sometimes browner, is very beautifully spangled with talc. It consists of a small roundish grit, cemented by a firm deep brown earth, and is remarkably hard even in the smallest pieces, but will not strike fire with steel, though it cuts with great difficulty; nor will it ferment with aqua fortis, though it burns to a deep chocolate colour. It is very plentiful near Bristol, where there are strata twenty feet thick. It stands the weather very well, and is used in some places for building.

The Soft Brittle SAND-STONE, of a brownish rusty colour, is composed of large roundish grit, cemented with a loose ferruginous earth. It is common in most counties of England, and is of little or no use.

The Grey Brittle Dull SAND-STONE consists of large, coarse, obtusely angular grits, cemented by a loose earthy spar. It is very soft and brittle in the mass, and much more so when reduced to small pieces. It will readily split into horizontal plates, and burns to a pale whitish red. It will not readily strike fire with steel, but ferments greatly with aqua fortis. It will not stand the weather very well; being very apt to crumble after hard frosts, though in

some places they cover their houses with it instead of tiles.

The Brownish White Glittering SAND-STONE has a moderately smooth and even texture, and is pretty firm, compact and heavy, but varies in colour on account of the earthy particles that get into the pores of this stone with the water. It is the most bright and glittering of any stone of this kind, and is commonly known by the name of the Flag-stone. It is always found in flat plates from a quarter of an inch to four or five inches thick, and the thinnest of these always lie uppermost. It is considerably hard, and will not break in any direction. It will not easily strike fire with steel; but ferments briskly with aqua fortis, and burns to a greyish white. It is used in the north of England for covering houses instead of tiles; that is, those of the thin sort, for the thicker are employed in paving and building. It consists of grit with blunt angles, cemented with an earthy spar, and interspersed with flakes of bright talc lying in a horizontal direction.

The Greenish Grey Shining SAND-STONE is of a hard, coarse, rough and somewhat spongy texture; but is considerably heavy, and full of bright glittering spangles. It consists of large angular grit that lie very close together, among which are dispersed great numbers of fine small very bright flakes of talc, which, with the grit, are cemented with a small quantity of a very pure transparent substance. It will readily split in a horizontal direction, but not into very thin flakes. It does not readily strike fire with steel, and makes but a slight fermentation with aqua fortis. It is used in some places for covering of houses.

The Yellowish Grey Glittering SAND-STONE somewhat resembles the former; but is very rough, coarse and harsh, and considerably heavy. It is met with in many parts of France.

The Hard Purple and White Laminated SAND-STONE is the hardest and most elegant of this class, though very rough and harsh. It is of a very close texture, extremely heavy, and the colour is finely variegated with greyish white and purple. The plates or flakes are much thicker than many of the former, and is extremely bright and glittering, on account of the large quantity of talc contained therein. It splits very easily, and is composed of fine glittering grit, cemented with a pure shining substance. It is extremely hard, and consequently will strike fire with steel; but it will not ferment with aqua fortis. It is common in Italy, where it is used for pavements.

The Bluish Glittering SLATE STONE is pretty fine and smooth, and of a close compact texture. It is extremely heavy, and full of talky particles, and more easily cleaves into plates than any of the former, which are generally about one tenth of an inch thick. It consists of small irregular sharp grit, that is often entirely blended with the cement, which is of the same crystalline substance with itself, though debased by a mixture of earthy particles. It is extremely hard, strikes fire with steel, and ferments slightly with aqua fortis. This stone is common in Italy.

The Dense Dull Whitish ROCK-STONE is moderately fine, but of a very irregular texture. It is composed of a soft whitish earthy spar, intersected with flat plates of the crystalline sort. The earthy part of this stone is pretty dense, but not so hard as the crystalline, and there is no grit of any kind. It ferments greatly with aqua fortis, and burns to a bluish white, mixed with a little red. This is very common in many counties, and is brought to London from different places, where it is used in building.

The Hard Greyish White Dull ROCK-STONE

is of a compact texture, with a smooth surface, and is considerably heavy. It is composed of no visible grit, and is easily cut; it will not readily strike fire with steel, but ferments violently with aqua fortis. It is common in several counties of England, is used in buildings, and stands the weather pretty well: some burn it into a poor coarse sort of lime.

The Hard Porous ROCK-STONE is of a coarse spongy texture, and yet very hard and heavy. It is generally of a greyish white, though sometimes brownish, yellowish or black, from the different kinds of earthy particles falling into it with the rain. It has no grit, and is very hard, even so much as to spoil the workmens tools. It strikes fire with steel, but will not ferment with aqua fortis. It is common in Yorkshire, where the strata lie very deep. It is used for building in that county.

The Hard Bright Grey ROCK-STONE is more like crystal to the naked eye than the former, and consists altogether of a sparry substance. It is a very elegant beautiful stone, for it is bright, shining, and very heavy. It will hardly strike fire with steel, but ferments violently with aqua fortis, and burns to a pale bluish red. It is not very common; but there is some of it in Yorkshire, where they both use it for building and for burning into lime.

The Hard Bright Brownish White ROCK-STONE is very heavy, and of a close texture, consisting of a crystalline spar, which in thin plates is a little transparent. It will not strike fire with steel; but ferments very briskly with aqua fortis, and burns to a pale whitish red. It is brought from Purbeck to London, where it is used for building and pavements. It is also used in Northamptonshire for building and making tomb-stones.

The Dull Yellowish White Hard ROCK-STONE has a close firm texture, with an irregular surface, and is very heavy. It is of a pale dull white, with pale yellow veins and spots in several places; but it is not bright, though composed of crystalline spar. It will not easily strike fire with steel, but ferments violently with aqua fortis, and burns to a white colour. It is common in Dorsetshire, and sometimes contains shells. It is very useful in building, because it wears the weather very well.

The Dull Hard Brownish White ROCK-STONE generally consists of above half shells, and is a very coarse harsh stone without any brightness. It will not readily strike fire with steel, but ferments violently with aqua fortis, and burns to a greyish white. It is brought in great quantities from Purbeck to London, where it is used for flat pavements.

The Whitish Grey Marble ROCK-STONE is considerably fine, remarkably heavy, and of a fine firm texture. It has a somewhat sparkling appearance, and is entirely without shells. It is considerably hard, and will bear a pretty good polish; it strikes fire with steel, but will not ferment with aqua fortis. It is found in the Eastern countries, as well as Italy, and some parts of Germany.

The Yellowish White Flinty ROCK-STONE is very fine, smooth and glossy, and its texture is pretty much like that of common flint. It will hardly strike fire with steel, but makes a very great and lasting fermentation with aqua fortis, and burns to a greyish or bluish white. It is common in some parts of England, and is known by the name of the Rag-stone and Lime-stone. It is generally free from clefts; but when there are any, the sides are always covered with a crystalline spar. It is used in the pavements of streets.

The Brownish White Flinty ROCK-STONE is in some parts of England called Chert or Wern, has a very compact firm texture, and is considerably heavy. It has sometimes veins and spots of red, white or black. It breaks with an even glossy surface, like that of flinty pebbles: and strikes fire

with

with steel, but makes no fermentation with aqua fortis. It is often found among other strata of stone, and Dr. Woodward mentions one of three feet thick in Yorkshire.

The Bluish Flinty ROCK-STONE is very soft and smooth, with a close even texture, and is considerably heavy and hard. It has sometimes bluish white veins, and is found in most counties of England. It strikes fire with steel with some difficulty, and makes a strong and lasting fermentation with aqua fortis. In some places it is burnt into lime, which is very good.

The Hard Bluish ROCK-STONE is very rough, and is generally full of shells or spar. Its texture is firm, and is extremely heavy; it will not readily strike fire with steel, but ferments violently with aqua fortis, and burns to a pale whitish grey. It is brought from Purbeck to London, where it is used in pavements. It is hard to cut, and therefore not much used in building.

The Brownish Blue Dull Hard ROCK-STONE is coarse and rough, and pretty heavy. It is generally variegated with lines and spots of a pale red and of an opaque white. It will not strike fire with steel, but makes a strong and lasting fermentation with aqua fortis, and burns to a pale bluish white. It is called in Leicestershire the Blue Lime-stone, for it makes good lime.

The Dull Pale Red ROCK-STONE is pretty fine and smooth, of a firm texture, and considerably heavy. It is variegated in most places with lines and spots of a pale red, or of an opaque white. It will not readily strike fire with steel, but ferments violently with aqua fortis, and burns to a very pale whitish or greyish red. It is used for building walls in some places, and is also burnt to lime.

The Hard Shining Red ROCK-STONE is very heavy, and is spangled in many places with small bits of a very glossy spar. It is extremely hard, and will take a good polish; it will not readily strike fire with steel, but ferments violently with aqua fortis, and burns to a pale red. It is imported from Sweden, Norway and Denmark, and is used in pavements; it is also to be met with in Yorkshire. That of Norway contains fine straight shells, but that in England is without them.

The Green and Red Variegated ROCK-STONE has a rude irregular structure, and is but coarse for one of this class. However, it is not porous, is pretty heavy, and interspersed with blotches and soft uneven lines of a fine paler green spar, as well as a few fragments of a white and semi-transparent one. It is found in the lead mines of Derbyshire; but is of no use.

The Hard Black Dull ROCK-STONE has a close firm texture with a smooth surface, is pretty heavy, and extremely hard; but has no gloss, except a few shining specks in some places. It is not unlike black marble, but will not readily strike fire with steel: it ferments violently with aqua fortis, and burns to a fine bluish white. In Leicestershire it is burnt into lime.

The Hard Black Shining ROCK-STONE is somewhat coarse, but extremely hard, very glittering, and remarkably heavy. It does not ferment with aqua fortis, and burns to a pale brownish red. It is found in Derbyshire, but is hitherto of no use.

The Soft Dull Black ROCK-STONE has a pretty smooth surface, but no very firm texture, and though very heavy, has not the least brightness. It has somewhat the appearance of slate, though it will not cleave; nor will it strike fire with steel, nor yet ferment with aqua fortis. This is known every where by the name of Rag-Stone, and is more properly so called than the yellowish white one before mentioned, because when broken it has a ragged appearance. This is used as a whetstone all over England, for common knives and carpenters tools.

C H A P. XXIV.

Of S L A T E S.

THE Brittle White SLATE-STONE has a pretty close texture, and is considerably heavy, though dull. It consists of various plates from one sixth of an inch to an inch thick, and will split pretty easily. It will not strike fire with steel, and ferments strongly with aqua fortis. It is very common in England, and particularly in Northamptonshire, where it lies near the surface of the ground. It is made use of to cover houses.

The Purple SLATE is a fine beautiful kind, and is pretty heavy. It is firm and compact, and the colour is a fine pale purple, glittering all over with small glossy spangles which are very bright, and so minute that they are not to be seen distinctly without a careful examination. It consists of very thin plates or flakes laid evenly upon each other. It will not strike fire with steel, nor ferment with aqua fortis; but is greatly valued as a covering for houses in the northern counties of England, where it is found.

The Common Blue SLATE is almost universally known, and is a very useful stone. The texture is fine and smooth, and consists of even plates laid close upon each other, which will readily split. It will not strike fire with steel, nor ferment with aqua fortis. It is used almost all over England for covering of houses, and is much better than tiles.

The Brownish Blue Brittle COAL-SLATE, which is always to be met with in coal-pits, it of no manner of use.

The Greyish Black Brittle SLATE, by some called Shiver, is of a very loose open texture, though pretty heavy: but the structure is regularly plated, and the plates seldom cohere to each other. It is very soft, and is readily penetrated by water. It will not ferment with aqua fortis, and burns to a faint red. It is common in the northern counties of England, and is made use of for manuring land, in the same manner as marl.

The Greyish Blue Sparkling SLATE has a very compact texture, but somewhat uneven, and consists of irregular plates, which will split into those that are very thin. When large masses are found, they are often bent and undulated, and towards the upper part of the stratum are frequently observed to be defective. They are composed of regular oblong fibres, which are all very bright and glittering when the mass is just broken, having somewhat of the appearance of talc. It will not strike fire with steel, nor ferment with aqua fortis; but burns to a yellow spangled mass. There are large strata of this in some of the counties of England, and is sometimes found on the sea shore. It is often used as a whetstone to give a good edge to tools.

The Irish SLATE is the most soft and brittle of all this class, it being coarse, rough, and of a crumbly texture; but is pretty heavy, and of a brownish black. It consists of a multitude of thin plates laid evenly upon each other, and splits very easily. It will not strike fire with steel, nor ferment with aqua fortis; but will burn to a strong bright red. It is somewhat of the nature of alum, and is very common in Ireland; it is also found in Somersetshire and other parts of England, where it always lies near the surface of the ground in a very thick stratum. It is used in medicine against bruises, and is given by some from one drachm to two in curing quartan agues; but its principal use is for internal bleedings.

At Isleb, in the county of Mansfield, there is found a black Slate, which has the images of various fishes of a black or yellow colour; and they appear to be so finely done, that the very scales may be seen.

C H A P. XXV.
Of M A R B L E S.

THE PARIAN MARBLE is so called because it was brought from the island of Paros. It is of a white colour, extremely hard, and takes a very fine polish. It has a firm, compact, close texture, and is considerably heavy; its extraordinary whiteness has sometimes a bluish cast, with blue streaks of different breadths. It is not very hard to cut, and therefore is in great esteem among the statuaries. It consists of pretty large particles with flat surfaces, but much smaller and more regular in their size and shape than those of the alabaster kind. It will not strike fire with steel, but ferments violently with aqua fortis, and when burnt is almost as white as snow. Some say this marble receives its name from Agoracritus Parius, who first carved a statue of Venus out of it.

The Hard White MARBLE, called Carrara by the moderns, is whiter than the Parian, but is not of so great value, because it is more hard to cut, and will not take a fine polish; however, it is used for building, as well as to make statues. It has a more firm and close texture than the former, and is very heavy; besides, it has greater transparency than any other white marble. It consists of small glittering particles, many of which appear to have flat surfaces, and consequently lie close together; and it is supposed to consist of a perfectly white spar. It will not strike fire with steel, but ferments violently with aqua fortis, and burns to a pure white. This marble is found in Italy, from which country large quantities are brought to England.

The Hard Pale Yellow Glossy MARBLE is of the same colour throughout, and is considerably heavy, with a close firm texture. It is very fine and smooth, and between the colour of honey and Venice turpentine. It will readily break in any direction into a smooth glossy surface. It will not strike fire with steel, nor ferment greatly with aqua fortis; but burns to a fine pale red.

The Numidian MARBLE of the ancients is hard, shining, of a bluish colour, and is very remarkable for its hardness. It will bear an extremely fine polish, on account of its compact even texture. It is not at all transparent, unless in very thin pieces. It will not strike fire with steel, but ferments greatly with aqua fortis, and burns to a pure white. It is found in Italy, Spain, France and Germany, and is a fine strong, durable marble, though not in great esteem.

The Black Namur MARBLE is very fine and smooth, having a close firm texture, and is very heavy. It is full of fine small glossy particles, which look like so many spangles. It will not strike fire with steel, but ferments violently with aqua fortis, and burns to a pure white. It is a useful marble, though not much esteemed.

The Chian MARBLE is of a black colour, and very fine and hard. It is used in England, as well as in other places, for a touch-stone; and is in great esteem with the goldsmiths for that use, it being the best of this kind. It is perfectly smooth when broken, but is very dull, and does not shine at all. It appears to be one pure, unmixed mass; and cuts with difficulty, but very smoothly. It will not strike fire with steel, but ferments very strongly with aqua fortis, and calcines to a pure white. It was formerly brought from the Island of Chios; but we have it now from Italy. It is capable of a very high polish, insomuch that it has been used instead of a mirror.

The Lydian STONE of the ancients is a hard black Marble, in the shape of columns, and is called Basaltes by Boet. It is reckoned among the Marbles

by Pliny; and indeed it is the hardest of this kind, for a file will not touch it. It is also called Basanus, from a Greek word that signifies to examine, because this was the touch-stone of the ancients. It is now met with in various parts of Germany, and particularly in Silesia; but the greatest quantity of it known is the Giants Causeway in Ireland, which appears so regular that it was at first taken to be a work of art. This Marble is of a very fine, smooth, even texture, and is of so glossy a black that it resembles high-polished steel, without any foreign matter. It is always found in one smooth homogeneous mass, but not in quarries like other Marbles; for it always stands upright in regular columns, consisting of a great many joints, one of which is exactly placed and fitted to the other. A vast number of these are so regularly put together, and joined by their sides, that they seem to have been placed so by a very skilful workman. Many of these columns make large pillars, some of which are at small distances from each other. The single columns are all angular, and consist of from four to seven angles; but the first are most uncommon. It will not strike fire with steel, which must be on account of its smoothness, for it is certainly hard enough for that purpose; likewise it makes little or no fermentation with aqua fortis. This stone may be made use of on various occasions, and is well known to make the very best kind of burnishers for polishing silver.

The Lacedemonian MARBLE of the ancients is of the green kind, and is taken notice of by Pliny. It is different from the Ophites, because that is variegated with spots like serpents, from whence it took its name, for that word signifies a serpent; besides, the columns that are made with this last are always very small. There is also another of this kind, of a dark green, which is finely painted with crosses of a lighter colour, which are so fine that common spectators would take them for the effect of art. This Marble has a close compact texture, and is very hard and heavy. It is of a fine bright green, and takes a very good polish. It will not strike fire with steel, but ferments violently with aqua fortis, and burns to a pure white. It was first brought from Lacedemonia, afterwards from Egypt, and is now found in Germany, Sweden, and England. There is said to be a stratum of it near Bristol, and many in Wales, where it may be had in any quantity.

The Derbyshire MARBLE is of a whitish brown colour, and has a fine close texture. It will not strike fire with steel, but ferments violently with aqua fortis, and burns to a pure white. It is so full of marine substances, that four fifths of the whole mass seem to be composed thereof; it is particularly full of entrochi, which are a sort of shell of an oblong round form, furrowed on the outside, as if it was divided into joints, marked with a star at the end, which are supposed to be part of the Star Fish; but this is uncertain. They are of all sizes, from the thickness of a large pin, to half an inch or more. They will take a very elegant polish in the mass, and are much used for chimney-pieces, tables, and the like. It is found in vast quantities in Derbyshire, and some will not allow it to be Marble, but call it the Derbyshire Stone.

The Green MARBLE, thick set with small sea shells, is of a very beautiful kind, and will bear a very fine polish. It is of a delightful bright green; but does not sparkle. The roundish black lines, and pale brownish white specks that are found in it, are thought to be small sea shells, filled up with an impure white earthy opaque spar; but, be that as it will, it is a very elegant curious Marble. It ferments violently with aqua fortis, and calcines to a pure white. There are very large quarries of it in Germany, Bohemia, and some parts of France, where

where it is used in the ornamental parts of buildings.

The Greyish Green MARBLE, thinly set with shells, is somewhat coarse and rough, and of an irregular and pretty firm texture, moderately heavy, and considerably hard. It is of a dull dusky greyish green colour, and will ferment violently with aqua fortis. It is found in Derbyshire, Dorsetshire, and Essex.

The Hard Greyish Black CORALLOIDE MARBLE, has a very fine smooth even texture, and is considerably bright and sparkling; but does not seem to consist of a homogeneous mass when broken, but of many closely compacted particles. It abounds with a sort of coral called Porus, set at small distances and in all directions: they are generally about an inch and a half long, and three quarters of an inch broad, and are composed of longitudinal plates, which are very fine, thin, and of a snow white colour. In the most perfect specimens there are processes like wings, of a close irregular net-like texture, expanded on each side near the top, and of this sort of texture the whole body is full; the interstices are filled up with a greyish white spar, and form a very beautiful figure. It is found in great plenty in Derbyshire, and according to Dr. Woodward in Wales. The tomb of Sir Thomas Gresham in Great St. Helen's church is built with it.

The Black CORALLOIDE, marbled with shells, is of a very close, firm, even texture, and is very hard and pretty heavy; it will bear a very fine polish. It is variegated with a Coralloide Porus not unlike the former, but smaller. There are also great numbers of large sea shells of the turbinated and bivalved kinds, lodged in various directions, and of a clear bright white. The cavity of the porus and shells are all filled up with the black substance of the marble; but they retain their shape in a very perfect manner. It ferments violently with aqua fortis, and is common in Ireland, from whence it is brought to London.

The Purple and White Variegated MARBLE is generally pretty fine, with white veins, spotted and variegated with purple. In some blocks the purple makes the ground, and the veins and spots are white; there are also blotches of other colours, as pale red, pale brown, yellowish, greenish, and yellowish brown. The different substances, which compose this Marble, are generally distinct masses, particularly those of the purple and white kind. The whitest is most pure, and therefore is hardest, brightest, and most transparent. The pale red is next, the purple next to that; but the brownish, greenish, and yellowish, are very earthy, and almost perfectly opaque. There are silvery particles in this Marble, which are supposed to be a very pure spar. This is a common Marble in Italy, and great quantities of it are brought to England.

The Brown and White Brittle MARBLE is the softest of this class, and has a pretty coarse texture; but it is considerably heavy, and of a pure snow white, finely variegated with slender lines, and veins of a deep brown earthy colour, and in some places there is a faint cast of pale red: when broken, glittering particles appear as in the former, which are disposed in small flakes. The white parts or ground are extremely like the finest loaf-sugar, and is so soft that it may be cut with a knife. Water will readily soak through it, and it makes a violent effervescence with aqua fortis. It is common in Italy, and serves to make chimney-pieces.

Hard Variegated Red and White MARBLE is very fine, remarkably heavy, and is somewhat of a bluish ground, finely variegated with red, brown, and yellow veins. It is very glittering in many parts, and will take a very fine polish. It will not strike fire with steel, nor ferment greatly with aqua

fortis. It is a beautiful Marble, and is found in great plenty in Devonshire, from whence it is sent to London.

The Blue and White Variegated MARBLE has a large rough grain, is moderately heavy, and is of a bluish white, or of a fine bright pearl colour, variegated with broad veins of a dusky blue, which often make up the greatest part of the Marble. The white parts when broken appear bright and sparkling, but their texture is loose. The blue is of a smooth texture, and extremely dull. It is moderately hard, and takes a very good polish. It ferments violently with aqua fortis, and burns to a greyish white. It is common in Italy, from whence large quantities are brought to England; where it is used for monuments.

The Pale Brown MARBLE, with white and red veins, has great variations, both with regard to the ground and the veins. The texture is pretty fine, close and smooth, and is considerably heavy. The veins are sometimes of a bluish white, without any other mixture, and in some they are only red. The red is of all degrees, from the brightest colour to the purple of porphyry. It is considerably hard, and takes a very beautiful polish. It ferments violently with aqua fortis, especially in the red and white veins. It is a common English Marble, and there is great plenty of it in Cornwall, Devonshire, and Wales. It is used in London for tables.

The Brown MARBLE variegated with white and black is pretty fine and smooth, though subject to cracks and flaws. It is moderately heavy, and the brown colour is variegated with very beautiful whitish and black branched veins of various figures: sometimes it is difficult to determine whether the white or brown is the ground. The brown is of different degrees of colour, and is disposed in a very odd manner; for it sometimes, when black, seems to resemble rocks, clouds, rivers and landscapes. It is common in many parts of Italy, where it is in good esteem for ornamental works.

The Hard Brown MARBLE, variegated with white, and is the hardest of this class, is remarkably heavy. It generally consists of only two colours, yellowish brown, and a dusky white; but they are in many different proportions, and the veins are composed of very different shades, which generally resemble the windings of rivers, and seldom any thing else. It ferments but little with aqua fortis, nor will it readily calcine; it is very hard to work, therefore is not much in use; it is found in Italy, but not very common.

The Yellow and Purple Variegated MARBLE is a very curious kind, and the ground is of a beautiful pale yellow, with fine purple veins; there are others that are dark brownish, blackish and white. The structure is smooth and even, and it will bear a very elegant polish. It will ferment somewhat briskly with aqua fortis; and when calcined turns to a beautiful pale red. It is found in Italy, and with us bears a very great price.

The Blue and Yellow Variegated MARBLE would be very valuable, if it would admit of a fine polish; but, as it does not, it is not in great esteem. The ground, which is coarse, is of a deep yellow, mixed with a fine blue; which in some places is so deep as to be almost black, and in other places so light that it looks like a pale grey. Its texture is loose and open, and it is common in Spain, Italy, and Africa.

The Black MARBLE, with white veins, has a very firm texture, and is of a fine deep black, variegated with narrow white veins, running generally straight and even. It is pretty hard, and will bear a good polish, and when broken one way it is very bright and sparkling. It ferments but little with aqua fortis, and calcines to a dusky grey: it is com-

mon in Italy, and is used with us for chimneys and tables.

The Bluish Black Hard MARBLE, with snow-white veins, has a somewhat rough and harsh texture; but is considerably hard, and will bear an excellent polish. It is somewhat bright and glittering when broken in the black part, and the white veins glitter greatly. It ferments violently with aqua fortis, and when calcined is of a mixed grey. It is common in Italy, and is brought to us from Leghorn.

The Black and Yellow Variegated MARBLE has a very fine close texture, and is very heavy. The black is deep, and variegated with a great number of yellow veins. It will bear a very fine polish, and then the yellow veins look like gold; but when there is any white, they appear like silver. There are great quantities of this Marble brought from Italy, because it is of very great use with us, and highly esteemed.

The Black MARBLE, with white and red veins, is of an irregular but close texture, and is considerably heavy. The ground is black, and sometimes inclines to blue, and the variegations are chiefly of a clear bright white; but there are some of a beautiful red. Sometimes the white part is so great, that it is hard to determine whether the white or black is the ground. The red veins commonly appear of a granulated structure, and the whole is very hard, and will bear a very fine polish. It will not strike fire with steel, but ferments pretty briskly with aqua fortis, and burns to a mixed grey. There is a great deal of this Marble in Ireland, from whence it is sometimes brought, though very rarely.

The Black MARBLE, with red, white and yellow veins, is pretty coarse and rough, though of a firm texture. The ground is of a deep black, which is beautifully variegated with all degrees of red, yellow and white, dispersed in irregular veins. It is brightest in the white part, and the red and black sparkle, though very little; but in the red it is scarcely perceivable. It takes a pretty good polish, and ferments though but little with aqua fortis, except in the white veins.

The Green MARBLE, variegated with white veins, was in much esteem with the ancient Romans. It has a firm compact texture, is remarkably heavy, and green and white are of such different degrees, that they make a very agreeable variegation. Besides these, there are spots and veins of a blackish colour, and the whole is so hard that it will bear a pretty good polish. It ferments briskly with aqua fortis, except where it is green and flaky; and is brought from Egypt and other places.

The Greenish Black and White Spotted MARBLE is the black Ophites or Serpent-Stone of the antients. It was so called because it had spots in the form of serpents; for the name was owing to the figure of the spots and lines, and not of the stone itself. It is a very beautiful and pretty hard marble, of a firm texture, and remarkably heavy; the ground is a very fine green, variegated with small black spots and irregular lines, and sometimes with those that are white. They are sometimes pretty large, and half blended with the general substance of the mass, and sometimes there is the blush of purple throughout the whole. It ferments violently with aqua fortis, and burns to a mottled grey. This marble is now found in various parts of the world, and particularly in the islands of the Archipelago; there is also a sort of it in Wales, which is known by the name of the Anglesea Marble.

The Greenish Soft MARBLE, variegated with white and black veins and spots, is the white Ophites of the antients. It is of a pretty fine smooth texture, moderately heavy, and when pure, of a very elegant pale green, with spots, clouds and lines of a

fine deep black and whitish green, which is sometimes entirely white. It is soft and easily cut, but looks very bright when wrought. It ferments violently with aqua fortis, and burns to a dusky grey. It is found in France, Italy, and Germany.

The Ash-coloured MARBLE with small black spots, is the Tephria and grey Ophites of the antients. It is a fine smooth marble, pretty firm and compact, and considerably heavy. The ash colour is lively and beautiful, the black spots of irregular figures, and the sixth part of an inch in length. It is pretty hard, and takes a fine polish. There is a great deal of this in Germany, but it is not so good as that of the antients, which is brought from Ethiopia and Egypt.

The Greyish Brown MARBLE, with bright green spots, has an even texture, is considerably firm, and very heavy. The spots are small, generally of an oblong figure, and will take a very fine polish. The green parts especially ferment greatly with aqua fortis, and burn to a pale mottled grey. It is common in Egypt and Arabia, and is said to be met with in England.

The pale grey MARBLE, with green spots and veins, is extremely firm and very heavy, and in some places slightly tinged with a very faint red, and in others with a colour that is nearly white. It is variegated with a very beautiful pale green, consisting of small oblong irregular spots, and sometimes of narrow uneven veins. It is very heavy, and will bear a beautiful polish. It is common in Germany, and Dr. Woodward takes notice of a specimen found on the sea shore in Cornwall.

The Red MARBLE, with white and gold veins, is the Theban marble of the antients. It is a very beautiful marble, and of a very smooth regular texture. The red is variegated in some places only with white, and in others only with yellow or gold colour; these are very large and broad in some places, and very narrow in others, for they generally make up almost half the mass. It is found in Egypt, Italy, Germany and England; but the Egyptian is the finest, and the English the worst.

C H A P. XXVI.

Of ALABASTER, PORPHYRY and GRANITE.

THE Snow-white Shining ALABASTER is that called the Lygdine by the antients. It is not very compact; but is heavy, and consists of a multitude of broad, flat, large particles, which are very bright and perfectly white. It cuts very freely, and is capable of a fine polish. There are very large strata of it in Arabia, Egypt, and many parts of Italy; but it is seldom brought over to England.

Whitish Yellow ALABASTER, of a soft consistence, is of a loose open texture, considerably heavy, and nearly of the colour of honey; but the colour is more deep in some places than others. It consists of irregular pieces that lie in tables one over another, though with regularity; however, they all together compose a remarkably bright mass, which is very brittle. It is found in Cappadocia, and has been met with in Germany and France, as well as in Derbyshire.

Yellowish and Reddish Variegated ALABASTER is the common Alabaster of the antients. It is so soft that it may be cut with a knife, and has the same name in all languages. It is remarkably bright, glittering and almost transparent, and its texture is very loose and open, though it is moderately heavy. The ground is of a fine clear pale yellow, between that of honey and amber, and has the same texture as the former; but is beautifully variegated with crooked undulated veins, some of which are broad, and

and others narrow; some of a pale red, others whitish, and others again of a very agreeable pale brown. It will bear a very fine polish, and consists of large angular sparry concretions. It is not proof against water, ferments violently with aqua fortis, and burns to a pale grey colour. It was formerly found in Egypt, and is now met with in many parts of England.

Purple PORPHYRY, with pale red and white spots, is the Porphyry of the antients, by whom it was placed among the red marbles, of which it was reckoned the chief, on account of its hardness and splendor. It is named Porfido by the Italians, and there are two columns of it before the gates of St. John Baptist, in Florence. The texture is not so fine as many of the common marbles, and it always breaks with a rough irregular surface; but is remarkably firm, compact and heavy, and of a fine deep purple variegated more or less with pale red and white spots, as also a few flaky black spots. The purple is of all degrees, from the colour of claret to that of a violet, and the variegations are generally distinct spots of various sizes. It approaches the nearest to the hardness of a gem, and was always in very high esteem. It is found in great plenty in Egypt, which was always famous for this stone; but now it is met with in other places, at least with variations. They will all strike fire with steel, but will not ferment with aqua fortis. This is frequently made use of as a stone for grinding colours.

The PORPHYRY of the colour of red lead, variegated with black, white and green, has the hardness and all the other characters of purple Porphyry; but it excels it in brightness, and in the beautiful variegations of the colours. The texture is harsh, rough and irregular, but it is remarkably heavy. The ground is of a bright red lead colour, and in various degrees. It has very regular green veins, and some that are perfectly white, with a great number of small black specks; but these are never mixed with the green, that make a considerable part of the whole. It takes an exceeding fine polish, strikes fire with steel, and will not ferment with aqua fortis. It is found in the island of Minorca, and this might serve for many valuable purposes, if it was imported into England.

The Pale Red PORPHYRY, variegated with black, white, and green, is of a very compact firm texture, considerably heavy, and of a pale flesh colour, often approaching to white. The variegations are in large blotches from half an inch to an inch broad, and now and then disposed in irregular veins. The surface is bright but does not glitter, and its extreme hardness renders it capable of a very high polish. The red, white and green parts appear to be all tabulated, and the green has a tinge like that of gems, and is the brightest of all, it being nearly transparent. It is found in Arabia Petraea, and in Upper Egypt. There are also small pieces of it in Germany and Ireland, and they have been sometimes seen in Devonshire on the sea shore.

The Hard White GRANITE, with black spots, called in Cornwall Moor-Stone, is of a large and gross texture, and appears to be a rude, but beautiful mass of variously constructed and differently coloured particles, distinct from each other, though they cohere very strongly. It is considerably hard, and mottled with black and white, among which there are perfectly transparent particles that are very bright; there are great numbers perfectly black, and others of the colour of brown crystal: some of these intersect, and are divided by other granulæ; but others lie parallel with, and others evenly upon them; and others again are quite buried in the substance of the crystalline particles, like flies in amber. Some again are single and thin plates, and others large and broad laid singly on each other.

The whole is extremely bright and glittering, and will take a pretty good polish. It strikes fire with steel, but will not ferment with aqua fortis, and undergoes little change in the fire. There are vast quantities of this in some parts of Ireland, as well as in Cornwall and Devonshire, where it is found in exceeding large masses on the surface of the ground. It is used in London for the steps of publick buildings.

The exceeding Hard Red GRANITE, variegated with white and black, is the Syenites of Pliny, and the Oriental Granite of the moderns. It is called by the Italians Granito Rosso, and of this the obelisks are generally made in Egypt. Travellers tell us of an obelisk, in Alexandria, made of one solid block of this Marble, which measures eighty feet in height. The texture of this Granite is coarse, harsh and rough, but extremely heavy. It is of a very beautiful pale red, variegated with white and black. All parts of it are bright and glittering, being capable of a very fine polish. It strikes fire with steel, but will not ferment with aqua fortis.

The Pale Whitish GRANITE, variegated with black and yellow, is found in the island of Minorca, where there are vast quantities of it. It is often found on the shores of the island of Guernsey, and is used for pavements in the streets of London.

C H A P. XXVII.

Of Common Circumscribed STONES.

THE Brown STONE, grey on the outside and divided by partitions, has a very firm compact even texture, with a smooth surface. It is of various sizes, but generally between six and twelve inches in diameter. They are not always of the same shape, but are most commonly roundish, or inclining thereto. They have always a multitude of fine flaws like those of common flints, which chiefly appear upon breaking them; and they always break in these flaws, which are lined on both sides with an extremely thick crust of grey clay. Besides these narrow cracks, there were originally others, which are now filled up with a pure spar of a pale yellowish white, and pretty transparent. These are always thickest in the centre of the stone, and become thinner and narrower as they approach the surface. The stony matter of this kind is considerably heavy, moderately hard, and will bear a slight polish. It will not strike fire with steel; but ferments violently with aqua fortis, and turns to a whiter colour in the fire; the matter, which divides the several parts, burns to a pure white. It is very common in England, and sometimes contains shells, besides a beautiful delineation of shrubs, plants, and mosses.

The Hard Brown STONE, with few divisions, has not a grey crust like the former, but the colour within is nearly the same. The texture is firm, but the surface rough and irregular; and the usual size is from four to twelve inches in diameter. The shape is different, but it has always somewhat of an oval; and when broken there are small shining sparry specks. The divisions or septa are very few, which appear in the form of shining veins; and there are some that have none at all. It will not strike fire with steel, but ferments greatly with aqua fortis, and calcines to a greyish white. It is common in the clay pits between London and Islington.

The Hard Blackish Brown STONE, with whitish partitions, is coarser than the former; but the texture is firm, and it breaks with a rugged uneven surface. It is seldom above six or eight inches in diameter, and often no bigger than a hen's egg, but the

the shape is nearly round. It is always covered with a pale brown crust, about the third of an inch thick, where it is softer than within. The divisions are very numerous, and always filled up with a whitish spar. The inside of the stone is of a dusky brown, with irregular variegations of black. It is considerably heavy, and will take a pretty good polish. It will not strike fire with steel, but ferments with aqua fortis, and burns to a pale reddish white. It is found in most parts of England, and is common near London.

The Hard Brownish Yellow STONE, with yellowish white partitions, is very firm and hard, with a smooth compact texture. When broken it has a smooth flinty surface, is of various sizes from four to twelve inches in diameter, and generally roundish with somewhat of flatness. It is covered with a deep yellow crust, softer than the substance of the Stone, which will crack when exposed for some time to the air. This Stone is very hard, heavy, and will bear a tolerable polish.

The Hard Greyish Brown STONE, with brown partitions, is very close and compact, and has a very smooth surface when broken. It is met with from three to four feet in diameter, and the shape is always irregular. It is without a crust, and sometimes appears a little bright. The veins, which are few, are very broad; and, though it is remarkably hard, it will not strike fire with steel, but ferments violently with aqua fortis, and calcines to a greyish white. It is common about London and elsewhere.

The Hard Ferruginous Brown STONE, with brown partitions, is very firm, strong, and of a compact regular texture, with a smooth even surface when broken. It is two or three feet in diameter, is generally broad and flat, and most commonly without a crust. It breaks into thin flakes in a very regular manner, with a great many shining specks. It is remarkably heavy, very hard, and will bear a pretty good polish. It will not strike fire with steel, but ferments greatly with aqua fortis, and burns to a brownish red. It is common on the shores in Yorkshire.

The Soft Whitish STONE, with brownish yellow partitions, is of a very soft and loose consistence, and full of great numbers of empty cracks. It is seldom above eight inches in diameter, and is of a roundish shape. Sometimes it is invested with a crust a little paler than the inside of the Stone, and when broken a few shining specks may be seen. It ferments greatly with aqua fortis, and calcines to a pure white.

The Elegant Crustated STONE, with a bluish nucleus or kernel, is of a very close even texture, and is generally about eight or ten inches in diameter, and of a roundish flattish shape. The crust is about the sixth of an inch thick, and of a pale yellowish brown, as well as the rest of the mass. The nucleus in the centre is usually about four or five inches broad, and about half an inch in diameter. It is of a pale bluish grey, and round it the substance is disposed in regular crusts, which grow thinner as they approach the centre. It ferments with aqua fortis, and burns to a pale red. It is not very common; but is found in Leicestershire.

The Hard Dusky Brown STONE, with very thick partitions, has a fine close texture, and an even surface. Its shape has a tendency to roundness, and is generally between four and five inches in diameter, with a pale yellowish brown crust, though sometimes it has none at all. When broken the surface is irregular, and looks like flint; but it has few spangles. The partitions are numerous, broad and thick, of a pale brown colour, and pretty transparent. They are all irregular, and this Stone will bear a pretty good polish. It will not strike fire with steel, but ferments most strongly with aqua fortis.

The Hard Greyish Brown STONE, with thick whitish partitions, is different from all the foregoing; for it is divided into angular squares of irregular shapes. The texture is firm and compact, and the surface irregular and rugged. The size is from four to eight inches, and it has a tendency to roundness. It seldom has a crust, and when broken does not at all sparkle. It may be generally observed, that in these sort of Stones the softer they are, the more they are spangled; but the harder, the less spar they contain. This stone is very heavy, and takes a good polish; but will not strike fire with steel, though it ferments violently with aqua fortis.

The Brown Compressed STONE, with yellow partitions, is generally of a very large size, it being from one to three feet in diameter. It is of a broad and flat shape, and seldom above four inches thick. It is sometimes invested with a thin yellowish brown crust, but is most commonly found naked. It has a reddish cast, which is owing to a slight tinge of iron, though the prevailing colour is a pure brown. It has a smooth surface when broken, but has no shining specks. The partitions consist of fine glittering spar of the colour of honey, which is disposed into columns, and is regularly and beautifully dispersed throughout the mass of the stone, dividing it into oblong angular pieces with three or four sides, and from one to two inches in diameter. It is very heavy, hard, and will bear a fine polish; but will not strike fire with steel, though it ferments violently with aqua fortis. It is common on the shores of Yorkshire, Suffex, and Kent.

The Whitish Grey and very Hard STONE, looking like flint, is of a firmer texture than any of the former, with a pretty smooth even surface. It seldom exceeds six inches in diameter, and is always of a round or oval shape. It is mostly covered with a thickish brown crust, and on the inside it is sometimes very pale, and sometimes mixed with more or less brown. It appears like flint when broken, and has no shining specks. It has but few partitions, and those very thin, and of a very pale brownish white. It is remarkably heavy, and very hard, though it will not strike fire with steel; but ferments violently with aqua fortis, and burns to a pale greyish white. It is not very common.

Bluish STONE, brown on the outside, with white partitions, is pretty hard, with a rough irregular surface; and is of various sizes, from a few inches to two feet in diameter. It is always flattish, being seldom more than six inches thick in the middle, from whence it becomes thinner to the edges every way. It is sometimes invested with a pale brown crust of earthy matter, mixed with a little spar; but is most commonly entirely naked. Wherever this stone breaks with ease, it is always of a pale brown, but elsewhere of a dusky blue or lead colour, with a few shining spangles. The partitions are of a very pure white, though sometimes a little tinged with the colour of brimstone. They are very numerous, and divide the mass into many pieces, which consist of several sides, and are from one to three inches in diameter. It is capable of a good polish, but will not strike fire with steel, though it ferments violently with aqua fortis, and burns to a pale dusky red. This stone is very uncommon.

Hard Pale Yellow STONE, with a few thin partitions, is of a pretty firm texture, but the surface is rough and unequal. It is sometimes three feet in breadth, and very flat, for it seldom exceeds two or three inches in thickness. The pale yellow is sometimes mixed with brown, and when broken its surface is pure and regular. It has a few shining spangles in different places, and is sometimes covered with a thin shell of a pale grey earthy matter. The partitions consist of a pale brown spar, disposed in short irregular columns, and generally lie in
straight

straight perpendicular directions, dividing the mass into large pieces; and on each side of the cracks filled with these partitions there is often a coat of white sparry earth; for which reason this stone may be easily divided into pieces. It is pretty heavy, and will bear a tolerable polish. It is common in the middle counties of England.

Soft Dusky Yellow STONE, with very thick partitions, has a pretty smooth texture, but not very compact: the surface is uneven, and the size is from two inches to two feet in diameter. It is always flattish, though generally thickest towards the centre, and thinner at the edges. When it has any crust, it is always a little softer than the rest of the stone; and the disagreeable dusky yellow is mixed with a little brown. When broken it appears in irregular flakes, with a rough surface, on which are a few spangles like talc. The partitions consist of a pale yellow spar regularly dispersed through the stone, and are pretty numerous, many of which are no less than one third of an inch in diameter. It is pretty heavy, though soft, and does not ferment greatly with aqua fortis. It may be seen in the clay pits near Deptford.

The Hard Bright Yellow STONE, variegated with brown, is of a pretty fine close texture, with a very rugged unequal surface; and the size is from four to twelve inches in diameter. It is always oblong and flat, being no thicker in the middle than elsewhere. It has commonly a thick crust of the same substance with the stone, but softer; and is of a very bright beautiful yellow, with sometimes a brown coat, and at other times veined in different directions. When broken, the surface is tolerably even, and there are shining specks of spar in different places. The partitions are thin, but consist of a pale brown spar. It is moderately hard, and will take a slight polish. It is common in the tile clay-pits about Pancras.

The Very Hard, Brownish, Yellow, Undulated STONE, with a very few whitish partitions, is of a very even compact texture, with a smooth regular surface. It is from three to nine inches broad, of a flattish shape, and oftener square than oblong. When broken it has a tolerably smooth surface, with long specks of spar. The partitions are very few and small, and it is often without any. It is very heavy, extremely hard, and will bear a fine polish; but yet it will not strike fire with steel. It is common on Mendip Hills in Somersetshire.

The Hard, Greyish, Yellow STONE, is divided into pieces by thin yellow partitions, and has a very fine close texture, but the surface is irregular and unequal. It has been found from four to twelve inches broad, of a roundish flat shape, and seldom with any crust. It appears smooth when broken, with a few glittering spangles. The partitions are of a fine pale honey colour, and are very numerous, running among each other in all directions, and forming a sort of net-work, somewhat like a honey-comb, but of various shapes. The pieces contained in these are about an inch in diameter, having from three to six sides, and the partitions consist of a transparent spar. The whole is very heavy, considerably hard, and will bear a good polish; but it will not strike fire with steel. It is frequently met with on the sea shore.

The Round Yellow Ferruginous STONE, with thin straw-coloured partitions, has a smooth even texture, is about eight or ten inches in diameter, and in the shape of a round ball. It is always crusted with a paler colour, which is softer than the substance of the Stone, and near an inch thick. The colour is a mixture of rusty iron, and a pale yellow; and when broken the surface is smooth and even, with a few shining spar specks that look like talc. The partitions are of a beautiful colour, and

are composed of most bright pure spar, without any order. They are always thickest at the centre, and very few reach to the surface. It is considerably heavy, pretty hard, and will bear a slight polish. They may be seen in the clay pits between London and Islington.

The Roundish STONE, of a rusty red colour, with yellowish partitions, is pretty like the former, and is between six and twelve inches in diameter. It is always covered with a thick crust, of a whitish brown clayey earth, containing a good deal of spar, and is commonly about half an inch thick. When broken the surface is even, and has a few shining specks. The partitions are principally about the centre, and are of a fine bright yellow. It is very heavy, pretty hard, and will bear a tolerable polish. It may be seen in the clay pits near Islington.

The Rusty Brown STONE, with whitish partitions, has a pretty smooth texture, but not very firm; the size is from two to twenty inches, and always broad and flat. It is generally covered with a thick whitish brown crust, and the surface when broken has many shining sparry specks. The partitions are pretty regular, running through the stone in perpendicular directions. It is so soft as hardly to bear any polish, and is common on the shores of Yorkshire.

The Hard Blackish Brown STONE, with a yellow coat, has an exceeding fine texture, with a pretty even surface; and is from four to six inches in diameter, and always of an oval figure. The crust is of an ochreous clay, different from the rest of the mass, and is very brittle. It is commonly composed of thin coats laid evenly one upon another, and adhering but slightly. They are of a fine deep yellow, and are easily broken from the stone by a small blow. The body of the stone is a mixture of rusty colour and black, and when broken has a smooth flinty surface. The partitions are of a very pale yellow, and are pretty thick, dividing the stone into irregular pieces. This Stone is very common in many parts of the kingdom.

The Hard Brown STONE, with snow-white earthy partitions, has a very close texture, with a pretty smooth and even surface. It is commonly of a roundish or oval shape, and from three to twelve inches in diameter. It is sometimes naked, but oftener met with in strata, covered with a thin brown earthy crust. The colour is of a pale brown, and when broken the surface is pretty smooth, with shining specks of spar thereon. The partitions are soft and crumbly, and consist of a white marl. It is very heavy, considerably hard, and will bear a very good polish; but will not strike fire with steel. It is not very common, though it has been found in the counties of Somerset and Huntingdon.

The Hard, Rusty, Brown STONE, with yellow earthy partitions, is of a very firm compact texture, with a rough surface, and is generally flattish, and from four to ten inches broad. It has seldom any coat, but when it has, it is of a pale yellowish soft substance. The brownish rust colour is commonly spotted and clouded with black, which sometimes appears in the shape of shrubs, trees, and mosses, like those of the Mocha Stone. When broken the surface is smooth, and there are usually no sparry specks. The partitions are narrow, few and irregular; these consist of ochre and marl, of which the first is in the largest quantity. It is considerably heavy, hard, and will take a good polish, but will not strike fire with steel. It has been found in Leicestershire, Northamptonshire, and near Highgate.

The Hard, Pale, Brown STONE, with partitions of a clayey earth, is of a close firm texture, with a rugged surface, and commonly of a roundish or oval shape, and from four to twelve inches in diameter. It is often covered with a thin crust of a pale brown colour,

colour, though it is sometimes without it. When the substance of this Stone is broken, it appears with a coarse surface of the same colour; but if according to the partitions, it is of the colour of rusty iron. The partitions are of a clayey earth, tinged with iron particles; and they are irregular and few in number: besides these there are exceeding fine cracks, in which places the Stone naturally breaks. It is very heavy, considerably large, and will bear a pretty good polish, but will not strike fire with steel.

The Soft, Pale, Brown STONE, with partitions consisting of the same substance as the pyrites, is of a pretty coarse and loose texture, and somewhat porous, with a very smooth surface. Its shape is very uncertain, though most commonly roundish, or oval, and seldom exceeds six inches in diameter. When it is broad and flat it is most commonly naked; but when roundish, it has a thick whitish crust. The surface is irregular when broken, and has a taste of vitriol, which none of the others have: the partitions are pretty numerous and irregular, but never thick, and consist of a double plate of the vitriolic pyrites. This stone may be readily divided at these partitions, as well as the plates from each other, after it has lain some time in the air; for before that it will break more easily any where else. The substance is soft and brittle, and consequently will not bear a polish.

The Rusty Red STONE, with yellowish brown partitions, has a very fine compact texture, with a very smooth glossy surface. It is of various shapes, sometimes oblong or oval, but more generally pretty much flatted, and is from three to twelve inches in diameter, and from four to six thick. Its colour is of a dusky brownish red, not always perfectly mixed; for in some places they are almost distinct, and form a sort of clouds or spots. When broken it appears to have an even glossy surface, without shining specks. The partitions are many and pretty thick, with a streaked texture, composed of an arrangement of brownish yellow columnar spar, which is pretty hard, though not very bright. The pieces divided by these partitions are of different shapes and sizes, and from half an inch to four inches in diameter. This Stone is very heavy, extremely hard, and will bear an exceeding fine polish. It will strike fire with steel, but with great difficulty, and ferments briskly with aqua fortis. It is very common in Yorkshire, and in most of the northern counties of England.

The Brownish Yellow STONE, with whitish partitions, is of a very firm texture, with generally a perfectly smooth surface. It is of various shapes and sizes, and is sometimes found in continued strata, though more commonly in irregular shapes; but always compressed and flatted, from three to fourteen inches in diameter, and about five inches thick. It is met with on the sea coast, particularly near Scarborough in Yorkshire. They have seldom any crust, but when they have it is of a rusty colour, and about a third of an inch thick. The colour of the stone is of a very fine ferruginous yellow, and when broken the surface is smooth and glossy, looking almost like flint. The partitions are numerous, and in many places thick and broad; they consist of a semi-transparent spar, which is very hard, and by these the stone is divided into a multitude of irregular pieces, from one to four inches in diameter. It is very heavy and hard, and will strike fire with steel, but with great difficulty.

The Bluish White STONE, with straw-coloured partitions, has the same texture as the two former, with a rough rugged surface. It is generally found in loose marshes, of a flattish shape, with some tendency to round or oval; but generally with rough edges, and from four to eighteen inches in breadth,

and from two to six thick. It has seldom or never any coat, and the colour consists of a mixture of blue and white. When broken the surface is glossy, and without any shining specks. The partitions are of a streaked texture, and are composed of a fine transparent bright spar, with irregular columns. It is considerably heavy, pretty hard, and will bear a good polish. It strikes fire with steel with great difficulty, and ferments briskly with aqua fortis. It is common in Yorkshire.

The Pale Yellow STONE, with a rusty-coloured nucleus, is of a pretty close compact texture, and of a roundish shape. It is about four inches in diameter, and is covered with a thin pale crust, within which there are from three to five coats of a different thickness, but all of the same substance, and much of the same colour, that is, of an agreeable pale yellow. When broken, the surface is pretty smooth, with many shining specks of spar. These coats have a nucleus or kernel in the centre, consisting of a hard ferruginous stone, and are divided from it by a thin regular partition of a straw-coloured spar, from which there run a great many other straight partitions directly to the circumference, but growing narrower as they come near it. It is pretty heavy, but not very hard, for it will not strike fire with steel. The nucleus is of a different substance from the rest, is very heavy, and of a firm texture; it strikes fire with steel, but will not ferment with aqua fortis. It consists of a large quantity of ferruginous matter, with a deep brown clay. It is to be met with on Mendip Hills in Somersetshire, and in a clay-pit near Islington.

The Brownish STONE, with a blackish brown nucleus, is of a pretty fine close texture, with a smooth regular surface, and is always roundish, though generally a little flatted. The size is two or three inches in diameter without any crust, and there is a hard blackish brown nucleus in the centre, of a close texture, contained in a thin crust of a paler colour, but of the same substance. It is about half an inch in diameter, and the crust about an eighth of an inch thick. The stone is composed of two other coats nearly of the same thickness, and of different degrees of brown. They are divided from the nucleus by a fine thin partition of whitish spar, from which others run that are straight towards the circumference, and yet but seldom pass through the inner coat. The nucleus is hard and stony, but not so much as the former, for it breaks pretty easily, and is full of small specks of loose spar. It consists of earthy and ferruginous matter, and will strike fire with steel, though with great difficulty, and will ferment a little with aqua fortis. It is to be met with in Northamptonshire, Leicestershire and Yorkshire, and has been sometimes found near London.

The Hard Whitish Grey STONE, with a brown nucleus, is of a very fine close texture with a smooth surface, and is always roundish or oval. It is generally about two inches in diameter, and is covered with a pale whitish yellow crust. The nucleus is brown and covered with a crust as hard as itself, but somewhat of a paler colour, and on its outside there is a fine sparry partition, which is firm and hard; from this there generally runs three or four narrow partitions towards the surface, which seldom reach the outer crust. It is very hard, and capable of a good polish, but will not strike fire with steel, nor yet the nucleus. It is a very uncommon stone, and hard to be met with.

The Small Ferruginous STONE, of a roundish or oblong shape, is generally known by the name of Mineral Bezoar, because it has coats like Animal Bezoar. It has a close, firm, compact texture, with a smooth surface, and is always either of a round or oblong form, generally about three quarters of an inch

inch in diameter, and from half an inch to two inches in length. They are constantly covered with a crust of a pale whitish substance of about a sixth of an inch thick. They always consist of a large central nucleus, sometimes surrounded with two or three coats of ferruginous matter, and sometimes irregularly blended with it, making together a single nucleus surrounded with a crust. Both the nucleus and the crust are generally divided into three, four or five parts, by pretty large cracks, which are widest on the outside, and usually become narrower as they approach the centre. They are commonly empty towards the surface, but near the centre they are filled up with a fine transparent spar. The Stone itself is pretty hard, and will bear a pretty good polish. It will hardly strike fire with steel, and ferments but very little with aqua fortis. It is common in the brick and tile clay-pits in all parts of England.

The Oblong, Pale, Brown STONE, with a long hollow nucleus, is of a very close firm texture, with a rugged unequal surface. The shape is oblong and cylindric, only it is largest in the middle, and becomes gradually less towards each end; but for half an inch they each terminate in a small cylinder of almost a whitish colour, and of a harder substance than the other parts. This is nothing but a lengthening of the inward substance, being only the extremity of the nucleus. It is between seven and eight inches long, and yet the diameter is three inches where thickest. The nucleus consists of a long cylindric tube, terminating in a blunt point at each end, which is sometimes empty, and sometimes filled with a white marl, or the matter of the stone that contains it. It is of a ferruginous colour, and is inclosed in a thin crust of a brownish substance, which is surrounded with a single, double, or triple partition of beautiful spar, and this again with two thick crusts consisting of the same substance as the rest of these stones. It is divided by three or four partitions, running like rays from the circular partition straight towards the circumference, but they generally vanish in the first and second coat. The whole is surrounded with an unequal whitish brown coat about a third of an inch thick. The cavity of the nucleus is half an inch in diameter, and the nucleus itself about an inch. This Stone is subject to a great number of cracks lying in different directions, so that when struck it will fall into many pieces, not more than the tenth of an inch in thickness each. The nucleus is very heavy and hard, but will not strike fire with steel, any more than the body of the Stone. The partitions consist of a pure white spar, which appear very bright when just broken. It has been found hitherto only in a great tile clay-pit near Oxford road, about three quarters of a mile beyond Tyburn.

The Very Hard Smooth STONE, with yellow, brown, and red coats, has a very fine compact texture, with a pretty smooth surface, and is remarkably heavy. Its shape is roundish or oblong, and the size is from a quarter of an inch to three or four inches in length; but most commonly of the shape and size of a pigeon's egg. It is sometimes found naked with a somewhat glossy surface, and at other times covered with a whitish crust. It consists of five or six coats, which inclose a firm solid hard nucleus of the same substance, that is sometimes of a deep dusky brown, and sometimes of a strong though not bright red; at other times it is composed of both these colours, either blended or in spots. The coats are alternately brownish, yellowish and reddish, that next the nucleus being brown, the next yellow, and the third reddish, with another that is yellow, and over these one that is brown. However, they sometimes vary in the disposition. It is very common in clay and gravel-pits, and particularly about London,

when covered with a crust. One fourth part of this Stone is iron.

The Hard, Glittering, Rough STONE, with brown, purple, and deep yellow coats, is of a coarse, uneven, and very irregular texture. The shape is always oblong, but of different lengths and thicknesses; it is from half an inch to eight inches long, and about three quarters of an inch in diameter. It has a rough surface made up of small prominences and cavities, less than the heads of the smallest pins; but this is uncommon, for it is usually stuck full of small pebbles. It is pretty hard, and breaks with a rough surface, and there is a nucleus surrounded with eight or ten coats, some of a paler, some of a deeper brown; others of a dusky and somewhat reddish colour, and others again of a deep brownish purple; but they are placed without any order or regularity. It is pretty bright and sparkling, not only when just broken, but on the surface; and the whole substance of the coats is full of small shining spangles like talc. It is common in the gravel-pits about Oxford, as well as in other places, and contains a small quantity of iron.

The Soft, Brownish, Yellow STONE, is almost as soft as earth, but is very compact, of a smooth texture, and considerably heavy. It is of a flattish oblong shape, and round at the ends; and is most commonly four inches long, two broad, and one thick. It is oily to the touch, and breaks with an irregular but smooth surface. It contains a nucleus of the same shape as the stone, and of the same colour, surrounded with coats of the same, which are extremely thin and exceeding numerous. It has no crusty covering, nor does it at all sparkle. It ferments very briskly with aqua fortis, and burns to a beautiful pale red. It is very uncommon, but has been seen in the potters clay-pits in Staffordshire, and in the forest of Dean.

The Soft STONE, with shining brown and dusky green coats, consists of a coarse opaque substance, and is of a loose texture. It is remarkably heavy, of an oblong shape, and commonly about an inch and a half in length, somewhat in the form of a ninepin. It is harsh and rough to the touch, the surface being extremely uneven, and when broken it has an irregular and pretty rough surface. It is generally composed of four coats, surrounding a nucleus of the same substance and shape as the stone. This is surrounded by a brown broad coat, and that by another that is broader. The next is a very beautiful one, it making a fine glittering appearance, and is of a very pale brown colour; over all there is a coat of dusky brown clay, which is always rugged and unequal. It is very common in clay-pits in many parts of the kingdom, and particularly in a clay-pit near London behind Black-Mary's-Hole.

The Soft STONE, with shining, whitish, yellowish and red coats, is of a loose brittle texture, and moderately heavy. It is commonly oblong, rounded at the ends, and of the size of a pigeon's egg. It is very rough, and will readily break with a small blow; it has from four to six coats of the same loose texture, but of different colours; but there is always one that sparkles, and is composed of the matter of the common selenites. The nucleus is commonly whitish, though sometimes with a mixture of yellow, and is of the same shape with the stone. The coat which immediately surrounds the nucleus is generally yellow, the next red, and the next whitish; then one that is yellow, and over these is the outermost, which is composed of great numbers of small columnar selenites, that together appear almost like crystal. It is very common in the clay-pits of Northamptonshire, and may be met with in several other counties.

C H A P. XXVIII.

Of the harder Common STONES.

THE Hard, Shining, Black and White STONE, is of a very irregular structure, but extremely firm, with a smooth though not glossy surface. It is from eighteen to twenty-five inches in diameter; but of different shapes, which all tend to be round, oval, or flat. At first sight it appears to be only of a dull yellowish white, and a glossy black. The white specks are sometimes slightly tinged with a flesh colour, others are of a cream colour, and others again shine like pure crystal. The surface is of a dull dead colour, but it is very bright and sparkling when just broken. It is considerably heavy, very hard, and will take an excellent polish. It strikes fire with steel, but will not ferment with aqua fortis. It is common on the shores of the island of Guernsey, and is met with in many places on the English coast. It is used in paving the streets of London.

The Hard, Shining, Red and White STONE, is of much the same texture as the former, but of a better colour, and the shape tends to roundness or an oval. It is found often of twenty or thirty inches in diameter, with a very smooth surface; and the colour is a pleasant light red, and sometimes a flesh colour, interspersed with small parcels of a pure bright white, from one eighth to one fourth of an inch in diameter. When broken it is smooth, bright, and beautiful; and is so hard that it will bear a very fine polish, as well as strike fire with steel. It is brought from the shores of Scotland, and is used in London for paving the streets.

The Red STONE variegated with white and black is of the same texture with the two former, and has a smooth, bright, glossy surface. Some are eight inches in diameter, and the shape is generally oblong and flattish. The colours are all beautiful and bright, the ground being red, variegated with all the different degrees and forms of a white transparent and black crystalline talc, which are so various in different stones, that they do not seem to be of the same kind. It is considerably heavy and hard, will take a fine polish, and strike fire with steel. They are found on the shores of Guernsey island, and brought to London to pave the streets, where they may be easily distinguished by their surfaces after a shower of rain.

The Hard, Heavy, Greyish Black STONE, variegated with white, is of a more rude, irregular, and harsh texture than any of the former, though it is more compact and hard. The surface is smooth and even, but not glossy, and is generally about ten or twelve inches in diameter; but the shape is uncertain, though it is commonly flat on one side. It is not so beautiful as the former, being of a greyish or bluish black, with opaque but very bright white, distinct from each other, yet regularly intermixed throughout the whole stone, so that it seems to consist of a regular mixture of black and white. When fresh broken the surfaces are remarkably smooth and bright, and it will bear a high polish. It strikes fire with steel, but will not ferment with aqua fortis, nor suffer any great alteration by fire. It is found on many parts of the shores of Yorkshire, and is sometimes seen in the streets of London.

The Brownish Red STONE, variegated with white and yellow, is of a pretty even fine texture, sometimes from three to four feet in diameter, and of a somewhat oblong and flattish shape. The ground is of a reddish brown colour, which is variegated with an impure talcky crystalline matter, generally about an inch long and half an inch in diameter, that is either of a pure or yellowish white; and these variegations are often four or five inches distant from

each other. It is pretty hard, will take a good polish, and strike fire with steel, but does not ferment with aqua fortis. It is found on the surface of the earth in Yorkshire and other counties.

The Reddish White STONE, variegated with black and gold colour, is of a more loose texture than any of the former, and very coarse. It is generally found between four and eight inches in diameter, and is of a very irregular shape, being seldom round, oval or flat. The colour is either a pale flesh, a deeper red, or entirely white. The particles of which this stone is composed seem to be a crystal debased with earth, and more or less of a metalline tinge, of the size of a horse-bean. Among these, black and yellow variegations are dispersed; which are composed of crystal, earth, and talc, of different degrees of brightness. It is considerably hard, very heavy, and capable of taking a fine polish. It is common on the shores of Yorkshire.

The hard White STONE, variegated with brown, is of a very coarse harsh texture, but extremely firm and hard, with a smooth glossy surface. The size is from two to ten inches in diameter, and it is generally of a roundish or oval shape. The ground is of a dusky white, variegated with pale brown; but they are distinct from each other, and interspersed with a great many flakes, some of which consist of a pure crystal lined with talc. When fresh broken, it glitters very much, especially in the white parts; it strikes fire with steel, but will not ferment with aqua fortis. It is common in Westmoreland and Yorkshire.

The Bluish, White, Bright, Brittle STONE, contains more talc and less crystal than the former; for which reason it is of a flaky texture, though very irregular, and the surface is rough and uneven. It is from ten to fourteen inches in diameter, and of a very uncertain shape, being generally rough and jagged at the ends and edges. Its colour consists of a dark bluish grey, and a pretty pure opaque white; the former of which is the ground, though sometimes it happens otherwise. It is composed of different masses, as in the other kinds; and those that are stony or crystalline are much of a size, and seldom larger than a horse-bean. It is but light in comparison of the rest, and is very brittle. It does not at all seem proper for polishing, though its stony parts will strike fire with steel; but it will not ferment with aqua fortis, and when burnt it is whitish with a silvery gloss. It is common in Yorkshire and the neighbouring counties, where the common people make use of it in the winter nights to keep the bed warm, or rather their feet, to which it is laid after it has been heated; for it will retain the heat a considerable time; and they give it the name of the Warming-Stone.

The Brown Brittle STONE, variegated with yellow, is very beautiful, with a pretty fine even texture, but more loose than the former, and with a rough surface occasioned by prominences and cavities. It is of various sizes, but seldom exceeds six inches in diameter; and the shape is quite irregular, though it is sometimes flat, and tending to an oval. The distinct parts of which it consists are seldom above one twelfth of an inch in length; and they are all of the same colour in the same mass, which is of a pale brown; among these are a great number of talcky flakes that are extremely bright, which are sometimes intermixed with spangles of black and whitish talc; but they are so uncommon, that brown and yellow may be said to be the true colours of the stone. When broken it appears extremely beautiful; but it is so soft as not to be capable of a good polish, and therefore will not readily strike fire with steel. It is found in many parts of Suffex and Yorkshire, and has been seen on Hampstead Heath.

The Hard, Purplish, Brown STONE, variegated with white and yellow, has a very rough, coarse, uneven texture; but it is firm and hard, with a rough unequal surface. It is commonly found from ten to eighteen inches in diameter, and the shape always approaches to round or oval, with a smoothness or flatness on one side. The colours are generally brown and white, or brown and yellow. The brownish purple parts make the ground, and consist of considerably large pieces, that are perfectly opaque. Those that are white and yellow are smaller, more bright, and in some degree transparent, they being composed of a mixture of crystal and talc. It is a little bright when fresh broken, and is very hard; for it will readily strike fire with steel. It is common on the shore near Scarborough, and has been sometimes seen in the streets of London.

The Hard Bluish Green STONE, variegated with white, is the most beautiful of the whole class. It is of a pretty firm, fine, but unequal texture; and in many places is loose, irregular, and porous. The surface is very smooth; the usual size is from three to four inches; and it is of a round or oval shape, but always flatted on one side. The greenish particles, of which the Stone chiefly consists, are all of a crystalline substance debased with earth, and tinged with metalline particles. Its variegations are small masses of white, consisting of crystal and talc, and debased with very little earth. It is very beautiful when broken, and is extremely heavy and hard; but it will not admit of a perfect polish, because its texture is a little porous: however, it readily strikes fire with steel. It is found on the shores of Suffex, but is most common in Wales, and contains a pretty deal of copper.

C H A P. XXIX.

Of STONES approaching to the Nature of Flint.

THE Yellowish White STONE, filled with pebbles, commonly called the Pudding-Stone, is of various shapes, according to the various pebbles it contains. It has been by some ranked among pebbles, but improperly; for they are no part of the Stone itself, which is a distinct species, and different from all others. The fementitious substance is an opaque Stone, of a very fine, close, and firm texture, with a pretty smooth surface on the inside, though in the masses it is frequently very rugged and unequal. In size it is from that of a walnut to three or four feet in diameter, with some tendency to roundness. It is of a pale yellowish colour, and when broken the surface is smooth, even, and flinty. It is pretty heavy and very hard, and consequently will take a very beautiful polish. It will readily strike fire with steel, but does not ferment with aqua fortis. The pebbles contained in it are of various kinds and sizes, from that of a pin's head to the bigness of a walnut. It is found in many parts of England, particularly in Hertfordshire, and is used for the tops of snuff-boxes and other toys.

The Greyish White STONE, filled with pebbles, is finer and harder than the former, but is very opaque, and has an exceeding smooth glossy surface, for it resembles a smooth spotted pebble. It seldom exceeds ten inches in diameter, and its shape is almost always roundish all over. The pale greyish white colour often contains more of blue than pure white, and the surface is very smooth when broken. When cut into thin pieces it is somewhat transparent, and is capable of a beautiful polish. It readily strikes fire with steel, but will not ferment with aqua fortis. It is almost always found in gravel-

pits among flints and pebbles, and is used for snuff-boxes like the former.

The Red STONE, filled with pebbles, is of the same nature with the two former, and is very opaque, with a pretty coarse texture and a rugged surface. It is found from six inches to four feet in diameter, and of very irregular shapes. The colour is a deep red, and sometimes there are different shades in different parts of the same piece. When broken, it is scarce at all bright or glossy, and its fineness is generally in proportion to its colour, for it is greatest where that is least. It will readily strike fire with steel, but will not ferment with aqua fortis. The pebbles it contains are of various sizes and kinds, and not so perfectly joined to the mass as in the other species; they are, however, not easily separated from it, and therefore it is as fit for use as any of the former. It is common in Lincolnshire, Derbyshire, and Yorkshire, but is seldom brought up to London.

The Brownish STONE, filled with pebbles, is of the same kind as the former, but is more impure and coarse. It is perfectly dull and opaque, with a rough harsh texture, but yet pretty firm; and the surface is rough, rugged, and unequal. It is from two to five feet in diameter, and is of a very irregular shape, though it sometimes shews a tendency to roundness. The colour is always of a dusky brown, but in various degrees. It is not so heavy as the former, though it strikes fire with steel. It contains very small, as well as some large pebbles, which are generally a little flattish. It is common in Leicestershire.

The Flesh-coloured STONE, filled with reddish impure crystalline nodules, is of a coarse, harsh, loose texture, and somewhat porous, with a rough irregular surface. It is found from four to twelve inches in diameter, and the shape is almost always flattish. It is generally so full of the masses it contains, that it is hard to find a speck of the pure cement of the bigness of a pea. Its colour is a very pale whitish red, and the surface when broken is uneven without any gloss. It strikes fire with steel, though not without some difficulty; but does not ferment with aqua fortis. The nodules are all of the same kind, but of various sizes, from the bigness of a pin's head to an inch in diameter. There is a great number of them, and they lie in different directions. Those that are large are easily struck out of the cement, leaving a pretty smooth cavity behind. These nodules consist of a sort of crystalline particles. This Stone is common in the sides of hills in Yorkshire.

The Bluish Glittering STONE, filled with white impure crystalline nodules, is of a pretty coarse, harsh, uneven, and irregular texture, with a rough surface; and is of various sizes, from one foot to four or five in diameter, and generally of a flattish shape. The colour is a deep dusky blue or lead colour, and there are many bright glittering spangles. The surface is roughish when broken, and it seems to be a-kin to some of the lime-stones. It is very heavy, moderately hard, and capable of a very good polish. It readily strikes fire with steel, and ferments a little with aqua fortis. The crystalline masses are the same as those in the former Stones, only they are without any colour. It is found in many parts of Leicestershire, as well as on the shore near Scarborough; but is never put to any use.

The Whitish Green Beautiful STONE, filled with crystalline nodules, has a pretty fine, close, firm and hard texture, with a rugged unequal surface, without the least gloss or brightness; and the crystalline nodules generally stand pretty far out of their cement. Its size is from two inches to two feet in diameter, and its shape is generally flattish, seldom inclining either to round or oval. The colour is a pale whitish-grey, irregularly tinged with a very beautiful

beautiful green; though it is not diffused through the whole Stone, but appears in the form of specks and clouds. It has a rough and wrinkled surface when broken, without the least transparency; and in breaking of it the nodules get out of their places, leaving cavities behind. They are generally smooth, but not glossy; and they seldom exceed the size of a small pea. They are outwardly of a very deep green, but within are white and opaque. They consist of a tabulated spar, and the green colour is owing to the mass in which they are included. This stone is moderately heavy and pretty hard; but it will not take a good polish, nor yet strike fire with steel without difficulty. It is found on the shores of Minorca, and now and then on the English coast.

The Brittle, Pale, Red STONE, variegated with white veins, and containing red nodules, is the softest and most brittle of this class, with a coarse loose texture, and a rough irregular surface. It is of various sizes, for it has been found from one to thirty inches, and is always flattish. The red colour is different in different masses, it being sometimes of a brick colour, while other parts are of a pale flesh. When broken, it is in many places perfectly spongy, without the least brightness, except in the white veins, which are not many. The red nodules are from the size of a pin's head to that of a hazle nut, and consist of the same substance as the stone itself. The stone is not proof against water, and will scarce give fire with steel. It is common in the shores about Scarborough.

C H A P. XXX.

Of Flinty STONES.

THE Common FLINT is a stone universally known, and of a very fine compact texture, with a surface that is generally rough and rugged, with various protuberances. The size is different, from an inch to two or three feet in diameter. The shape is extremely irregular, it being in gravel-pits of the form of a common pebble; but in chalk, where it is found in greater plenty, it is met with in all shapes. It is always covered with a white crust, which is sometimes very thin, and sometimes one sixth of an inch thick. It consists of crystal, debased with a large mixture of white earth, of the clay kind. The substance of this stone is uniform and equal, and is generally blackish, though sometimes grey. When broken it is of a fine even glossy surface, is semi-transparent, and will bear a fine polish. It is met with in all countries, and is put to various uses.

The White Flinty STONE is pretty fine, with a smooth compact texture, and a smooth surface, only it is furrowed with shallow wrinkles. It is generally roundish, but sometimes oblong, and its size is from half an inch to eighteen inches in diameter. The colour is uniform throughout, which is always white, with a small bluish cast. It is not equally pure, nor of the same degree of transparency; for some resemble the white cornelian, and others the common ground of agate. The coat is sometimes a little reddish, but is more commonly grey, or of a greyish brown. When broken it appears to have a fine even flinty surface, and, as it is very hard, it will bear a good polish. It will readily strike fire with steel, but will not ferment with aqua fortis. This is a common stone in many parts of England.

The Red Flinty STONE is of a very fine firm texture, with a surface not so even as the former; for it has deeper wrinkles, and often many prominences and cavities in different parts. It is generally roundish, and from an inch to three inches in diameter. It is naturally uniform, being without

spots, clouds, or streaks, and its colour is very fine, but it is of different degrees of red in different stones, as well as of different degrees of purity. It has sometimes small, whitish, opaque spots, and some are brighter and more transparent than others. It often nearly resembles the different cornelians, and has generally a whitish coat, with a small mixture of ash-colour, or yellowish brown. When broken, it appears to have a flinty surface, is very hard, and capable of a good polish. It strikes fire readily with steel, but will not ferment with aqua fortis. It is very common in our gravel-pits, and many of the seals sold for cornelian are made there-with.

The Yellow Flinty STONE is of a very fine even texture, and is extremely firm; but the surface is rough and irregular, it being full of wrinkles and other inequalities, and the shape is generally rugged and unequal. The size is from one inch to seven in diameter, and it consists of crystal, debased with a yellow earth, to which it owes its colour. They are sometimes of a deep yellow, and sometimes inclining to a whitish grey. It resembles the yellow cornelian, and is often equal to the finest stones of that kind; but is sometimes subject to imperceptible flaws, which will make it fly to pieces when broken. However, the surfaces are fine and glossy, and it is more transparent than the former; as it is very hard, it will take a fine polish. It readily strikes fire with steel, but will not ferment with aqua fortis. It is not very common, but has been found on Hampstead Heath.

The Bluish Flinty STONE is of a pretty smooth and close texture, with a rough irregular wrinkled surface and a very uncertain shape. It is generally about two inches in diameter, and is not of so simple a colour as the former; for it is of different degrees of blue in the different parts, some of which are deep, and others approaching to white, appearing in clouds, spots, and short lines. It is without cavities or cracks, and its outer coat is of various colours, but generally with a white and chalk-like appearance; sometimes it is of a bluish brown, and sometimes very thick and yellow. It is pretty hard, will take a good polish, and freely strike fire with steel. It is very common in gravel-pits.

The Greenish Flinty STONE is not so close and compact as the former, nor yet so fine, though the surface is pretty smooth and even. It is generally of a roundish or oblong shape, and from half an inch to two inches in diameter. It is always of the same colour, without either spot or cloud, which is of a deep dusky and somewhat bluish green. It is sometimes of the colour of green jasper, but has a coarse look, as it contains a great deal of earth. The coat is generally thick and white, and sometimes of a bluish dusky grey. When broken the surface is even, and as it is very hard, it will bear a good polish. It readily strikes fire with steel, but will not ferment with aqua fortis. It is not very common, and consequently is but seldom found.

C H A P. XXXI.

Of STONES that outwardly appear like PEBBLES.

THE Stone called PEBBLE CRYSTAL has a very smooth equal texture, it being in reality nothing else but Crystal in this form. It is free from all mixtures, and is found from the size of a pin's head to twelve inches in diameter. It is generally pretty round, though sometimes not without irregularities on the surface, and is sometimes flattish. It has a close firm texture, is pretty heavy, and as transparent as water. It is very hard, is capable of

a very high polish, and when broken is very bright and glittering. It strikes fire with steel, but does not ferment with aqua fortis. They are found almost in all parts of the world; but are most common in America, where they are very large, and are generally known here by the name of Brasil Pebbles. They are found in that country on the banks of rivers, as well as in Germany, Italy, and France. They are also met with in England; but their size is very small. Spectacles are made with this stone.

The Purple, Half-transparent, Crystalline STONE, has a rough uneven texture, but it is very firm, with a smooth surface; it is generally between an inch and four inches in diameter, and of a roundish shape, a little flatted. It is of an unpleasant yellowish white on the outside, but is pretty heavy, and when broken the colour is a reddish purple, very bright and glittering. The colour is not uniform, but appears sometimes in blotches, and sometimes in veins, in such large quantities, that they seem to tinge the whole mass. It is not quite so hard as the former, but will strike fire with steel. This is found in rivers and gravel-pits, and has been brought from Germany and Bohemia. It is said also to have been met with in gravel-pits near London.

The Snow-white, Opaque, Crystalline STONE, is of a very smooth, firm, and close texture, with a smooth even surface: its size is generally between a quarter of an inch and two inches, and though it is sometimes round, it is more frequently oval and flattish. It is as white as chalk on the outside, is pretty heavy, and when broken the colour is bright and shining, and as white as snow. It consists of a homogeneous substance, and is extremely hard. It freely strikes fire with steel, but will not ferment with aqua fortis. It will take a very fine polish, and is common in the gravel-pits of Norfolk.

The Opaque, Whitish, Reddish or Yellowish Crystalline STONE, commonly known by the name of the red, white, and yellow sparry Pebble, is the most common stone we have. It consists of a rough irregular and opaque substance, which is pretty firm and compact in its texture, with a pretty smooth surface, though often full of cracks, which sometimes penetrate deep into the body of the stone. It is met with from the size of a pea to six or seven inches in diameter, and is inclinable to a roundish shape, though it is sometimes flattish, especially on one side. The colour is much the same without and within, and it is irregularly tinged with different colours. These are sometimes uniform throughout the whole substance of the stone, but sometimes appears in spots, blotches, and irregular veins. It has a little brightness when broken, and appears to be of a loose texture. They are to be met with in gravel-pits and other places all over the kingdom.

The Yellowish, White, Spungy STONE, has somewhat of the nature of sand-stones hewn out of quarries, inasmuch that it might be mistaken for a fragment of that kind. The texture is coarse, but pretty firm, though there are small cavities that give it some resemblance of a sponge; the surface also has the same appearance, and it is generally from half an inch to two inches in diameter. It is pretty heavy, and more or less of a yellowish white, without the least brightness. It is composed of an irregular crystalline matter, debased with a mixture of a whitish and yellowish opaque substance. Though it is pretty hard, it will not easily strike fire with steel, nor does it ferment with aqua fortis. When examined with a microscope it appears to be a petrified sponge, for there are more cavities than solid matter.

The Hard, Porous, Whitish, Crystalline STONE has a rough cavernous and spungy surface; but it has not so many pores on the inside as the former kind. There are veins on the outside, dispersed in

an irregular manner, of different breadths, and often interwoven with each other; likewise they all stand up in ridges above the surface of the stone. Sometimes the pores on the inside are wanting, which renders the texture the more firm; it is from one inch to six in diameter, and generally of a flattish shape, though somewhat roundish. It is naturally white, and sometimes has a mixture of faint red, or pale yellow. It is pretty heavy, very hard, and is glossy when broken; especially in its veins, which are more close and compact than the rest of the mass. It strikes fire with steel, but will not ferment with aqua fortis.

The Greyish, White, Opaque STONE, is of a very close texture, with a smooth even surface; but it is subject to cracks of various sizes, and is from an inch to a foot in diameter, sometimes roundish, and sometimes flat; but in this last case it is always subject to superficial cracks. It is perfectly opaque and dull when broken, though it consists of an uniform crystalline substance; debased by a mixture of white and grey clay. It is very heavy, pretty hard, and will readily strike fire with steel. This, as well as the two former, is commonly in gravel-pits.

The Brittle, White, Sandy STONE, is of a very loose brittle texture, with a pretty smooth regular surface, though it is somewhat rough to the touch; the shape is irregular, though generally flattish, and the size is from one to twelve inches in diameter. It is pretty heavy, and when broken appears of a bright glittering white. It consists of a great deal of pure white sand, to which it may be reduced, and it breaks with the slightest blow into a great number of pieces. It is readily penetrated by water, which will pass through it unchanged. It will not ferment with aqua fortis. It is not very common, but has been found in the gravel-pits of Northamptonshire.

The White Crystalline STONE, with yellow specks, is by some called the Worm-seed Stone. It is of a pretty hard compact texture, and generally has a smooth surface, though sometimes there are irregular cavities. It is of a roundish or oblong shape, and thicker at the middle than at the edges. It is commonly about three or four inches in diameter, and the colour is generally white, though it has sometimes a pale brown cast. The specks are about the breadth of a small pin's head, and are of a very bright pale yellow, by which characteristic it is easily distinguished from all other stones. The colour is dull on the outside, but bright and glittering when broken; and it consists of a large angular grit, extremely well united. It strikes fire with steel; but does not ferment with aqua fortis. It is common in Yorkshire, and is sometimes found in the gravel-pits near London.

Whitish, Brown, Dull STONE, is softer than any of the former, and yet the texture is pretty even and regular. It is generally above a foot in diameter, and its shape is always broad and flat, with deep longitudinal cracks on the surface, which are crossed with some that are smaller. It is of a very pale brown, and has sometimes a faint yellowish or reddish tinge. The surface is dull and opaque, and when broken is generally full of cracks, the largest of which are often filled up with crystals, which look very bright and glittering. It is pretty heavy, and is harder in some places than others. It is found in many parts of England, and particularly on Hampstead Heath, very deep in the ground. It sometimes contains large pieces of petrified wood, which are so stony that they cannot be perceived, except by the knots.

The Blueish, White, Hard, Crystalline STONE, is not of a very fine structure, but firm and close, with a smooth surface. It is generally from three to ten inches in diameter, and of a flattish shape, somewhat

what approaching to roundness. It is of a dull light lead colour on the outside, but when broken is bright and glossy, and the thin pieces are a little transparent. It is very heavy, will take a fine polish, and readily strikes fire with steel. It is very common on the shores of Italy, France, and England.

The Brownish, White, Hard, Shining STONE, is pretty coarse, but very firm, and has a rough irregular surface. It is about six or seven inches in diameter, though sometimes much smaller, and at other times extremely large. It is of a dusky white on the outside, with a small mixture of pale brown; but when broken it is bright and glittering, with an unequal surface. It consists of a grit with blunt angles, together with roundish bright particles, cemented together with a substance nearly as bright. It is sometimes full of black and green specks, of the size of very small grains of sand. It is pretty heavy, and capable of a good polish; but it will not strike fire with steel. It ferments violently with aqua fortis, which discovers its nature, which is that of consisting pretty much of spar. It is found in Derbyshire.

C H A P. XXXII.

Of Common PEBBLE-STONES.

THE Yellowish Green PEBBLE, with a bluish white crust, is of a fine close texture, and the surface, though regular, is a little wrinkled. The shape is roundish or oblong, and the size from one to five inches in diameter. It has commonly a large nucleus in the centre, inclosed in a broad coat, which is covered with a very thin crust. The nucleus is of a greyish yellow, sometimes perfectly blended together, and sometimes irregularly mixed in the form of clouds or large spots. There are often white opaque spots dispersed here and there, and the nucleus approaches to pure flint. The coat next to it is of a bluish white, and of a somewhat coarser texture. The external crust is of a whiter colour, and is of the same substance, only there is a greater mixture of earth. When broken it has a smooth glossy surface, and the nucleus is pretty transparent. It is very hard, will bear a good polish, and strikes fire with steel. It is found in the gravel-pits in Northamptonshire, and sometimes in those near London; however, when found, it is of no value.

The Whitish, Grey, and Reddish Coated PEBBLE, with a yellow centre, is more beautiful than the former, and has a fine close texture, with a pretty even surface, though full of wrinkles. It is of a flattish round shape, and the common size is about three inches in diameter. It is composed of a large nucleus, which is the principal part of the stone, and is of a deep bright yellow, and pretty transparent. It is sometimes marked with roundish white spots, from the bigness of a pin's head to that of a pea, and is surrounded with a coat of a pale greyish white, of a flinty substance, which sometimes receives the matter of the nucleus into itself in the form of clouds, making a broad undulated line. This is generally covered with a red coat, and that with the external crust, which consists of a great quantity of earth. When broken it has a glossy surface, and is hard enough to take a polish. It is very common on Hampstead Heath, and in many other places.

The White, Black, Brown, and Straw-coloured PEBBLE, with a yellow nucleus, is a very beautiful stone, and of a fine texture. It is generally of a roundish or oval shape, and seldom exceeds three inches in diameter. The nucleus is large, and is the principal part of the stone. It is surrounded with several coats, which resemble the zones of the

onyx. The nucleus is very bright, and pretty transparent, and of a deep but not bright yellow. It is sometimes of the same colour throughout, and has clouds of a different yellow and flint colour, also opaque specks of a palish white, and sometimes likewise the centre is transparent crystal. The nucleus is usually surrounded with a narrow black circular line, and is covered with a coat of a paler yellow than the nucleus, and that by another of an opaque white; the next is of a pale brown, besides which there are four or five others of the same colours placed alternately. These are all covered with a bluish crust, but sometimes with a whitish, and always greatly wrinkled. When broken, the surface is glossy and pretty transparent, is very hard, and will bear a good polish. It strikes fire with steel, but will not ferment with aqua fortis. It is common on Hampstead Heath.

The Whitish, Bluish, and Brown PEBBLE, with a dull brown nucleus, has a close firm texture, with an even surface, only it is wrinkled. It is generally of a roundish or oval shape somewhat flattened, and the size is from one to five inches in diameter. The nucleus is pretty large, of a deepish brown, and of a pretty fine texture, but not very transparent or bright. It is commonly surrounded with a broad whitish coat, then with a narrower of the same colour as the nucleus; after that is a third of the same substance with the inner-coat, and these are covered by one of a bluish colour, of a more flinty texture than the other part of the Stone, over which there is a crust like the rest, but more earthy. When broken the surface is very bright and glossy, and as it is pretty hard, it will bear a good polish. It is common on Hampstead Heath, and in the gravel-pits about London.

The PEBBLE, with white and brown coats, and a shining brown nucleus, is a very pure and beautiful Stone, and has a fine close texture, with the common wrinkled surface of other Pebbles. It is generally of a round or oval form a little flattened, and commonly four or five inches in diameter. The nucleus is very large and oblong, and of a deep bright pleasant brown. It is transparent, though sometimes subject to whitish specks. It is surrounded with a coat of a milky white, sometimes mixed with a little pearly blue; and next to that is one of the same colour with the nucleus, only it is not so transparent nor bright. Over this is the crust that covers the whole, and in general it is not inferior to an agate. When broken, it has a bright glossy surface, and where thin is pretty transparent; it is extremely hard, capable of a fine polish, and will strike fire with steel. It is found in gravel-pits, but is not so common as the former.

The PEBBLE, with white, brown and yellow coats, with a small brownish yellow nucleus, has a fine close texture, with the wrinkled surface of other Pebbles. It is commonly roundish or oval, and the common size is about an inch in diameter. The nucleus is about as big as a small nutmeg, and is surrounded by a coat of a dull opaque impure white, and that with one of a pale whitish brown; the next is of a pale red or flesh-colour, and the fourth of a blackish brown. The outer crust is a pale yellow, and as thick as any of the rest. The nucleus is pretty bright, but has little or no transparency; however, this Stone, as well as all others, is subject to some varieties. It is very hard, will bear a fine polish, and readily strikes fire with steel. It is pretty common in the gravel-pits about London, and might be put to good uses by the lapidaries.

The PEBBLE, with greyish white, pale brown, and reddish coats, with a small brown nucleus, is of a very fine close texture, and has the wrinkled surface common to other Pebbles. The shape is roundish or oval, and is commonly four or five

inches in diameter. The nucleus is usually of the size of a nutmeg, and of a deep brown colour. This is covered with a coat of a pale whitish grey, and that by another that is of the like but thinner, and next to these there are generally four or five of the same colour as the nucleus, and others of a very pale whitish brown alternately disposed. It is more transparent than most other Pebbles, and when broken has a flinty surface; it is very hard, will bear a good polish, and strikes fire with steel. It is common in the gravel-pits on Hampstead Heath.

The PEBBLE with yellow, red, and bluish white coats, with a reddish brown nucleus, is of an exceeding fine firm texture, and is not so wrinkled on the surface as most of the other kinds. It is of a roundish flattish shape, and commonly about three inches in diameter; the nucleus is pretty large, of a very fine texture, and pretty bright and transparent. It is of a pale red, and is inclosed in a coat of a fine pearl colour or bluish white, which is pure, bright, and transparent; next to this is a fine red coat, and after that several pearl-coloured and red coats alternately placed; over these there are three or four coats of a pale yellow, and the outer crust is of a pale bluish colour. It is more transparent than most other Pebbles, and when broken has an even surface; it is very hard, will bear the highest polish, and readily strikes fire with steel. It is common in the gravel-pits about Kensington, and many other places. It is in some use with our lapidaries.

The PEBBLE, with white, orange, brown, and dusky yellow coats, and a brown nucleus, is of a very fine close texture, with a wrinkled surface, like the rest of the Pebbles. It is of a roundish or oval shape, and from one to three inches in diameter. The nucleus is small, and the coat that immediately surrounds it is of a clear white. The next to that is orange, and then there are eight or ten of different colours, composed of brown or yellow, after which are colours of a dusky white, with a fine orange colour between them. The whole is very pure, bright and transparent, though it is subject to many variations. When broken it has a fine glossy surface, is extremely hard, and consequently will bear a very fine polish. It is common in the gravel-pits on Hampstead Heath, and in many other places about London.

The PEBBLE, with whitish, brownish, and yellowish coats, and a brown nucleus, is of a more coarse texture, than any of the former, though pretty firm and hard. The surface is more smooth than that of other Pebbles, and is generally pretty round, and between two and three inches in diameter. The nucleus seldom exceeds the size of a horse-bean, and is surrounded by an irregular undulated coat, composed of others that are narrow; next to this are three or four others, which are composed partly of a very deep brown, with some that are yellowish, and others of a dusky pale blue. They have all a mean appearance, and are perfectly opaque. They are very scarce, and are of no value.

The PEBBLE, with yellowish, brown, and ash-coloured coats, and a bluish white large nucleus, is a very beautiful stone, and has a fine firm texture with a wrinkled surface. It is generally roundish, and from one to four inches in diameter. The nucleus is large and very beautiful, and sometimes makes the principal part of the stone. It is of an exceeding fine texture, and very bright and transparent, approaching to a white cornelian. It is of the colour of pearl with a bluish white, which is often debased with clouds, spots, and veins of an opaque white. This is surrounded with a yellowish brown coat that is clear and transparent, and then there is another of a pale ash coloured grey as fine as the former: these are surrounded with the outer crust, which is of a bluish or ash colour; however, the coats and the

stones are met with in different proportions. It is more transparent than any of the rest, is very hard, will take a fine polish, and strike fire with steel. It is common in the gravel-pits on Hampstead Heath, and about Windsor.

The PEBBLE, with flesh coloured, brown, and bluish white coats, and a fine large white nucleus, has a fine, close and firm texture, and the surface has only some slight wrinkles; the shape is roundish or oval, and generally about two or three inches in diameter. The nucleus is oblong, and not so blue as that of the former, but is as fine, bright and transparent. It is encompassed with a great number of coats of a pale brown, bluish white, and a pale white light red placed alternately, and covered with a whitish crust. They seem all to be of an equal degree of brightness and transparency; but it is subject to great variations. It is hard enough to strike fire with steel, and will bear a very fine polish. It is common in the gravel-pits of Hertfordshire, and is used in London to make tops for snuff-boxes.

The PEBBLE, with red, flesh coloured and yellow coats, and a white nucleus, is a fine beautiful Stone, and of a very close texture, with a wrinkled surface like that of other Pebbles. It is generally roundish, though sometimes oblong, and is commonly about three inches in diameter. The nucleus is commonly pretty large and opaque, though of a very fine texture, and is frequently full of coarse roundish white spots. This is commonly encompassed by a thin bright red coat, and that by one of a beautiful bright yellow, next to which there is another of a flesh colour, and then four, five, or six others of the same colours, but not placed in an alternate order. They are all very bright, and more transparent than the nucleus. When broken, the surface is fine and smooth, is very hard, and will take an elegant polish, as well as strike fire with steel. It is common in the gravel-pits on Hampstead Heath.

The PEBBLE, with very thin, numerous, brown and yellow coats, and a greyish white nucleus, is of an exceeding fine close texture, with a surface not so much wrinkled as in other Pebbles. It is generally of a roundish shape, and from one to four inches in diameter. The nucleus is large and of a fine texture, but not quite so transparent as the rest of the Stone. The grey and the white are sometimes distinct, and at others blended together; but is subject to small grey opaque spots. The coats are many in number, but only of a pale brownish yellow and a dusky brown colour placed alternately. They are bright, beautiful, very transparent, and covered with white opaque dull crusts. It has a glossy surface when broken, is very hard, will bear a fine polish, and will strike fire with steel. It is common among gravel in Hertfordshire.

The PEBBLE, with brown, yellow and white coats, and a greyish white nucleus, is of a fine close texture, with a rugged wrinkled surface; is generally oblong and flattish, and from one inch to five in diameter. The nucleus is sometimes no bigger than a horse-bean, though the Pebble be large; and yet it is sometimes an inch broad in smaller. The surface is glossy, but very opaque, encompassed by many fine regular coats of a fine deep brown, a very pale yellow with a little mixture of brown, and a fine white. The brown is next to the nucleus, and the other colours are placed alternately, but tinged more than one at a time. Its surface is glossy when broken, and, as it is very hard, will bear a good polish, and strike fire with steel. It is common on Hampstead Heath, and in the gravel-pits about Islington.

The PEBBLE, with white, grey, and flesh coloured coats, and a very white nucleus, is of an even close

close texture, with a very rough wrinkled surface, and a flat roundish shape, from two to three inches in diameter. The nucleus is of various sizes, from the bigness of a pea to that of a walnut, and is of a fine texture, but opaque and dull, as are all the other colours. It is irregularly surrounded with many coats of different thickneses and different colours. When broken, it has a smooth but not a glossy surface, and is so hard as to be capable of a good polish, and strikes fire with steel. It is common in the gravel-pits about London.

The PEBBLE, with brown, ferruginous, and yellow coats, and a brownish white nucleus, is one of the coarsest of this kind; but the texture is hard and compact, and the surface is not so wrinkled as many others; however, there are several prominences and cavities, which render the shape irregular, though it is generally somewhat oblong. It is from one to four inches in diameter; and the nucleus is sometimes so pale, that it is almost white. It is encompassed with four or five coats, whose colours are very good: that next the nucleus is of a rusty coloured brown; the next to that pale brown; after which is another of a rusty brown, then one of a deep yellow; the next is brown, and then comes the crust, which is of a pale whitish grey. It appears rough when broken, and is so hard as to strike fire with steel. It is not very common, though it has been met with in different places.

The PEBBLE, with brown and grey coats, and a bluish nucleus, is of a very fine firm texture, with a smooth surface, and not so much wrinkled as many others. The shape is oblong, and from one to three inches in diameter. The nucleus is of a pure flinty substance, sometimes of the same uniform colour, but more frequently veined or spotted with a lighter or darker colour of the same kind. This is encompassed with a fine deep brown coat, which is very bright; and that is succeeded by one of an ash colour, as bright as the nucleus. The crust is next to these, which is pretty thick. It has somewhat more of a transparency than most of this kind; and as it is extremely hard, it is capable of a good polish. It is met with in some parts of Hertfordshire.

The PEBBLE, with thick, whitish, and red coats, and a grey nucleus, is of a very fine texture, but the surface is rough, irregular, and deeply wrinkled. Its shape generally tends to roundish, and it is most commonly an inch and a half in diameter. The nucleus is hard, bright, glossy, and transparent; the next coat is usually red, with a little mixture of rusty brown, and is not so transparent as the other parts of the stone; next to this is a coat of a bluish white or pearl colour, very bright; after this comes the crust, which is thick, coarse, of a very bright white, and of a loose stony substance. This is the common appearance of the stone, and sometimes the coats are more numerous. It is very hard, the substance being flinty, and capable of the highest polish. It is not common; but has been found in Northamptonshire, and near Paddington.

The PEBBLE, with white, flesh-colour, and bright red coats, and a bluish white nucleus, is of a fine close even texture, with a very rugged wrinkled surface, and a roundish shape. It is not above two inches in diameter, and the nucleus is surrounded with many white, flesh-coloured, and red crusts, beautifully disposed, but not always alternately; though that next it is generally red, and they all together have a very fine effect. This stone is generally very bright and transparent, and when broken has a smooth glossy surface; it is very hard, and will bear a fine polish. It is very common, on Hampstead Heath.

The PEBBLE, with brown, yellow, and flesh-coloured coats, and a greyish blue nucleus, is of an exceeding fine smooth texture, with a surface a little

wrinkled, and is of a roundish or oblong shape, but a little flatted, and seldom more than three inches in diameter. The nucleus is very beautiful, bright and transparent. It is encompassed with many coats of a pale brown, and a fine red, which sometimes is of a flesh colour, and also of a somewhat dark yellow. It is often debased with small coarse spots, and perhaps more than any other. When broken, it is of a fine glossy surface, is extremely hard, and capable of a very fine polish.

The PEBBLE, with white, yellow, flesh-coloured, and red coats, and a greenish blue nucleus, is undoubtedly the most beautiful of the English Pebbles, for it comes up to the German Agates. The texture is exceeding fine, smooth, and hard, with a surface less wrinkled than most other kinds. The shape is roundish or oblong, and from three to four inches in diameter. The nucleus is pretty large, and sometimes round, but more commonly oval. It is of a very fine texture, with a glossy surface, and in thin pieces quite transparent. It is generally of a deep bluish green, which is sometimes so dark as to appear almost black, and often of a dusky blue: it is likewise sometimes of so bright a green, that it is not inferior to the green jasper. The coats are fine, and beautifully disposed like the zones of an onyx, and are all bright and transparent. Some are of a bright white, others of a fine deep yellow, others of an agreeable pale flesh colour, and others again of a bright deep red. The coats are very thin, and lie evenly throughout the whole substance of the stone; but the flesh colour and white are most commonly near the nucleus, and the yellow towards the surface: however, like most others, it is subject to great varieties. It is more transparent than any other Pebble, and when broken is of a fine even flinty surface, capable of bearing the most perfect polish. It is common in many parts of England, in particular near London in the road to Highgate, and formerly was in great plenty among the gravel in the foot-path from Pancras to Kentish-Town. It is sometimes used by our lapidaries, but not so much as it deserves.

The PEBBLE, with whitish, brown, and yellowish coats, and a flesh coloured nucleus, is of a fine and smooth texture, with a very firm, rough, unequal, thick crust, it being full of prominences and cavities. The shape is very irregular and uncertain, it being ragged and uneven in several parts, and looking more like a flint than a pebble. The size is from an inch to eight in diameter, and the nucleus is pretty large, with a shape like that of the stone itself. It is of an agreeable flesh colour, with a slight tinge of blue, and the coats are not above three or four in number, which are of a fine deep brown, a dusky white, and a pale and darkish yellow. The yellow coat lies next the nucleus, the white next to that, and then the brown; and in some a thick yellow coat lies over these, bounded by a very narrow one of deep brown. The surface is of a pale whitish brown, and extremely coarse, being often half an inch thick. It is pretty transparent, when broken has a fine flinty surface, and is so hard as to bear a very good polish. It may be met with in Yorkshire.

The PEBBLE, with white and brown coats, and a white nucleus, is of a very fine close texture, with a rugged unequal surface, having prominences like warts, with small irregular cavities and deep wrinkles. It is commonly of a roundish, oblong, flattish shape, and from two to three inches in diameter. The nucleus is bright and white, but not very clear; and the number of coats is uncertain, being sometimes three or four, and at other times six or eight; which are all of two colours, a fine deep brown, and a very bright white. The brown parts are very bright and glossy, and pretty transparent; but the white is much

much more opaque. When broken it is bright and smooth, and being extremely hard will bear a pretty fine polish. It is very common in the gravel-pits of Northamptonshire and Leicestershire.

The PEBBLE, with black, white, and flesh-coloured coats, and a red nucleus, is of an exceeding fine close texture, with a smooth even surface, the wrinkles being very superficial. The shape is generally roundish, and seldom exceeds three inches in diameter. The nucleus is encompassed with many thin coats of a fine jet black, a clear white, and a flesh-colour. The black is commonly next to the nucleus, then the flesh-colour, and after that the white; but it is sometimes one, and sometimes the other: the rest follow alternately, though not always. The outermost coat is generally of a flesh-colour, and over that is the crust, which is very thin. The nucleus is of a fine bright transparent red, and equal to many of the best cornelians. The flesh-coloured parts are the most opaque of any in the stone; but the black coats are extremely beautiful, being very bright and glossy, and when thin are pretty transparent. When broken the surface appears to be flinty, it being extremely hard, and capable of an excellent polish. It is not very common; but it has been found on Hampstead Heath, and in the gravel-pits of Northamptonshire.

The PEBBLE, with yellow and greenish white coats, and a yellow nucleus, is of a very fine close texture, with a remarkable smooth surface, it having only a few superficial wrinkles. It is generally pretty round, and between one and three inches in diameter. The nucleus is small, but of a fine texture, a glossy surface, and pretty transparent. It is of the colour of the common yellow cornelian, and encompassed generally with but a small number of coats of two colours, namely, a yellow, a little deeper than the nucleus, and a very pleasant whitish green, of which colour the coat next the nucleus always is, and after that is a yellow, next a green, and so on alternately. The outer coat, on which the thin crust is laid, is sometimes of a pale brownish white, but not always; besides which there are often other varieties. The nucleus and the yellow coats are transparent, and much more so than the green. It is extremely hard, capable of a fine polish, and readily strikes fire with steel, like the rest of this kind. It is very uncommon, but has been seen on the shores of Yorkshire.

The PEBBLE, with purple and pale yellow coats, and a red nucleus, is of a fine firm texture; but the surface is remarkably rough, being full of inequalities, though it has but a few deep wrinkles. The shape is irregular, and the size various, some being less than an inch, and others four inches in diameter. The nucleus is also irregular, and of a strong deep red, though pretty bright and glossy, but with little transparency. It is surrounded by two or three coats of a fine pale yellow, and a purplish black colour; which last, held up to the light, appear of a fine deep purple. All parts of the stone are bright and glossy, but those that are yellow are most transparent, and there is generally a yellow coat next the nucleus: those that follow are commonly placed alternately, and are pretty thick; there is likewise a yellow one next the outward crust, which is white within, and yellowish on the surface. This stone is always exceeding hard, and when cut into plates is very transparent. It is very uncommon; but some have been found on the shores of Sussex, and in the gravel-pits about Oxford.

The PEBBLE, with grey and pale red coats, and a yellow nucleus, is pretty fine and firm, with a smooth even surface, only there are superficial wrinkles. It is generally roundish, and from one to six inches in diameter. The nucleus is of a dusky yellow, and commonly about the size of a hazle nut.

It is opaque, has a curdled look, and is surrounded by several coats of a pale red, placed alternately with some that are thicker, of a pale ash-colour or bluish grey, not unlike some of the paler flints. The pale red or flesh-colour is made so by a mixture of grey, and the outermost coat is usually of this last colour, over which there is a pale bluish grey crust. This is coarse in comparison with one of the former, though it is pretty hard, and takes a tolerable polish. It is found in great plenty on the shores of Yorkshire, and sometimes in the gravel-pits about London.

The PEBBLE, with red, purple, bluish, and brown coats, and a pale grey nucleus, is not of so fine a texture as any of the rest, though it is pretty smooth, and very firm, with a surface furrowed with deep wrinkles. It is commonly of a roundish shape, and about four inches in diameter. The nucleus is of a pale grey, or whitish ash colour, encompassed with a great number of thin coats of several colours, as a deep red, a bright purple, a greyish blue, and a glossy brown; these last are more transparent than any of the rest: but these, upon the account of their coarseness, have but a dull look, which renders the stone less beautiful. The coat next the stone is of a red colour, and thickish, but not clear or bright; next this is one of brown, but the rest of the coats are disposed without any regularity, though they are very prettily variegated. The outer coat is generally of a bluish grey, and thicker than the rest; but the crust is commonly very thin and whitish. It has a smooth flinty surface when broken, and is so hard as to take an even polish. It is not common, though it has been sometimes met with in Hertfordshire.

The PEBBLE, with black and white coats, and a black nucleus, is of an exceeding fine close texture, with a rough surface, generally full of deep wrinkles and protuberances, of the size of a horse-bean. It is of a flattish round shape, and commonly four or five inches in diameter; the nucleus is pretty large, and of a fine glossy black. The coats are of a pearl colour, and black like the nucleus, and placed alternately; but the whitest are the thinnest, and the outermost is always black, and thinner than the rest. The crust that covers the whole is generally very thick, and seems to be of a coarse chalky substance. It is more transparent than any of the former, it being extremely hard, and when broken has a fine glossy surface. It will bear a very good polish, and like the rest strikes fire with steel, but will not ferment with aqua fortis any more than they. It is pretty common on the Sussex and Yorkshire shores. It is sometimes made into seals and other toys, and looks like an oriental stone.

The PEBBLE, with brown and greyish black coats, and a yellowish brown nucleus, has a pretty fine firm texture, though the surface is rough and unequal, and deeply wrinkled. It is commonly of a flattish round shape, and from two to six inches in diameter. The nucleus is large, and of a brownish yellow, or tawny, surrounded with a few thick coats, some of which are of a greyish black, and others of a pretty clear brown. The nucleus is generally surrounded with a pale grey coat, after which the brown and darker grey are placed alternately. The outermost coat is always brown, though but thin, and the crust that covers it is thin and bluish, but of a much paler colour on the protuberances, than on the other parts. It is not very transparent, but has a glossy surface when broken, and is so very hard as to be capable of a good polish. It is to be met with in the gravel-pits of Hertfordshire, Buckinghamshire, and Northamptonshire.

The PEBBLE, with white and greenish coats, and a pale grey nucleus, is of a pretty fine texture, and very firm, with a smooth surface, without many wrinkles.

wrinkles. It is almost always round, and is from one to three inches in diameter. The nucleus is small and round, and encompassed with coats of two colours, some of which are entirely white, and others of a faint greyish green; but a white coat is generally next the nucleus. Sometimes these colours are blended with each other, and have undulated edges running through one another, to the succeeding coat; the outermost coat is of a paler or greyer green than the rest, and but thin, as well as the crust that lies over it, which is of a pale bluish ash colour. It is but little transparent, though it breaks with an even surface; however, it is so hard as to bear a pretty good polish. It is found on the shores of the river Thames, and sometimes in the gravel-pits about Islington.

The PEBBLE, with yellowish brown and black crusts, with a brownish white nucleus, is the Egyptian Pebble of the lapidaries. It has an exceeding fine close texture, and the surface is not so wrinkled as many of our Pebbles. It is commonly of an oblong shape, though sometimes very irregular; it is of various sizes, but the most common seems to be about four or five inches long. The nucleus is of a very irregular shape, and of different sizes, but is always of a pale whitish brown, and sometimes with veins or spots of a dusky colour. It is also often variegated with the colours of black trees, shrubs and mosses. When it is large, it spreads itself so much as to have some resemblance to a beast or fish, or at least some of their parts; likewise some have had the distinct representation of a human face. The nucleus is commonly surrounded with a pretty thick crust, of a pale brownish yellow, and that by one of black; these are encompassed with others which are many in number, partly black, and partly of a deeper or paler yellow. Every part is much of the same degree of purity; but, if any, the black is finer than the rest. It is met with in Egypt, Arabia, and some of the islands of the Archipelago. There is a species of this kind in Germany, and some parts of Suffex, but they are not so fine as the Egyptian.

The PEBBLE, with yellow and pale brown coats, and a deep green nucleus, is very beautifully variegated, but is not so pure as some of the former, and is of a pretty coarse, rough, unequal texture, though it is tolerably firm, and has a smooth surface, with very few wrinkles. It is generally roundish, and from one to five inches in diameter. The nucleus is large, and of a dark dusky green, surrounded by a number of crusts in different tones, which are also different in their thicknesses. Some are of a deep yellow, and others of a pale whitish brown, disposed alternately; but one that is whitish, or very pale, usually surrounds the nucleus, and the outer coat is commonly yellow, and pretty thick; the crust is always whitish, and has a chalky look, but not very thick. The surface when broken is not very smooth, and yet is so hard as to bear a good polish. It has been found on Hampstead Heath, and about Kennington.

C H A P. XXXIII.

Of SANDS and GRITS.

FINE Shining White SAND is generally made use of to dry up the wetness of the ink in writing, lest it should blot, and for this reason is almost universally known. It is pretty fine, and is generally found very pure, and of a pretty fine white. It has some brightness, and, if it be very good, is a little sparkling, and the particles seem to be much of a size. It feels a little rough between the fingers, and settles very quick when mixed with water; but

viewed through a microscope the particles appear to be of very different sizes and shapes, though they are all somewhat angular. They are all white, and though some are opaque, many are as transparent as crystal glass. It makes no fermentation with aqua fortis, nor yet any of the rest, and therefore this circumstance needs not be repeated. It is found in many parts of England, in strata of great depth; but as there are some of yellow sand lying near it, it is no great wonder it should be sometimes mixed therewith. It is of great use in making glass, but not so good as that with flint; however, it does not require so laborious a process. Sands in general will serve for the same purpose, and they are made use of in some counties to manure stiff clay lands; for though they are barren of themselves, the lands are rendered fertile by their mixture, because they are thereby made more susceptible of water, which otherwise would not penetrate stiff clay. This likewise is the principal part which bestows firmness to bricks, tiles and stone. It is also of great use in making mortar, which commonly unites the joints of bricks and stones, and renders them immoveable. Likewise Sand mixed with mud or clay will make a sort of mortar, but less durable, though often used in the country for the walls of cottages. It is also Sand that gives a consistence to potters clay; for otherwise it would crack when wrought into vessels, and consequently fall in pieces, or at least the vessels would be useless. It sometimes serves for polishing the hardest bodies, and for cleaning those that are tarnished.

The Large Shining White SAND is coarse, with respect to the former, though it is generally very pure. It is of a pretty good white, with some brightness and sparkling, and seems to consist of regular uniform particles, which are harsh and rough to the touch. When mixed with water it settles immediately, leaving no foulness behind it. All the particles are of a somewhat oblong and irregularly angular shape, and when viewed through a microscope, the surfaces appear to be smooth, and as transparent as white glass. It is of great value among those that make glass, and is commonly brought out of Kent to London.

Fine White very Shining SAND is the best of all of that colour, it being perfectly pure, pretty heavy, and of a pure white, and is very remarkable for its lustre. It is composed of very uniform particles with even surfaces, and is extremely hard. When thrown into water it sinks immediately, without leaving foulness behind it. When viewed through a microscope, the particles appear to be a little oblong, and of irregular angular shape, with a fine clear water, it being little inferior to the purest crystal; and indeed this and the two former are entirely of that substance, except, as some suppose, there is a small mixture of white earth. It is found on the shores of most of the rivers in Italy, and is of great value in glass-making.

Fine brownish white dull SAND is pretty heavy, but does not shine to the naked eye, for it appears rather like a heap of fine dust. The particles seem to be very regular and uniform, with regard to their size and shape; however, when it is mixed with water it does not subside with such speed as the former, and leaves a whitish muddiness behind it. When viewed by a microscope, the particles appear to be of different shapes and sizes, but chiefly roundish, some of them having rough surfaces, and others flattish; but they are all more or less transparent. It is found in Suffex and Kent, but is not made use of for glass, because better sorts are plenty.

Yellowish White Fine Dull SAND is pure, and pretty heavy; but has no brightness. The particles are very small, and seemingly very uniform and regular:

regular: to the touch it seems to be softer and finer than most other sands, and yet mixed with water it soon subsides to the bottom, but leaves a yellowish muddiness behind it. When viewed through a microscope, the particles appear to be of irregular shapes, though they have somewhat of a roundness, and the surfaces of many are rough; they are transparent in different degrees, and the colour is not quite the same in all, for some are almost without any. It is met with in all parts of the world.

Reddish White very Fine Dull SAND, is pretty heavy, and of a whitish colour, tinged with a little flesh-colour. It has not the least brightness, and the particles seem to be all of a size, though they are exceeding small, and feel harsh to the touch. Shaken together with water, it subsides very slowly, but when thoroughly settled it leaves no muddiness behind; however, when viewed through a microscope, the particles appear to be of different shapes and sizes, some of them being at least twenty times smaller than the rest. They are all more or less transparent, and some of them are perfectly so. There are some of this sort in England, particularly in Suffex.

Large Brownish White Shining SAND contains a mixture of coloured particles, and is coarse, heavy, and of a colour which seem to be made up of a mixture of brownish, yellowish and whitish, with a faint reddishness. It is very bright, and its particles, though of different colours, seem to be much of a size to the naked eye. When shook with water it immediately settles, without leaving any foulness. When viewed through a microscope, the particles still appear to be much of a size, and of an oblong shape with angular edges; but there are some that are roundish, and of a fine clear yellow; some dusky, but very beautiful, and some of a pale flesh-colour. The white particles are perfectly transparent, but the reddish are almost opaque. It is found at Hedgerly near Windsor, where it lies among loam.

Large Yellowish White Shining SAND consists of pretty large coarse particles, which are very heavy, though somewhat less than the former. It is very clean, and remarkably bright and shining, and feels very harsh between the fingers; when mixed with water it subsides immediately, without leaving any muddiness. When the particles are viewed through a microscope, they appear to be of all shapes and figures, though in general they have a tendency to roundness; but they are much of the same size. They are generally transparent, and are chiefly white, mixed with some of a pale yellow or lemon colour. It is found all over England, and particularly near Deptford, Highgate and Hampstead.

Large, Coarse, Shining, Variegated SAND, is a very common sort, and is a beautiful Sand, though not pure. It differs in its coarseness and fineness, and in the different shapes of the particles. It is pretty heavy, and of a transparent white colour, variegated with black, red and brown, and of a chalky white, as also with different shades of yellow. The white particles, which are much the most numerous, have a considerable brightness, and feels very hard, though not so rough as some others. When viewed through a microscope, it appears to be mixed with small pebbles, that are opaque and of different colours, besides fragments of larger pebbles and flints, with many pieces of the white opaque crusts of flints. It is sometimes found in strata by itself, and at other times mixed with gravel. That on the sea shore is always clean and bright, and mixed with fragments of shells; in this last case it will ferment with aqua fortis, which is owing to the shells mixed therewith.

Fine, Dull, Brownish, White SAND, with heterogeneous particles, is of a dead disagreeable colour; but is pretty fine, though not so heavy as many other

Sands. There is little or no brightness, excepting a very few white glittering particles, which are here and there interspersed, and which are certainly of a different nature from the other particles. The principal part seem to be pretty uniform with regard to their size, and the whole does not appear so harsh as other Sands; when shook together in water it subsides but slowly, and leaves a brownish foulness behind it. The shining particles, when examined by a microscope, appear to be fragments of talc, for they will not ferment with aqua fortis. It is common almost every where, and is mixed with lime and hair to make mortar for plastering walls and ceilings.

Fine, Dull, Greenish White SAND, with heterogeneous particles, is pretty fine, though it has a dirty look, and the heterogeneous particles are not many. It is very heavy, is of a deep brownish white, with a sort of a greenish cast, and does not at all glitter except where the heterogeneous particles lie, which are certainly of a talcky nature. The other particles are not all of the same size, and the whole feels hard and harsh between the fingers; when mixed with and shook up with water it settles but slowly, and leaves a whitish brown muddiness. When examined by a microscope, it appears to consist of particles of all shapes and sizes, but mostly with smooth surfaces, and of a different colour. They are generally transparent and of a glossy white; but there are many of a sort of greenish brown, and not so transparent. It is common near Deptford, Black Heath and Woolwich. This is pretty much used for the making of green glass.

Fine Glittering Greyish White SAND, with heterogeneous particles, owes its brightness to the great quantity of talc it contains; for the sandy particles are small and fine, and seem to have little or no transparency. It is pretty heavy, and the particles are irregular in their sizes, but all of them small. The talc also is of different sizes, but larger than the sand, though at the same time very thin. It feels hard and harsh between the fingers, and when it has been mixed with water and shook up, it subsides in a short time, and leaves the water clear. When examined by a microscope, the particles seem to be of three different kinds; for besides the talc, there are some that have a glossy appearance, and a few that consist of an opaque spar; for which reason it will ferment a little with aqua fortis. It is found on the shores of the islands of Scilly.

Large Shining Red SAND consists of coarse heavy particles, and is of a strong red, approaching to a deep orange colour. It is not quite so bright as some of the white sands, but the particles which compose it seem to be pretty much of the same size, though of various shapes, with a tendency to roundness. It feels extremely hard and harsh, and when mixed with water subsides immediately, leaving it clear. It is a foreign sand.

Large Shining Flesh-coloured SAND is pretty coarse, very heavy, and is of a bright agreeable pale red, or rather of a flesh-colour. It is remarkably bright and sparkling, and the particles appear to be pretty much of the same size, though not all exactly of the same colour. It feels very harsh and rough, and when mixed with water subsides immediately, leaving no foulness behind. When examined with a microscope, some have glossy surfaces, others are quite transparent, and others again entirely opaque; many are semi-transparent; and, with regard to the colours, some are white, others yellow, and others of a pale red. It is common near Naples.

Coarse Shining Brownish SAND, with a reddish cast, consists of large but pure particles which are very heavy, and seemingly roundish. It is remarkably bright and sparkling, and the particles are of very different sizes. It is no wonder it is very rough to the touch, nor that it subsides immediately in

water. It is common on the heaths of Suffex and Buckinghamshire.

Fine, Bright, Shining, Brownish Red SAND, is very heavy, and the brown colour is more predominant than the red. The particles seem to be nearly of the same size and shape, and it feels harsh to the touch; when mixed with water it sinks pretty soon, and leaves a whitish muddiness behind it. It is met with in many parts of England, and particularly on Hampstead Heath.

Very Fine, Pale, Shining, Brownish Red SAND, is not of an agreeable colour, but is pure, though not so heavy as many other Sands. It is pretty hard to the touch, and subsides but slowly in water, leaving a reddish brown muddiness behind it. It is common on the heaths of Suffex.

Very Fine Pale Red SAND, with heterogeneous particles, is heavy, and of a very pleasant colour, which consists of a mixture of white, pale brown, and pale red. It glitters pretty much, and is composed of small uniform particles, with a slight mixture of talc. It is harsh to the touch, and when mixed with water settles but slowly. When examined by a microscope, the particles appear to be roundish and quite transparent. In the fire it loses all its redness, which is a circumstance not very common.

The Fine Palish Brown Yellow SAND makes but a dull appearance, though it is pure, fine, and pretty heavy. The colour seems to be made up of white, pale brown, and pale yellow, which are all very dull. The particles are of different sizes, and so small that they seem soft to the touch, and settle very slowly in water, leaving a whitish muddiness. When examined with a microscope, some of the particles appear to be perfectly transparent, and others almost opaque. It is very common all over the kingdom.

The Fine Shining Pale Yellow SAND, is pretty heavy, and of a fine colour, made up of white, yellow, and reddish brown. It is bright and shining, and the particles seem to be tolerably uniform. It is rough to the touch, and settles but slowly in water, leaving a yellowish muddiness behind it. When examined by a microscope, the particles are found to have different degrees of transparency, and those that are angular are as clear as crystal. It is found about Hampstead and Highgate.

The very Fine, Shining, Pale Yellow SAND, is considerably heavy, and there is no mixture of any other colours with the yellow. It is also very clean, with uniform particles, which shine pretty much. It is harsh to the touch, and when mixed with water quickly subsides, and leaves it clear. It is found in Kent and Suffex, and other parts of England.

The Fine, Shining, Gold-coloured SAND, is very pure, and heavy, and is of a fine bright yellow resembling the colour of gold. It glitters pretty much, and seems to consist of uniform particles. It is harsh to the touch, and settles immediately in water, leaving it clear. It is common on Hampstead Heath, and in most other parts of the kingdom.

The very Coarse, Shining, Pale Yellow SAND, consists of very large heavy particles, and is generally pure, with an uniform colour. It glitters very much, but the particles are irregular with regard to their size. It is very rough to the touch, and subsides in water immediately. This is commonly called Scouring Sand, and is used by stone-cutters in cutting their hard stones: it also serves to polish those that are designed for the more curious sorts of pavements. It is common in most parts of the kingdom, and particularly may be met with at Hampstead and Highgate.

The very Coarse, Dull, Whitish Yellow SAND, is generally found among gravel, and is remarkable for its coarseness. It seems to have no brightness,

unless viewed very nearly, and its particles are of very different sizes. It is common about London, and in most other parts of the kingdom.

The Large Shining Yellow SAND, is also common among gravel, and is quite pure, though coarse and heavy. It shines pretty much, and the particles are tolerably regular with regard to size. It is extremely coarse to the touch, and when mixed with water settles immediately, leaving it clear. When viewed through a microscope, it seems to consist of particles like small pebbles, with pretty smooth surfaces. It is common about London and other places.

The very Coarse Bright Yellow SAND, is always found at considerable depths, and is perfectly pure, though remarkably coarse and rough. The particles are heavy and regular in their size, and perhaps it feels the roughest of all Sands; when mixed with water, it settles immediately, leaving it clear. Viewed through a microscope, it appears to consist of large crystalline particles of an amber colour, and of the shape of pebbles. It is found in Northamptonshire, and other places, under the strata of gravel.

The Large Dull Yellow SAND, is of a disagreeable colour, though generally pure. It is considerably coarse, very heavy, and of a little deeper yellow than the former, but is very far from being so bright. The particles are of a very irregular size, and though considerably hard they do not seem so harsh as any of the former. When mixed with water they quickly subside, leaving a little yellow muddiness. When viewed by a microscope, the particles seem to resemble pebbles; but many of their surfaces are very unequal and somewhat flattish, and others crooked. It is a common Sand, and is found not only in pits, but on the shores of the English rivers. It is used by the plumbers in London as a bed whereon to cast their sheet lead, and is generally brought from Hackney river. It is also used by stone-cutters, in sawing their marble.

The Fine Dull Deep Yellow SAND, is pretty fine, though the particles are of different sizes. It is lighter than most other Sands, and the deep yellow colour is entirely without brightness. It is soft to the touch, and when mixed with water subsides very slowly, leaving a yellow muddiness behind it. When viewed through a microscope, the particles seem to be of the shape of common pebbles, with very irregular surfaces; they are pretty transparent, and of an amber colour. Some of the particles are so small, that they appear like dust sticking to the surfaces of the rest. It is common in Wiltshire, and is found in other parts of England.

The Very Large Dull Saffron-coloured SAND, is very pure, hard, coarse, pretty heavy, and of a deep strong bright yellow. The particles are not all of the same size; it is hard and rough to the touch; and when mixed with water subsides immediately, leaving it clear. It is found on the Gold Coast of Guinea in Africa.

The Coarse, Shining, Dirty, Yellow SAND, is very pure, large, heavy, and of a deep dusky yellow. The particles glitter pretty much, and seem to be regular and uniform, with regard to their size. It is harsh and rough to the touch, and when mixed with water quickly settles, leaving it clear. When viewed by a microscope, the particles appear in the shape of pebbles, and are pretty transparent, though of different degrees of yellow. It is common on Hampstead Heath, and many other parts of the kingdom.

The Very Coarse Brownish Yellow SAND, is very large, harsh, and considerably heavy; the colour is of a deep, dusky, brownish yellow, but very bright and sparkling. The particles, with regard to size and shape, are very regular, and exceeding harsh to the touch; when mixed with water it soon subsides, and

and leaves a brownish yellow muddiness. When viewed through a microscope, the particles appear to be uniform, and in the shape of pebbles, with very uneven surfaces, but pretty bright and transparent. It is common among the gravel in many parts of England.

The Fine Greenish Yellow Pale Dull SAND is of a faint straw colour, with a mixture of green particles, which are generally the largest. The sizes are very irregular, and it is soft to the touch; when mixed with water, it subsides slowly, and leaves a white muddiness therein. When viewed through a microscope, the particles appear to be different in shape, size and colour, and the greatest part have uneven surfaces. Some are of the colour of sulphur, others without any colour at all, both of which are very transparent; but the largest are in shape like common pebbles, without much transparency, and of a deep dusky green. It is found on Hampstead Heath, and many other places.

The Fine Greenish Red Pale Dull SAND, in many respects, resembles the former; but it is considerably lighter than most others, and of a pale yellowish flesh colour, with a mixture of green specks. The particles are of different sizes and shapes, those that are green being considerably larger than the rest, and it is hard and rough to the touch. When mixed with water it subsides but slowly, and leaves a yellowish brown muddiness therein. It is common in Suffex.

The Very Coarse Shining Blackish Yellow SAND is large, considerably heavy, and of a deep yellow, but mixed with black particles. It is very bright and shining for one of this kind, and the particles are nearly of the same size, only those that are black are a little smaller than the rest. It is remarkably rough, and harsh to the touch, and when mixed with water settles immediately, leaving it extremely clear. When viewed by a microscope, the particles appear in the shape of common pebbles, and are very bright and transparent, except the black, which are almost opaque. It is common in sand-pits.

The Fine, Shining, Blackish, Straw-coloured SAND, is neither large nor heavy, and the straw-coloured particles are mixed with those that are black. It is very bright and shining, considering the smallness of its particles; but these are of different sizes, and those that are black are somewhat larger than most of the rest. It is hard to the touch, but not very rough, and when thrown into water subsides very soon, leaving a little brownish muddiness therein. When viewed through a microscope, the particles appear to be of an oblong, blunt, angular shape, and are all very transparent and bright; and even the black particles, which are not very numerous, have some degree of transparency; but they are of a roundish shape, with smooth surfaces. It is common in Suffex, and may be met with in many other places.

The Shining, Coarse, Blackish, Sulphur-coloured SAND, is hard, heavy, and of a fine brimstone colour, with a considerable mixture of black. The particles are bright and shining, but irregular with regard to size, and are very harsh and rough to the touch; being mixed with water, it subsides immediately, leaving it clear. When viewed with a microscope, the particles appear to be in the shape of pebbles, but are very transparent, and the black seems to be nothing else but fragments of dark coloured flints. It is common in the sand-pits on Hampstead Heath.

The Shining Fine SAND, of a rusty yellow colour, is very heavy, and of a deep dusky yellowish brown, with a mixture of white particles, and others that have no colour at all. The brightness is owing to the last mentioned particles, for those that

are yellow and brown are entirely dull. They are all very irregular, with regard to their size and shape, and are very harsh to the touch: being mixed with water, they subside very soon, and leave a muddiness therein, as if mixed with ochre. When viewed through a microscope, they all appear to be somewhat angular, and the greatest part are of the colour of rusty iron, and entirely opaque.

The Finest Brown Yellow SAND, with heterogeneous particles, is light, and of a pale brownish yellow, with small spangles of talc, which are not very numerous; is sharp and harsh to the touch, and when mixed with water subsides slowly, but leaves it clear. When viewed with a microscope, the particles appear to be roundish, with unequal surfaces nearly of the same size, and very bright and transparent. The spangles appear to be thin flakes of fine talc, having the appearance of silver. It is common in the sand-pits on Hampstead Heath.

The Very Fine Yellowish Flesh-coloured SAND is very heavy, and the colour seems to be made up of a pale yellow, and a very pale red: when mixed with a great number of small glittering particles, those that are sandy have also some brightness, and are pretty uniform with regard to size; when mixed with water, it subsides very slowly, leaving a yellowish muddiness therein. When viewed with a microscope, the particles appear to be pretty much of the same size and shape, but of different degrees of transparency; some are reddish, others yellowish, and some transparent; they are of the shape of common pebbles, and the yellow much more bright and transparent than the red. The spangles are exceeding small, and appear to be thin flakes of talc. It is common in America, and is to be met with in some parts of England.

The Coarse Straw-coloured SAND, with heterogeneous particles, is very heavy, and of a pleasant pale yellow, with a considerable brightness, and pretty large white spangles. It looks very clear, and consists of regular particles, with regard to the size. It is sharp to the touch, and, when mixed with water, it subsides immediately, leaving it clear. When viewed through a microscope, the particles appear to be roundish, very bright and transparent, and the spangles are pretty large thick flakes of talc. It is common in the sand-pits about London.

The Coarse Sulphur-coloured SAND, with heterogeneous particles, is pretty heavy, and of a fine pale colour, somewhat between sulphur and saffron; it abounds with a great number of flat glittering spangles, which are broader than the other particles. It is harsh and rough to the touch, and when mixed with water subsides immediately, leaving it clear. When viewed through a microscope, the particles appear to be irregular in their size and shape, and many of them are not very transparent, though most of them are very bright. The shape is like that of common pebbles, and the spangles appear to be fine thin flakes of talc. It is common in Italy, and may be met with in Suffex.

The very Coarse, extremely Shining Yellow SAND, with heterogeneous particles, is very heavy, and of a fine yellow, though a little deeper than the ordinary pale gold colour. It glitters very much, and has also a great number of glittering spangles. The particles are regular and uniform, with regard to size, and it is rough to the touch; being shook in water it subsides in a moment, and yet leaves a little yellow muddiness therein. When viewed through a microscope, the particles appear to be very like small pebbles, and are all pretty transparent. The spangles are pretty numerous, but more white and less transparent than in many other of these Sands, because they are more thick. It may be met with on Hampstead Heath, and in many other parts of the kingdom.

The Fine Dusky Yellow SAND, with heterogeneous particles, is not heavy, and somewhat of a brownish yellow. It has a very dull look; but is mixed with glittering spangles, and the particles are very irregular with regard to their size; however, the spangles are very few, upon which account it has a more dead look than many others. It is soft to the touch, and subsides but slowly in water, leaving a yellow foulness therein. When viewed through a microscope, the particles appear to be of various sizes, with unequal surfaces, resembling small pebbles. The spangles consist of very thin talc. It is common in the sand-pits about London, as well as in many other places, and is generally mixed with ochreous clay, unless when found on the shores of rivers.

The Large SAND, of a yellow gold colour, with heterogeneous particles, is hard, coarse, and pretty heavy, and of a deep yellow colour, between saffron and gold. The particles are pretty bright and shining, but irregular, with regard to their size, and the white spangles which are large and bright are but few. It is harsh and rough to the touch, and subsides immediately in water, leaving a little yellow foulness therein. When viewed through a microscope, the particles appear in the shape of pebbles; are very transparent, and of a fine yellow: the spangles consist of flat fragments of selenites. It has been met with in Northamptonshire, Kent, and Suffex.

The very Coarse Saffron-coloured SAND, with heterogeneous particles, is pretty heavy, and of a fine strong saffron colour, or rather of a deep reddish yellow. The particles themselves are without brightness, but it is full of glittering spangles of talc. The particles are very irregular with regard to size, and they are pretty harsh to the touch; when mixed with water, they settle very slowly, leaving a yellow foulness therein. It is common in Germany, and has been found in Suffex and Leicestershire.

The very Fine Dusky Saffron-coloured SAND, with heterogeneous particles, is not heavy; the colour is a dusky brownish yellow, with somewhat of a brightness; but the numerous spangles of talc make it appear greatly so. The particles are pretty regular, with regard to size, and the spangles are but little broader than they. It is harsh to the touch, settles slowly in water, and leaves a brownish muddiness therein. When viewed through a microscope, the particles appear to be small, and in the shape of pebbles, but not very transparent; the spangles appear to be thin flakes of talc. It is common in the sand-pits about Highgate and Hampstead, and in other parts of the kingdom.

The very Fine Brown Dull SAND consists of fine particles, which are not very heavy nor bright, inasmuch that they appear like a heap of dust; however, they are pretty regular and uniform, with regard to size, and are harsh to the touch; in water it subsides but slowly, and leaves a muddiness therein. Through a microscope, the particles resemble small pebbles with unequal surfaces, and are pretty transparent, but not bright. It is met with in the sand-pits about Woolwich and Blackheath.

The very Coarse Shining Pale Brown SAND is one of the coarsest that is met with in this kingdom, though it is not remarkably heavy. The particles are pretty bright and sparkling, and regular with regard to size. It is very coarse and harsh to the touch, and mixed with water subsides immediately, leaving it clear. It is common about Woolwich.

The very Coarse Shining Dusky Purple SAND is very large and heavy, and of a deep purplish brown or chocolate colour, interspersed with white. The brightness is in a great measure owing to the white particles, and it is very rough to the touch; when

mixed with water it subsides almost immediately, leaving a somewhat yellow muddiness therein; through a microscope, the particles appear to be much of the same size and shape, being roundish. They are of two different colours, namely, chocolate colour, and white, which last are always smooth, and the former rough. It is to be met with near the Hot-Well at Bristol.

The Dull Brown Coarse SAND, with heterogeneous particles, is pretty heavy and of a pale brown, but very dull. The particles are irregular with regard to size and colour, some being much browner and coarser than the rest. When mixed with water, it subsides immediately, leaving it clear. When viewed through a microscope, the particles appear of different shapes and sizes, but chiefly like pebbles, and pretty bright and transparent. There are flatish fragments among them, which seem to be a sort of flint of different shapes, and there are others which are fragments of spar, upon which account it will ferment with aqua fortis. It is met with near Oxford.

The very Coarse Shining Pale Brown SAND, with heterogeneous particles, is large, pretty heavy, and of a faint pale brown colour; the particles are bright and pretty uniform, with regard to size. It is harsh to the touch, and mixed with water subsides immediately, leaving it clear. When viewed through a microscope, the particles appear to be of different shapes and colours, some being opaque and bluish, others transparent and inclining to yellow; but the greatest number are in the shape of pebbles with smooth surfaces, and of different degrees of a pale brown. Also there are many fragments of white brown transparent spar, upon which account it will ferment a little with aqua fortis.

Small Shining Greyish Black SAND is perfectly pure, and considerably fine and heavy; the colour is of a bright greyish black, and has a very agreeable look, the particles being uniform, both with regard to shape and size, and of a considerable brightness. It is harsh to the touch, and when mixed with water settles but slowly, though it does not leave the least foulness therein. When viewed through a microscope, it seems to be very bright and quite transparent, the particles appearing to be of an obtusely angular figure, and without any manner of colour. It is brought from Italy, where it is common.

The Fine very Shining Reddish Black SAND is clean, heavy and variegated with pale red, flesh-colour and white. The brightness is inherent in the particles it consists of, which are nearly of the same size, though different in shape, those that are black appearing roundish, and the others flat. It is sharp and harsh to the touch, and when mixed with water settles immediately, leaving it very clear. Viewed through a microscope, the particles appear like different gems; those that are black are almost opaque, with smooth surfaces and pretty round, but the others are all very bright and quite transparent, some being roundish and others flat. It has been hitherto found only in America, on the sides of hills and the shores of rivers.

The Coarse Dusky Green SAND, variegated with white, is pretty heavy, and of a deep dull green, with a considerable number of white particles. They are all nearly of the same size, but of different shapes. It is commonly harsh to the touch, and when mixed with water settles immediately, leaving it entirely clear. Viewed through a microscope, the white particles appear to be of two sorts, some of which are half transparent and cloudy, with obtuse angles, and others have sharper ridges, but are bright and quite without colour, besides which there are a few tinged with a faint yellow. The green particles, which are most numerous, are of a deep yellowish green, and

and of various shapes. It is brought from Virginia, where it is common.

The Fine Snow-white Stony GRIT is a perfectly pure and homogeneous substance, and small in proportion to its weight. Its particles are very bright and sparkling, and very regular in the size. It is harsh to the touch, subsides immediately in water, and leaves it quite clear. It ferments violently with aqua fortis; for which reason it seems to be composed of a very fine spar. It has been found in Mendip Hills in Somersetshire, in the perpendicular fissures of the strata of stone.

The Dull, Coarse, White, Stony GRIT, is much inferior to the former; for though it is perfectly pure, it is very hard and coarse. The colour is dull, there being little or no brightness; but the particles are very regular, with regard to their size. It is harsh to the touch, and in water subsides immediately, leaving it of a sort of milky colour. This also ferments briskly with aqua fortis, and therefore must consist of spar. It is met with in the same places as the former.

The Fine Cream-coloured Stony GRIT is pale, very heavy, and of a yellowish white or cream colour. It is very bright and sparkling, and consists of particles that are irregular with regard to size. It is harsh to the touch, and in water subsides immediately, leaving it a little milky. Viewed through a microscope, the particles appear to be of different shapes and sizes. They are all pretty transparent and bright, and seem to be without any colour. It consists of spar, for it will ferment violently with aqua fortis. It is found in one of the islands of the Archipelago.

The very Coarse Bright White Stony GRIT is very impure, and consists of two sorts of particles. It is very heavy, and of a dusky white colour, which however glitters in some places. The particles are all large, but very different in size, shape and colour. It is hard and harsh to the touch, and in water leaves a little milky foulness. Viewed through a microscope, it appears to be composed of a confused mixture of crystalline and sparry particles. It ferments strongly with aqua fortis, and a thin stratum of it has been found near Loughborough in Leicestershire.

The Very Coarse, White, Stony GRIT, with heterogeneous particles, is considerably heavy, and of a pure white, with black, yellow, and white flakes of talc. It is harsh and gritty to the touch, and subsides immediately in water, leaving a little whiteness therein. When viewed through a microscope, it appears to consist of large irregular particles, pretty transparent, and very white. The particles of talc have all very glossy surfaces, though of different kinds; but will not ferment with aqua fortis. It is common in Wales on the sea shore under cliffs.

The Dull, White, Fine, Stony GRIT is heavy, and of a dull whitish colour, with particles that appear to be much of the same size. It is rough to the touch, subsides quickly in water, and leaves a foulness therein. Viewed through a microscope, it appears to consist of opaque particles with rough surfaces, and of no certain shape. Among these there are a few loose specks, with surfaces as bright as crystal. It ferments violently with aqua fortis, and is entirely white when burnt. It is common in Derbyshire, and other places, where there are strata of stone.

The Dull, White, Coarse, Stony GRIT, is hard, pretty heavy, and void of brightness, and the particles are of different sizes and shapes. It is hard to the touch, and when mixed with water subsides immediately, leaving a muddiness therein. Viewed through a microscope, the particles appear to have rough surfaces, and are quite opaque; but there are

a few very small shining crystalline specks. It ferments very strongly with aqua fortis, and when burnt is entirely white. It is common in Yorkshire, and some other counties, where there are very large strata of it.

The Brownish, White, Fine, Stony GRIT resembles the former, is not very heavy, and void of all manner of brightness. The particles differ both in shape and size, and are not very rough or hard to the touch. When mixed with water, it leaves a muddiness therein after the subsidence. When viewed through a microscope, the particles seem to be of a loose spongy texture, and opaque, only there are a few shining specks in some parts. It is met with in the great stone quarry near Bath in the cavities of the stone, and ferments briskly with aqua fortis. It is also common in Liecestershire.

Glittering, Greyish, White, Fine, Stony GRIT, with heterogeneous particles, is pretty heavy, and of a pleasant pale greyish white. The particles are mixed with fine shining white spangles, and are different with regard to size, without the least brightness. The glittering proceeds from a mixture of a considerable quantity of talc. It is hard and rough to the touch, and when mixed with water subsides but slowly, leaving a whitish muddiness therein. When viewed through a microscope, the particles appear to be different, both with regard to size and shape, and besides the talc there are a few crystalline specks. It ferments violently with aqua fortis, and is common in the hills of Yorkshire.

Greenish, White, Stony GRIT, with heterogeneous particles, is pretty fine, very heavy, and of a dusky greenish white colour. The particles are different, both with regard to size and shape, without any brightness; but there is a mixture of broad flat particles of talc, which makes it glitter very much; it is not very rough to the touch, and when mixed with water subsides but slowly, leaving a greenish muddiness therein. When viewed through a microscope, it appears to consist of stony particles, which are different both with regard to their shape and size; but they are pretty transparent and bright, and the white talc appears in flakes. When burnt, it is of a pale brownish colour, and is met with in some parts of this kingdom.

The Coarse, Greenish, Grey, Dull, Stony GRIT, with a few heterogeneous particles, is very large, harsh, pretty heavy, and of a dull greenish grey colour, intermixed with a very few talky spangles, which are much less than the stony particles, that are alike both with regard to their size and shape. It feels pretty harsh and rough, and subsides immediately in water, leaving it quite clear. When viewed through a microscope, the whitish coarse particles, though not bright, are a little transparent, and there is here and there a crystalline speck, besides the particles of talc. It burns to a pale dusky red, and is common in Yorkshire and other places.

The GRIT, called the Puteolan powder by the antients, is a sort of greyish powder, composed of particles which are so exceeding small, that, when viewed through the best microscopes, no distinction appears among them. It looks perfectly dull of itself, for what brightness there is may be probably owing to the talky particles. When mixed with water, it subsides very slowly, leaving a great whitish muddiness therein. When mixed with salt water, it soon dries into a hard stony mass, which will not afterwards easily dissolve when mixed with common water. It was used by the antients as a mixture for their cements of buildings near the sea. It is now known by the name of the Pozzolane, and is an ingredient of hard plasters, in several parts of France and Italy.

Fine Pale Reddish Stony GRIT is heavy, and of a

very pale whitish or brownish red; it is very bright and sparkling, and even to a greater degree than many of the sands. It is harsh and rough to the touch, and mixed with water subsides immediately, leaving it entirely clear. The particles, when viewed through a microscope, appear to be of irregular shapes, some of which are of a pale red, others brownish, and others without any colour at all. It ferments slightly with aqua fortis, and undergoes little change in the fire. It has been found near Bristol.

The Pale Red, Shining, Coarse, Stony GRIT, is pretty heavy, with particles that are irregular, with regard to their size, and remarkably bright. It is very harsh to the touch, and immediately subsides in water, leaving it extremely clear. When viewed through a microscope, the particles appear to be crystalline and quite transparent, but of irregular shapes; some of them are without colour, and others are of a very pale red. It will not ferment with aqua fortis, nor will the fire produce any great change. It is found on the coast of Fife, in Scotland.

The Greyish Red, Coarse, Shining, Stony GRIT, is very heavy, and the particles are of various shapes and sizes, many of which are very bright and shining, and others quite opaque. It is very harsh and hard to the touch, and immediately subsides in water, leaving it very clear. When viewed through a microscope, some of the particles appear to be white, and very opaque; others are without colour and transparent, and others again are stained with a pale red. It ferments strongly with aqua fortis, and burns to a fine red. It is found on the shores of the island of Minorca.

The very Coarse Greenish Red Dull GRIT is very heavy, and of a fine flesh colour, variegated with green. The particles are pretty uniform and regular, with regard to their size, and they are of an irregular angular shape. It is very hard to the touch, and subsides immediately in water, leaving it clear. Through a microscope, some of the particles appear to be whitish, others of a pale red, and others of a fine light green; but they are all pretty transparent. It is found on the shores of the Mediterranean sea.

The Fine Shining GRIT, of the colour of rusty iron, but darker, is full of spangles that appear bright and glittering, which are not talc but crystalline, and without any colour. They are much of the same size, and extremely harsh to the touch; they subside very soon in water, leaving it extremely clear. Through a microscope, the particles appear to be of different colours; for some are whitish, others yellowish and semi-transparent, and others without any colour, and as bright as crystal; but the greatest number are brown. It is found near Lisbon in Portugal.

Fine Red Stony GRIT, with heterogeneous particles, is very heavy, and of an agreeable red colour, with a whitish cast. The stony particles are a little bright, but the mixture of glittering flat spangles renders the mass extremely so. All the particles seem to be uniform with regard to their size, and are very rough to the touch; in water they subside immediately, leaving it quite clear. Through a microscope, the particles of this grit appear to be transparent crystal, of a pale red, and all somewhat angular, interspersed with very bright transparent particles of brownish white talc. It is found on the shores of the island of Minorca.

The Coarse Red Variegated GRIT, with heterogeneous particles, is very bright and heavy, though light and coarse; the colour is variegated, though the red predominates, and the particles of that part are very bright and sparkling; besides these, there are many white crystalline fragments, and a vast

variety of yellow and black flakes of talc, all which glitter very much, and give the whole a pretty pleasing appearance. They are all nearly of the same size, feel extremely harsh and rough, and in water subside immediately, leaving it clear. It is found on the coast of Scotland.

The very Coarse, extremely Shining, Flesh-coloured, Variegated GRIT, with heterogeneous particles, is more beautiful than the former, and pretty heavy. The flesh colour or pale red is very lively, and variegated with black and brown particles of talc, besides some that are white and crystalline; and all the particles in general are very bright and glittering, but irregular with regard to their size. It is hard and harsh to the touch, and subsides immediately in water, leaving it clear. When viewed through a microscope, the particles all appear to be large and coarse, but of very different shapes and colours, though some are reddish and yellowish, others without colour, and others again, that are blackish and reddish, or opaque. The talky spangles are brown and black, for there are none that are white.

The Fine Brownish Red Variegated GRIT, with heterogeneous particles, is not so glittering as the former; but it is very fine, heavy, and of a faint brownish red, variegated with white, black and yellow. The particles are all bright and shining, and much of the same size. It is sharp to the touch, and in water subsides but slowly; however, it leaves it clear. The particles, when viewed through a microscope, appear to be of irregular shapes, some of which seem to be spar, are semi-transparent, and whitish, reddish, or brownish; others are crystalline without colour, though some are reddish or brownish and very bright, and others opaque and stony, and of a blackish or reddish colour. Those with the talky flakes make a very agreeable appearance; for they are of different colours, as white, yellow, and black. It ferments a little with aqua fortis, but undergoes no change in the fire.

The Fine Flesh-coloured Variegated GRIT, with heterogeneous particles, is not so beautiful as any of the former, though it is very fine, pretty heavy, of a bright flesh-colour, and very glittering. The particles are all nearly of the same size, and there is little variegation of white and black. It is sharp to the touch, and subsides immediately in water, leaving it clear. When viewed through a microscope, the particles appear to be of very irregular shapes, and some are white, others reddish, and others without any colour at all. They are not all equally transparent, but the greatest part of them are very bright, and there is a mixture of flaky spangles of talc, of white, brown, and black colours, with a few blackish stony particles. It burns to a paler colour.

The extremely Pale, Whitish Red, Variegated GRIT, with heterogeneous particles, is not so finely coloured as some of the former; but it is extremely fine, very heavy, and of a pale whitish flesh-colour. It is variegated with many black spangles, the particles are all very bright and glittering, and are nearly of the same size. The talky spangles are black, and remarkably thin. It is sharp to the touch; and, though it subsides slowly in water, it leaves it very clear. When viewed through a microscope, all the particles appear to be transparent, except a few that are black, and the fire turns it to a grey colour. This and the four former are common on the shores of islands in the northern parts of the world.

The Brownish Red Coarse Stony GRIT, with heterogeneous particles, is considerably heavy, and of a fine pale flesh-colour, variegated with brown, and there are a few glittering plates of white talc. The particles are regular with regard to their size, and pretty bright and shining, which render the

whole

whole mass very glittering. It is sharp and harsh to the touch, and subsides immediately in water, leaving a little muddiness therein. Through a microscope, the particles appear of different shapes; but most of them are flattish and bright, though not very transparent. Some are of different degrees of flesh-colour, others of no colour at all, and there are also brown particles that are more transparent than the rest. There are a few spangles of white talc, which are very thin, and smaller than the other particles. It burns to a little pale red. It is met with on the shores of the Red Sea.

The very Coarse Shining Blackish Flesh-coloured GRIT, with heterogeneous particles, is remarkably heavy, and of a mixed colour; between pale red and black, and the particles are bright and shining, besides which there are a few black flakes of talc, but not so large as the other particles, though they are of different sizes. They are very hard to the touch, and subside immediately in water, leaving it clear. Through a microscope, the particles appear of various colours, shapes and sizes; for some are white, others of a pale red, and a great number are black, and though they are not transparent, they shine more than the rest. It does not undergo any change in the fire. It is found on the shores of the islands of Sicily.

The very Coarse Shining Reddish Green Stony GRIT, with heterogeneous particles, is considerably heavy, and a reddish green, or rather of a greenish red. The particles are partly green and partly red, intermixed with many that are white, and all together are bright and sparkling: there are also a few spangles of greenish white talc. All the particles are nearly of the same size, and are very hard and sharp to the touch; they subside immediately in water, leaving a reddish muddiness therein. It is found on the shores of the Mediterranean sea.

The CRYSOCOLLA of the ancients is a beautiful green, though dull Grit; it is somewhat coarse, moderately heavy, and of an exceeding lively and agreeable green, with very uniform particles, which are nearly of the same size, but of little brightness. It is not very harsh to the touch, and subsides immediately in water, leaving it quite clear. Through a microscope the particles appear to be pure, and in angular figures, generally approaching to a rhomboidal form. It ferments strongly with aqua fortis, and tinges it with a bluish green. It is found on the shores of New England, and is taken to be green sand; it has also been brought from the shores of the Red Sea. It is used by goldsmiths for the foldering gold, and by painters as a colour. That is looked upon to be the best, which comes nearest the colour of an emerald.

The Fine Shining Pale Green GRIT is very heavy, and variegated with white; it is very bright and shining, the particles are regular in their size, and it is harsh and sharp to the touch; it subsides immediately in water, leaving it entirely clear. It is found upon the shores of the Red Sea.

The Shining Gold-coloured GRIT, with heterogeneous particles, is light in comparison of many others. The flakes are of different sizes, and it is softer to the touch than any other kind; it subsides slowly in water, and leaves a whitish yellow muddiness therein. Through a microscope, the stony particles appear to be reddish, whitish, and seemingly transparent. It is found in Virginia, Germany, France, and England.

The very Hard Fine Black GRIT, variegated with white, is the hardest, heaviest, and brightest of all the Grits, and is of a fine jet black colour, with a few specks of white. It consists of particles nearly of the same size, and is exceeding hard to the touch; it subsides immediately in water, and leaves it entirely clear. Through a microscope, the particles

appear to be all angular, of which some are whitish, and others greyish, but both are very transparent; yet those of a jet black, which are most numerous, are entirely opaque. It is met with in France.

The Fine Black and White GRIT, with heterogeneous particles, is pretty heavy, and the principal particles are bright and shining, but they are rendered more so by the mixture of fine white flakes of talc; it is harsh and sharp to the touch, and subsides very soon in water, leaving it quite clear. Through a microscope, the black particles appear to be opaque, and there are a great many transparent, without any colour, and exceeding bright; the flakes of talc are also transparent. It is brought from the shores of the Mediterranean sea.

The very Coarse Black and White GRIT, with heterogeneous particles, is extremely heavy, and its particles seem to be all nearly of the same size; the greatest part seem to be coarse and dull, but there are a few that are bright; however, the quantity of talc makes it glitter pretty much; for they are white and glossy. It is rough to the touch, and subsides immediately in water, leaving it very clear. Through a microscope, it seems to consist of a great number of white semi-transparent particles, of which there are some as clear as crystal, and very bright, besides many of coarse white talc, and a great many others that are black and opaque. When burnt it is of a flesh colour, with black and white spots. It is found in Wales.

The Shining GRIT, of a rusty black colour, with heterogeneous particles, is considerably fine and heavy, but entirely dull of itself, though the great number of black flat shining particles make it shine very much. It is harsh and rough to the touch, and settles immediately in water, leaving it entirely clear. Through a microscope, it appears to consist of different particles; and those without colour, as well as the yellowish and reddish, are like small pebbles; these are bright and pretty transparent, besides which there are many others of uncertain shapes, and quite opaque: these seem to be fragments of stones of different kinds; and there are a great many that are dusky, with somewhat of a reddish colour, supposed to be pieces of iron ore. Besides these, there are multitudes of spangles of different shapes and sizes, which are all very bright, and are taken for fragments of lead ore. In the fire it becomes blacker, and is known in England by the name of black writing sand.

The Coarse Sparkling Brownish Black GRIT is much like the former, but is more coarse, and remarkably heavy. It owes its sparkling to flat shining particles like the former, though they are not so many in number. It is very sharp to the touch, and subsides in water immediately, leaving a little blackness therein. Through a microscope, the particles appear to be various, of different shapes and figures, but nearly of the same size. They are partly fragments of stone, and partly iron and lead ores; but they are not so bright as in the former, they having smaller surfaces. The iron ore is discovered in this by means of a loadstone, as well as in the former. It is common on the shores of Wales, and serves for the same purpose as the preceding.

The Fine Brownish Black Sparkling GRIT is pretty fine, and remarkably heavy, with an agreeable bluish black bright colour. The particles are of various shapes and sizes, and it is pretty harsh to the touch; it subsides immediately in water, and leaves it quite clear. Through a microscope, the particles appear to be of various colours; for some are reddish, some greenish, and others blackish, mixed among a vast number of particles of various sizes and shapes, but all of a bluish black, with glossy surfaces. It ferments slightly with aqua fortis, which is probably owing to the sparry matter

ter contained therein. It is common on the shores of Wales.

C H A P. XXXIV.

Of MARCHASITES and PYRITES,
or FIRE STONES.

THE generality of Authors think Marchasites and Pyrites to be the same substance, and others distinguish them, making two different species thereof. Boet observes, there are several kinds of Pyrites, and that all stones, that strike fire properly, deserve that name. Some are bright like silver, others consist of several coats, others are like dice. Some are like red marble, and shine with a metal-line splendour, others are purple, quadrangular and transparent, and others again are spongy and shining or pumictous. Some have eight angles, others have twelve, others are like bismuth, and others again are tinged with a gold colour, from whence they take the name of Marchasites. Some are of a copper-colour; others are of various colours and forms, and others are mixed with stones. Among these, some will melt in the fire, and are added to metals instead of lead, to render them more fusible, and when they are broken they shine like sugar-candy. He adds to this, that there are stones called Pyrites, which will not strike fire with steel, and these he thinks ought not to be placed in that class. Among the Marchasites so called by some there are,

The Silver-coloured MARCHASITE, which is of a very firm and compact texture, and remarkably heavy. It is found making strata of itself, which though very broad are thin, being from three inches to a foot in thickness. Sometimes there are pieces found by themselves, and in general they have a very irregular and unequal surface, they being made up of great numbers of irregular flakes, and of various sizes; they being bent, undulated, and sometimes infold each other. However, these plates are not at all distinguishable by the naked eye, but seem to constitute one solid mass. The colour resembles that of silver, but is more glittering. It readily strikes fire with steel, but will not ferment with aqua fortis; and when put into the fire it cracks and breaks, emitting a blue flame with the smell of brimstone. After it has burnt a considerable time, it turns to a deep red. Sometimes this Marchasite is mixed with lead ore, sometimes with that of tin, and very often a dusky brown ferruginous substance. It is found in great plenty in lead and tin mines.

The gold-coloured MARCHASITE is more glittering than the former, but not so compact, though pretty heavy. It is commonly found in thin strata, and sometimes in pieces. It seems to be composed of flat flakes, not unlike great numbers of irregular fragments of leaf gold, placed together without the least order. However, some parts of this Marchasite are more loose and open than others, though it is all in its natural shape of a deep yellow gold-colour; however, it is sometimes paler, sometimes deeper, and at other times will reflect all the colours of the rainbow. It will not strike fire with steel so readily as the former, nor will it ferment with aqua fortis. When thrown into the fire, it will slowly emit a blue flame from all parts of its surface. It is plenty in Germany, particularly in Hartz forest, and has been met with in England, but not so often as in the former.

Heavy white MARCHASITE is very firm and solid, and more heavy than the other two. It is often found in strata by itself, and sometimes in detached pieces; but is more commonly met with in the cavities of other strata, of the breadth of several

yards. It has a smoother surface than the others, and is more uniform in its composition; though, if it be carefully examined, it seems to consist of undulated flakes laid closely upon each other. It strikes fire with steel; it will not ferment with aqua fortis, and when put into the fire burns pretty briskly, emitting a blue flame, with the smell of brimstone. It is found in Devonshire, Cornwall, and some other counties. These are all the Marchasites properly so called, taken notice of by authors.

The Flat Pyrites or FIRE-STONE, with a rough coat, can hardly be distinguished from other Stones by its external appearance. It is pretty firm and hard, as well as heavy, and is of no certain size, being found from one inch to ten in diameter. It is always flat and thin, and has very unequal and irregular edges. When it is about four inches long, it is half an inch thick, and requires a strong blow to break it in pieces. When broken its texture seems to be regular and uniform, consisting of one homogeneous mass, of a dusky brownish green colour, surrounded with a coat of a dusky ferruginous substance, which is rough and beset with small pebbles of different shapes and sizes, though generally no bigger than grains of sand. It is always of the colour of rusty iron, and is thicker in some than in others. It will strike fire with steel, but not ferment with aqua fortis; and in the fire it emits a blue flame which soon goes out, and when sufficiently burnt it turns to a deep purple. It is found in gravel-pits all over the kingdom.

The Round PYRITES, with a cracked coat, is coarser than the former, it being composed of visible grit. It is very heavy, and of various sizes, from half an inch to twelve in diameter, and requires a strong blow to break it. The colour is pale, with a mixture of dull whitish green, and a dusky brownish cloud. The outer coat or crust is of a brownish yellow, and of different thickness; the surface is divided by shallow cracks, and after it has been for some time in the air, they become deeper. It readily strikes fire with steel, and in the fire emits a strong blue flame, and last of all calcines to a purple powder. It is common in the chalk-pits of Kent, and many other places.

The Flat PYRITES, with a very thick whitish brown crust, is extremely hard and firm, though moderately heavy. It is commonly flat and round, or oval, and its usual size is two inches and a half in length, two in breadth, and one in depth. The surface is rough, it being full of small tubercles, and it has the look of a lump of brownish clay; it requires a smart blow to break it, and when broken, a nucleus is found of the same shape with the whole stone. This is very compact, firm, and hard, and of a deep dusky green. The nucleus will strike fire with steel, and burns to a red; but the crust itself turns to a pale brick colour. It was found in a clay-pit near the end of Gray's-Inn-Lane, and very probably may be met with in many other places.

The Green PYRITES, without a crust, is met with in a great variety of different shapes. It is of a hard firm close texture, and very heavy, and is found from half an inch to ten inches and upwards in length. Sometimes it is in the shape of a common pebble, but it is more generally flat, with an uneven undulated surface, and seems to consist of many plates laid one upon another. It is extremely hard before it has been exposed long to the air, and is, both within and without, of a pale silvery green. It readily strikes fire with steel, but will not ferment with aqua fortis; it readily cracks and breaks in the fire, emitting a fine deep blue flame, and turning at last to a florid red. It is very common in all parts of England, particularly in strata of blue clay.

The PYRITES, resembling a bunch of grapes
without

without a coat, is of a firm hard structure, and remarkably heavy. It is commonly small, and of a longish form, though sometimes round, and many pounds in weight. It is most commonly without any crust, and requires a strong blow to break it. When broken, it appears to be a kind of a metallic body. It is most commonly of a very pale green, though sometimes deeper, and the surface is always covered with tubercles of various sizes, so as to have a distant resemblance of a bunch of grapes. It strikes fire readily with steel, emits a blue flame in the fire, and soon falls to pieces; but at length turns to a beautiful purple. It is common in many parts of England, and when it has been long exposed to the air, has often a thin coat of a rusty colour.

The Round PYRITES, with a streaked structure, and an irregular surface, is very heavy, and is usually found in a roundish shape. The general size is from four to six ounces in weight, though there are some of two or three pounds. The surface is irregular, and sometimes beset with flattish tubercles, and sometimes raised in ridges, on account of their being placed in distinct rows, which meet in various angles. It is pretty hard, and when broken appears to be of a streaked texture, and the streaks run from the centre to the circumference. It is of a whitish green within, is covered with a brown crust, and is very bright and glittering when just broken. It strikes fire with steel, and burns to a purple powder. It is common in chalk-pits.

The Round PYRITES, with angular tubercles, is remarkably heavy, and is found from an ounce to a pound or upwards in weight. It is generally roundish, and the surface is remarkably rough. It is of a rusty colour, and is covered over with short quadrangular pyramids, which are broad at their basis, and blunt at their points, commonly standing very upright and close to each other. It cannot be broken without a strong blow; but when it is in pieces, these are found to be streaked, and of a greenish colour, with some small mixture of yellow. It strikes fire with steel, and will flame soon in the fire, with the smell of brimstone, and bursts to pieces; after which it calcines to a fine deep purple. It is common in England in the strata of chalk.

The Silver-coloured Round PYRITES, with a smooth surface, is of a pretty firm texture, and remarkably heavy. It is commonly round, and the usual size is about an inch and a half in diameter; but it is sometimes met with to the weight of two pounds. It is always without tubercles and ridges, and the surface is of the same colour as the inside, though not quite so bright. It breaks with a small blow, and when broken appears to be of a streaked texture, of a beautiful silvery green colour, and the streaks run from the centre to the circumference. It strikes fire with steel, and in the fire emits a blue flame, with a strong smell of brimstone, after which it bursts and calcines to a deep purple powder.

The PYRITES, with a foliaceous surface, is of a very firm though uneven texture, but very heavy; it is of various shapes, but commonly round. It is of different sizes, but generally large, though those of six or eight inches are commonly round. It is harder than most other stones of this kind, and when broken appears to be of a streaked texture, and the extremities of the surface are seen in rows of thin leafy plates, which cover the whole. They generally lean one way, but are of unequal thicknesses, and sometimes notched at the end. The colour is a dusky green, which when broken is very bright and glittering. In the fire it emits a deep blue flame and bursts, after which it calcines to a purple powder. It is found at Goslar in Saxony, and in Hartz forest, and sometimes in England, particularly Mendip hills, Derbyshire, and Cornwall.

No. 47.

The PYRITES, with a smooth glossy surface, is of a very firm coarse regular substance, and remarkably heavy. It is of a very particular shape, being always more or less hollow, and in various forms, often like pebbles, but more particularly rugged and knobby. The common size is five or six inches in diameter, and the surface is so glossy, that even the tubercles thereon appear to be so. It is very hard, and when broken appears to be streaked with irregular cavities, and the streaks are more narrow than in other stones of this kind. On the inside they commonly terminate in broad plates, nearly of a square figure, and are disposed in rows. The general colour is greenish; but if it is broken where these plates are, it is commonly of a bright beautiful yellow. It emits a blue flame like the rest, and calcines to a fine red.

The Large Foliateous PYRITES, in the shape of a cube, is of so regular a figure, that it has by many been thought to have been the effect of art. It is of a firm regular structure, very heavy, and is commonly found about one third of an inch in diameter. All sides are perfectly smooth, and it breaks in all directions; for it consists of plates in the direction of all the surface. It is glossy on the inside when just broken, and seems to be composed of plates like talc. It is of a fine whitish green colour, with a small mixture of yellow. In the fire it emits a deep blue flame, with a strong smell of brimstone, and calcines to a deep purple. It is found in Germany, Hungary, and the East Indies.

The Small Solid PYRITES, in the shape of a cube, is not unlike the former, it being firm and hard, and very heavy. The shape is regular, and the size is commonly about an eighth of an inch in diameter. It is perfectly smooth on every side, and when broken is very bright and glossy. Its colour is commonly a pale yellowish green, though in those that are large it is somewhat of a rust colour. It cracks and bursts in the fire, emitting a deep blue flame, and at last calcines to a fine red. It is frequently to be met with in the northern parts of England, and many other countries. It is here found in common black slate, but in Germany about the earth on the mountains.

The Bright PYRITES, with eight sides, is very firm and compact, of a pretty even texture, and very heavy. It is always composed of eight triangular planes, though it is subject to some varieties. Its most perfect shape is when two pyramids are placed evenly one against the other; but they are more commonly set uneven and slanting, and their planes are very irregular, with regard to their size. It is from the bigness of a large pin-head to that of a walnut; they are naturally smooth, and of the colour of polished iron. When broken the pieces appear very bright and sparkling, and often much paler than the outer surface. They seem to be composed of irregular thin undulated plates, laid more closely together than in the marcasites. In the fire it cracks and bursts, emitting a blue flame, with the smell of brimstone, and at last calcines to a deep purple. It is found in Cornwall, and is very common in North America.

The Hard Shining PYRITES, with twelve sides, when perfect, is extremely beautiful, but is seldom met with in that state. It is pretty hard, of a regular texture, and very heavy. It is subject to great irregularities; but often wants one or more of its sides, and has commonly other bodies of its own substance sticking fast to it. It is of various sizes, it being from one inch to four in diameter; but is more frequently about the third part of an inch. The surface is smooth and shining, and generally of a pale yellow, sometimes of the colour of rusty iron, and sometimes of polished steel. When broken it appears to be of a foliaceous substance, and to consist

6 B

of

of very thin plates irregularly placed, and may often be distinguished by the naked eye. In the fire it emits a blue flame, with the smell of brimstone, and calcines to a bluish purple. It is found in Cornwall, but is more common in Germany, as well as in the East and West Indies. It is observable, that all these kinds of stones strike fire with steel, and will not ferment with aqua fortis.

C H A P. XXXV.

OF FOSSILE PETRIFIED BODIES.

BEFORE we come to particulars, it will not be improper to take notice of petrifications in general, some of which are performed, as it were, within our sight, and therefore are most easy to be understood. The first of these is the stalactites, which is a kind of cylinder formed on the roofs of some caves and grottos, and which has been already taken notice of in its proper place. This is evidently brought to pass by means of the water, which carries with it very fine sand, that by length of time increases to different sizes, and forms the different layers which are successively produced one over another.

Another kind of petrification, which is well known, are the crusts of stone, which the water of some springs fixes by little and little to the pipe through which it passes; for these are almost every where to be seen. From these it plainly appears, that the matter of the petrifications, let their nature be what they will, is driven by water to the sides of the pipe in small particles; which being applied to each other without any regularity, forces the water itself to turn from the centre of its course, to make a passage for itself; because the stony matter is applied as it were by chance.

Another sort of petrification, also very well known, is that of the pieces of wood, shells, and other substances, that are petrified in the bowels of the earth, or in springs, without losing their shape, or distinguishing marks by which they are commonly known. These may be distinguished into three kinds; that made in plates or layers, that done by pellets or balls, and that by penetration.

The substances by which these are brought about, are water, salt, oily juice, sand, mud, and clay. The water seldom penetrates the substance of stones to no purpose, but carries with it and mixes the materials of which it is composed; much in the same manner as the masons make use of water wherewith to blend and intimately unite the materials of which they make mortar or cement, that grows hard in proportion as the water flies off.

The three different petrifications are performed likewise by minute masses or lumps, and a very fine cement. The masses to be incorporated are the sand, clay, and loam: the most durable cements are the salts, and several kinds of bitumen. Sometimes the salts, intermingled with the clay, serve as a cement for the sand; at other times, the mass is composed of clay, or loam alone, without any intermixture. From the different degrees of these several bodies, thus differently intermixed, proceed a vast variety of productions.

To the first kind of petrification we may refer tals, slates, plumous alum, and plaster. As for crystal, it is nothing but a heap of sand, perhaps in a pyramidal or triangular shape, which the water applies successively one upon another, uniting them together with a little salt, and very fine mud; this is the more probable, because when crystal is decomposed in the fire, there remains nothing but calcined sand, earth, and a little salt. We need not wonder that crystal should be thus formed into a transparent mass, because several sorts of white sand,

viewed through a microscope, appear to be nothing else but true white crystal. The earth or mud, that is joined thereto, only hinders them from shining like a diamond.

It is easy to imagine, that a fall of water may bring into any place a layer of sand and blackish earth, and that a second may throw another upon the former, and so on; insomuch that, in length of time, slate may be produced of different thicknesses. In the same manner different substances may form talc, plumous alum, and plaster.

The second sort of petrification is that, which is performed by small bullets or balls, and often by bunches composed thereof. It is probably by this means that gems receive their formation; because many of them are found in the chinks and cavities of certain rocks, where the water can bring nothing with it but sand, salts and a little bitumen, and by chance some metalline particles. These small congelations of matter, coming to sink and harden by degrees, may carry along with them the very fine particles they meet with. The generation of irregular flints, and all other stones that will strike fire with steel, seems to be the same as that of gems; for the water meeting in its course certain cavities more or less wide, in marl, chalk or clay, that are in rocks, there deposits the salts, the oily fluids, and the fine sand with which it is imbuted. This water afterwards evaporating, the sand, and every thing that is introduced within the cavity, becomes hard as in a mould, and forms a mass which takes the same figure. When fine sand is the principal ingredient, the concretion is more or less transparent and hard, as are all sorts of gems. The colours are dull; variegated, or marbled with veins, in proportion to the different mixtures of the substance of which they are formed. When there is a great deal of salt or sulphur, which are well known to contain particles that strike the nose and yield fire, then the stone will have a strong smell of sulphur, when it is broken or struck, and will sparkle when it meets the blows of another stone as hard as itself, or when it is struck with the steel or hammer, that by its extraordinary hardness discomposes the pores wherein the particles of fire are lodged. These sorts of stones very evidently contain a great deal of fire, and therefore they might be supposed by some to be electrical, and yet it is plain they have no such quality, which may be owing to the earthy particles in which the fire lies hid; and which may prevent the effects of rubbing, in the same manner as a lock of wool placed against a glass, or when tied to the string of a musical instrument, prevents the vibrations, and consequently the sound.

There are a great many flints and flinty stones that are exactly round or oval, or approaching thereto, and of all sizes, which seem to be composed of, or form small pellets or plates, by means of a nucleus which is the basis of the whole. When the water is loaded with a small bit of marl, or some small stone, as it repasses through this small mass, it will fill up its pores or inequalities with the clay or other particles contained therein, and will bestow upon it a smooth and pretty regular surface. If this is repeated several times by the application of the water to the mass, it will always leave a small layer or coat of sand, before it flies off. These circular layers or coats growing hard, by the evaporation of the water, will form a small arch, which will grow still stronger and stronger, by the successive application of several other layers or coats. The whole will grow more thick in proportion to the number of times that the water returns, and deposits fresh matter. It may so happen that the nucleus of chalk, marl, stone, or clay, which has been as it were the foundation of the first arch, being rendered hot by some external means, all the moisture will evaporate

and

and diminish the size. By these means it may often come to pass, that there may be a nucleus in the middle of the stone, as we often find by experience; which may be sometimes chalk, sometimes common earth, or other substances, quite different from that of the stone; so that at length by shaking the stone it may be easily found by the rattling, that some substance is contained therein. Thus the formation of round and oval stones becomes much the same as that of certain stones which are known by the name of Bezoars, and which are found in the bellies of several animals, both in the East and West Indies, and to which great virtues are attributed.

Some of these stones, that have a cavity in the middle, often contain a hard substance, or another stone, which may be easily known from the noise it makes when shaken; and this is commonly called by the name of the Eagle Stone, to which most extraordinary qualities have falsely been attributed.

The third manner of petrification is what is called by some penetration, and this is the most common; thus a large bed of sand, clay, or other matter, may be petrified by the salts and other particles which with the water is imbued when it sinks therein. The water will carry with it all the fine salts it has dissolved and taken up by the way, as well as the exceeding fine earthy particles which have remained therein. This water will readily pass, as well as every thing it contains, through a bed of sand, that is too full of pores to stop it; but it will fill by degrees all the interstices of more compact sand, and will closely unite all the particles; and by this means we may understand the formation of what we commonly call free-stone. A bed of earth or of sand will be changed into a stone more or less hard in proportion to the quantity of clay or sand contained therein. Marl and potters clay thus mixed with sand will be changed into marble, whose ground may be either red, green, or black, according to the nature of the petrified bed. Perhaps the ground of any marble may be nothing but very fine sand, into which the water has penetrated, and carried at many thousand different times the fine particles of marl and potters clay, and which in process of time may obtain the hardness in which they are found; and consequently their natures, colours, mixtures, and clouds, may vary to infinity. If the potters clay has been dried and cracked by some subterraneous heat, the fine sand, or marl, or other substances which are carried by the water, and deposited in the chinks or cracks, may produce veins of all colours, and of all shapes. Likewise, when there are particles of gold, or any other metal, that are fine enough to be dragged along by the water, they may serve to augment the richness of these variegations. The drops of oily fluids, which the water carries along with it, may expand and form a multitude of small spots, which may be round when they are at liberty, or oval when they are a little confined on each side; or, in short, they may be angular, or of any other shape, according to the impediments they meet with. All the winding veins, on the sides of which we sometimes see rows of small specks of gold, or other metals, extremely fine, serve to shew very evidently the progress that the water has made; for when it happens to be stopped, and obliged to turn, it penetrates wherever it can, and so produces very irregular variegations. The particles which the water contains, being naturally a little more heavy than itself, must needs be deposited in time, and stopping by the way, must penetrate the very first cracks or other cavities that they meet with. We may compare the formation of a marble, or other stone, to that of cloth or tapestry; for the body of the sand or clay, which is capable of penetration by water, may be compared to that

which weavers call the warp, and the water to the shuttle, which passes across the other without stopping. The fine sand, the particles of common clay, the colours of potters clay, the fine threads or small leaves of metallic substances, may all together be compared to the wool, which is introduced into the body of the work, and which fills it by little and little.

However, it sometimes happens, that there are thin plates or layers of clay between the different beds or strata of stone, and which are free from any mixture at all; from whence it appears, that they have hindered the progress of the water, for they only served to sustain, and could not be penetrated by it. Perhaps it may be thought a wonder, why there should be any stratum of stone or marble under this clay, since the water could not get through it; but this will soon cease, when we consider, that many parts of the clay may be very thin and full of cracks, and consequently will admit the water to pass very freely through it. All the water with its contents may run over the clay, and may be shed, at the extremity of this layer, into the bed which lies beneath; and it has been found by experience, that many rocks of an enormous size will not prevent the water from passing through their bowels, and falling into beds of sand that are placed underneath.

That which the water performs, by the penetration of the different strata contained in the earth, it brings about in some degree with regard to pieces of wood, bones, and other substances which it enters into; and which affords us a reason or method of explanation of all the different petrifications, though never so odd, which are to be met with in all parts of the world. We cannot determine whether there has ever been an universal earthquake or not, which has changed its primitive form; for we find several sorts of animals, and sometimes mankind, in small islands at a vast distance from the main land, which can hardly be accounted for, but from some extraordinary cause, that has produced great irregularities in the face of the earth, making that to be a sea, which was dry land before, and raising up mountains out of the bosom of the deep; especially since we find, from some such change, that there are a vast number of marine bodies at a great distance from the sea, and a great deal higher than its surface. However, this is certain, that many substances, which seem to have been proper only to the sea, are now found in the bowels of the earth; and which have perhaps been petrified by degrees, by the insinuation of water, salts, and exceeding small crystalline or stony particles, proper to fill up their pores, without alteration of their shape. To this all the productions which some have looked upon as *lusus naturæ*, or sports of nature, are evidently owing. Besides the bones of crocodiles, the skeletons of sea horses, the entire bodies of petrified fish, there are almost every where found sea shells of all kinds, and all sorts of the parts of sea animals, converted into stone. Some are very wonderful with regard to their situation, and others as to the oddness of their shapes. However, some are of opinion, that if these changes have been in reality produced by earthquakes, it will not from thence follow we should find them converted into stone; but this may be easily accounted for, if we reflect a little on what has just been said: for their situation is no more difficult to be comprehended than that of flints, which are generated in the middle of other substances; for, though they undoubtedly were in their natural state before the alterations were made, yet it is easy to conceive in what manner they have been petrified since that time. These petrifications have had different names bestowed upon them by naturalists, and therefore it will be necessary to give a more distinct account thereof.

thereof. They are principally of two kinds, that is, animal and vegetable substances; some of which have remained in the earth a vast number of years without any great alteration, and others have been covered with or turned into stone; however, they all come under the denomination of Fossils.

With regard to trees, there have many been found buried under ground in many parts of the world, and particularly in England; as on the coast of Suffolk near Dunwich, in the fens of Lincolnshire and Yorkshire, and more particularly in the isle of Axholm, which is made by rivers, and lies between Nottinghamshire, Lincolnshire, and Yorkshire; as also on the coast of Pembrokehire in Wales. These have not only been found near the sea, but in inland countries at the depth of ten or twenty ells.

In England, there are some that lie at a distance from the sea, as in Chatmoss in Lancashire, several parts of Yorkshire and Cheshire, as well as in Staffordshire. The places in this last county where they are found are Laynton, and the old Pewit Pool in the parish of Norbury; Shebben Pool, in the parish of High Offley; the mosses near Eardley, in the parish of Audley, and near the town of Betley; all which lie in the high country of the moor lands. They are found still farther from the sea in Cranmoor near Wrottesly; in Rotten Meadow under Wednesbury Hall; on Dorley Common in the parish of Gnosal; in a place called Peat-Moor, and in the moors of Handsworth; none of which are less than thirty, and some are above fifty miles from the sea. Some will have these to have been originally formed in the earth, especially because they resemble firs, of which sort none ever grew naturally in England, if we may believe the account that Cæsar gives in his Commentaries; but his authority is not always sufficient. However, this appears plainly to be a mistake; because many of these trees have their roots still remaining, as well as the stumps of their branches. If there is any such thing in reality as fossile wood; it is generally allowed not to swim on the surface of the water; whereas all these before mentioned will: besides, they still retain the qualities of wood, and sometimes they are found swimming in pools, which the country people get out, cleave into splinters, and make use of them instead of candles. The chief difficulty lies in knowing whether firs ever grew in England or not; and some, to solve this, have pretended that they have been brought hither by some flood, particularly that of Noah, where they have lain ever since. It must be acknowledged, that there is no impossibility in this, or at least that they may have been brought hither by some such means; because they are full of a large quantity of bitumen, which no doubt would preserve them from corruption a vast number of years. However, this account is not very probable, because if they had been brought hither by a flood, they would have been found in all the low places alike, and in the south of England as well as in the north; for there are none in the vales of Evesham and Aylesbury, nor indeed in many others, which seem to be most likely. Some of these trees appear as if they were burnt, and others have the marks of the ax still remaining upon them; besides, the stumps, from which they were cut, are in some places also remaining, and appear in the same posture as when the tree was growing; particularly in Shebben Pool, when the summer is dry and the waters low. Others, with more probability, have thought that these trees were not fir, but birch or alder; because they delight to grow in moist places, and having been soaked many years in a bituminous stuff, have been so well impregnated with an oily matter as to imitate fir both in smell and burning: however, this can hardly be the case, because they

split exactly like fir, and because they have evidently a turpentine smell; and besides, at Axholm in Lincolnshire, there have been found trees, thirty-six yards long, exclusive of the tops, which lay very near the roots to which they belonged. But it would detain the reader too long, and be foreign to our present purpose, to endeavour to account for the manner in which these trees have been brought into this island.

Other trees, besides firs, have been found to have been buried under ground; for Dr. Moreton takes notice of a small maple-tree that he met with in a stratum of clay at a considerable depth; and near Bath part of an elm-tree has been discovered of a considerable length: no doubt there have been many others, which have not been thought worth notice. But besides entire trees, or the principal parts, there have been commonly found in the fuel known in many parts of England by the name of Peat; and which is dug out of the earth, several fruits and catkins of other trees, that have been little altered in their texture. The most common of these are hazle-nuts; and near Whitesea the twigs, as well as leaves, of white poplar have been seen, with the branches of hazle, and great numbers of the skeletons of leaves and catkins, besides the stones of plumbs or some such fruit. There have been some pretty large branches of trees found in the strata of stone, and commonly more or less changed into the nature of the strata in which they lay. A great variety of smaller branches have been found in the strata of blue clay, which serves to make tiles in the neighbourhood of London; but though they were in their original shape, yet their internal structure was much altered; for they seemed to be changed into the substance of the common vitriolic pyrites. These, and others of the like kind, are thought to have been branches of oak, and they are generally altered in some sense to the nature of the strata in which they lie, by the insinuation of crystal or stony particles; but in some the veins of the wood are still preserved, and appear very beautiful when polished.

Dr. Plott takes notice of stones which he calls STELECHITES, whereof one in his time was met with near Dudley, called by the country people the Pox Stone, that is, a stone which undergoes little alteration by fire. It was so much like petrified wood, that he took it for the stump of a tree at first sight. There are others of this name that are not so worthy of it, particularly the Stelechites of Aldrovandus, that has the appearance of antimony; whereof many are found in the rocks near Beresford and Stanfop, and among the rubble stones that lie loose above ground in the fields near Heatly and Pagots-Bromley. They are a sort of annular stones, regularly jointed and regularly streaked at the top and bottom; and therefore as unlike the trunk of a tree, though some of them are branched, as any thing can well be; nor indeed do they resemble the trunk or stem of any plant whatever. Mr. Ray takes them to be the petrified back or tail bones of fish, because they generally consist of several plates or pieces sticking together, like the vertebræ of the back-bones of some sorts of fish; though he acknowledges, that they are shorter and thinner than the bones of any fish he had then seen.

Besides trees, and parts of trees, there have been different kinds of plants, which have undergone the same fate; and have either been wrapped in the black slaty stone found over the strata of coals, or in loose stones of a ferruginous substance. Some sorts of stones contain the perfect images of plants, which seem to be nothing more than a painting, because the fluid contained in the plant, has so intimately penetrated the substance of the stone, that it seems to be all of a piece with it, and has preserved no-

thing

thing more than the figure. The plants that are thus found are of different sorts, but the most common are of the fern kind, yet not such as we have in England, for some pretend they are only to be met with in America. There are also a great number of sea mosses, with which many parts of the bottom of the sea are covered. An ear of barley has been found in one, or at least its image, very exactly painted. Some of the stones, when they have been split, have contained the figure only of the plant, while the other side has appeared more prominent; which seems to have been occasioned by the petrification of the plant itself. Some of the ferns thus found have been different from any species hitherto known; insomuch that it is hard to say, whether or not they were precedent to the formation of the present globe of the earth.

Though these impressions have been most commonly found in the slaty stones above mentioned, yet there have been other stones met with in which they have been seen, though perhaps not so commonly; particularly, there is a whitish stone in Germany, not much harder than chalk, in which they have been frequently seen; as also a grey slate stone of a very fine texture, where they have been often found, besides one of a blackish blue colour. Not only the entire branches of plants appear in these stones, but sometimes the leaves of trees; particularly those of the poplar, willow, white thorn, pear-trees, and many others.

Perhaps it will not be improper to take notice of others that are less singular, and which are common in Germany. These are the leaves of oak and other trees which hang over springs whose waters have a petrifying quality, by whose means they are often covered with a crust like the mosses in many parts of England. The stone that covers them seems chiefly to consist of a sort of spar. Many specimens of all these kinds are frequently to be met with in the cabinets of the curious.

Dr. Plott has met with some sorts of these petrifications in Oxfordshire, particularly at Somerton, where the grass is covered with a soft stone, yet in such a manner that when it is broken off the grass appears as fresh and green as before it was incrufted. Some of the blades of grass grow at least to a foot in length, and yet when pulled up with the root, and held up by that part, it might be pulled out as entire as a sword out of the scabbard. At North Aston, in a field north-west of the church, there is another petrifying water, where the roots of rushes, grass, and moss are in a short time eaten away, insomuch that nothing remains afterwards except the figures of those plants, with some augmentation. In the parish of St. Clement's in the suburbs of Oxford there is a ditch, the water whereof covers with a crust the sticks that fall out of a hedge. At Carfax, in the city itself, there is a pump, that not only covers the boards that fall into it with a crust, but also enters the very pores of the wood, which by degrees rotting away, there is nothing left at length but the linaments of the wood itself.

Petrifications of this kind are always very brittle; though they leave a faint representation of the grain of the wood, yet they never preserve its colour; and in the fire they are as incombustible as stone; for they change nothing but their colour, which becomes more whitish; however, they will entirely dissolve in aqua fortis. There are some indeed that are petrified in a different manner, and will preserve both the colour and texture of the wood: they are sometimes so hard that they will cut glass, and will always strike fire with steel.

The petrifications of marine substances are more common than those of any other sort; and among them are found fish of various kinds, more especially shell-fish, or rather the shell of those fish. However,

it is not very common to find any which represent the figures of river fish; though there is one called the Barbel Stone.

There are other fossils called OSTRACOMORPHOS, which consist of heaps of oyster-shells cemented together. There are many other petrified shells that are not found in clusters, but each of them lie single in a separate state. Of these some are curiously streaked or furrowed, and others plain, with few or no ornaments. Of these again some are of a turbinated form, and others bivalvular, joined together by a hinge, yet the shells of these are commonly found apart. Among these are those called the Stromboites, from their wreathing like a screw, and generally from the right hand to the left, and from the greater to the smaller end. The largest exceed nine inches in length; but those in England, at least that have been hitherto found, are not much above five, with a plain surface; and the least are not above half an inch long, but curiously streaked. They are of an ash colour, somewhat inclined to yellow, and of a harder consistence than the stone in which they lie.

There are some petrifications that resemble cockles, scollops, and oysters; and these are very numerous. The CONCHITES, or cockles, may be divided into the greater and the less; whereof some of the greater are streaked with broad streaks and pretty deep furrows, descending as it were from a centre at the top, and expanding themselves to the rim of the stone. They have also six or seven transverse simple lines, bent circularly to the hinge or joint; these appear to be a stone without, of a dark ash colour; but within they are found to be black flint. There are others again whose streaks descend from the hinge or joint, and yet not in straight lines, but undulated, and much broader than the former.

There are several kinds of the smaller Conchites, which differ in their colour, lines, and valves; for some are yellow, and are found in the fields near Burford in Oxfordshire; their valves rise high, and approach to a roundish shape. These made red hot, and put into beer, are accounted by the country people to be an immediate remedy for a stitch. In another part of this country, there are some of this sort that are flatter, and of an ash colour; but in both the lines run from the joint to the rim. These last are found only at the head of a spring, but never at any distance from it. Some of these have been found only streaked on one side, and rubble-stone on the other; and others have but just begun to be marked with lines.

There are others of this kind found in a bank of yellowish clay, and are of a different form from those just mentioned, for they are streaked transversely. Many of them appear to be hard stones, and yet several that have been met with were nothing but clay; which may justly raise a doubt, whether or not many of these, which have been generally supposed to be petrified shells, are properly so called.

There is another sort of Conchites found in Hornton quarry, nearly approaching to an oval, and scarcely streaked at all; which inclines Dr. Plott, as well as Dr. Lister, to think that these stones, which are so like cockles, never were in reality the shells of that fish.

There is still another sort of Conchites found in Hornton quarry, which is not stony on the inside like the former, but is hollow, and filled up with spar. It is sometimes in irregular figures, but generally forked. The base, or place where the branches of the fork are united, is at the joint or hinge of the valves; which seems somewhat hard to account for.

There are also petrifications or stones, which resemble scollop-shells, and are always found separate.

One of these is very curious, and resembles the Rough Scollop of Aldrovandus. It is of a yellowish colour, and has ears on both sides, with lines that run from the hinge or joint to the rim of the shell. These are very prominent; and there are others that run transversely, not bending towards, but from the hinge or joint; however, these do not pass through the deep furrows so as to join with each other, for they are only upon the ridges. There is another kind of scollop, where the direct and transverse lines are of an equal depth, but very shallow, very numerous and fine. In these the transverse lines bend towards the joint. It is of a light reddish colour, with ears on both sides, and is found in the quarries of Heddington in Oxfordshire.

There is another shell or stone like a small scollop, of a whitish yellow colour: the streaks are large and broad in proportion, but the transverse lines are small and narrow; however, it is eared, like the former, on both sides. These are called *Pectunculi* by Rondeletius, and he makes them a distinct species from the larger sort, which he names *Pectines*; but then those that he speaks of have never more than one ear, which is sometimes on the right, and sometimes on the left side; but this has ears on both sides. There is another of the small kind intirely without ears, nor is there any sign of the ears being broken off; however, there are real shells of this kind taken notice of by different authors. There is still another sort resembling a scollop, or, as some think, a sort of cockle, because it bears too much on one side for the former. It cannot be a *Tellenites*, because if it has any streaks at all, they never run that way. These are in great plenty in several parts of Oxfordshire; some of which are large, and as it were heaped one upon another; and others single, or found by themselves. The real shell-fish that answers to these are called *Streaked Cockles*; but they are always very smooth within, whereas some of these are evidently streaked on the inside; and the streaks not only run from the joint or hinge to the rim, but there are four or five broad transverse streaks, made up of several lines almost close to each other; for which reason some would have it to be a stone of a particular kind.

Besides the shells already mentioned, there are others that seem to be of the oyster kind, which are very common in the gravel-pits in some parts of Oxfordshire; among these, there is one of an oblong shape, which is very thick, and of a bluish colour, and seems to be the same as the thick oblong concha taken notice of by Dr. Merrit, which he found in Worcester-shire, where they are called *Crow-stones*, *Crow-cups*, and *Egg-stones*.

There are other shells or stones that have some resemblance to muscles; but they are of an odd sort of a figure, and there are no real shells that we know of like them. They are not hollow, but are filled on the inside with a stony earth of a yellowish colour, and their covering is white and shining, with oblong lines. It is very long and narrow in proportion, and is marked, but very faintly, like the shell of a common muscle.

There are other petrifications resembling shell-fish, of the softer crustaceous kind, such as the *Sea Urchin*, which for substance and hardness are much like a pebble, and of a yellowish colour. They are divided at first by five pretty straight lines, adorned on each side by a double row of points, ascending from a protuberant centre in the basis of the stone to another shape at the top, but foliated round in the manner of a rose. It is likewise subdivided by five other indented lines, which terminate before they reach the centre; but they make the spaces between them appear like pentagons, or like the shells of some kinds of tortoises. Aldrovandus takes notice of a stone of this kind, which he ima-

gined resembled the *Sea Hedge-hog* deprived of its prickly coat. Dr. Plott calls it the *Porcupine Stone* without bristles. There is another that is curiously embroidered and resembles the *Sea Hedge-hog* of Imperatus. It is of a whitish ash colour without, but within is a hard black flint covered over with thin glittering plates placed edgeways on the ball of the flint, and which compose the uniform eminences and depressures with waved and transverse lines. Some Writers calls these *Serpents Eggs*.

There is another sort of *Hedge-Hog Stone*, which resembles the shell of a kind of sea hedge-hog, and is said to be like the stelled eggs of that hedge-hog. Their outermost coat is full of sharp prickles, upon which account they are sometimes called *Sea Chest-nuts*, because of their likeness to the rough prickles that encompass chestnuts while they are on the tree. When they are dead, all the prickles will fall off, and then the shell is discovered, which is curiously wrought, and resembles the stone of which we are now speaking. They consist of many compartments and eminences, which are so regularly disposed, that the most ingenious embroiderer cannot easily imitate them. It may be doubted, whether there is any animal with a shell like this stone; for no account has been given of any such hitherto. There is also another kind of *Echinites* or *Hedge-hog Stone* found in the quarries near Shotover Hill. The inward shell of this fish is very small though the prickles are long and stiff; and it is always found in the deepest waters sticking to the rocks.

The *Cornu Ammonis*, or *Ammon's Horn*, is so called because it is like the horns of rams, which were consecrated in the temple of Jupiter Ammon, seated in the sandy desarts of Lybia. They were formerly taken to be petrified serpents, and several authors have compared them to the nautilus, or have confounded them with each other. The unpetrified *Ammon's Horns* are divided by several partitions; but they have fewer sinuosities than the nautilus, and they have no small pipes that run through them to preserve a communication one with another. There is also some difference in their covering; for the nautilus is very smooth, or at least the streaks of the surface only answer to the windings on the inside, and are very broad; whereas *Ammon's Horns* have several external turns, are covered often with tubercles, and almost always with streaks. There are plenty of the fossile kind in the county of Oxford, which are of different colours, shapes and sizes, but always so curled up, that the place of the head is in the circumference, and the tail is in the centre of the stone. Some are small, with protuberant parts swelling almost to a round; others are broader and more depressed; but the lines in both are undulated, and extended from near the centre to a single edged ridge on the back of the stone. In this respect they differ from a third sort that has broader lines, but not undulated, and they terminate at the large protuberances on each side the stone, between which and the broad back thereof there run other lines; the whole body of the stone being likewise divided into sutures not much unlike the leaves of an oak.

A sort of these stones have been found in the parish of Cleydon in Oxfordshire, which have many more turns than the former, though they are not much bigger; but they are without a covering, and are of a yellowish colour, with streaks that run from the innermost part of the stone, and are all single, except that some of them are divided into two parts before they reach the rim of the stone, where they terminate with a back much more protuberant than the rest of the stone, though streaked in the same manner. There are also others met with that are not stones like the former, but consist of a fine stony earth, or hardened yellow clay; contrary to

the opinion of some authors, who affirm that they are all of the same consistence.

The OPHIOMORPHITES nearly resemble the former, and are so called from their being like serpents rolled up. Some of these are also found so soft, that it is easy to break them with the fingers; but there are others that consist of a hard bluish stone. They differ from these in their lines or furrows; for in the former the streaks are wider, and more open near the rim; but in some of these they are closer, and also united into pretty large protuberant knobs on each side the back of the stone, which in these is broad and somewhat rising, and is crossed by other crooked or curve lines that run between the eminences. There are other stones of this kind, that have only straight single ribs, which likewise terminate in straight ridges, that run on each side the back of the stone; between which there is a third that is more prominent, and might be taken for the spine of the back; however, it is not wreathed, but plain like those on each side of it. The largest of this kind in Oxfordshire was found at Langford, near Oxford, and is eleven inches over, and weighs seventeen pounds. The ribs are single, and there are no knobs or ridges at the back, which is plain and even.

The BELEMNITES are so called from the Greek word *Belemnion*, which signifies a dart, because they are nearly of that shape. Authors are not agreed in what class to place this stone. The shape is, however, sometimes conical, sometimes cylindrical, and they most commonly consist of a substance that is black and horny; the length is from two inches to eight, and the diameter from the sixth part of an inch to three or four inches in circumference. The inward parts consist of rays, and there is generally a cell at the large end, and a furrow that runs from the top to the bottom.

There are other stones that represent herbs and plants, among which are FUNGITES, or TUBEROIDES, so called from their resemblance to mushrooms: these are of an ash colour without, but a black flint within. Others resemble only the parts of plants, one of which has been met with like a root of briony broken off transversely, which shewed the small fibres that run from the centre to the circumference; as well as the other streaks that run down the sides, and the annular divisions. The colour also is so like that of briony, that it can hardly be distinguished from it, except by the weight. It was found in quarries of rubble-stone near Shotover-Hill in Oxfordshire.

There are other stones like the fruit of trees, some of which are called PYRIFORMES, from their likeness to pears: one of these was found of eleven inches in circumference, and in size and form resembling a king-pear. This was a black flint; but there is another that is whitish without, and yellow within, in the shape of a warden pear. Other stones have been found in the shape of apricots, with the cleft or furrow from the stalk to the top, exactly representing a real apricot; likewise there have been spars found resembling mulberries, and white flints in the shape of Lucca olives.

There are also stones in the shape of those belonging to fruits. Most of these have a kind of pedicle or stalk, from which they seem to have had their growth, and are ridged and furrowed the whole length of the stone. Their texture is very curious, they being made up of little thin plates, not unlike the stone called the Selenite, only they are opaque, and the bulk of the stone much different. The plates seem to be made up of strings, some of which run two ways, and others three, and according to their directions the stone will readily cleave; yet they are all oblique to the axis of the stone.

There are other stones that resemble animals either entirely or in part, among which there are some that seem to have been petrified reptiles, and very likely have been really such, which may easily be accounted for without the help of a flood. There are others that represent the shells of garden snails, and are very numerous. There are others called Worm-stones, which are of two sorts, and one of them is of a whitish yellow colour; but not hollow within; for they seem to be of the same texture with the pebble-stones among which they are found.

There are some stones that represent the parts of four-footed beasts; particularly in the quarries at Heddington there are some that are like the head of a horse, having the ears and crest of the mane, with the places of the eyes, as prominent as in a real horse; and the rest of the face entire, only the mouth and nose are wanting in them all. These are not uncommon, and they are of several sizes; though they are not taken notice of by any ancient authors. There are other stones in the form of hearts, and on account of their size are by authors called Bucardites, or stones like bulls hearts. They are of a whitish yellow colour, with a smooth plain surface; though there are some that are ribbed on each side; these are ten inches in circumference, and weigh about two pounds; and there have been some found that have weighed twice as much.

Dr. Plott met with some sort of stones in the quarries of the rubble-stone near Shotover, which were composed of filaments like hair; and which could not be the Polytrix of Pliny, because they are not greenish, nor the Bestrychites of Zoroaster, nor the Corsoides of Pliny, because they are neither grey nor long. However, it is a sort of Thrichites, because it is most like the short hair of beasts. The colour is yellowish, and each hair when viewed through a microscope appears to be streaked and furrowed throughout its whole length.

Some stones have been found accurately representing the combs of bees, with the cells of each cavity all hexangular, exactly like those of honeycombs. There was one stone found in a marl-pit that was very like a mole both in the head and tail, but more especially in the foot; it was so very exact that it was divided into claws, and represented the foot of that animal in all particulars. Some have been found so nearly resembling the head of an Owl, as almost to imitate life, having the eyes and beak of that animal very perfect. Another was of the shape and size of a partridge's skull, with the eyes and short beak, and was hollowed behind just as if the brains had been taken out: to these may be added still another, which was the accurate representation of a pullet's heart, with the fat near the basis thereof, and the coronary vessels descending from it most exactly delineated. All these are taken notice of by Dr. Plott.

There are some stones that seem to belong to the oviparous quadrupeds, among which is the Bufonites or Toad-stone. Authors acquaint us there are two kinds of these, the first of which are those that are called Brontixæ and Ombria, which are sometimes of a dusky reddish, yellowish or greenish colour, of the size of a hen's egg. From the flat or the concave side there generally runs five lines to the centre of the convex side, at equal distances, and marked with exceeding small tubercles.

There has been another stone found in the rubble-quarry near Shotover Hill, that is a lively representation of olfactory nerves entire and whole: many of these are of a yellowish colour, smooth without, and hollow within. Dr. Plott found another of an oval shape, and chiefly of a reddish colour; but at one end it had a circle of white within, which is a zone of the colour of the stone, and then a round pupil of white, so that it looked like an eye darkened by a cataract.

There

There are other stones, which resemble the ears of a man, though much less, and Dr. Plott calls them *Otites* or *Auriculares*; they are common in the rubble-quarries near Shotover, but more so in a bank near a spring at Somerton town's-end, eastward from the church. There are other stones met with in the shape of human breasts, having not only the nipple, but the areola studded with small protuberances, and therefore may be properly called *Mammillares*.

There are other stones, which exactly resemble the heart of a man, with the trunk of the descending part of the vena cava, as also the ascending part of the vein of the same name. Likewise from the left ventricle there proceeded the trunk of the great artery, and a portion of the same artery tending downwards. Within it appeared to be a whitish sort of flint, and certainly deserves the name of *Anthropocardites*.

Other stones have been found exactly representing the private parts of a man; and others in the shape of kidneys, with the trunk of one of the ureters descending from the hollow part of it. When found it was the colour of a kidney, and was so soft that it might be readily cut with a knife, that is, the part of it resembling an ureter; but in less than an hour's time it grew as hard as the rest of the stone. To this class may be added the *Triorchites*, or *Diorchites*, which resemble the testicles of man or beast.

Some stones have been met with in the shape of human bones; particularly one exactly resembling the lowermost part of the thigh-bone of a man, with the lower head; between which are the anterior and the larger posterior sinus, which is the seat of the strong ligament that rises out of the thigh, and that allows a passage to the vessels descending into the leg. A little above the sinus, where the bone seems to have been broken off, there is a shining spar-like substance, resembling marrow in the hollow of the bone. Its circumference near the head is exactly two feet, and at the top above the sinus about fifteen inches, and the weight is near twenty pounds; which shews that the bulk is too monstrous to have belonged to a man, though it is precisely of the same shape. With this there was found a tooth that weighed two ounces and a quarter; but it was not at all petrified, which perhaps may be owing to the nature of teeth, whose hardness and want of large pores do not so readily subject them to putrefaction: for the same reason in graves they are often found sound and good, when all the other parts have been consumed. Not far from Bath in Somersetshire, there have been hundreds of teeth picked up by those who followed the plough, though no other bones were met with to which they might have been supposed to belong. We are informed by Tazellus in his history of Sicily, that two large skeletons were found, which, when they came to be touched, all fell into dust, except the teeth called the grinders. What animal the thigh-bone above mentioned did belong to is hard to say, though some have taken it to be the bone of an elephant brought over by the Romans when they were masters of this kingdom. However, it does not appear from any authors, that those animals were ever brought over into Britain; and yet it cannot be denied that several have been brought over hither for public shews: but whether any died in Oxfordshire, and were there buried, must be left to the judgment of the reader.

There has been a great number of monstrous teeth found in different parts of England; and in Essex there were two met with in the reign of Richard I which were large enough to make two hundred each of the common size. One dug up near Maidstone in Kent was near seven inches in circumference, and weighed five ounces and one eighth. In the year

1666, after the fire of London, when St. Mary Woolchurch was pulled down, there was a thigh-bone found larger than the above-mentioned, which however was not turned to stone. There was also another found in London three feet and two inches long. After all, we may be certain that these bones did not belong to elephants, because they are of a quite different shape, which has been found by comparing them together; and therefore Dr. Plott was of opinion they belonged to men or women. To support his opinion, he takes notice of the sizes of the several giants that have been mentioned by authors; and he likewise mentions a giant in France, who lived there about two hundred years ago: this man was said to be so tall, that a man of a common stature might go upright between his legs.

Dr. Plott likewise takes notice of a stone found at the foot of Shotover Hill, which represents the leg and foot of a man cut off above the ankle, and which from the toe to the heel is about a yard long. However, he does not take this to be a petrification, but a stone formed in this shape by the plastic power of nature.

Besides these stones resembling the parts of animals, there are others not unlike things made by art. Among these are some of the shape of buttons, and others like the heel of an old shoe, with the lifts plainly distinguished from each other. One of the button stones was found at Teynton in Oxfordshire, pretty near resembling a hair button.

Other stones have been seen like the bags called the Sleeves of Hippocrates, made use of by the chemists; and there have been three one above another, as they usually place them. Others have been found in the shape of a whetstone; and some in that of a cap. There is another stone of an ash colour called *Trochites*, from its likeness to a wheel; for it has rays or spokes which proceed from the center, like those of a cart-wheel from its nave. Some of these are called *Entrochi*, or *Wheels within Wheels*; the rays of one of the *Trochites* being in relief, and always lying in the furrows between the two protuberances of the other, as in the sutures of a skull. The round part is smooth, and the nave is flat; from which, as in common wheels, the prominent rays proceed to the outward circumference, so as to leave furrows between them. They are joined together so curiously, that they seem to be the effect of art; for the spokes of one are inserted in the furrows of the other, so as to represent the sutures of a human skull. Sometimes there are twenty united together in this manner. When the *Entrochos* is smooth in every part, the spokes are prominent. These stones differ in colour from each other; for some are white, others ash-coloured, and others again yellow: they differ also in size, for the largest are near an inch broad, and about a third as much thick. It is found in Saxony, in the clefts of marble, of a whitish ash-colour.

The *Entrochi* of Staffordshire are much larger, longer, and consequently compounded of more *trochites*, than those of Yorkshire or Somersetshire; for some are three inches and a half in circumference, whose center or nave is half an inch over. One found in a rock was near six inches long, but it was so fast inclosed that it could not be got out entire. Some of two inches and a half long consisted of thirty-five *trochites*.

At Beresford, and other places in Staffordshire, there are stones that seem to be made up of thick *trochites*, that have no bore at all, nor any rays at the top proceeding from a solid centre; which is no wonder, because when they are broken they do not seem to consist of plates like the rest. There is another sort that seem to be made up of joints like the *Entrochi*, in which the *trochites* neither appear round nor square on their outermost rims, but sharp like

like the edge of a screw, tapering from the place of their joining, and are streaked on their surfaces; so that the rays of one do not enter into the furrows of the other, nor yet do the rays join to the centre at right angles; and this in these is a large cylinder of black flint. Neither are all these cylindrical as the former; for some of them taper upwards from a broad basis, the lowermost rims being greatest, and decreasing gradually to the top. Some of these are so different from the former, that they have a thin streaked plate passing from each rim to the sides of the cylindrical concavity; so that there appears a distinct concavity between each ring. Some again have others included within them, and appear like rings parallel to each other, and not like a screw, nor do the protuberant edges of the one enter into the furrows of the other, like the male and female screws.

Some sorts of these stones, that have such cavities, are in the form of five columns joined together without any addition; and others are bound by thin rings that stand pretty thick and at equal distances, which are not streaked. Some again are knit together by the same sort of rings, that are only in pairs, there being some distance between each pair; and others have four placed in the same manner. There is still another sort fenced in the same way, some of which are of an equal bigness from the bottom to the top, and are curiously wrought in small rings, first with two at some distance, and then with four close together; and so on alternately the whole length of the stone: but others, though like the former in other respects, are bigger both at the top and at the bottom, and resemble a pillar with a pedestal and capital. Lastly, there are some very small ones, that stand in cavities like straight smooth pillars, only they are marked with a row of knobs on each side; and there are others that look like so many buttons piled upon each other.

ASTERIÆ, or STAR-STONES, are found in several parts of the kingdom, and particularly in the fields about Cleydon in Oxfordshire. They consist of thin plates lying obliquely to the horizontal position, much after the manner of the Jews Stone; and the colour is various, according to the different soils in which they are found: for this reason, in Gloucestershire and Yorkshire, where they are taken out of a blue clay, they are nearly of the same colour, and break like flints with a dark shining surface. In Warwickshire, as well as in some parts of Gloucestershire, they are of an ash colour; and at Cleydon they are yellowish, because they are found in a yellowish earth. They are here about an inch and a half in length, and seldom less than an inch in circumference: and whereas in other countries they are so hard, that it is difficult, if at all possible, to separate one from another without spoiling them; yet if these are steeped in vinegar for a night, they may be divided the next morning with safety and ease. They likewise differ from those of other places in shape; for, besides the sculpture that makes up the angles, there is the representation of a rose in the middle thereof, which is not commonly seen in those found elsewhere.

Many of the longest jointed Star-Stones have some of their joints a little broader and more prominent than others, dividing the whole body as it were into certain conjugations of two, three, or more joints, which, as Dr. Lister observes, are marked with sets of wires, as he calls them.

The Star-Stones found in Staffordshire are exactly of the same shape, in which stars are commonly painted; for they have all five principal rays of an equal length, shape, and make, and proceeding from the centre, which is either solid or hollow, and where they join in angles of seventy-two degrees. They differ somewhat from each other in the dif-

ferent places where they are found, as also from those in Oxfordshire, as well as from those taken notice of by Dr. Lister in the Philosophical Transactions; for though they are placed on each other in columns, and seem to be fragments, some having three, four, or more joints, yet none of them seem to be made up of plates lying obliquely to the horizontal position of the star; and some of them have their angles so very acute, and consequently their sides so deeply furrowed, that they seem to represent the rowel of a spur, without any sculpture or indented future; but when there is any such, they are of a quite different kind from those already mentioned.

The first sort are placed in a case of a flinty kind of stone, consisting of five angles; and the rays proceed from a solid centre, of a coal-black colour, not bigger than a common pin; yet they are evidently of a flat figure, consisting of five angles; though the angles of the inner one do not point against the sharp rays of the outer, but against the deep furrows between them; however, they are both smoothly jointed, without any hatching or engraving.

The second sort consists of a flat and not hollow-sided piece, such as Dr. Lister has described in the Philosophical Transactions; and the hatchings thereof are very different from all his. There is one principal ray which extends itself from the centre to the extremity of each angle, with oblique lines proceeding upwards therefrom, in such a manner that they in some sense represent so many boughs of a tree.

The third kind has also flat sides; but the joints are all unequal, one of them being always more protuberant than the next, and so alternately throughout the whole column. It consists of twelve joints, and the hollow of each angle is neither hatched on the top, nor is the column bent, or the least inclining, as those commonly are which are of a greater length. These have the property of moving in vinegar, like the former; and this property seems to have been known to Roger Bacon near five hundred years ago; for in one of his epistles he affirms they would run in vinegar.

The ASTROITES are a kin to the Asteriæ, and are of different sizes, but are adorned all over with many stars; and there are no less than four different kinds found in Oxfordshire, in two whereof the stars are in mezzo-relievo, they being prominent and standing outwards, with the streaks descending from the center at the top and all sides to the rock on which they grow. Some of these are of a larger and others of a smaller kind, which are both found in the quarries of rubble-stone. There is a third sort, which are more beautiful than the rest, and are deeply engraved like a seal, and streaked from the prominent edges above, to a centre in the bottom. These are generally hexagons, and sometimes pentagons; and yet they agree with the former in this, that the stars are only superficial, and not found in the body of the stone.

The fourth sort has been imperfectly described by Gesner, and after him by several others. The streaks of these are like the third sort, descending in a concave; but from the edges are generally round, or with five angles at the top, and tend to a center, but not of their own kind, for they are smooth and apparently prominent. They are found in quarries of rubble-stone, and are stellated, not only on the surface of the stone, but quite through the depth thereof; yet not so as to have one continued star reach through the whole, but many, according to the thickness of the stone; for about ten of them lie in the depth of an inch, much after the same manner as the star-stones; only they are not separate, but join together, and make as it were so many rows

of the stone. Some of these are so large in France, that they have been there used for the building of walls and houses; but with us they are generally employed in paving causeways, particularly in Oxfordshire.

The property of moving in vinegar is common both to the Asteriæ and the Astroids; though the Asteriæ will move not only in a whole joint, but two or three connected together; whereas the Astroids must be broken into very small pieces before they will move. The Asteriæ has not only a progressive motion, but will turn round in vinegar, and will stir more briskly and longer than any other stone that vinegar has the like effect upon; and though it has been steeped therein for three or four days, yet when fresh is poured upon it, it will still emit a great many little bubbles as at first from underneath it, and at the instant it begins to move.

Linnæus places the LAPIS JUDAICUS, or JEW'S STONE, among petrifications; and Boet informs us that it is in the shape of an olive, and is roundish, tender, and brittle, with streaks that run according to the length, and placed at equal distances, as if they were done by art. The colour is whitish, or a faint ash colour, shining within, and it may be obliquely cloven into foliaceous plates. It is called a Jew's Stone, because it has been found in Judæa, and other parts of Syria; but some of these have been found in England, particularly in Oxfordshire, which are of a more slender and longer shape than any sort of olive. Some are about two inches in length, and an inch and a half in circumference; but others have been met with less than an inch long, and not much above half an inch round. Most of them have a kind of pedicle or stalk, from which they seem to have had their growth, and there are ridges or furrows through the whole length of the stone. The ridges are marked with small knots, in four points placed in a square, and a fifth in the middle. Their texture is very curious, for they consist of thin plates, as above, not unlike the felenites, only they are opaque.

Linnæus likewise places CORAL, Madrepore, and the like, among petrifications: and he calls them Lithophytes, though they have been commonly placed among sea plants. Those of the Coral kind are a little flexible, like wood; when in the water, and to a small degree when out of it; but they may be reduced into powder like chalk. There are a great many of this kind, which resemble small trees without leaves: others are in the form of a net, sometimes with large meshes, and sometimes with small. The inside of the branches seem to be of the nature of horn; for it has the same smell when put into the fire: but the bark is of a stony nature, and contains a great deal of salt. Coral, properly so called, is of a stony nature, and is placed in the animal kingdom, because it produces sea insects. Some of these are red, and others white, and others of various colours. However, the red, of the colour of vermillion, is best, and is by some said to be of the male kind, and that which is palish of the female. The white Coral is the next in value, and then the black; but those of the other colours some will not allow to be Corals, though they are found in the same places. It is always covered with a bark, and is stony, solid, and very hard, even in the water; though the branches are a little flexible, but soon grow hard in the air. The bark of Coral is a mixture of tartar and a fluid of a gluey nature; and though it is a little rough, it takes a very fine polish. Some take the black Coral to be the sea plant of a different nature.

Red Coral is not so much esteemed in Europe as it is in Asia, and particularly in Arabia. It is used for making several sorts of toys, such as spoons, heads of canes, knife-handles, sword-hilts, and

beads; and, when set in silver, it serves as a plaything for children, and is designed to rub their gums therewith, that they may breed their teeth more easily.

On the young branches of Coral there are found small eminences, pierced in the form of stars, and full of a milky fluid when they are just taken out of the water. Many learning men have thought sea plants to be nothing but petrifications, consisting of plates of salt, and layers of tartar, placed one upon another; and as coral always grows with its head downwards, in caverns of rocks in the sea, the situation has caused them to suspect that they were nothing else but petrifications like those found on the roofs of certain caves in the rocks. But since the discovery of the flowers of coral, and some other marine productions, it is not at all doubted but they have a regular organization; and if their seeds have not yet been perceived, it is because their smallness renders them imperceptible.

But some have thought that the generation of these plants is not owing to these seeds; because, as they always hang with their heads downwards, they would fall off to the bottoms of the caverns, and not place themselves on the top; but this difficulty may be removed, by supposing they are lighter than the sea water, and that the milk which surrounds them is of so thick a nature, that it may help to assist them in swimming. Hence indeed it may happen, that many of them may rise to the top of the water, and there perish; but then likewise others may ascend to the top of the caverns, and there fix themselves, and then they will grow like the coral from which they proceed. Hence we may conclude, from the regularity of these productions, the organization of their parts, the great numbers of small pores in their bark to receive the bitumen and other sea juices, the eminences regularly hollowed in the form of stars, which serve for the cases of flowers in the same shape, the vessels full of a milky fluid which is found between the bark and the body of the plant, to make it grow thicker by little and little, and the perpetual uniformity of the same circumstances; we say, from all these particularities we have reason to believe, that the bottom of the sea is covered with plants, with characteristics different from ours. In Spain they have a particular sort of a machine for the getting of Coral, particular at a promontory in Catalonia. This is a wooden cross which is very large, and in the centre there is a wooden ball of a great weight, to which a very long and thick rope is fastened. At each end of the cross they hang a net in the form of a bag, which being let down into the sea, there are proper persons, who know where the Coral is to be found, and have the care of managing the rope. They guide one or more ends of the cross into the caverns, and then the nets lay hold of the Coral, break it off, and let it fall into the hollow part of the net; and when they have got as much as can well be contained in each of them, the machine is drawn up. The Red Coral is only chosen for medicinal uses, and many authors have ascribed great virtues thereto, which are in a great measure imaginary; however, it cannot be denied that it is a good absorbent, and therefore is proper to restrain the orgasm of the blood, and to blunt the acrimony of the bile and other humours in various sorts of fluxes, as well as for the gripes in children. Its dose is from a scruple to a drachm.

The MADREPORE has no bark like the former, but it is branched like it, though the branches are not so numerous. There are several sorts of them, and some are only a thick plate of a hardish stony matter, pierced with a great number of holes or pores, which are disposed in the form of small pipes, waves, stars, and other figures; but it is most commonly in the shape of a small tree, and the branches

are

are always full of holes or pores. It is found in various parts of the world, but no where in such great plenty as near the Caribbee islands.

There are several sorts of them, as the stellular Madreporé akin to Coral; the branched Madreporé akin to Coral; the Madreporé or Milleporé of Tournefort; the common Madreporé or fistulous white Coral; the Madreporé like southernwood; the warty-pointed Madreporé, by some called the water-pointed white Coral; and the white stellular Madreporé.

Though Madreporé is generally found growing in the sea, yet it is sometimes found on the tops of mountains: that met with by Jussieu on Mount Chaumont in Normandy was porous, light, white, and in all respects like the common Madreporé. It is, like most petrifications, alkaline and absorbent, and has much the same virtues as Coral. In fluxes of the belly, the dose is from half a scruple to two scruples.

We cannot conclude this History of Minerals, &c. without paying that just tribute, which is due to the wise Author of Nature, who has not only provided man with every thing that is necessary either for his

use or amusement, but has furnished him with reason to enquire into their various properties. The beasts of the field either assist him in the ease of this labour, or supply him with the most nourishing food; the inhabitants of the air above him, and those of the waters beneath, furnish his table with the most delicate repasts; the earth affords him the most wholesome vegetables, which preserve the temperature of his body, and relieve those disorders which arise from too free a use of grosser food; beneath his feet, and deep in the bowels of the earth, inexhaustible treasures lie hid, such as gold, silver, and the most precious jewels; iron, to secure him in his habitation from assassination and plunder, and to make him every kind of instrument indispensibly necessary in agriculture, navigation, and mechanical arts. Vain indeed is the attempt to enumerate, in a few lines, those wonders of the creation! Let us, however, from what we have read, draw this conclusion, that, in proportion as we increase our knowledge of natural causes, the more elevated idea shall we have of him, who is the author of them all.

A

NEW, COMPLETE, and UNIVERSAL BODY, or SYSTEM of

NATURAL HISTORY;

Being a Grand, Accurate and Extensive

Display of Animated Nature.

B O O K VI.

Containing the THEORY of the EARTH in general.

THE general history of the Earth, is a necessary study for those who desire to make themselves acquainted with nature and her productions, and the detail of singular circumstances of the life and manners of animals, or of the culture and vegetation of plants, belong perhaps, less to natural history than to the general results of observations made on the different matters which compose the terrestrial globe; the eminences, depths, and inequalities of its form, the motion of the sea, the direction of mountains, the position of quarries, the rapidity and effects of currents, &c. This is nature in its ample extent, and these are her principal operations; they influence all the rest, and the theory of these effects is a first science of which the intelligence of particular phenomena, as well as the exact knowledge of terrestrial substances depends.

C H A P. I.

Containing a Sketch of the UNIVERSE.

THE world may be considered as one vast mansion, where man has been admitted to enjoy, to admire, and to be grateful. The first desires of savage nature are merely to gratify the importunities of sensual appetite, and to neglect the contemplation of things, barely satisfied with their enjoyment: the beauties of nature, and all the wonders of creation, have but little charms for a being taken up in obviating the wants of the day, and anxious for precarious subsistence.

Philosophers, therefore, who have testified such surprize at the want of curiosity in the ignorant, seem not to consider that they are usually employed in making provisions of a more important nature; in providing rather for the necessities than the amusements of life. It is not till our more pressing wants are sufficiently supplied, that we can attend to the calls of curiosity; so that in every age scientific refinement has been the latest effort of human industry.

But human curiosity, though at first slowly excited, being at last possessed of leisure for indulging its propensity, becomes one of the greatest amusements of life, and gives higher satisfactions than what even the senses can afford. A man of this disposition turns all nature into a magnificent theatre, replete with objects of wonder and surprize, and fitted up chiefly for his happiness and entertainment: he industriously examines all things, from the minutest insect to the most finished animal; and when his limited organs can no longer make the disquisition, he sends out his imagination upon new enquiries.

Nothing, therefore, can be more august and striking than the idea which his reason, aided by his imagination, furnishes of the universe around him. Astronomers tell us, that this earth which we inhabit forms but a very minute part in that great assemblage of bodies of which the world is composed. It is a million of times less than the sun, by which it is enlightened. The planets also, which like it, are subordinate to the sun's influence, exceed the earth a thousand times in magnitude. These, which were at first supposed to wander in the heavens without any fixed path, and took their name from their apparent deviations, have long been found to perform their circuits with great exactness and strict regularity. They have been discovered as forming with our earth a system of bodies circulating round the sun, all obedient to one law, and impelled by one common influence.

Modern philosophy has taught us to believe that, when the great Author of nature began the work of creation, he chose to operate by second causes; and, that, suspending the constant exertion of his power, he endued matter with a quality by which the universal œconomy of nature might be continued, without his immediate assistance. This quality is called attraction; a sort of approximating influence, which all bodies, whether terrestrial or celestial, are found to possess; and which in all increases as the quantity of matter in each increases. The sun, by far the greatest body in our system, is, of consequence, possessed of much the greatest share

of this attracting power; and all the planets of which our earth is one, are of course, entirely subject to its superior influence. Were this power, therefore, left uncontrouled by any other, the sun must quickly have attracted all the bodies of our celestial system to itself; but it is equably counteracted by another power of equal efficacy; namely a progressive force which each planet received when it was impelled forward, by the divine architect, upon its first formation. The heavenly bodies of our system being thus acted upon by two opposing powers; namely, by that of attraction, which draws them towards the sun; and that of impulsion, which drives them strait forward into the great void of space; they pursue a track between these contrary directions; and each like a stone whirled about in a sling, obeying two opposite forces, circulates round its great centre of heat and motion.

In this manner, therefore, is the harmony of our planetary system preserved. The sun, in the midst, gives heat, and light, and circular motion to the planets which surround it: Mercury, Venus, the Earth, Mars, Jupiter, and Saturn, perform their constant circuits at different distances, each taking up a time to complete its revolutions proportion to the greatness of the circle which it is to describe. The lesser planets also, which are attendants upon some of the greater, are subject to the same laws; they circulate with the same exactness; and are, in the same manner, influenced by their respective centres of motion.

Besides those bodies which make a part of our peculiar system, and which may be said to reside within its great circumference; there are others, that frequently come among us, from the most distant tracts of space, and that seem like dangerous intruders upon the beautiful simplicity of nature. These are comets, whose appearance was once so terrible to mankind, the theory of which is better understood at present: we know that their number is much greater than that of the planets; and that, like these, they roll in orbits, in some measure, obedient to solar influence. Astronomers have endeavoured to calculate the returning periods of many of them; but experience has not, as yet, confirmed the veracity of their investigations; indeed, who can tell when those wanderers have made their excursions into other worlds and distant systems, what obstacles may be found to oppose their progress, to accelerate their motions, or retard their return?

But what we have hitherto attempted to sketch, is but a small part of that great fabric in which the Deity has thought proper to manifest his wisdom and omnipotence. There are multitudes of other bodies dispersed over the face of the heavens, that lie too remote for examination: these have no motion, such as the planets are found to possess, and are therefore, called fixed stars; and from their extreme brilliancy and their immense distance, philosophers have been induced to suppose them to be suns resembling that which enlivens our system; as the imagination also, once excited, is seldom content to stop, it has furnished each with an attendant system of planets belonging to itself, and has even induced some to deplore the fate of those systems, whose imagined suns, which, sometimes happens, have become no longer visible.

But conjectures of this kind, which no reasoning can ascertain, nor experiment reach, are rather amusing than useful. Though we see the greatness and wisdom of the Deity in all the seeming worlds that surround us, it is our chief concern to trace him in that which we inhabit. The examination of the earth, the wonders of its contrivance, the history of its advantages, or of the seeming defects in its formation, are the proper business of the natural historian. A description of this earth, its animals,

vegetables, and minerals, is the most delightful entertainment the mind can be furnished with, as it is the most interesting and useful. We would beg leave, therefore, to conclude these common-place speculations, with an observation, which is not entirely so.

An use, hitherto not much insisted upon, that may result from the contemplation of celestial magnificence, is, that it will teach us to make an allowance for the apparent irregularities we find below. Whenever we can examine the works of the Deity at a proper point of distance, so as to take in the whole of his design, we see nothing but uniformity, beauty, and precision. The heavens present us with a plan, which, though inexpressibly magnificent, is yet regular beyond the power of invention. Whenever, therefore, we find any apparent defects in the earth, which we are about to consider, instead of attempting to reason ourselves into an opinion that they are beautiful, it will be wise to say, that we do not behold them at the proper point of distance, and that our eye is laid too close to the objects to take in the regularity of their connexion. In short, we may conclude that God, who is regular in his great productions, acts with equal uniformity in the little.

CHAP. II.

Containing a short Survey of the GLOBE, from the light of Astronomy and Geography.

ALL the sciences are in some measure linked with each other, and before the one is ended the other begins. In a natural history, therefore of the earth, we must begin with a short account of its situation and form, as given us by astronomers and geographers: it will be sufficient however, upon this occasion, just to hint to the imagination, what they, by the most abstract reasonings, have forced upon the understanding. The earth we inhabit is, as has been said before, one of those bodies which circulate in our solar system; it is placed at an happy middle distance from the centre; and even seems in this respect, privileged beyond all other planets that depend upon our great luminary for their support. Less distant from the sun than Saturn, Jupiter, and Mars, and yet less parched up than Venus and Mercury, that are situated too near the violence of its power, the earth seems in a peculiar manner to share the bounty of the Creator: it is not, therefore, without reason, that mankind consider themselves as the peculiar objects of his providence and regard.

Besides that motion which the earth has round the sun, the circuit of which is performed in a year, it has another upon its own axle, which it performs in twenty-four hours. Thus like a chariot-wheel, it has a compound motion; for while it goes forward on its journey, it is at the same time turning upon itself. From the first of these two arise the grateful vicissitude of the seasons; from the second, that of day and night.

It may be also readily conceived that a body thus wheeling in circles will most probably be itself a sphere. The earth, beyond all possibility of doubt, is found to be so. Whenever its shadow happens to fall upon the moon, in an eclipse, it appears to be always circular, in whatever position it is projected: and it is easy to prove, that a body which in every position makes a circular shadow, must itself be round. The rotundity of the earth may be also proved from the meeting of two ships at sea: the top-mast of each are the first parts that are discovered by both, the under parts being hidden by the convexity of the globe which rises between them. The ships in this instance may be resembled to two

men who approach each other on the opposite sides of an hill: their heads will first be seen, and gradually as they come nearer they will come intirely into view.

However, though the earth's figure is said to be spherical, we ought only to conceive it as being nearly so. It has been found in the last age to be rather flatted at both poles, so that its form is commonly resembled to that of a turnep. The cause of this swelling of the equator is ascribed to the greater rapidity of the motion with which the parts of the earth are there carried round; and which, consequently, endeavouring to fly off, act in opposition to central attraction. The twirling of a mop may serve as an homely illustration; which, as every one has seen, spreads and grows broader in the middle as it continues to be turned round.

As the earth receives light and motion from the sun, so it derives much of its warmth and power of vegetation from the same beneficent source. However, the different parts of the globe participate of these advantages in very different proportions, and accordingly put on very different appearances; a polar prospect, and a landscape at the equator, are as opposite in their appearances as in their situation.

The polar regions, that receive the solar beams in a very oblique direction, and continue for one half of the year in night, receive but few of the genial comforts which other parts of the world enjoy. Nothing can be more mournful or hideous than the picture which travellers present of those wretched regions. The ground, which is rocky and barren, rears itself in every place in lofty mountains and inaccessible cliffs, and meets the mariner's eye at forty leagues from shore. These precipices, frightful in themselves, receive an additional horror from being constantly covered with ice and snow, which daily seem to accumulate and to fill all the vallies with increasing desolation. The few rocks and cliffs, that are bare of snow, look at a distance of a dark brown colour, and quite naked. Upon a nearer approach, however, they are found replete with many different veins of coloured stone, here and there spread over with a little earth, and a scanty portion of grass and heath. The internal parts of the country are still more desolate and deterring. In wandering through these solitudes, some plains appear covered with ice, that, at first glance, seem to promise the traveller an easy journey. But these are even more formidable and more unpassable than the mountains themselves, being cleft with dreadful chasms, and every where abounding with pits that threaten certain destruction. The seas that surround these inhospitable coasts, are still more astonishing, being covered with flakes of floating ice, that spread like extensive fields, or that rise out of the water like enormous mountains. These, which are composed of materials as clear and transparent as glass, assume many strange and fantastic appearances. Some of them look like churches or castles, with pointed turrets; some like ships in full sail; and people have often given themselves the fruitless toil to attempt piloting the imaginary vessels into harbour. There are still others that appear like large islands, with plains, valleys, and hills, which often rear their heads two hundred yards above the level of the sea; and although the height of these be amazing, yet their depth beneath is still more so; some of them being found to sink three hundred fathom under water.

The earth presents a very different appearance at the equator, where the sun-beams, darting directly downwards, burn up the lighter soils into extensive sandy deserts, or quicken all the moister tracts with incredible vegetation. In these regions, almost all the same inconveniencies are felt from the proxi-

mity of the sun, that in the former were endured from its absence. The deserts are intirely barren, except where they are found to produce serpents, and in such quantities, that some extensive plains seem almost entirely covered with them.

It not unfrequently happens also that this dry soil, which is so parched and comminuted by the force of the sun, rises with the smallest breeze of wind; and the sands being composed of parts almost as small as those of water, they assume a similar appearance, rolling onward in waves like those of a troubled sea, and overwhelming all they meet with inevitable destruction. On the other hand, those tracts which are fertile, teem with vegetation even to a noxious degree. The grass rises to such an height as often to require burning; the forests are impassable from underwoods, and so matted above, that even the sun, fierce as it is, can seldom penetrate. These are so thick as scarce to be extirpated; for the tops being so bound together by the climbing plants that grow round them, though an hundred should be cut at the bottom, yet not one would fall, as they mutually support each other. In these dark and tangled forests, beasts of various kinds, insects in astonishing abundance, and serpents of surprising magnitude, find a quiet retreat from man, and are seldom disturbed except by each other.

In this manner the extremes of our globe seem equally unfitted for the comforts and conveniencies of life; and, although the imagination may find an awful pleasure in contemplating the frightful precipices of Greenland, or the luxurious verdure of Africa, yet true happiness can only be found in the more moderate climates, where the gifts of nature may be enjoyed without incurring danger in obtaining them.

It is in the temperate zone, therefore, that all the arts of improving nature, and refining upon happiness, have been invented: and this part of the earth is, more properly speaking, the theatre of natural history. Although there be millions of animals and vegetables in the unexplored forests under the line, yet most of these may for ever continue unknown, as curiosity is there repressed by surrounding danger. But it is otherwise in these delightful regions which we inhabit, and where this art has had its beginning. Among us there is scarce a shrub, a flower, or an insect, without its particular history; scarce a plant that could be useful which has not been propagated; nor a weed that could be noxious which has not been pointed out.

CHAP. III.

Containing a View of the Surface of the EARTH.

IF we take a slight survey of the surface of our globe, a thousand objects offer themselves, which, though long known, yet still demand our curiosity. The most obvious beauty that every where strikes the eye is the verdant covering of the earth, which is formed by an happy mixture of herbs and trees of various magnitudes and uses. It has been often remarked that no colour refreshes the sight so much as green; and it may be added, as a further proof of the assertion, that the inhabitants of those places where the fields are continually white with snow, generally become blind long before the usual course of nature.

This advantage, which arises from the verdure of the fields, is not a little improved by their agreeable inequalities. There is scarce two natural landscapes that offer prospects entirely resembling each other; their risings and depressions, their hills and valleys, are never entirely the same, but always offer

fer something new to entertain and refresh the imagination.

But to increase the beauties of the face of nature; the landscape is enlivened by springs and lakes, and intersected by rivulets. These lend a brightness to the prospect; give motion and coolness to the air; and, what is much more important, furnish health and subsistence to animated nature.

Such are the most obvious and tranquil objects that every where offer: but there are objects of a more awful and magnificent kind; the Mountain rising above the clouds, and topt with snow; the River pouring down its sides, increasing as it runs, and losing itself, at last, in the ocean; the Ocean spreading its immense sheet of waters over one half of the globe, swelling and subsiding at well-known intervals, and forming a communication between the most distant parts of the earth.

If we leave those objects that seem to be natural to our earth, and keep the same constant tenor, we are presented with the great irregularities of nature. The burning mountain; the abrupt precipice; the unfathomable cavern; the headlong cataract; and the rapid whirlpool.

If we carry our curiosity a little further, and descend to the objects immediately below the surface of the globe, we shall there find wonders still as amazing. We first perceive the earth for the most part lying in regular beds or layers, every bed growing thicker in proportion as it lies deeper, and its contents more compact and heavy. We shall find, almost wherever we make our subterranean enquiry, an amazing number of shells that belonged to aquatic animals. Here and there, at a distance from the sea, beds of oyster-shells, several yards thick, and many miles over; sometimes testaceous substances of various kinds on the tops of mountains, and often in the heart of the hardest marble. These, which are dug up by the peasants, in every country, are regarded with little curiosity; for being so very common, they are considered as substances entirely terrene. But it is otherwise with the enquirer after nature, who finds them, not only in shape but in substance, every way resembling those that are found in the sea; and he, therefore, is at a loss to account for their removal.

Yet not one part of nature alone, but all her productions and varieties, become the object of the speculative man's enquiry: he takes different views of nature from the inattentive spectator; and scarce an appearance, how common soever, but affords matter for his contemplation: he enquires how and why the surface of the earth has those risings and depressions which most men call natural; he demands in what manner the mountains were formed, and in what consist their uses; he asks from whence springs arise, and how rivers flow round the convexity of the globe; he enters into an examination of the ebbings and flowings, and the other wonders of the deep; he acquaints himself with the irregularities of nature, and endeavours to investigate their causes; by which, at least, he will become better versed in their history. The internal structure of the globe becomes an object of his curiosity; and, although his enquiries can fathom but a very little way, yet, if possessed with a spirit of theory, his imagination will supply the rest. He will endeavour to account for the situation of the marine fossils that are found in the earth, and for the appearance of the different beds of which it is composed. These have been the enquiries that have splendidly employed many of the philosophers of the last and present age; and, to a certain degree, they must be serviceable. But the worst of it is, that, as speculations amuse the writers more than facts, they may be often carried to an extravagant length; and that time may be spent in reasoning

upon nature, which might be more usefully employed in writing her history.

Too much speculation in natural history is certainly wrong; but there is a defect of an opposite nature that does much more prejudice; namely, that of silencing all enquiry, by alledging the benefits we receive from a thing, instead of investigating the cause of its production. If we enquire how a mountain came to be formed, such a reasoner, enumerating its benefits, answers, because God knew it would be useful. If we demand the cause of an earthquake, he finds some good produced by it, and alledges that as the cause of its explosion. Thus such an enquirer has some ready reason for every appearance in nature, which serves to swell his periods, and give splendor to his declamation: every thing about him is, on some account or other, declared to be good; and he thinks it presumption to scrutinize its defects, or endeavour to imagine how it might be better. Such writers, and there are many such, add very little to the advancement of knowledge. It is finely remarked by Bacon, that the investigation of final causes is a barren study; and, like a virgin dedicated to the Deity, brings forth nothing. In fact, those men who want to compel every appearance and every irregularity in nature into our service, and expatiate on their benefits, combat that very morality which they would seem to promote. God has permitted thousands of natural evils to exist in the world, because it is by their intervention that man is capable of moral evil; and he has permitted that we should be subject to moral evil, that we might do something to deserve eternal happiness by shewing we had recititude to avoid it.

CHAP. IV.

A Review of the different THEORIES of the EARTH.

HUMAN invention has been exercised for several ages to account for the various irregularities of the earth. While those philosophers mentioned in the last chapter see nothing but beauty, symmetry, and order; there are others, who look upon the gloomy side of nature, enlarge on its defects, and seem to consider the earth, on which they tread, as one scene of extensive desolation. Beneath its surface they observe minerals and waters confusedly jumbled together; its different beds of earth irregularly lying upon each other; mountains rising from places that once were level; and hills sinking into vallies; whole regions swallowed by the sea, and others again rising out of its bosom: all these they suppose to be but a few of the changes that have been wrought in our globe; and they send out the imagination to describe its primæval state of beauty.

Of those who have written theories describing the manner of their original formation of the earth, or accounting for its present appearances, the most celebrated are Burnet, Whiston, Woodward, and Buffon. As speculation is endless, so it is not to be wondered that all these differ from each other, and give opposite accounts of the several changes, which they suppose our earth to have undergone. As the systems of each have had their admirers, it is, in some measure, incumbent upon the natural historian to be acquainted, at least, with their outlines; and, indeed, to know what others have even dreamed, in matters of science, is very useful, as it may often prevent us from indulging similar delusions ourselves, which we should never have adopted, but because we take them to be wholly our own. However, as entering into a detail of these theories,

ries, is rather furnishing an history of opinions than things, we will endeavour to be as concise as possible.

The first who formed this amusement of earth-making into system, was the celebrated Thomas Burnet, a man of polite learning and rapid imagination. His Sacred Theory, as he calls it, describing the changes which the earth has undergone, or shall hereafter undergo, is well known for the warmth with which it is imagined, and the weakness with which it is reasoned, for the elegance of its style, and the meanness of its philosophy. "The earth," says he, "before the deluge, was very differently formed for what it is at present: it was at first a fluid mass; a chaos composed of various substances, differing both in density and figure: those which were most heavy sunk to the centre, and formed in the middle of our globe an hard solid body; those of a lighter nature remained next; and the waters, which were lighter still, swam upon its surface, and covered the earth on every side. The air, and all those fluids which were lighter than water, floated upon this also; and in the same manner encompassed the globe; so that between the surrounding body of waters, and the circumambient air, there was formed a coat of oil, and other unctuous substances, lighter than water. However, as the air was still extremely impure, and must have carried up with it many of those earthy particles with which it once was intimately blended, it soon began to defecate, and to depose these particles upon the oily surface already mentioned, which soon uniting, the earth and oil formed that crust, which soon became an habitable surface, giving life to vegetation, and dwelling to animals.

"This imaginary antideluvian abode was very different from what we see it at present. The earth was light and rich; and formed of a substance entirely adapted to the feeble state of incipient vegetation: it was an uniform plain, every where covered with verdure; without mountains, without seas, or the smallest inequalities. It had no difference of seasons, for its equator was in the plain of the ecliptic, or, in other words, it turned directly opposite to the sun, so that it enjoyed one perpetual and luxuriant spring. However, this delightful face of nature did not long continue in the same state; for, after a time, it began to crack and open in fissures: a circumstance which always succeeds when the sun exhales the moisture from rich or marshy situations. The crimes of mankind had been for some time preparing to draw down the wrath of Heaven; and they, at length, induced the Deity to defer repairing these breaches in nature. Thus the chasms of the earth every day became wider, and, at length, they penetrated to the great abyss of waters; and the whole earth, in a manner, fell in. Then ensued a total disorder in the uniform beauty of the first creation, the terrene surface of the globe being broken down: as it sunk the waters gushed out in its place; the deluge became universal; all mankind, except eight persons, were destroyed, and their posterity condemned to toil upon the ruins of desolated nature."

It only remains to mention the manner in which he relieves the earth from this universal wreck, which would seem to be as difficult as even its first formation. "These great masses of earth falling into the abyss, drew down with them vast quantities also of air; and by dashing against each other, and breaking into small parts by the repeated violence of the shock, they, at length, left between them large cavities filled with nothing but air. These cavities naturally offered a bed to receive the influent waters; and in proportion as they filled, the face of the earth became once more visible. The higher parts of its broken surface, now become the tops of mountains, were the first that appeared; the

plains soon after came forward, and, at length, the whole globe was delivered from the waters, except the places in the lowest situations; so that the ocean and the seas are still a part of the ancient abyss that have not had a place to return. Islands and rocks are fragments of the earth's former crust; kingdoms and continents are larger masses of its broken substance; and all the inequalities that are to be found on the surface of the present earth, are owing to the accidental confusion into which both earth and waters were then thrown."

The next theorist was Woodward, who, in his Essay towards a Natural History of the Earth, which was only designed to precede a greater work, has endeavoured to give a more rational account of its appearances; and was, in fact, much better furnished for such an undertaking than any of his predecessors, being one of the most assiduous naturalists of his time. His little book, therefore, contains many important facts, relative to natural history, although his system may be weak and groundless.

He begins by asserting that all terrene substances are disposed in beds of various natures, lying horizontally one over the other, somewhat like the coats of an onion; that they are replete with shells, and other productions of the sea: these shells being found in the deepest cavities, and on the tops of the highest mountains. From these observations, which are warranted by experience, he proceeds to observe, that these shells and extraneous fossils are not productions of the earth, but are all actual remains of those animals which they are known to resemble; that all the beds of the earth lie under each other, in the order of their specific gravity; and that they are disposed as if they had been left there by subsiding waters. All these assertions he affirms with much earnestness, although daily experience contradicts him in some of them; particularly we find layers of stone often over the lightest soils, and the softest earth under the hardest bodies. However, having taken it for granted, that all the layers of the earth are found in the order of their specific gravity, the lightest at the top, and the heaviest next the centre, he consequently asserts, and it will not improbably follow, that all the substances of which the earth is composed, were once in an actual state of dissolution. This universal dissolution he takes to have happened at the time of the flood. He supposes that at that time a body of water, which was then in the centre of the earth, uniting with that which was found on the surface, so far separated the terrene parts as to mix altogether in one fluid mass; the contents of which afterwards sinking according to their respective gravities, produced the present appearances of the earth. Being aware, however, of an objection that fossile substances are not found dissolved, he exempts them from this universal dissolution, and, for that purpose, endeavours to shew that the parts of animals have a stronger cohesion than those of minerals; and that, while even the hardest rocks may be dissolved, bones and shells may still continue entire.

So much for Woodward; but of all the systems which were published respecting the earth's formation, that of Whiston was most applauded, and most opposed. Nor need we wonder; for being supported with all the parade of deep calculation, it awed the ignorant, and produced the approbation of such as would be thought otherwise, as it implied a knowledge of abstruse learning, to be even thought capable of comprehending what the writer aimed at. In fact, it is not easy to divest this theory of its mathematical garb; but those who have had leisure, have found the result of our philosopher's reasoning to be thus. He supposes the earth to have been originally a comet; and he considers the history

tory of the creation, as given us in scripture, to have its commencement just when it was, by the hand of the Creator, more regularly placed as a planet in our solar system. Before that time, he supposes it to have been a globe without beauty or proportion; a world in disorder; subject to all the vicissitudes which comets endure; some of which have been found, at different times, a thousand times hotter than melted iron; at others, a thousand times colder than ice. These alternations of heat and cold, continually melting and freezing the surface of the earth, he supposes to have produced, to a certain depth, a chaos entirely resembling that described by the poets, surrounding the solid contents of the earth, which still continued unchanged in the midst, making a great burning globe of more than two thousand leagues in diameter. This surrounding chaos, however, was far from being solid: he resembles it to a dense though fluid atmosphere, composed of substances mingled, agitated, and shocked against each other; and in this disorder he describes the earth to have been just at the eve of creation.

But upon its orbit's being then changed, when it was more regularly wheeled round the sun, every thing took its proper place; every part of the surrounding fluid then fell into a situation, in proportion as it was light or heavy. The middle, or central part, which always remained unchanged, still continued so, retaining a part of that heat which it received in its primæval approaches towards the sun; which he calculates, may continue for about six thousand years. Next to this fell the heavier parts of the chaotic atmosphere, which serve to sustain the lighter: but as in descending they could not entirely be separated from many watery parts, with which they were intimately mixed, they drew down a part of these also with them; and these could not mount again after the surface of the earth was consolidated: they, therefore, surrounded the heavy first descending parts, in the same manner as these surround the central globe. Thus the entire body of the earth is composed internally of a great burning globe: next which, is placed an heavy terrene substance, that encompasses it; round which also is circumfused a body of water. Upon this body of water, the crust of earth on which we inhabit is placed: so that, according to him, the globe is composed of a number of coats, or shells, one within the other, all of different densities. The body of the earth being thus formed, the air, which is the lightest substance of all, surrounded its surface; and the beams of the sun darting through, produced that light which, we are told, first obeyed the Creator's command.

The whole œconomy of the creation being thus adjusted, it only remained to account for the risings and depressions on the surface of the earth, with the other seeming irregularities of its present appearance. The hills and vallies are considered by him as formed by their pressing upon the internal fluid, which sustains the outward shell of earth, with greater or less weight: those parts of the earth which are heaviest, sink into the subjacent fluid more deeply, and become vallies: those that are lightest rise higher upon the earth's surface, and are called mountains.

Such was the face of nature before the deluge; the earth was then more fertile and populous than it is at present; the life of man and animals was extended to ten times its present duration; and all these advantages arose from the superior heat of the central globe, which ever since has been cooling. As its heat was then in full power, the genial principle was also much greater than at present; vegetation and animal increase were carried on with more vigour; and all nature seemed teeming with the seeds of life. But these physical advantages

were only productive of moral evil; the warmth which invigorated the body increased the passions and appetites of the mind; and, as man became more powerful, he grew less innocent. It was found necessary to punish this depravity; and all living creatures were overwhelmed by the deluge in universal destruction.

This deluge, which simple believers are willing to ascribe to a miracle, philosophers have long been desirous to account for by natural causes: they have proved that the earth could never supply from any reservoir towards its centre, nor the atmosphere by any discharge from above, such a quantity of water as would cover the surface of the globe to a certain depth over the tops of our highest mountains. Where, therefore, was all this water to be found? Whiston has found enough, and more than a sufficiency, in the tail of a comet; for he seems to allot comets a very active part in the great operations of nature.

He calculates, with great seeming precision, the year, the month, and the day of the week on which this comet (which has paid the earth some visits since, though at a kinder distance) involved our globe in its tail. The tail may be supposed to be a vaporous fluid substance, exhaled from the body of the comet, by the extreme heat of the sun, and increasing in proportion as it approached that great luminary. It was in this that our globe was involved at the time of the deluge; and as the earth still acted by its natural attraction, it drew to itself all the watery vapours which were in the comet's tail; and the internal waters being also at the same time let loose, in a very short space the tops of the highest mountains were laid under the deep.

The punishment of the deluge being thus completed, and all the guilty destroyed, the earth, which had been broken by the eruption of the internal waters, was also enlarged by it; so that upon the comet's recess, there was found room sufficient in the internal abyss for the recess of the superfluous waters; whither they all retired, and left the earth uncovered, but in some respects changed; particularly in its figure, which, from being round, was now become oblate. In this universal wreck of nature Noah survived, by a variety of happy causes, to re-people the earth, and to give birth to a race of men slow in believing ill-imagined theories of the earth.

After so many theories of the earth, which had been published, applauded, answered, and forgotten; Mr. Buffon ventured to add one more to the number. This philosopher was, in every respect, better qualified than any of his predecessors for such an attempt, being furnished with more materials, having a brighter imagination to find new proofs, and a better style to cloath them in. However, in our opinion, this seems the weakest part of his admirable work; and we could wish, that he had been content with giving us facts instead of systems; that, instead of being a reasoner, he had contented himself with being merely an-historian.

He begins his system by making a distinction between the first part of it and the last; the one being found only on conjecture, the other depending entirely upon actual observation. The latter part of his theory may, therefore, be true, though the former should be found erroneous.

The planets, says he, and the earth, among the number, might have been formerly (he only offers this as conjecture) a part of the body of the sun, and adherent to its substance. In this situation, a comet falling in upon that great body might have given it such a shock, and so shaken its whole frame, that some of its particles might have been driven off like streaming sparkles from red hot iron; and each

of these streams of fire, small as they were in comparison of the sun, might have been large enough to have made an earth as great, nay many times greater than ours. So that in this manner the planets, together with the globe which we inhabit, might have been driven off from the body of the sun by an impulsive force: in this manner also they would continue to recede from it for ever, were they not drawn back by its superior power of attraction; and thus, by the combination of the two motions, they are wheeled round in circles.

Being in this manner detached at a distance from the body of the sun, the planets, from having been at first globes of liquid fire, gradually became cool. The earth also having been impelled obliquely forward, received a rotatory motion upon its axis at the very instant of its formation; and this motion being greatest at the equator, the parts there acting against the force of gravity, they must have swollen out, and given the earth an oblate or flattened figure.

As to its internal substance, our globe having once belonged to the sun, it continues to be an uniform mass of melted matter, very probably vitrified in its primæval fusion. But its surface is very differently composed. Having been in the beginning heated to a degree equal to, if not greater, than what comets are found to sustain, like them it had an atmosphere of vapours floating round it, and which cooling by degrees, condensed and subsided upon its surface. These vapours formed, according to their different densities, the earth, the water, and the air; the heavier parts falling first, and the lighter remaining still suspended.

Thus far our philosopher is, at least, as much a system-maker as Whiston or Burnet; and, indeed, he fights his way with great perseverance and ingenuity through a thousand objections that naturally arise. Having, at last, got upon the earth, he supposes himself on firmer ground, and goes forward with greater security. Turning his attention to the present appearance of things upon this globe, he pronounces from the view that the whole earth was at first under water. This water he supposes to have been the lighter parts of its former evaporation, which, while the earthy particles sunk downwards by their natural gravity, floated on the surface, and covered it for a considerable space of time.

"The surface of the earth," says he, "must have been in the beginning much less solid than it is at present; and, consequently, the same causes, which at this day produce but very slight changes, must then, upon so complying a substance, have had very considerable effects. We have no reason to doubt but that it was then covered with the waters of the sea; and that those waters were above the tops of our highest mountains, since, even in such elevated situations, we find shells and other marine productions in very great abundance. It appears also that the sea continued for a considerable time upon the face of the earth: for as these layers of shells are found so very frequent at such great depths, and in such prodigious quantities, it seems impossible for such numbers to have been supported all alive at one time; so that they must have been brought there by successive depositions. These shells also are found in the bodies of the hardest rocks, where they could not have been deposited, all at once, at the time of the deluge, or at any such instant revolution; since that would be to suppose, that all the rocks in which they are found, were, at that instant, in a state of dissolution, which would be absurd to assert. The sea, therefore, deposited them where-soever they are now to be found, and that by slow and successive degrees.

"It will appear, also, that the sea covered the whole

earth, from the appearance of its layers, which lying regularly one above the other, seem all to resemble the sediment formed at different times by the ocean. Hence, by the irregular force of its waves, and its currents driving the bottom into sand-banks, mountains must have been gradually formed within this universal covering of waters; and these successively raising their heads above its surface, must, in time, have formed the highest ridges of mountains upon land, together with continents, islands and low grounds, all in their turns. This opinion will receive additional weight by considering, that in those parts of the earth where the power of the ocean is greatest, the inequalities on the surface of the earth are highest: the ocean's power is greatest at the equator, where its winds and tides are most constant; and, in fact, the mountains at the equator are found to be higher than in any other part of the world. The sea, therefore, has produced the principal changes in our earth: rivers, volcanoes, earthquakes, storms, and rain, having made but slight alterations, and only such as have affected the globe to very inconsiderable depths."

This is but a very slight sketch of Mr. Buffon's Theory of the Earth; a theory which he has much more powerfully supported, than happily invented; and it would be needless to take up the reader's time from the pursuit of truth in the discussion of plausibilities. In fact, a thousand questions might be asked this most ingenious philosopher, which he would not find it easy to answer; but such is the lot of humanity, that a single Goth can in one day destroy the fabric which Cæsars were employed an age in erecting. We might ask, how mountains, which are composed of the most compact and ponderous substances, should be the first whose parts the sea began to remove? We might ask, how fossil-wood is found deeper even than shells? which argues, that trees grew upon the places he supposes once to have been covered with the ocean. But we hope this excellent man is better employed than to think of gratifying the petulance of incredulity, by answering endless objections.

CHAP. V.

Containing the NATURAL HISTORY of FOSSIL-SHELLS, and other extraneous FOSSILS.

WE may affirm of Mr. Buffon, that which has been said of the chymists of old: though he may have failed in attaining his principal aim, of establishing a theory, yet he has brought together such a multitude of facts relative to the history of the earth, and the nature of its fossil productions, that curiosity finds ample compensation even while it feels the want of conviction.

Before, therefore, we enter upon the description of those parts of the earth, which seem more naturally to fall within the subject, it will not be improper to give a short history of those animal productions that are found in such quantities, either upon its surface, or at different depths below it. They demand our curiosity, and, indeed, there is nothing in natural history that has afforded more scope for doubt, conjecture, and speculation. Whatever depths of the earth we examine, or at whatever distance within land we seek, we most commonly find a number of fossil-shells, which being compared with others from the sea, of known kinds, are found to be exactly of a similar shape and nature. They are found at the very bottom of quarries and mines, in the retired and inward parts of the most firm and solid rocks, upon the tops of even the highest hills and mountains, as well as in the valleys and plains: and this

this not in one country alone, but in all places where there is any digging for marble, chalk, or any other terrestrial matters, that are so compact as to fence off the external injuries of the air, and thus preserve these shells from decay.

These marine substances, so commonly diffused, and so generally to be met with, were for a long time considered by philosophers, as productions, not of the sea, but of the earth. "As we find that spars," said they, "always shoot into peculiar shapes, so these seeming snails, cockles, and muscle-shells, are only sportive forms that nature assumes amongst others of its mineral varieties: they have the shape of fish, indeed, but they have always been terrestrial substances."

With this plausible solution mankind were for a long time content; but upon closer enquiry, they were obliged to alter their opinion. It was found that these shells had, in every respect, the properties of animal and not of mineral nature. They were found exactly of the same weight with their fellow shells upon shore. They answered all the chemical trials in the same manner as sea shells do. Their parts, when dissolved, had the same appearance to view, the same smell and taste. They had the same effects in medicine when inwardly administered; and, in a word, were so exactly conformable to marine bodies, that they had all the accidental concretions growing to them, (such as pearls, corals, and smaller shells) which are found in shells just gathered on the shore. They were, therefore, from these considerations, given back to the sea; but the wonder was, how to account for their coming so far from their own natural element upon land.

As this naturally gave rise to many conjectures, it is not to be wondered that some among them have been very extraordinary. An Italian, quoted by Mr. Buffon, supposes them to have been deposited in the earth at the time of the crusades, by the pilgrims who returned from Jerusalem: who gathering them upon the sea shore, in their return carried them to their different places of habitation. But this conjecturer seems to have but a very inadequate idea of their numbers. At Touraine, in France, more than an hundred miles from the sea, there is a plain of about nine leagues long, and as many broad, from whence the peasants of the country supply themselves with marle for manuring their lands. They seldom dig deeper than twenty feet, and the whole plain is composed of the same materials, which are shells of various kinds, without the smallest portion of earth between them. Here then, is a large space, in which are deposited millions of tons of shells, that pilgrims could not have collected, though their whole employment had been nothing else. England is furnished with its beds, which though not quite so extensive, yet are equally wonderful. "Near Reading in Berkshire, for many succeeding generations, a continued body of oyster-shells has been found through the whole circumference of five or six acres of ground. The foundation of these shells is an hard rocky chalk; and above this chalk, the oyster-shells lie in a bed of green sand, upon a level, as nigh as can possibly be judged, and about two feet thickness." These shells are in their natural state, but they were found also petrified, and almost in equal abundance in all the Alpine rocks, in the Pyrenees, on the hills of France, England, and Flanders. Even in all quarries from whence marble is dug, if the rocks be split perpendicularly downwards, petrified shells, and other marine substances, will be plainly discerned.

"About a quarter of a mile from the river Medway, in the county of Kent, after the taking off the coping of a piece of ground there, the workmen

came to a blue marble, which continued for three feet and a half deep, or more, and then beneath appeared an hard floor or pavement, composed of petrified shells crowded closely together. This layer was about an inch deep, and several yards over; and it could be walked upon as upon a beach. These stones, of which it was composed, (the describer supposes them to have always been stones) were either wreathed as snails, or bivalvular like cockles. The wreathed kinds were about the size of an hazelnut, and were filled with a stony substance of the colour of marle; and they themselves, also, till they were washed, were of the same colour; but when cleaned they appear of the colour of bezoar, and of the same polish. After boiling in water they became whitish, and left a chalkiness upon the fingers."

In several parts of Asia and Africa, travellers have observed these shells in great abundance. In the mountains of Castravan, which lie above the city Barut, they quarry out a white stone, every part of which contains petrified fishes in great numbers, and of surprising diversity. They also seem to continue in such preservation, that their fins, scales, and all the minutest distinctions of their make, can be perfectly discerned.

From all these instances we may conclude, that fossils are very numerous; and, indeed, independent of their situation, they afford no small entertainment to observe them as preserved in the cabinets of the curious. The varieties of their kinds is astonishing. Most of the sea shells which are known, and many others to which we are entirely strangers, are to be seen either in their natural state, or in various degrees of petrefaction. In the place of some we have mere spar, or stone, exactly expressing all the lineaments of animals, as having been wholly formed from them. For it has happened that the shells dissolving by very slow degrees, and the matter having nicely and exactly filled all the cavities within, this matter, after the shells have perished, has preserved exactly and regularly the whole print of their internal surface. Of these there are various kinds found in our pits; many of them resembling those of our own shores; and many others that are only to be found on the coasts of other countries. There are some shells resembling those that are never stranded upon our coasts, but always remain in the deep: and many more there are which we can assimilate with no shells known amongst us. But we find not only shells in our pits, but also fishes and corals in great abundance; together with almost every sort of marine production.

It is extraordinary enough, however, that the common red coral, though so very frequent at sea, is scarce seen in the fossil world; nor is there any account of its having ever been met with. But to compensate for this, there are all the kinds of the white coral now known; and many other kinds of that substance with which we are unacquainted. Of animals there are various parts; the vertebræ of whales, and the mouths of lesser fishes; these, with teeth also of various kinds, are found in the cabinets of the curious; where they receive long Greek names, which it is neither the intention nor the province of this work to enumerate. Indeed, few readers would think themselves much improved, should we proceed with enumerating the various classes of the Conicthyodonts, Polyteptoginglimi, or the Orthoceratites. These names, which mean no great matter when they are explained, may serve to guide in the furnishing a cabinet; but they are of very little service in furnishing the page of instructive history.

From all these instances we see in what abundance petrefactions are to be found; and, indeed,
Mr.

Mr. Buffon, has not been sparing in the variety of his quotations, concerning the places where they are mostly to be found. However, we are surpris'd that he should have omitted the mention of one, which, in some measure, more than any of the rest, would have serv'd to strengthen his theory. We are inform'd by almost every traveller, that has described the pyramids of Egypt, that one of them is entirely built of a kind of free-stone, in which these petrified shells are found in great abundance. This being the case, it may be conjectured, as we have accounts of these pyramids among the earliest records of mankind, and of their being built so long before the age of Herodotus, who lived but fifteen hundred years after the flood, that even the Egyptian priests could tell neither the time nor the cause of their erection; therefore it may be conjectured that they were erected but a short time after the flood. It is not very likely, therefore, that the marine substances found in one of them, had time to be formed into a part of the solid stone, either during the deluge, or immediately after it; and, consequently, their petrefaction must have been before that period. And this is the opinion Mr. Buffon has so strenuously endeavour'd to maintain; having given specious reasons to prove, that such shells were laid in the beds where they are now found, not only before the deluge, but even antecedent to the formation of man, at the time when the whole earth, as he supposes, was buried beneath a covering of waters.

But while there are many reasons to persuade us that these extraneous fossils have been deposited by the sea, there is one fact that will abundantly serve to convince us that the earth was habitable, if not inhabited, before these marine substances came to be thus deposited; for we find fossil-trees, which no doubt once grew upon the earth, as deep, and as much in the body of solid rocks, as these shells are found to be. Some of these fallen trees also have lain at last as long, if not longer, in the earth, than the shells, as they have been found sunk deep in a marly substance, compos'd of decayed shells, and other marine productions. Mr. Buffon has prov'd that fossil-shells could not have been deposited in such quantities all at once by the flood; and we think, from the above instance, it is pretty plain, that howsoever they were deposited, the earth was covered with trees before their deposition; and, consequently, that the sea could not have made a very permanent stay. How then shall we account for these extraordinary appearances in nature? A suspension of all assent is certainly the first, although the most mortifying conduct. Were we to offer a conjecture (and all that has been said upon this subject is but conjecture) instead of supposing them to be the remains of animals belonging to the sea, we would consider them rather as bred in the numerous fresh-water lakes that, in primæval times, covered the face of uncultivated nature. Some of these shells we know to belong to fresh waters: some can be assimilated to none of the marine shells now known; why, therefore, may we not as well ascribe the production of all to fresh waters, where we do not find them, as we do that of the latter to the sea only, where we never find them? We know that lakes, and lands also, have produced animals that are now no longer existing; why, therefore, might not these fossil productions be among the number? We allow that this is making a very harsh supposition; but we cannot avoid thinking, that it is not attended with so many embarrassments as some of the former; and that it is much easier to believe that these shells were bred in fresh water, than that the sea had for a long time covered the tops of the highest mountains.

C H A P. VI.

NATURAL HISTORY of the internal Structure of the EARTH.

HAVING, in some measure, got free from the regions of conjecture, let us now proceed to a description of the earth as we find it by examination, and observe its internal composition, as far as it has been the subject of experience, or expos'd to human enquiry. These enquiries, indeed, have been carried but to a very little depth below its surface, and even in that disquisition men have been conducted more by motives of avarice than of curiosity. The deepest mine, which is that at Cotteberg in Hungary, reaches not more than three thousand feet deep; but what proportion does that bear to the depth of the terrestrial globe, down to the centre, which is above four thousand miles? All, therefore, that has been said of the earth, to a deeper degree, is merely fabulous or conjectural: we may suppose with Buffon, that it is a globe of glass; with Whiston, a sphere of heated iron; with Burnet, a great mass of waters; and with Kircher, one dreadful volcano; but let us, at the same time, shew our consciousness, that all these are but suppositions.

Upon examining the earth, where it has been opened to any depth, the first thing that occurs, is the different layers or beds of which it is compos'd; these all lying horizontally one over the other like the leaves of a book, and each of them compos'd of materials that increase in weight in proportion as they lie deeper. This is, in general, the disposition of the different materials where the earth seems to have remained unmolested; but this order is frequently inverted; and we cannot tell whether from its original formation, or from accidental causes. Of different substances, thus dispos'd, the far greatest part of our globe consists, from its surface downwards to the greatest depths we ever dig or mine.

The first layer most commonly found at the surface, is that light coat of blackish mould, which is called, by some, garden earth. With this the earth is every where invest'd, unless it be wash'd off by rains, or removed by some other external violence. This seems to have been formed from animal and vegetable bodies decaying, and thus turning into its substance. It also serves again as a storehouse, from whence animal and vegetable nature are renewed; and thus are all vital blessings continued with unceasing circulation. This earth, however, is not to be supposed entirely pure, but is mixed with much stony and gravelly matter, from the layers lying immediately beneath it. It generally happens, that the soil is fertile in proportion to the quantity that this putrified mould bears to the gravelly mixture; and as the former predominates, so far is the vegetation upon it more luxuriant. It is this external covering that supplies man with all the true riches he enjoys. He may bring up gold and jewels from greater depths; but they are merely the toys of a capricious being, things upon which he has plac'd an imaginary value, and for which fools alone part with the more substantial blessings of life. It is this earth, says Pliny, that, like a kind mother, receives us at our birth, and sustains us when born. It is this alone, of all the elements around us, that is never found an enemy to man. The body of waters deluge him with rains, oppress him with hail, and drown him with inundations. The air rushes in storms, prepares the tempest, or lights up the volcano; but the earth, gentle and indulgent, ever subservient to the wants of man, spreads his walks with flowers, and his table with plenty;

plenty; returns with interest every good committed to her care; and, though she produces the poison, she still supplies the antidote; though constantly teized more to furnish the luxuries of man than his necessities, yet, even to the last, she continues her kind indulgence, and, when life is over, she piously covers his remains in her bosom.

This external and fruitful layer which covers the earth, is, as was said, in a state of continual change. Vegetables, which are naturally fixed and rooted to the same place, receive their adventitious nourishment from the surrounding earth and water: animals, which change from place to place, are supported by these, or by each other. Both, however, having for a time enjoyed a life adapted to their nature, give back to the earth those spoils, which they had borrowed for a very short space, yet still to be quickened again into fresh existence. But the deposits they make are of very dissimilar kinds, and the earth is very differently enriched by their continuance. Those countries that have for a long time supported men and other animals, having been observed to become every day more barren, while, on the contrary, those desolate places, in which vegetables only are abundantly produced, are known to be possessed of amazing fertility. "In regions which are uninhabited," says Mr. Buffon, "where the forests are not cut down, and where animals do not feed upon the plants, the bed of vegetable earth is constantly increasing. In all woods, and even in those often cut, there is a layer of earth of six or eight inches thick, which has been formed by the leaves, branches and bark, which fall and rot upon the ground. It has frequently been observed on a Roman way which crosses Burgundy for a long extent, that there is a bed of black earth, of more than a foot thick, gathered over the stony pavement, on which several trees, of a very considerable size, are supported. This is found to be nothing else than an earth formed by decayed leaves and branches, which have been converted by time into a black soil. Now as vegetables draw much more of their nourishment from the air and water than they do from the earth, it must follow, that in rotting upon the ground, they must give more to the soil than they have taken from it. Hence, therefore, in woods kept a long time without cutting, the soil below increases to a considerable depth; and such we actually find the soil in those American wilds where the forests have been undisturbed for ages. But it is otherwise where men and animals have long subsisted; for as they make a considerable consumption of wood and plants, both for firing and other uses, they take more from the earth than they return to it: it follows, therefore, that the bed of vegetable earth, in an inhabited country, must be always diminishing; and must, at length, resemble the soil of Arabia Petrea, and other provinces of the East, which having been long inhabited, are now become plains of salt and sand; the fixed salt always remaining while the other volatile parts have flown away."

If from this external surface we descend deeper, and view the earth cut perpendicularly downwards, either in the banks of great rivers, or steepy sea shores; or, going still deeper, if we observe it in quarries or mines, we shall find its layers regularly disposed in their proper order. We must not expect, however, to find them of the same kind or thickness in every place, as they differ in different soils and situations. Sometimes marle is seen to be over sand, and sometimes under it. The most common disposition is, that under the first earth is found gravel or sand, then clay or marle, then chalk or coal, marbles, ores, sands, gravels; and thus an alternation of these substances, each growing more

dense as it sinks deeper. The clay, for instance, found at the depth of an hundred feet, is usually more heavy than that found not far from the surface. In a well which was dug at Amsterdam, to the depth of two hundred and thirty feet, the following substances were found in succession: seven feet of vegetable earth, nine of turf, nine of soft clay, eight of sand, four of earth, ten of clay, four of earth, ten of sand, two of clay, four of white sand, one of soft earth, fourteen of sand, eight of clay mixed with sand, four of sea-sand mixed with shells, then an hundred and two feet of soft clay, and then thirty-one feet of sand.

In a well dug at Marly, to the depth of an hundred feet, Mr. Buffon gives us a still more exact enumeration of its layers of earth. Thirteen of a reddish gravel, two of gravel minged with a vitrifiable sand, three of mud or slime, two of marle, four of marly stone, five of marle in dust mixed with vitrifiable sand, six of very fine vitrifiable sand, three of earthy marle, three of hard marle, one of gravel, one of eglantine, a stone of the hardness and grain of marble, one of gravelly marle, one of stony marle, one of a coarser kind of stony marle, two of a coarser kind still, one of vitrifiable sand mixed with fossil shells, two of fine gravel, three of stony marle, one of coarse powdered marle, one of stone, calcifiable like marble, three of grey sand, two of white sand, one of red sand streaked with white, eight of grey sand with shells, three of very fine sand, three of a hard grey stone, four of red sand streaked with white, three of white sand, and fifteen of a reddish vitrifiable sand.

In this manner the earth is every where found in beds over beds; and, what is still remarkable, each of them, as far as it extends, always maintains exactly the same thickness. It is found also, that, as we proceed to considerable depths, every layer grows thicker. Thus in the adduced instances we might have observed, that the last layer was fifteen feet thick, while most of the others were not above eight; and this might have gone much deeper, for ought we can tell, as before they got through it the workmen ceased digging.

These layers are sometimes very extensive, and often are found to cover a space of some leagues in circumference. But it must not be supposed that they are uniformly continued over the whole globe without any interruption: on the contrary, they are ever, at small intervals, cracked through as it were by perpendicular fissures; the earth resembling, in this respect, the muddy bottom of a pond, from whence the water has been dried off by the sun, and thus gaping in several chinks, which descend in a direction perpendicular to its surface. These fissures are many times found empty, but oftener closed up with adventitious substances, that the rain, or some other accidental causes, have conveyed to fill their cavities. Their openings are not less different than their contents, some being not above half an inch wide, some a foot, and some several hundred yards asunder; which last form those dreadful chasms that are to be found in the Alps, at the edge of which the traveller stands, dreading to look down at the immeasurable gulph below. These amazing clefts are well known to such as have past these mountains, where a chasm frequently presents itself several hundred feet deep, and as many over, at the edge of which the way lies. It often happens also, that the road leads along the bottom, and then the spectator observes on each side frightful precipices several hundred yards above him; the sides of which correspond so exactly with each other, that they evidently seem torn asunder.

But these chasms to be found in the Alps, are nothing to what Ovalle tells us are to be seen in the

Andes. These amazing mountains, in comparison of which the former are but little hills, have their fissures in proportion to their greatness. In some places they are a mile wide, and deep in proportion; and there are some others, that running under ground, in extent resemble a province.

Of this kind also is that cavern called Elden-hole, in Derbyshire; which, Dr. Plot tells us, was founded by a line of eight and twenty hundred feet, without finding the bottom, or meeting with water: and yet the mouth at the top is not above forty yards over. This immeasurable cavern runs perpendicularly downward; and the sides of it seem to tally so plainly as to shew that they once were united. Those who come to visit the place, generally procure stones to be thrown into its mouth; and these are heard for several minutes, falling and striking against the sides of the cavern, producing a sound that resembles distant thunder, dying away as the stone goes deeper.

Of this kind also is that dreadful cavern described by Ælian; his account of which the reader may not have met with. "In the country of the Arrian Indians, is to be seen an amazing chasm, which is called, The Gulph of Pluto. The depth, and the recesses of this horrid place, are as extensive as they are unknown. Neither the natives, nor the curious who visit it, are able to tell how it first was made, or to what depths it descends. The Indians continually drive thither great multitudes of animals, more than three thousand at a time, of different kinds, sheep, horses, and goats; and, with an absurd superstition, force them into the cavity, from whence they never return. Their several sounds, however, are heard as they descend; the bleating of sheep, the lowing of oxen, and the neighing of horses, issuing up to the mouth of the cavern. Nor do these sounds cease, as the place is continually furnished with a fresh supply."

There are many more of these dreadful perpendicular fissures in different parts of the earth; with accounts of which Kircher, Gaffarellus, and others, who have given histories of the wonders of the subterranean world, abundantly supply us. The generality of readers, however, will consider them with less astonishment, when they are informed of their being common all over the earth: that in every field, in every quarry, these perpendicular fissures are to be found; either still gaping, or filled with matter that has accidentally closed their interstices. The inattentive spectator neglects the enquiry, but their being common is partly the cause that excites the philosopher's attention to them: the irregularities of nature he is often content to let pass unexamined; but when a constant and a common appearance presents itself, every return of the object is a fresh call to his curiosity; and the chink in the next quarry becomes as great a matter of wonder as the chasm in Elden-hole. Philosophers have long, therefore, endeavoured to find out the cause of these perpendicular fissures, which our own countrymen, Woodward and Ray, were the first that found to be so common and universal. Mr. Buffon supposes them to be cracks made by the sun, in drying up the earth immediately after its emergence from the deep. The heat of the sun is very probably a principal cause; but it is not right to ascribe to one only, what we find may be the result of many. Earthquakes, severe frosts, bursting waters, and storms tearing up the roots of trees, have, in our own times, produced them: and to this variety of causes we must, at present, be content to assign those that have happened before we had opportunities for observation.

C H A P. VII.

Of CAVES and Subterraneous PASSAGES that sink, but not perpendicularly, into the Earth.

WHEN we survey the subterrenean wonders of the globe, besides those fissures that descend perpendicularly, we frequently find others that descend but a little way, and then spread themselves often to a great extent below the surface. Many of these caverns, it must be confessed, may be the production of art and human industry; retreats made to protect the oppressed, or shelter the spoiler. The famous labyrinth of Candia, for instance, is supposed to be entirely the work of art: Mr. Tournefort assures us, that it bears the impression of human industry, and that great pains have been bestowed upon its formation. The stone-quarry of Maestricht is evidently made by labour: carts enter at its mouth, and load within, then return and discharge their freight into boats that lie on the brink of the river Maese. This quarry is so large, that forty thousand people may take shelter in it: and it in general serves for this purpose, when armies march that way; becoming then an impregnable retreat to the people that live thereabout. Nothing can be more beautiful than this cavern, when lighted up with torches; for there are thousands of square pillars, in large level walks, about twenty feet high; and all wrought with much neatness and regularity. In this vast grotto there is very little rubbish; which shews both the goodness of the stone, and the carefulness of the workmen. To add to its beauty, there also are, in various parts of it, little pools of water, for the convenience of the men and cattle. It is remarkable also, that no droppings are seen to fall from the roof, nor are the walks any way wet under foot, except in cases of great rains, where the water gets in by the air shafts. The Salt-mines in Poland are still more spacious than these. Some of the catacombs, both in Egypt and Italy, are said to be very extensive. But no part of the world has a greater number of artificial caverns than Spain, which were made to serve as retreats to the Christians, against the fury of the Moors, when the latter conquered that country. However, an account of the works of art does not properly belong to a natural history. It will be sufficient to observe, that though caverns be found in every country, far the greatest part of them have been fashioned by the hand of Nature only. Their size is found beyond the power of man to have effected; and their forms but ill adapted to the conveniences of an human habitation. In some places, indeed, we find mankind still make use of them as houses; particularly in those countries where the climate is very severe; but in general they are deserted by every race of meaner animals, except the bat: these nocturnal solitary creatures are usually the only inhabitants; and these only in such whose descent is sloping, or, at least, not directly perpendicular.

There is scarce a country in the world without its natural caverns; and many new ones are discovered every day. Of those in England, Oakey-hole, the Devil's-hole, and Penpark-hole, have been often described. The former, which lies on the south side of Mendip-hills, within a mile of the town of Wells, is much resorted to by travellers. To conceive a just idea of this, we must imagine a precipice of more than an hundred yards high, on the side of a mountain which shelves away a mile above it. In this is an opening not very large, into which you enter, going along upon a rocky uneven pavement, sometimes ascending, and sometimes descending. The roof of it, as you advance,

grows higher; and, in some places, is fifty feet from the floor. In some places, however, it is so low that a man must stoop to pass. It extends itself, in length, about two hundred yards; and from every part of the roof, and the floor, there are formed sparry concretions of various figures, that by strong imaginations have been likened to men, lions, and organs. At the farthest part of this cavern rises a stream of water, well stored with fish, large enough to turn a mill, and which discharges itself near the entrance.

Penpark-hole, in Gloucestershire, is almost as remarkable as the former. Captain Sturmeý descended into this by a rope, twenty-five fathoms perpendicular, and at the bottom found a very large vault in the shape of an horse-shoe. The floors consisted of a kind of white stone enamelled with lead ore, and the pendent rocks were glazed with spar. Walking forward on this stony pavement, for some time, he came to a great river, twenty fathoms broad, and eight fathoms deep; and having been informed that it ebbed and flowed with the sea, he remained in his gloomy abode for five hours, to make an exact observation. He did not find, however, any alteration whatsoever in its appearance. But his curiosity was ill requited; for it cost this unfortunate gentleman his life: immediately after his return, he was seized with an unusual and violent head-ach, which threw him into a fever, of which he died soon after.

But of all the subterraneous caverns now known, the grotto of Antiparos is the most remarkable, as well for its extent, as for the beauty of its sparry incrustations. This celebrated cavern was first discovered by one Magni, an Italian traveller, about an hundred years ago, at Antiparos, an inconsiderable island of the Archipelago. The account he gives of it is long and inflated, but upon the whole amusing. "Having been informed," says he, "by the natives of Paros, that in the little island of Antiparos, which lies about two miles from the former, of a gigantic statue that was to be seen at the mouth of a cavern in that place, it was resolved that we (the French consul and himself) should pay it a visit. In pursuance of this resolution, after we had landed on the island, and walked about four miles through the midst of beautiful plains, and sloping woodlands, we at length came to a little hill, on the side of which yawned a most horrid cavern, that with its gloom at first struck us with terror, and almost repressed curiosity. Recovering the first surprize, however, we entered boldly; and had not proceeded above twenty paces, when the supposed statue of the giant presented itself to our view. We quickly perceived, that what the ignorant natives had been terrified at as a giant, was nothing more than a sparry concretion, formed by the water dropping from the roof of the cave, and by degrees hardening into a figure that their fears had formed into a monster. Incited by this extraordinary appearance, we were induced to proceed still farther, in quest of new adventures in this subterranean abode. As we proceeded, new wonders offered themselves; the spars, formed into trees and shrubs, presented a kind of petrified grove; some white, some green; and all receding in due perspective. They struck us with the more amazement, as we knew them to be mere productions of Nature, who, hitherto in solitude, had, in her playful moments, dressed the scene, as if for her own amusement.

"But we had as yet seen but a few of the wonders of the place; and we are introduced only into the portico of this amazing temple. In one corner of this half illuminated recess, there appeared an opening of about three feet wide, which seemed to lead to a place totally dark, and that one of the

natives assured us contained nothing more than a reservoir of water. Upon this we tried, by throwing down some stones, which rumbling along the sides of the descent for some time, the sound seemed at last quashed in a bed of water. In order, however, to be more certain, we sent in a Levantine mariner, who, by the promise of a good reward, with a flambeaux in his hand, ventured into this narrow aperture. After continuing within it for about a quarter of an hour, he returned, carrying some beautiful pieces of white spar in his hand, which art could neither imitate nor equal. Upon being informed by him that the place was full of these beautiful incrustations, I ventured in once more with him, for about fifty paces, anxiously and cautiously descending by a steep and dangerous way. Finding, however, that we came to a precipice which led into a spacious amphitheatre, if I may so call it, still deeper than any other part, we returned, and being provided with a ladder, flambeaux, and other things to expedite our descent, our whole company, man by man, ventured into the same opening, and descending one after another, we at last saw ourselves all together in the most magnificent part of the cavern.

"Our candles being now all lighted up, and the whole place completely illuminated, never could the eye be presented with a more glittering, or a more magnificent scene. The roof all hung with solid isicles, transparent as glass, yet solid as marble. The eye could scarce reach the lofty and noble ceiling; the sides were regularly formed with spars; and the whole presented the idea of a magnificent theatre, illuminated with an immense profusion of lights. The floor consisted of solid marble; and in several places magnificent columns, thrones, altars, and other objects appeared, as if nature had designed to mock the curiosities of art. Our voices, upon speaking or singing, were redoubled to an astonishing loudness; and upon the firing of a gun, the noise and reverberations were almost deafening. In the midst of this grand amphitheatre rose a concretion of about fifteen feet high, that, in some measure, resembled an altar; from which, taking the hint, we caused masks to be celebrated there. The beautiful columns that shot up round the altar, appeared like candlesticks; and many other natural objects represented the customary ornaments of this sacrament.

"Below even this spacious grotto, there seemed another cavern; down which I ventured with my former mariner, and descended about fifty paces by means of a rope. I at last arrived at a small spot of level ground, where the bottom appeared different from that of the amphitheatre, being composed of soft clay, yielding to the pressure, and in which I thrust a stick to about six feet deep. In this, however, as above, numbers of the most beautiful crystals were formed; one of which, particularly, resembled a table. Upon our egress from this amazing cavern, we perceived a Greek inscription upon a rock at the mouth, but so obliterated by time, that we could not read it. It seemed to import that one Antipater, in the time of Alexander, had come thither; but whether he penetrated into the depths of the cavern, he does not think fit to inform us."

Such is the account of this beautiful scene, as communicated in a letter to Kircher. We have another, and a more copious description of it by Tournefort, which is in every body's hands; but we have given the above, both because it was communicated by the first discoverer, and because it is a simple narrative of facts, without any reasoning upon them. According to Tournefort's account, indeed, we might conclude, from the rapid growth of the spars in this grotto, that it must every year

be growing narrower, and that it must, in time, be choaked up with them entirely; but no such thing has happened hitherto, and the grotto at this day continues as spacious as we ever knew it.

This is not a place for an enquiry into the seeming vegetation of those stony substances with which this and almost every cavern are incrusted. It is enough to observe, in general, that they are formed by an accumulation of that little gritty matter which is carried thither by the waters, and which in time acquires the hardness of marble. What in this place more imports us to know is, how these amazing hollows in the earth came to be formed. In the three instances above-mentioned, it is pretty evident, that their excavation has been owing to water. These finding subterraneous passages under the earth, and by long degrees hollowing the beds in which they flowed, the ground above them has slipt down closer to their surface, leaving the upper layers of the earth or stone still suspended. The ground that sinks upon the face of the waters forming the floor of the cavern; the ground, or rock that keeps suspended, forming the roof: and, indeed, there are but few of these caverns found without water, either within them, or near enough to point out their formation.

C H A P. VIII.

Of MINES, DAMPS, and Mineral VAPOURS.

THE caverns, which we have been describing, generally carry us but a very little way below the surface of the earth. Two hundred feet, at the utmost, is as much as the lowest of them is found to sink. The perpendicular fissures run much deeper; but few persons have been bold enough to venture down to their deepest recesses: and some few who have tried, have been able to bring back no tidings of the place, for unfortunately they left their lives below. The excavations of art have conducted us much farther into the bowels of the globe. Some mines in Hungary are known to be a thousand yards perpendicular downwards; and we have been informed, by good authority, of a coal-mine in the north of England, an hundred yards deeper still.

It is beside our present purpose to enquire into the peculiar construction and contrivance of these, which more properly belongs to the history of fossils. It will be sufficient to observe in this place, that as we descend into the mines, the various layers of earth are seen, as we have already described them; and in some of these are always found the metals or minerals, for which the mine has been dug. Thus frequently gold is found dispersed and mixed with clay and gravel; sometimes it is mingled with other metallic bodies, stones, or bitumens; and sometimes united with that most obstinate of all substances, platina, from which scarce any art can separate it. Silver is sometimes found quite pure, sometimes mixed with other substances and minerals. Copper is found in beds mixed with various substances, marbles, sulphurs, and pyrites. Tin, the ore of which is heavier than that of any other metal, is generally found mixed with every kind of matter: lead is also equally common; and iron we well know can be extracted from all the substances upon earth.

The variety of substances which are thus found in the bowels of the earth, in their native state, have a very different appearance from what they are afterwards taught to assume by human industry. The richest metals are very often less glittering and splendid than the most useless marcasites, and the basest ores are in general the most beautiful to the eye.

This variety of substances, which compose the

internal parts of our globe, is productive of equal varieties both above and below its surface. The combination of the different minerals with each other, the heats which arise from their mixture, the vapours they diffuse, the fires which they generate, or the colds which they sometimes produce, are all either noxious or salutary to man; so that in this great laboratory of nature, a thousand benefits and calamities are forging, of which we are wholly unconscious; and it is happy for us that we are so.

Upon our descent into mines of considerable depth, the cold seems to increase from the mouth as we descend; but after passing very low down, we begin, by degrees, to come into a warmer air, which sensibly grows hotter as we go deeper, till, at last, the labourers can scarce bear any covering as they continue working.

This difference in the air was supposed by Boyle to proceed from magazines of fire that lay nearer the centre, and that diffused their heat to the adjacent regions. But we now know that it may be ascribed to more obvious causes. In some mines, the composition of the earth all around is of such a nature, that upon the admission of water or air, it frequently becomes hot, and often bursts out into eruptions. Besides this, as the external air, cannot readily reach the bottom, or be renewed there, and observable heat is perceived below, without the necessity of recurring to the central heat for an explanation.

Hence, therefore, there are two principal causes of the warmth at the bottom of mines: the heat of the substances of which the sides are composed; and the want of renovation in the air below. Any sulphureous substance mixed with iron, produces a very great heat, by the admission of water. If, for instance, a quantity of sulphur be mixed with a proportionable share of iron filings, and both kneaded together into a soft paste, with water, they will soon grow hot, and at last produce a flame. This experiment, produced by art, is very commonly effected within the bowels of the earth by nature. Sulphurs and irons are intimately blended together, and want only the mixture of water or air to excite their heat; and this, when once raised, is communicated to all bodies that lie within the sphere of their operation. Those beautiful minerals called marcasites and pyrites, are often of this composition; and wherever they are found, either by imbibing the moisture of the air, or having been by any means combined with water, they render the mine considerably hot.

The want of fresh air, also, at these depths, is, as we have said, another reason for their being found much hotter. Indeed, without the assistance of art, the bottom of most mines would, from this cause, be insupportable. To remedy this inconvenience, the miners are often obliged to sink, at some convenient distance from the mouth of the pit where they are at work, another pit, which joins the former below, and which, in Derbyshire, is called an air-shaft. Through this the air circulates; and thus the workmen are enabled to breathe freely at the bottom of the place; which becomes, as Mr. Boyle affirms, very commodious for respiration; and also very temperate as to heat and cold. Mr. Locke, however, who has left us an account of the Mendip mines, seems to present a different picture. "The descent into these is exceeding difficult and dangerous; for they are not sunk like wells, perpendicularly, but as the crannies of the rocks happen to run. The constant method is to swing down by a rope, placed under the arms, and clamber along, by applying both feet and hands to the sides of the narrow passage. The air is conveyed into them through a little passage that runs along the sides from the top, where they set up some turfs, on the lee-side of the hole, to catch and force it down. These turfs being removed to the windy side, or laid over the

the mouth of the hole, the miners below presently want breath, and faint; and if sweet-smelling flowers chance to be placed there, they immediately lose their fragrancy, and stink like carrion." An air so very putrifying can never be very commodious for respiration.

Indeed, if we examine the complexion of most miners, we shall be very well able to form a judgment of the unwholesomeness of the place where they are confined. Their pale and fallow looks shew how much the air is damaged by passing through those deep and winding ways, that are rendered humid by damps, or warmed with noxious exhalations. But although every mine is unwholesome, all are not equally so. Coal-mines are generally less noxious than those of tin; tin than those of copper; but none are so dreadfully destructive as those of quicksilver. At the mines near the village of Idra, nothing can adequately describe the deplorable infirmities of such as fill the hospital there: emaciated and crippled, every limb contracted or convulsed, and some in a manner transpiring quicksilver at every pore. There was one man, says Dr. Pope, who was not in the mines above half a year, and yet whose body was so impregnated with this mineral, that putting a piece of brass money in his mouth, or rubbing it between his fingers, it immediately became as white as if it had been washed over with quicksilver. In this manner all the workmen are killed sooner or later; first becoming paralytic, and then dying consumptive: and all this they sustain for the trifling reward of seven-pence a day.

But these metallic mines are not so noxious from their own vapours, as from those of the substances with which the ores are usually united, such as arsenic, cinnabar, bitumen, or vitriol. From the fumes of these, variously combined, and kept enclosed, are produced those various damps that put on so many dreadful forms, and are usually so fatal. Sometimes those noxious vapours are perceived by the delightful fragrance of their smell, somewhat resembling the pea-blossom in bloom, from whence one kind of damp has its name. The miners are not deceived, however, by its flattering appearances; but as they have thus timely notice of its coming, they avoid it while it continues, which is generally during the whole summer season. Another shews its approach by the burning of the candles, which seem to collect their flame into a globe of light, and thus gradually lessen, till they are quite extinguished. From this also the miners frequently escape; however, such as have the misfortune to be caught in it, either swoon away, and are suffocated, or slowly recover in excessive agonies. Here also is a third, called the fulminating damp, much more dangerous than either of the former, as it strikes down all before it, like a flash of gunpowder, without giving any warning of its approach. But there is another, more dangerous than all the rest, which is found in those places where the vapour has been long confined, and has been, by some accident, set free. The air rushing out from thence, always goes upon deadly errands; and scarce any escape to describe the symptoms of its operations.

Some colliers in Scotland, working near an old mine that had been long closed up, happened inadvertently to open an hole into it, from the pit where they were then employed; luckily they at that time perceived their error, and instantly fled for their lives. The next day, however, they were resolved to renew their work in the same pit, and eight of them ventured down, without any great apprehensions; but they had scarce got to the bottom of the stairs that led to the pit, but coming within the vapour, they all instantly dropped down dead, as if they had been shot. Amongst these unfortunate

No. 49.

poor men; there was one whose wife was informed that he was stifled in the mine; and as he happened to be next the entrance, she so far ventured down as to see where he lay. As she approached the place, the sight of her husband inspired her with a desire to rescue him, if possible, from that dreadful situation; though a little reflection might have shewn her it was then too late. But nothing could deter her; she ventured forward, and had scarce touched him with her hand, when the damp prevailed; and the misguided, but faithful creature, fell dead by his side.

Thus, the vapours found beneath the surface of the earth, are very various in their effects upon the constitution: and their are not less in their appearances. There are many kinds that seemingly are no way prejudicial to health, but in which the workmen breathe freely; and yet in these, if a lighted candle be introduced, they immediately take fire; and the whole cavern at once becomes one furnace of flame. In mines, therefore, subject to damps of this kind, they are obliged to have recourse to a very peculiar contrivance to supply sufficient light for their operations. This is by a great wheel; the circumference of which is beset with flints, which striking against steels placed for that purpose at the extremity, a stream of fire is produced, which affords light enough; and yet which does not set fire to the mineral vapour.

Of this kind are the vapours of the mines about Bristol; on the contrary, in other mines a single spark struck out from the collision of flint and steel, would set the whole shaft in a flame. In such, therefore, every precaution is used to avoid a collision; the workmen making use only of wooden instruments in digging; and being cautious before they enter the mine, to take out even the nails from their shoes. Whence this strange difference should arise, that the vapours of some mines catch fire with a spark, and others only with a flame, is a question that we must be content to leave in obscurity, till we know more of the nature both of mineral vapour and of fire. This only we may observe, that gunpowder will readily fire with a spark, but not with the flame of a candle: on the other hand, spirits of wine will flame with a candle, but not with a spark; but even here the cause of this difference, as yet, remains a secret.

As, from this account of mines, it appears that the internal parts of the globe are filled with vapours of various kinds, it is not surprising, that they should at different times reach the surface, and there put on various appearances. In fact, much of the salubrity, and much of the unwholesomeness of climates and soils, is to be ascribed to these vapours, which make their way from the bowels of the earth upwards; and refresh or taint the air with their exhalations. Salt mines being naturally cold, send forth a degree of coldness to the external air, to comfort and refresh it: on the contrary, metallic mines are known, not only to warm it with their exhalations, but often to destroy all kinds of vegetation by their volatile corrosive fumes. In some mines dense vapours are plainly perceived issuing from their mouths, and sensibly warm to the touch. In some places, neither snow nor ice will continue on the ground that covers a mine; and over others the fields are found destitute of verdure. The inhabitants, also, are rendered dreadfully sensible of these subterraneous exhalations, being affected with such a variety of evils proceeding entirely from this cause, that books have been professedly written upon this class of disorders.

Nor are these vapours which thus escape to the surface of the earth, entirely unconfined; for they are frequently, in a manner circumscribed to a spot: the grotto Del Cane, near Naples, is an instance of

this; the noxious effects of which have made that cavern so very famous. This grotto, which has so much employed the attention of travellers, lies within four miles of Naples, and is situated near a large lake of clear and wholesome water. Nothing can exceed the beauty of the landscape which this lake affords; being surrounded with hills covered with forests of the most beautiful verdure, and the whole bearing a kind of amphitheatrical appearance. However, this region, beautiful as it appears, is almost entirely uninhabited; the few peasants that necessity compels to reside there, looking quite consumptive and ghastly, from the poisonous exhalations that rise from the earth. The famous grotto lies on the side of an hill, near which place a peasant resides, who keeps a number of dogs for the purpose of shewing the experiment to the curious. These poor animals always seem perfectly sensible of the approach of a stranger, and endeavour to get out of the way. However, their attempts being perceived, they are taken and brought to the grotto; the noxious effects of which they have so frequently experienced. Upon entering this place, which is a little cave, or rather a hole dug into the hill, about eight feet high and twelve feet long, the observer can see no visible marks of its pestilential vapour; only to about a foot from the bottom, the wall seems to be tinged with a colour resembling that which is given by stagnant waters. When the dog, this poor philosophical martyr, as some have called him, is held above this mark, he does not seem to feel the smallest inconvenience; but when his head is thrust down lower, he struggles to get free for a little; but in the space of four or five minutes he seems to lose all sensation, and to be taken out without life. Being plunged in the neighbouring lake, he quickly recovers, and is permitted to run home seemingly without the smallest injury.

This vapour, which thus for a time suffocates, is of the humid kind, as it extinguishes a torch, and fuddies a looking-glass: but there are other vapours perfectly inflammable, and that only require the approach of a candle to set them blazing. Of this kind was the burning well at Brofely, which is now stopped up; the vapour of which, when a candle was brought within about a foot of the surface of the water, caught flame like spirits of wine, and continued blazing for several hours after. Of this kind, also, are the perpetual fires in the kingdom of Persia. In that province, where the worshippers of fire hold their chief mysteries, the whole surface of the earth, for some extent, seems impregnated with inflammable vapours. A reed struck into the ground continues to burn like a flambeau; an hole made beneath the surface of the earth, instantly becomes a furnace answering all the purposes of a culinary fire. There they make lime by merely burying the stones in the earth, and watch with veneration the appearances of a flame that has not been extinguished for times immemorial. How different are men in various climates! This deluded people worship these vapours as a deity, which in other parts of the world are considered as one of the greatest evils.

C H A P. IX.

OF VOLCANOES and EARTHQUAKES.

MINES and caverns, as we have said, reach but a very little way under the surface of the earth, and we have hitherto had no opportunities of exploring further. Without all doubt the wonders that are still unknown surpass those that have been represented, as there are depths of thousands of miles which are hidden from our enquiry. The

only tidings we have from those unfathomable regions are by means of volcanoes, those burning mountains that seem to discharge their materials from the lowest abysses of the earth. A volcano may be considered as a cannon of immense size, the mouth of which is often near two miles in circumference. From this dreadful aperture are discharged torrents of flame and sulphur, and rivers of melted metal. Whole clouds of smoke and ashes, with rocks of enormous size, are discharged to many miles distance; so that the force of the most powerful artillery is but as a breeze agitating a feather, in comparison. In the deluge of fire and melted matter which runs down the sides of the mountain, whole cities are sometimes swallowed up and consumed. Those rivers of liquid fire are often two hundred feet deep; and, when they harden, frequently form considerable hills. Nor is the danger of these confined to the eruption only: but the force of the internal fire struggling for vent, frequently produces earthquakes through the whole region where the volcano is situated. So dreadful have been these appearances, that men's terrors have added new horrors to the scene, and they have regarded as prodigies, what we know to be the result of natural causes. Some philosophers have considered them as vents communicating with the fires of the centre, and the ignorant as the mouths of hell itself. Astonishment produces fear, and fear superstition: the inhabitants of Iceland believe the bellowings of Hecla are nothing else but the cries of the damned, and that its eruptions are contrived to encrease their tortures.

But if we regard this astonishing scene of terror with a more tranquil and inquisitive eye, we shall find that these conflagrations are produced by very obvious and natural causes. We have already been apprized of the various mineral substances in the bosom of the earth, and their aptness to burst out into flames. Marcasites and pyrites, in particular, by being humidified with water, or air, contract this heat, and often endeavour to expand with irresistible explosion. These, therefore, being lodged in the depths of the earth, or in the bosom of mountains, and being either washed by the accidental influx of waters below, or fanned by air, insinuating itself through perpendicular fissures from above, take fire at first by only heaving in earthquakes, but at length by bursting through every obstacle, and making their dreadful discharge in a volcano.

These volcanoes are found in all parts of the earth: in Europe there are three that are very remarkable; *Ætna* in Sicily, *Vesuvius* in Italy, and *Hecla* in Iceland. *Ætna* has been a volcano for ages immemorial. Its eruptions are very violent, and its discharge has been known to cover the earth sixty-eight feet deep. In the year 1537, an eruption of this mountain produced an earthquake through the whole island, for twelve days, overturned many houses, and at last formed a new aperture which overwhelmed all within five leagues round. The cinders thrown up were driven even into Italy, and its burning were seen at Malta, at the distance of sixty leagues. There is nothing more awful, says Kircher, than the eruptions of this mountain, nor nothing more dangerous than attempting to examine its appearances, even long after the eruption has ceased. As we attempt to clamber up its steepy sides, every step we take upward, the feet sink back half way. Upon arriving near the summit, ashes and snow, with an ill assorted conjunction, present nothing but objects of desolation. Nor is this the worst, for, as all places are covered over, many caverns are intirely hidden from the sight, into which, if the enquirer happens to fall, he sinks to the bottom and meets inevitable destruction. Upon coming to the edge of the great crater, nothing can sufficiently

ficiently represent the tremendous magnificence of the scene. A gulph two miles over, and so deep that no bottom can be seen; on the sides pyramidical rocks starting out between apertures that emit smoke and flame; all this accompanied with a sound that never ceases, louder than thunder, strikes the bold with horror, and the religious with veneration for him that has power to controul its burnings.

In the descriptions of Vesuvius, or Hecla, we shall find scarce any thing but a repetition of the same terrible objects, though rather lessened, as these mountains are not so large as the former. The crater of Vesuvius is but a mile across, according to the same author; whereas that of *Ætna* is two. On this particular, however, we must place no dependence, as these caverns every day alter; being lessened by the mountains sinking in at one eruption, and enlarged by the fury of another. It is not one of the least remarkable particulars respecting Vesuvius, that Pliny the naturalist was suffocated in one of its eruptions; for his curiosity impelled him too near, he found himself involved in smoke and cinders when it was too late to retire; and his companions hardly escaped to give an account of the misfortune. It was in that dreadful eruption that the city of Herculaneum was overwhelmed; the ruins of which have been lately discovered at sixty feet distance below the surface, and what is still more remarkable, forty feet below the bed of the sea. One of the most remarkable eruptions of this mountain was in the year 1707, which is finely described by Valetta, a part of whose description we beg leave to translate.

“Towards the latter end of summer, in the year 1707, the mount Vesuvius, that had for a long time been silent, now began to give some signs of commotion. Little more than internal murmurs at first were heard, that seemed to contend within the lowest depths of the mountain; no flame, nor even any smoke, was as yet seen. Soon after some smoke appeared by day, and a flame by night, which seemed to brighten all the Campania. At intervals also it shot off substances with a sound very like that of artillery, but which, even at so great a distance as we were at, infinitely exceeded them in greatness. Soon after it began to throw up ashes, which becoming the sport of the winds, fell at great distances, and some many miles. To this succeeded showers of stones, which killed many of the inhabitants of the valley, but made a dreadful ravage among the cattle. Soon after a torrent of burning matter began to roll down the sides of the mountain, at first with a slow and gentle motion, but soon with increased celerity. The matter thus poured out, when cool, seemed, upon inspection, to be of a vitrified earth, the whole united into a mass of more than stony hardness. But what was particularly observable was, that upon the whole surface of these melted materials, a light spongy stone seemed to float, while the lower body was of the hardest substance, of which our roads are usually made. Hitherto there were no appearances but what had been often remarked before; but on the third or fourth day, seeming flashes of lightning were shot forth from the mouth of the mountain, with a noise far exceeding the loudest thunder. These flashes, in colour and brightness, resembled what we usually see in tempests, but they assumed a more twisted and serpentine form. After this followed such clouds of smoke and ashes, that the whole city of Naples, in the midst of the day, was involved in nocturnal darkness, and the nearest friends were unable to distinguish each other in this frightful gloom. If any person attempted to stir out without torch-light, he was obliged to return, and every part of the city was filled with supplica-

tions and terror; at length after a continuance of some hours, about one o'clock at midnight, the wind blowing from the north, the stars began to be seen; the heavens, though it was night, began to grow brighter; and the eruptions, after a continuance of fifteen days, to lessen. The torrent of melted matter was seen to extend from the mountain down to the shore; the people began to return to their former dwellings, and the whole face of nature to resume its former appearance.”

Bishop Berkley gives an account of one of these eruptions in a manner something different from the former. “In the year 1717, and the middle of April, with much difficulty I reached the top of mount Vesuvius, in which I saw a vast aperture full of smoke, which hindered me from seeing its depth and figure. I heard within that horrid gulph certain extraordinary sounds, which seemed to proceed from the bowels of the mountain, a sort of murmuring, sighing, dashing sound, and between whiles a noise like that of thunder or cannon, with a clattering like that of tiles falling from the tops of houses into the streets. Sometimes, as the wind changed, the smoke grew thinner, discovering a very ruddy flame, and the circumference of the crater streaked with red and several shades of yellow. After an hour's stay, the smoke being moved by the wind, gave us short and partial prospects of the great hollow; in the flat bottom of which I could discern two furnaces almost contiguous; that on the left seeming about three yards over, glowing with ruddy flame, and throwing up red hot stones, with an hideous noise, which, as they fell back, caused the clattering already taken notice of. May 8, in the morning, I ascended the top of Vesuvius a second time, and found a different face of things. The smoke ascending upright, gave a full prospect of the crater, which, as I could judge, was about a mile in circumference, and an hundred yards deep. A conical mount had been formed since my last visit in the middle of the bottom, which I could see was made by the stones, thrown up and fallen back again into the crater. In this new hill remained the two furnaces already mentioned. The one was seen to throw up every three or four minutes, with a dreadful sound, a vast number of red hot stones, at least three hundred feet higher than my head, as I stood upon the brink; but as there was no wind, they fell perpendicularly back from whence they had been discharged. The other was filled with red hot liquid matter, like that in the furnace of a glass-house; raging and working like the waves of the sea, with a short abrupt noise. This matter would sometimes boil over, and run down the side of the conical hill, appearing at first red hot, but changing colour as it hardened and cooled. Had the wind driven in our faces, we had been in no small danger of stifling by the sulphureous smoke, or being killed by the masses of melted minerals, that were shot from the bottom. But as the wind was favourable, I had an opportunity of surveying this amazing scene for above an hour and an half together. On the fifth of June, after an horrid noise, the mountain was seen at Naples to work over; and about three days after, its thunders were renewed so, that not only the windows in the city, but all the houses shook. From that time it continued to overflow, and sometimes at night were seen columns of fire shooting upward from its summit. On the tenth, when all was thought to be over, the mountain again renewed its terrors, roaring and raging most violently. One cannot form a juster idea of the noise, in the most violent fits of it, than by imagining a mixed sound, made up of the raging of a tempest, the murmur of a troubled sea, and the roaring of thunder and artillery, confused all together. Though we heard this at the distance of

twelve miles, yet it was very terrible. I therefore resolved to approach nearer to the mountain; and, accordingly, three or four of us got into a boat, and were set ashore at a little town, situated at the foot of the mountain. From thence we rode about four or five miles, before we came to the torrent of fire that was descending from the side of the volcano; and here the roaring grew exceeding loud and terrible as we approached. I observed a mixture of colours in the cloud, above the crater, green, yellow, red, blue. There was likewise a ruddy dismal light in the air, over that tract where the burning river flowed. These circumstances, set off and augmented by the horror of the night, made a scene the most uncommon and astonishing I ever saw; which still increased as we approached the burning river. Imagine a vast torrent of liquid fire, rolling from the top, down the side of the mountain, and with irresistible fury bearing down and consuming vines, olives, and houses; and divided into different channels, according to the inequalities of the mountain. The largest stream seemed half a mile broad at least, and five miles long. I walked so far before my companions up the mountain, along the side of the river of fire, that I was obliged to retire in great haste, the sulphureous steam having surpris'd me, and almost taken away by breath. During our return, which was about three o'clock in the morning, the roaring of the mountain was heard all the way, while we observed it throwing up huge spouts of fire and burning stones, which falling, resembled the stars in a rocket. Sometimes I observed two or three distinct columns of flame, and sometimes one only that was large enough to fill the whole crater. These burning columns, and fiery stones, seemed to be shot a thousand feet perpendicular above the summit of the volcano: and in this manner the mountain continued raging for six or eight days after. On the eighteenth of the same month the whole appearance ended, and the mountain remained perfectly quiet, without any visible smoke or flame."

The matter which is found to roll down from the mouth of all volcanoes in general, resembles the dross that is thrown from a smith's forge. But it is different, perhaps, in various parts of the globe; for, as we have already said, there is not a quarter of the world that has not its volcanoes. In Asia, particularly in the islands of the Indian ocean, there are many. One of the most famous is that of Albouras, near Mount Taurus, the summit of which is continually on fire, and covers the whole adjacent country with ashes. In the island of Ternate there is a volcano, which some travellers assert; burns most furiously in the times of the equinoxes, because of the winds which then contribute to increase the flames. In the Molucca islands there are many burning mountains; they are also seen in Japan, and the islands adjacent; and in Java and Sumatra, as well as in other of the Philippine islands. In Africa there is a cavern, near Fez, which continually sends forth either smoke or flames. In the Cape de Verde islands, one of them, called the Island del Fuego, continually burns; and the Portuguese, who frequently attempted a settlement there, have as often been obliged to desist. The Peak of Teneriffe is, as every body knows, a volcano that seldom desists from eruptions. But of all parts of the earth, America is the place where those dreadful irregularities of nature are the most conspicuous. Vesuvius, and *Ætna* itself, are but mere fire-works, in comparison to the burning mountains of the Andes; which as they are the highest mountains of the world, so also are they the most formidable for their eruptions. The mountain of Arequipa in Peru, is one of the most celebrated; Carrassa, and Malahallo, are very considerable; but

that of Cotopaxi, in the province of Quito, exceeds any thing we have hitherto read or heard of. The mountain of Cotopaxi, as described by Ulloa, is more than three miles perpendicular from the sea; and it became a volcano at the time of the Spaniards first arrival in that country. A new eruption of it happened in the year 1743, having been some days preceded by a continual roaring in its bowels. The sound of one of these mountains is not like that of the volcanoes in Europe, confined to a province, but is heard at an hundred and fifty miles distance. An aperture was made in the summit of this immense mountain; and three more about equal heights, near the middle of its declivity, which was at that time buried under prodigious masses of snow. The ignited substances ejected on that occasion, mixed with a prodigious quantity of ice and snow, melting amidst the flames, were carried down with such astonishing rapidity, that in an instant the valley from Callo to Latacunga was overflowed; and besides its ravages in bearing down the houses of the Indians, and other poor inhabitants, great numbers of people lost their lives. The river of Latacunga was the channel of this terrible flood; till being too small for receiving such a prodigious current, it overflowed the adjacent country, like a vast lake, near the town, and carried away all the buildings within its reach. The inhabitants retired into a spot of higher ground behind the town, of which those parts which stood within the limits of the current were totally destroyed. The dread of still greater devastations did not subside for three days; during which, the volcano ejected cinders, while torrents of melted ice and snow poured down its sides. The eruption lasted several days, and was accompanied with terrible roarings of the wind, rushing through the volcano still louder than the former rumblings in its bowels. At last all was quiet, neither fire nor smoke to be seen, nor noise to be heard; till, in the ensuing year, the flames again appeared with recruited violence, forcing their passage through several other parts of the mountain, so that in clear nights the flames being reflected by the transparent ice, formed an awfully magnificent illumination.

Such is the appearance and the effect of those fires which proceed from the more inward recesses of the earth; for that they generally come from deeper regions than man has hitherto explored, we cannot avoid thinking, contrary to the opinion of Mr. Buffon, who supposes them rooted but a very little way below the bed of the mountain. We can never suppose, says this great naturalist, that these substances are ejected from any great distance, below, if we only consider the great force already required to fling them up to such vast heights above the mouth of the mountain; if we consider the substances thrown up, which we shall find upon inspection to be the same with those of the mountain below; if we take into our consideration, that air is always necessary to keep up the flame; but, most of all, if we attend to one circumstance, which is, that if these substances were exploded from a vast depth below, the same force required to shoot them up so high, would act against the sides of the volcano, and tear the whole mountain in pieces. To all this specious reasoning, particular answers might easily be given; as that the length of the funnel increases the force of the explosion; that the sides of the funnel are actually often burst with the great violence of the flame; that air may be supposed at depths at least as far as the perpendicular fissures descend. But the best answer is a well-known fact; namely, that the quantity of matter discharged from *Ætna* alone, is supposed, upon a moderate computation, to exceed twenty times the original bulk of the mountain. The greatest part of Sicily, seems covered

covered with its eruptions. The inhabitants of Catania have found, at the distance of several miles, streets and houses, sixty feet deep, overwhelmed by the lava or matter it has discharged. But what is still more remarkable, the walls of these very houses have been built of materials evidently thrown up by the mountain. The inference from all this is very obvious; that the matter thus exploded cannot belong to the mountain itself, otherwise, it would have been quickly consumed; it cannot be derived from moderate depths, since its amazing quantity evinces, that all the places near the bottom must have long since been exhausted; nor can it have any extensive, and, if we may so call it, a superficial spread, for then the country round would be quickly undermined; it must, therefore, be supplied from the deeper regions of the earth; those undiscovered tracts where the Deity performs his wonders in solitude, satisfied with self-approbation!

C H A P. X. Of EARTHQUAKES.

HAVING given the theory of volcanoes, we have in some measure given also that of earthquakes. They both seem to proceed from the same cause, only with this difference, that the fury of the volcano is spent in the eruption, that of an earthquake spreads wider and acts more fatally by being confined. The volcano only affrights a province, earthquakes have laid whole kingdoms in ruin.

Philosophers have taken some pains to distinguish between the various kinds of earthquakes, such as the tremulous, the pulsative, the perpendicular, and the inclined; but these are rather the distinctions of art than of nature, mere accidental differences arising from the situation of the country or of the cause. If, for instance, the confined fire acts directly under a province or a town, it will heave the earth perpendicularly upward, and produce a perpendicular earthquake. If it acts at a distance, it will raise that tract obliquely, and thus the inhabitants will perceive an inclined one.

Nor does it seem that there is much greater reason for Mr. Buffon's distinction of earthquakes. One kind of which he supposes to be produced by fire in the manner of volcanoes, and confined but to a very narrow circumference. The other kind he ascribes to the struggles of confined air, expanded by heat in the bowels of the earth, and endeavouring to get free. For how do these two causes differ? Fire is an agent of no power whatsoever without air. It is the air, which being at first compressed, and then dilated in a cannon, that drives the ball with such force. It is the air struggling for vent in a volcano, that throws up its contents to such vast heights. In short, it is the air confined in the bowels of the earth, and acquiring elasticity by heat, that produces all those appearances generally ascribed to the operation of fire. When, therefore, we are told that there are two causes of earthquakes, we only learn, that a greater or smaller quantity of heat produces those terrible effects; for air is the only active operator in either.

Some philosophers, however, have been willing to give the air as great a share in producing these terrible efforts as they could; and, magnifying its powers, have called in but a very moderate degree of heat to put it in action. Although experience tells that the earth is full of inflammable materials, and that fires are produced wherever we descend; although it tells us that those countries, where there are volcanoes, are most subject to earthquakes, yet they step out of the way, and so find a new solution.

No. 49.

These only allow but just heat enough to produce the most dreadful phenomena, and backing their assertions with long calculations, give theory an air of demonstration. Mr. Amontons has been particularly sparing of the internal heat in this respect; and has shewn perhaps accurately enough, that a very moderate degree of heat may suffice to give the air amazing powers of expansion.

It is astonishing, however, to trace the progress of a philosophical fancy let loose in imaginary speculations. They run thus: "A very moderate degree of heat may bring the air into a condition capable of producing earthquakes; for the air at the depth of forty-three thousand five hundred and twenty-eight fathom below the surface of the earth, becomes almost as heavy as quicksilver. This, however, is but a very slight depth in comparison of the distance to the centre, and is scarce a seventieth part of the way. The air, therefore, at the centre must be infinitely heavier than mercury, or any body that we know of. This granted, we shall take something more, and say, that it is very probable there is nothing but air at the centre. Now let us suppose this air heated, by some means, even to the degree of boiling water, as we have proved that the density of the air is here very great, its elasticity must be in proportion: an heat, therefore, which at the surface of the earth would have produced but a slight expansive force, must at the centre produce one very extraordinary, and, in short, be perfectly irresistible. Hence this force may with great ease produce earthquakes; and if increased it may convulse the globe; it may (by only adding figures enough to the calculation) destroy the solar system, and even the fixed stars themselves." These revelations generally produce nothing; for as we have often observed, increased calculations, while they seem to tire the memory, give the reasoning faculty perfect repose.

However, as earthquakes are the most formidable ministers of nature, it is not to be wondered that a multitude of writers have been curiously employed in their consideration. Woodward has ascribed the cause to a stoppage of the waters below the earth's surface, by some accident. These being thus accumulated, and yet acted upon by fires, which he supposes still deeper, both contribute to heave up the earth upon their bosom. This he thinks accounts for the lakes of water produced in an earthquake, as well as for the fires that sometimes burst from the earth's surface upon those dreadful occasions. There are others who have supposed that the earth may be itself the cause of its own convulsions. When, say they, the roots or basis of some large tract is worn away by a fluid underneath, the earth sinking therein, its weight occasions a tremour of the adjacent parts, sometimes producing a noise, and sometimes an inundation of water. Not to tire the reader with an history of opinions instead of facts, some have ascribed them to electricity, and some to the same causes that produce thunder.

It would be tedious, therefore, to give all the various opinions that have employed the speculative upon this subject. The activity of the internal heat seems alone sufficient to account for every appearance that attends these tremendous irregularities of nature. To conceive this distinctly, let us suppose at some vast distance under the earth, large quantities of inflammable matter, pyrites, bitumens, and marcasites disposed, and only waiting for the aspersions of water, or the humidity of the air, to put their fires in motion; at last, this dreadful mixture arrives; waters find their way into those depths, through the perpendicular fissures; or air insinuates itself through the same minute apertures; immediately new appearances ensue: those substances, which for ages before lay dormant, now conceive

new apparent qualities; they grow hot, produce new air and only want room for expansion. However, the narrow apertures by which the air or water had at first admission, are now closed up; yet as new air is continually generated, and as the heat every moment gives this air new elasticity, it at length bursts, and dilates all round; and, in its struggles to get free, throws all above it into similar convulsions. Thus an earthquake is produced, more or less extensive, according to the depth or the greatness of the cause.

But before we proceed with the causes, let us take a short view of the appearances which have attended the most remarkable earthquakes. By these we shall see how far the theorist corresponds with the historian. The greatest we find in antiquity, is that mentioned by Pliny, in which twelve cities in Asia Minor were swallowed up in one night: he tells us also of another, near the lake Thrasymene, which was not perceived by the armies of the Carthaginians and Romans, that were then engaged near that lake, although it shook the greatest part of Italy. In another place he gives the following account of an earthquake of an extraordinary kind. "When Lucius Marcus, and Sextus Julius, were consuls, there appeared a very strange prodigy of the earth, (as I have read in the books of Ætruscan discipline) which happened in the province of Mutina. Two mountains shocked against each other, approaching and retiring with the most dreadful noise. They, at the same time, and in the midst of the day, appeared to cast forth fire and smoke, while a vast number of Roman knights and travellers from the Æmilian way, stood and continued amazed spectators. Several towns were destroyed by this shock; and all the animals that were near them were killed." In the times of Trajan, the city of Antioch, and a great part of the adjacent country, was buried by an earthquake. About three hundred years after, in the times of Justinian, it was once more destroyed, together with forty thousand inhabitants: and, after an interval of sixty years, the same ill-fated city was a third time overturned, with the loss of not less than sixty thousand souls. In the year 1182, most of the cities of Syria, and the kingdom of Jerusalem, were destroyed by the same accident. In the year 1594, the Italian historians describe an earthquake at Puteoli, which caused the sea to retire two hundred yards from its former bed.

But one of those most particularly described in history, is that of the year 1693; the damages of which were chiefly felt in Sicily, but its motion perceived in Germany, France, and England. It extended to a circumference of two thousand six hundred leagues; chiefly affecting the sea-coasts, and great rivers; more perceivable also upon the mountains than in the vallies. Its motions were so rapid, that those who lay at their length, were tossed from side to side, as upon a rolling billow. The walls were dashed from their foundations; and no less than fifty-four cities, with an incredible number of villages, were either destroyed or greatly damaged. The city of Catania, in particular, was utterly overthrown. A traveller, who was on his way thither, at the distance of some miles, perceived a black cloud, like night, hanging over the place. The sea, all of a sudden, began to roar; Mount Ætna to send forth great spires of flame; and soon after a shock ensued, with a noise as if all the artillery in the world had been at once discharged. Our traveller, being obliged to alight instantly, felt himself raised a foot from the ground; and turning his eyes to the city, he with amazement saw nothing but a thick cloud of dust in the air. The birds flew about astonished; the sun was darkened; the beasts ran howling from the hills; and, although the

shock did not continue above three minutes, yet near nineteen thousand of the inhabitants of Sicily perished in the ruins. Catania, to which city the describer was travelling, seemed the principal scene of ruin; its place only was to be found; and not a footstep of its former magnificence was to be seen remaining.

The earthquake which happened in Jamaica, in 1692, was very terrible, and its description sufficiently minute. "In two minutes time it destroyed the town of Port-Royal, and sunk the houses in a gulph forty fathoms deep. It was attended with an hollow rumbling noise, like that of thunder; and, in less than a minute, three parts of the houses, and their inhabitants, were all sunk quite under water. While they were thus swallowed up on one side of the street or the other, the houses were thrown into heaps; the sand of the street rising like the waves of the sea, lifting up those that stood upon it, and immediately overwhelming them in pits. All the wells discharged their waters with the most vehement agitation. The sea felt an equal share of turbulence, and, bursting over its mounds, deluged all that came in its way. The fissures of the earth were, in some places, so great, that one of the streets appeared twice as broad as formerly. In many places, however, it opened and closed again, and continued this agitation for some time. Of these openings, two or three hundred might be seen at a time; in some whereof the people were swallowed up: in others, the earth closing, caught them by the middle, and thus crushed them instantly to death. Other openings, still more dreadful than the rest, swallowed up whole streets; and others, more formidable, spouted up whole cataracts of water, drowning such as the earthquake had spared. The whole was attended with the most noisome stench; while the thundering of the distant falling mountains, the whole sky overcast with a dusky gloom, and the crash of falling habitations, gave unspeakable horror to the scene. After this dreadful calamity was over, the whole island seemed converted into a scene of desolation; scarce a planter's house was left standing; almost all were swallowed up; houses, people, trees, shared one universal ruin; and, in their places appeared great pools of water, which, when dried up by the sun, left only a plain of barren sand, without any vestige of former inhabitants. Most of the rivers, during the earthquake, were stopt up by the falling in of the mountains; and it was not till after some time that they made themselves new channels. The mountains seemed particularly attacked by the force of the shock; and it was supposed that the principal seat of the concussion was among them. Those who were saved, got on board ships in the harbour; where many remained above two months, the shocks continuing during that interval with more or less violence every day."

As this description seems to exhibit all the appearances that usually make up the catalogue of terrors belonging to an earthquake, we will suppress the detail of that which happened at Lisbon, in our own times, and which is too recent to require a description. In fact, there are few particulars in the accounts of those who were present at that scene of desolation, that we have not more minutely and accurately transmitted to us by former writers, whose narratives we have for that reason preferred. We will, therefore, close this description of human calamities, with the account of the dreadful earthquake at Calabria, in 1638. It is related by the celebrated Father Kircher, as it happened while he was on his journey to visit Mount Ætna, and the rest of the wonders that lie towards the south of Italy. The reader, need scarce be informed, that Kircher is considered, by scholars, as one of the greatest prodigies of learning.

"Having

“ Having hired a boat, in company with four more, two friars of the order of St. Francis, and two seculars, we launched, on the twenty-four of March, from the harbour of Messina, in Sicily, and arrived, the same day, at the promontory of Pelorus. Our destination was for the city of Euphæmia, in Calabria, where we had some business to transact, and where we designed to tarry for some time. However, Providence seemed willing to cross our design; for we were obliged to continue for three days at Pelorus, upon account of the weather; and though we often put out to sea, yet we were as often driven back. At length, however, wearied with the delay, we resolved to prosecute our voyage; and, although the sea seemed more than usually agitated, yet we ventured forward. The gulph of Charybdis, which we approached, seemed whirled round in such a manner, as to form a vast hollow verging to a point in the centre. Proceeding onward, and turning my eyes to Ætna, I saw it cast forth large volumes of smoke, of mountainous sizes, which entirely covered the whole island, and blotted out the very shores from my view. This, together with the dreadful noise, and the sulphureous stench, which was strongly perceived, filled me with apprehensions that some more dreadful calamity was impending. The sea itself seemed to wear a very unusual appearance; those who have seen a lake in a violent shower of rain covered all over with bubbles, will conceive some idea of its agitations. My surprize was still encreased by the calmness and serenity of the weather; not a breeze, not a cloud which might be supposed to put all Nature thus into motion. I therefore warned my companions that an earthquake was approaching; and, after some time, making for the shore with all possible diligence, we landed at Tropæa, happy and thankful for having escaped the threatening dangers of the sea.

“ But our triumphs at land were of short duration; for we had scarce arrived at the Jesuits College in that city, when our ears were stunned with an horrid sound, resembling that of an infinite number of chariots driven fiercely forward, the wheels rattling, and the thongs cracking. Soon after this, a most dreadful earthquake ensued; so that the whole tract upon which we stood seemed to vibrate, as if we were in the scale of a balance that continued wavering. This motion, however, soon grew more violent; and being no longer able to keep my legs, I was thrown prostrate upon the ground. In the mean time, the universal ruin round me redoubled my amazement. The crash of falling houses, the tottering of towers, and the groans of the dying, all contributed to raise my terror and despair. On every side of me I saw nothing but a scene of ruin; and danger threatening wherever I should fly. I commended myself to God as my last great refuge. At that hour, O how vain was every sublunary happiness! wealth, honour, empire, wisdom, all mere useless sounds, and as empty as the bubbles in the deep. Just standing on the threshold of eternity, nothing but God was my pleasure; and the nearer I approached, I only loved him the more. After some time, however, finding that I remained unhurt, amidst the general concussion, I resolved to venture for safety, and running as fast as I could, reached the shore, but almost terrified out of my reason. I did not search long here till I found the boat in which I had landed, and my companions also, whose terrors were even greater than mine. Our meeting was not of that kind where every one is desirous of telling his own happy escape; it was all silence, and a gloomy dread of impending terrors.

“ Leaving this seat of desolation, we prosecuted our voyage along the coast; and the next day came

to Rochetta, where we landed, although the earth still continued in violent agitations. But we were scarce arrived at our inn, when we were once more obliged to return to the boat; and, in about half an hour, we saw the greatest part of the town, and the inn at which we had set up, dashed to the ground, and burying all its inhabitants beneath its ruins.

“ In this manner, proceeding onward in our little vessel, finding no safety at land, and yet, from the smallness of our boat, having but a very dangerous continuance at sea, we at length landed at Lopi-zium, a castle midway between Tropæa and Euphæmia, the city to which, as I said before, we were bound. Here, wherever I turned my eyes, nothing but scenes of ruin and horror appeared; towns and castles levelled to the ground; Strombalo, though at sixty miles distance, belching forth flames in an unusual manner, and with a noise which I could distinctly hear. But my attention was quickly turned from more remote to contiguous danger. The rumbling sound of an approaching earthquake, which we by this time were grown acquainted with, alarmed us for the consequences; it every moment seemed to grow louder, and to approach more near. The place on which we stood now began to shake most dreadfully; so that being unable to stand, my companions and I caught hold of whatever shrub grew next us, and supported ourselves in that manner.

“ After some time, this violent paroxysm ceasing, we again stood up, in order to prosecute our voyage to Euphæmia, that lay within sight. In the mean time, while we were preparing for this purpose, I turned my eyes towards the city, but could see only a frightful dark cloud, that seemed to rest upon the place. This the more surprized us, as the weather was so very serene. We waited, therefore, till the cloud was past away: then turning to look for the city, it was totally sunk. Wonderful to tell! nothing but a dismal and putrid lake was seen where it stood. We looked about to find some one that could tell us of its sad catastrophe, but could see none. All was become a melancholy solitude; a scene of hideous desolation. Thus proceeding pensively along, in quest of some human being that could give us some little information, we at length saw a boy sitting by the shore, and appearing stupified with terror. Of him, therefore, we enquired concerning the fate of the city; but he could not be prevailed on to give us an answer. We entreated him with every expression of tenderness and pity to tell us; but his senses were quite wrapt up in the contemplation of the danger he had escaped. We offered him some victuals, but he seemed to loath the sight. We still, persisted in our offices of kindness; but he only pointed to the place of the city, like one out of his senses; and then running up into the woods, was never heard of after. Such was the fate of the city of Euphæmia: and as we continued our melancholy course along the shore; the whole coast, for the space of two hundred miles, presented nothing but the remains of cities; and men scattered, without an habitation, over the fields. Proceeding thus along, we at length ended our distressful voyage by arriving at Naples, after having escaped a thousand dangers both at sea and land.”

We hope the reader will excuse this long translation from a favourite writer, and that the sooner, as it contains some particulars relative to earthquakes not to be found elsewhere. From the whole of these accounts we may gather, than the most concomitant circumstances are these:

1. A rumbling sound before the earthquake. This proceeds from the air, or fire, or both, forcing their way through the chasms of the earth, and endeavouring

deavouring to get free, which is also heard in volcanoes.

A violent agitation, or heaving of the sea, sometimes before and sometimes after that at land. This agitation is only a similar effect produced on the waters with that at land, and may be called, for the sake of perspicuity, a sea-quake; and this also is produced by volcanoes.

A spouting up of waters to great heights. It is not easy to describe the manner in which this is performed; but volcanoes also perform the same, Vesuvius being known frequently to eject a vast body of water.

A rocking of the earth to and fro, and sometimes a perpendicular bouncing, if it may be so called, of the same. This difference chiefly arises from the situation of the place with respect to the subterranean fire. Directly under it lifts; at a farther distance, it rocks.

Some earthquakes seem to travel onward, and are felt in different countries at different hours the same day. This arises from the great shock being given to the earth at one place, and that being communicated onward by an undulatory motion, successively affects different regions in its progress; as the blow given by a stone falling in a lake is not perceived at the shores till some time after the first concussion.

The shock is sometimes instantaneous, like the explosion of gunpowder; and sometimes tremulous, and continuing for several minutes. The nearer the place where the shock is first given, the more instantaneous and simple it appears. At a greater distance the earth redoubles the first blow, with a sort of vibratory continuation.

As waters have generally so great a share in producing earthquakes, it is not to be wondered that they should generally follow those breaches made by the force of fire, and appear in the great chasms which the earthquake has opened.

These are some of the most remarkable phenomena of earthquakes, presenting a frightful assemblage of the most terrible effects of air, earth, fire, and water.

The valley of Solfatara, near Naples, seems to exhibit, in a minuter degree, whatever is seen of this horrible kind on the great theatre of Nature. This plain, which is about twelve hundred feet long, and a thousand broad, is embosomed in mountains, and has in the middle of it a lake of noisome blackish water, covered with a bitumen, that floats upon its surface. In every part of this plain, caverns appear smoking with sulphur, and often emitting flames. The earth, wherever we walk over it, trembles beneath the feet. Noises of flames, and the hissing of waters, are heard at the bottom. The water sometimes spouts up eight or ten feet high. The most noisome fumes, foetid water, and sulphureous vapours, offend the smell. A stone thrown into any of the caverns, is ejected again with considerable violence. These appearances generally prevail when the sea is any way disturbed; and the whole seems to exhibit the appearance of an earthquake in miniature. However, in this smaller scene of wonders, as well as in the greater, there are many appearances for which perhaps we shall never account; and many questions may be asked, which no conjectures can thoroughly resolve. It was the fault of the philosophers of the last age, to be more inquisitive after the causes of things, than after the things themselves. They seemed to think that a confession of ignorance cancelled their claims to wisdom: they, therefore, had a solution for every demand. But the present age has grown, if not more inquisitive, at least more modest; and none are now ashamed of that ignorance which labour can neither remedy nor remove.

CHAP. XI.

Of the Appearance of New ISLANDS, and TRACTS; and of the disappearing of others.

HITHERTO we have taken a survey only of the evils which are produced by subterranean fires, but we have mentioned nothing of the benefits they may possibly produce. They may be of use in warming and cherishing the ground, in promoting vegetation, and giving a more exquisite flavour to the productions of the earth. The imagination of a person who has never been out of our own mild region, can scarcely reach to that luxuriant beauty with which all Nature appears clothed in those very countries that we have but just now described as desolated by earthquakes, and undermined by subterranean fires. It must be granted, therefore, that though in those regions they have a greater share in the dangers, they have also a larger proportion in the benefits of Nature.

But there is another advantage arising from subterranean fires, which, though hitherto disregarded by man, yet may one day become serviceable to him; namely, that while they are found to swallow up cities and plains in one place, they are also known to produce promontories and islands in another. We have many instances of islands being thus formed in the midst of the sea, which though for a long time barren, have afterwards become fruitful seats of happiness and industry.

New islands are formed in two ways; either suddenly, by the action of subterraneous fires; or more slowly, by the deposition of mud, carried down by rivers, and stopped by some accident. With respect particularly to the first, ancient historians, and modern travellers, give us such accounts as we can have no room to doubt of. Seneca assures us, that in his time the island of Therasia appeared unexpectedly to some mariners, as they were employed in another pursuit. Pliny assures us, that thirteen islands in the Mediterranean appeared at once emerging from the water; the cause of which he ascribes rather to the retiring of the sea in those parts, than to any subterraneous elevation. However, he mentions the island of Hiera, near that of Therasia, as formed by subterraneous explosions; and adds to his list several others, formed in the same manner. In one of which he relates that fish in great abundance were found, and that all those who eat of them died shortly after.

“On the twenty-fourth of May, in the year 1707, a slight earthquake was perceived at Santorin; and the day following, at sun-rising, an object was seen by the inhabitants of that island, at two or three miles distant at sea, which appeared like a floating rock. Some persons, desirous either of gain or excited by curiosity, went there, and found, even while they stood upon this rock, that it seemed to rise beneath their feet. They perceived also that its surface was covered with pumice stones and oysters, which it had raised from the bottom. Every day after, until the fourteenth of June, this rock seemed considerably to increase; and then was found to be half a mile round, and about thirty feet above the sea. The earth of which it was composed seemed whitish, with a small portion of clay. Soon after this the sea again appeared troubled, and steams arose, which were very offensive to the inhabitants of Santorin. But on the sixteenth of the succeeding month, seventeen or eighteen rocks more were seen to rise out of the sea, and at length to join together. All this was accompanied with the most terrible noise, and fires which proceeded from the island that was newly formed. The whole mass, however, of all this new-formed earth, uniting, increased every day, both in height and breadth, and,

by

by the force of its explosions, cast forth rocks to seven miles distance. This continued to bear the same dreadful appearances till the month of November in the same year; and it is at present a volcano which sometimes renews its explosions. It is about three miles in circumference; and more than from thirty-five to forty feet high."

It seems extraordinary, that about this place in particular, islands have appeared at different times, particularly that of Hiera, mention above, which has received considerable additions in succeeding ages. Justin tells us, that at the time the Macedonians were at war with the Romans, a new island appeared between those of Theramenes and Thersia, by means of an earthquake. We are told, that this became half as big again about a thousand years after; another island rising up by its side, and joining to it, so as scarce at present to be distinguished from the former.

A new island was formed, in the year 1720, near that of Tercera, near the continent of Africa, by the same causes. In the beginning of December, at night, there was a terrible earthquake at that place, and the top of a new island appeared, which cast forth smoke in vast quantities. The pilot of a ship, who approached it, founded on one side of this island, and could not find ground at sixty fathom. At the other side the sea was totally tinged of a different colour, exhibiting a mixture of white, blue, and green; and was very shallow. This island, on its first appearance, was larger than it is at present; for it has, since that time, sunk in such a manner, as to be scarce above water.

A traveller, whom these appearances could not avoid affecting, speaks of them in this manner: "What can be more surprising than to see fire not only break out of the bowels of the earth, but also to make itself a passage through the waters of the sea! What can be more extraordinary or foreign to our common notions of things, than to see the bottom of the sea rise up into a mountain above the water, and become so firm an island as to be able to resist the violence of the greatest storms! I know that subterraneous fires, when pent in a narrow passage, are able to raise up a mass of earth as large as an island. But that this should be done in so regular and exact a manner that the water of the sea should not be able to penetrate and extinguish those fires; that, after having made so many passages, they should retain force enough to raise the earth; and, in fine, after having been extinguished, that the mass of earth should not fall down, or sink again with its own weight, but still remain in a manner suspended over the great arch below! This is what to me seems more surprising than any thing that has been related of Mount *Ætna*, *Vesuvius*, or any other volcano."

Such are his sentiments; however, there are few of these appearances any way more extraordinary than those attending volcanoes and earthquakes in general. We are not more to be surprised that inflammable substances should be found beneath the bottom of the sea, than at similar depths at land. These have all the force of fire giving expansion to air, and tending to raise the earth at the bottom of the sea, till it at length heaves above water. These marine volcanoes are not so frequent; for, if we may judge of the usual procedure of Nature, it must very often happen that, before the bottom of the sea is elevated above the surface, a chasm is opened in it, and then the water pressing in, extinguishes the volcano before it has time to produce its effects. This extinction, however, is not effected without very great resistance from the fire beneath. The water, upon dashing into the cavern, is very probably at first ejected back with great violence; and thus some of those amazing water-spouts are seen,

which have so often astonished the mariner, and excited curiosity.—But of these in their place.

Besides the production of those islands by the action of fire, there are others, as was said, produced by rivers or seas carrying mud, earth, and such like substances, along with their currents; and at last depositing them in some particular place. At the mouths of most great rivers, there are to be seen banks, thus formed by the sand and mud carried down with the stream, which have rested at that place, where the force of the current is diminished by its junction with the sea. These banks, by slow degrees, increase at the bottom of the deep; the water in those places, is at first found by mariners to grow more shallow; the bank soon heaves up above the surface; it is considered, for a while, as a tract of useless and barren sand; but the seeds of some of the more hardy vegetables are driven thither by the wind, take root, and thus binding the sandy surface, the whole spot is clothed in time with a beautiful verdure. In this manner there are delightful and inhabited islands at the mouths of many rivers, particularly the Nile, the Po, the Mississippi, the Ganges, and the Senegal. There has been, in the memory of man, a beautiful and large island formed in this manner, at the mouth of the river Nanquin, in China, made from depositions of mud at its opening: it is not less than sixty miles long, and about twenty broad. La Loubere informs us, in his voyage to Siam, that these sand-banks increase every day, at the mouths of all the great rivers in Asia: and hence he asserts, that the navigation up these rivers becomes every day more difficult; and will, at one time or another, be totally obstructed. The same may be remarked with regard to the Wolga, which has at present seventy openings into the Caspian sea; and of the Danube, which has seven into the Euxine. We have had an instance of the formation of a new island, not very long since, at the mouth of the Humber, in England. "It is yet within the memory of man," says the relator, "since it began to raise its head above the ocean. It began its appearance at low water, for the space of a few hours; and was buried again till the next tide's retreat. Thus, successively, it lived and died, until the year 1666, when it began to maintain its ground against the insult of the waves; and then first invited the aid of human industry. A bank was thrown about its rising grounds; and being thus defended from the incursions of the sea, it became firm and solid, and, in a short time, afforded good pasturage for cattle. It is about nine miles in circumference, and is worth to the proprietor about eight hundred pounds a year." It would be endless to mention all the islands that have been thus formed, and the advantages that have been derived from them. However, it is frequently found, that new islands may often be considered as only turning the rivers from their former beds; so that, in proportion as land is gained at one part, it is lost by the overflowing of some other.

Little, therefore, is gained by such accessions; nor is there much more by the new islands which are sometimes formed from the spoils of the continent. Mariners assure us, that there are sometimes whole plains unrooted from the main lands, by floods and tempests. These being carried out to sea, with all their trees and animals upon them, are frequently seen floating in the ocean, and exhibiting a surprising appearance of rural tranquillity in the midst of danger. The greatest part, however, having the earth at their roots at length washed away, are dispersed, and their animals drowned; but now and then some are found to brave the fury of the ocean, till being stuck either among rocks or sands, they again take firm footing, and become permanent islands.

As different causes have thus concurred to produce new islands, so we have accounts of others that the same causes have contributed to destroy. We have already seen the power of earthquakes exerted in sinking whole cities, and leaving lakes in their room. There have been islands, and regions also, that have shared the same fate; and have sunk with their inhabitants, never more to be heard of. Thus Pausanias tells us of an island, called Chryses, that was sunk near Lemnos. Pliny mentions several; among others, the island of Cea, for thirty miles, having been washed away, with several thousands of its inhabitants. But of all the noted devastations of this kind, the total submersion of the island of Atalantis, as mentioned by Plato, has been most the subject of speculation. Mankind, in general, now consider the whole of his account as an ingenious fable; but when fables are grown famous by time and authority, they become an agreeable, if not a necessary part of literary information.

"About nine thousand years are passed," says Plato, "since the island of Atalantis was in being. The priests of Egypt were well acquainted with it; and the first heroes of Athens gained much glory in their wars with the inhabitants. This island was as large as Asia Minor and Syria united; and was situated beyond the pillars of Hercules, in the Atlantic ocean. The beauty of the buildings, and the fertility of the soil, were far beyond any thing a modern imagination can conceive; gold and ivory were every where common; and the fruits of the earth offered themselves without cultivation. The arts, and the courage of the inhabitants, were not inferior to the happiness of their situation; and they were frequently known to make conquests, and over-run the continent of Europe and Asia. The imagination of the poetical philosopher riots in the description of the natural and acquired advantages, which they long enjoyed in this charming region. If, says he, we compare that country to our own, ours will appear a mere wasted skeleton, when opposed to it. Their mountains to the very tops were clothed with fertility, and poured down rivers to enrich the plains below."

However, all these beauties and benefits were destroyed in one day by an earthquake sinking the earth, and the sea overwhelming it. At present, not the smallest vestiges of such an island are to be found; Plato remains as the only authority for its existence; and philosophers dispute about its situation. However, we do not mean to enter into the controversy, as there appears but little probability to support the fact; and, indeed, it would be useless to run back nine thousand years in search of difficulties, as we are surrounded with objects that more closely affect us, and that demand admiration at our very doors. When we consider, as Lactantius suggests, the various vicissitudes of nature; lands swallowed by yawning earthquake, or overwhelmed in the deep; rivers and lakes disappearing, or dried away; mountains levelled into plains; and plains swelling up into mountains; we cannot help regarding this earth as a place of very little stability: as a transient abode of still more transitory beings.

CHAP. XII.

OF MOUNTAINS.

HAVING at last, in some measure, emerged from the deeps of the earth, we come to a scene of greater splendour; the contemplation of its external appearance. In this survey, its mountains are the first objects that strike the imagination, and excite our curiosity. There is not, perhaps, any thing in all nature that impresses an unaccustomed

spectator with such ideas of awful solemnity, as these immense piles of Nature's erecting, that seem to mock the minuteness of human magnificence.

In countries where there are nothing but plains, the smallest elevations are apt to excite wonder. In Holland, which is all a flat, they shew a little ridge of hills, near the sea-side, which Boerhaave generally marked out to his pupils, as being mountains of no small consideration. What would be the sensations of such an auditory, could they at once be presented with a view of the heights and precipices of the Alps, or the Andes! Even among us, in England, we have no adequate ideas of a mountain-prospect; our hills are generally sloping from the plain, and clothed to the very top with verdure; we can scarce, therefore, lift our imaginations to those immense piles whose tops peep up behind intervening clouds, sharp and precipitate, and reach to heights that human avarice or curiosity have never been able to ascend.

We, in this part of the world, are not, for that reason, so immediately interested in the question which has so long been agitated among philosophers, concerning what gave rise to these inequalities on the surface of the globe. In our own happy region, we generally see no inequalities but such as contribute to use and beauty; and we, therefore, are amazed at a question enquiring how such necessary inequalities came to be formed, and seeming to express a wonder how the globe comes to be so beautiful as we find it. But though with us there may be no great cause for such a demand, yet in those places where mountains deform the face of Nature, where they pour down cataracts, or give fury to tempests, there seems to be good reason for enquiry either into their causes or their uses. It has been, therefore, asked by many, in what manner mountains have come to be formed; or for what uses they are designed?

To satisfy curiosity in these respects, much reasoning has been employed, and very little knowledge propagated. With regard to the first part of the demand, the manner in which mountains were formed, we have already seen the conjectures of different philosophers on that head. One supposing that they were formed from the earth's broken shell, at the time of the deluge: another, that they existed from the creation, and only acquired their deformities in process of time: a third, that they owed their original to earthquakes: and still a fourth, with much more plausibility than the rest, ascribing them entirely to the fluctuations of the deep, which he supposes in the beginning to have covered the whole earth. Such as are pleased with disquisitions of this kind, may consult Burnet, Whiston, Woodward, or Buffon. Nor would we be thought to decry any mental amusements, that at worst keep us innocently employed; but we cannot help wondering how the opposite demand has never come to be made; and why philosophers have never asked how we come to have plains? Plains are sometimes more prejudicial to man than mountains. Upon plains, an inundation has greater power; the beams of the sun are often collected there with suffocating fierceness; they are sometimes found desert for several hundred miles together, as in the country east of the Caspian sea, although otherwise fruitful, merely because there are no risings nor depressions to form reservoirs, or collect the smallest rivulet of water. The most rational answer, therefore, why either mountains or plains were formed, seems to be, that they were thus fashioned by the hand of Wisdom, in order that pain and pleasure should be so contiguous, as that morality might be exercised either in bearing the one, or communicating the other.

Indeed, the more we consider this dispute respecting

specting the formation of mountains, the more we are struck with the futility of the question. There is neither a straight line, nor an exact superficies, in all nature. If we consider a circle, even with mathematical precision, we shall find it formed of a number of small right lines, joining at angles together. These angles, therefore, may be considered in a circle as mountains are upon our globe; and to demand the reason for the one being mountainous, or the other angular, is only to ask why a circle is a circle, or a globe is a globe. In short, if there be no surface without inequality in Nature, why should we be surprised that the earth has such? It has often been said, that the inequalities of its surface are scarce distinguishable, if compared to its magnitude; and indeed we have every reason to be content with the answer.

Some, however, have avoided the difficulty by urging the final cause. They alledge that mountains have been formed merely because they are useful to man. This carries the enquirer but a part of the way; for no one can affirm that in all places they are useful. The contrary is known, by horrid experience, in those valleys that are subject to their influence. However, as the utility of any part of our earthly habitation, is a very pleasing and flattering speculation to every philosopher, it is not to be wondered that much has been said to prove the usefulness of these. For this purpose, many conjectures have been made that have received a degree of assent even beyond their evidence; for men were unwilling to become more miserably wise.

It has been alledged, as one principal advantage that we derive from them, that they serve, like hoops or ribs, to strengthen our earth, and to bind it together. In consequence of this theory, Kircher has given us a map of the earth, in this manner hooped with its mountains; which might have a much more solid foundation, did it entirely correspond with truth.

Others have found a different use for them, especially when they run surrounding our globe; which is, that they stop the vapours which are continually travelling from the equator to the poles; for these being urged by the heat of the sun, from the warm regions of the line, must all be accumulated at the poles, if they were not stopped in their way by those high ridges of mountains which cross their direction. But an answer to this may be, that all the great mountains in America lie lengthwise, and therefore do not cross their direction.

But to leave these remote advantages, others assert, that not only the animal but vegetable part of the creation would perish for want of convenient humidity, were it not for their friendly assistance. Their summits are, by these, supposed to arrest, as it were, the vapours which float in the regions of the air. The large inflexions, and channels, are considered as so many basins prepared for the reception of those thick vapours, and impetuous rains, which descend into them. The huge caverns beneath are so many magazines or conservatories of water for the peculiar service of man: and those orifices by which the water is discharged upon the plain, are so situated as to enrich and render them fruitful, instead of returning through subterraneous channels to the sea, after the performance of a tedious and fruitless circulation.

However this be, certain it is that almost all our great rivers find their source among mountains; and, in general, the more extensive the mountain, the greater the river: thus the river Amazons, the greatest in the world, has its source among the Andes, which are the highest mountains on the globe; the river Niger travels a long course of several hundred miles from the mountains of the Moon, the highest in all Africa; and the Danube

and the Rhine proceed from the Alps, which are probably the highest mountains of Europe.

It need scarce be said that, with respect to height, there are many sizes of mountains, from the gently rising upland, to the tall craggy precipice. The appearance is in general different in those of different magnitudes. The first are clothed with verdure to the very tops, and only seem to ascend to improve our prospects, or supply us with a purer air: but the lofty mountains of the other class have a very different aspect. At a distance their tops are seen, in wavy ridges, of the very colour of the clouds, and only to be distinguished from them by their figure, which, as we have said, resemble the billows of the sea. As we approach, the mountain assumes a deeper colour; it gathers upon the sky, and seems to hide half the horizon behind it. Its summits also are become more distinct, and appear with a broken and perpendicular line. What at first seemed a single hill, is now found to be a chain of continued mountains, whose tops running along in ridges, are embosomed in each other: so that the curvatures of one are fitted to the prominences of the opposite side, and form a winding valley between, often of several miles in extent; and all the way continuing nearly of the same breadth.

Nothing can be finer, or more exact, than Mr. Pope's description of a traveller straining up the Alps. Every mountain he comes to, he thinks will be the last; he finds, however, an unexpected hill rise before him; and that being scaled, he finds the highest summit almost at as great a distance as before. Upon quitting the plain, he might have left a green and a fertile soil, and a climate warm and pleasing. As he ascends, the ground assumes a more ruflet colour; the grass becomes more mossy, and the weather more moderate. Still as he ascends, the weather becomes more cold, and the earth more barren. In this dreary passage, he is often entertained with a little valley of surprising verdure, caused by the reflected heat of the sun collected into a narrow spot on the surrounding heights. But it much more frequently happens that he sees only frightful precipices beneath, and lakes of amazing depths; from whence rivers are formed, and fountains derive their original. On those places next the highest summits, vegetation is scarcely carried on; here and there a few plants of the most hardy kind appear. The air is intolerably cold; either continually refrigerated with frosts, or disturbed with tempests. All the ground here wears an eternal covering of ice, and snows that seem constantly accumulating. Upon emerging from this war of the elements, he ascends into a purer and a serener region, where vegetation is entirely ceased; where the precipices, composed entirely of rocks, rise perpendicularly above him; while he views beneath him all the combat of the elements; clouds at his feet; and thunders darting upward from their bosoms below. A thousand meteors, which are never seen on the plain, present themselves. Circular rainbows; mock suns; the shadow of the mountain projected upon the body of the air; and the traveller's own image, reflected as in a looking-glass, upon the opposite cloud.

Such are, in general, the wonders that present themselves to a traveller in his journey either over the Alps or the Andes. But we must not suppose that this picture exhibits either a constant or an invariable likeness of those stupendous heights. Indeed, nothing can be more capricious or irregular than the forms of many of them. The tops of some run in ridges for a considerable length, without interruption; in others, the line seems indented by great valleys to an amazing depth. Sometimes a solitary and a single mountain rises from the bosom of the plain; and sometimes extensive plains, and even provinces,

provinces, as those of Savoy and Quito, are found embosomed near the tops of mountains. In general, however, those countries that are most mountainous, are the most barren and uninhabitable.

If we compare the heights of mountains with each other, we shall find that the greatest and highest are found under the Line. It is thought by some, that the rapidity of the earth's motion in these parts, together with the greatness of the tides there, may have thrown up those stupendous masses of earth. But, be the cause as it may, it is a remarkable fact, that the inequalities of the earth's surface are greatest there. Near the Poles, the earth, indeed, is craggy and uneven enough; but the heights of the mountains there are very inconsiderable. On the contrary, at the Equator, where Nature seems to sport in the amazing size of all her productions, the plains are extensive; and the mountains remarkably lofty. Some of them are known to rise three miles perpendicular above the bed of the ocean.

To enumerate the most remarkable of these, according to their size, we shall begin with the Andes, of which we have an excellent description by Ulloa, who went thither by command of the king of Spain, in company with the French Academicians, to measure a degree of the meridian. His journey up these mountains is too curious not to give an extract from.

After many incommodious days sailing up the river Guayaquil, he arrived at Caracol, a town situated at the foot of the Andes. Nothing could exceed the inconveniences which he experienced in this voyage, from the flies and moschetoes (an animal resembling our gnat).

"We were the whole day," says he, "in continual motion to keep them off; but at night our torments were excessive. Our gloves, indeed, were some defence to our hands; but our faces were entirely exposed; nor were our cloaths a sufficient defence for the rest of our bodies; for their stings penetrating through the cloth, caused a very painful and fiery itching. One night, in coming to an anchor near a large and handsome house that was uninhabited, we had no sooner seated ourselves in it, than we were attacked on all sides by swarms of moschetoes, so that it was impossible to have one moment's quiet. Those who had covered themselves with cloaths made for this purpose, found not the smallest defence; wherefore, hoping to find some relief in the open fields, they ventured out, though in danger of suffering in a more terrible manner from the serpents. But both places were equally obnoxious. On quitting this inhospitable retreat, we the next night took up our quarters in a house that was inhabited; the host of which being informed of the terrible manner we had passed the night before, he gravely told us, that the house we so greatly complained of, had been forsaken on account of its being the purgatory of a soul. But we had more reason to believe that it was quitted on account of its being the purgatory of the body. After having journeyed for upwards of three days, through boggy roads, in which the mules at every step sunk up to their bellies, we began at length to perceive an alteration in the climate; and having been long accustomed to heat, we now began to feel it grow sensibly colder.

"It is remarkable, that at Tariguagua we often see instances of the effects of two opposite temperatures, in two persons happening to meet; one of them leaving the plains below, and the other descending from the mountain. The former thinks the cold so severe, that he wraps himself up in all the garments he can procure; while the latter, finds the heat so great, that he is scarce able to bear any cloaths whatsoever. The one thinks the water so cold, that he avoids being sprinkled by it; the other

is so delighted with its warmth, that he uses it as a bath. Nor is the case very different in the same person, who experiences the same diversity of sensation upon his journey up, and upon his return. This difference only proceeds from the change naturally felt at leaving a climate to which one has been accustomed, and coming into another of an opposite temperature.

"The ruggedness of the road from Tariguagua, leading up the mountain, is not easily described. In some parts, the declivity is so great, that the mules can scarce keep their footing; and in others, the acclivity is equally difficult. The trouble of having people going before to mend the road, the pains arising from the many falls and bruises, and the being constantly wet to the skin, might be supported, were not these inconveniences augmented by the sight of such frightful precipices, and deep abysses, as must fill the mind with ceaseless terror. There are some places where the road is so steep, and yet so narrow, that the mules are obliged to slide down, without making any use of their feet whatsoever. On one side of the rider, in this situation, rises an eminence of several hundred yards; and on the other, an abyss of equal depth; so that if he in the least checks his mule, so as to destroy the equilibrium, they both must unavoidably perish.

"After having travelled about nine days in this manner, slowly winding along the side of the mountain, we began to find the whole country covered with an hoar frost; and an hut in which we lay had ice on it. Having escaped many perils, we at length, after a journey of fifteen days, arrived upon the plain, on the extremity of which stands the city of Quito, the capital of one of the most charming regions upon earth. Here, in the centre of the torrid zone, the heat is not only very tolerable, but in some places the cold also is painful. Here they enjoy all the temperature and advantages of perpetual spring; their fields being always covered with verdure, and enamelled with flowers of the most lively colours. However, although this beautiful region be higher than any other country in the world, and although it took up so many days of painful journey in the ascent, it is still overlooked by tremendous mountains; their sides covered with snow, and yet flaming with volcanoes at the top. These seemed piled one upon the other, and rise to a most astonishing height, with great coldness. However, at a determined point above the surface of the sea, the congelation is found at the same height in all the mountains. Those parts which are not subject to a continual frost, have here and there growing upon them a rush, resembling the genista, but much more soft and flexible. Towards the extremity of the part where the rush grows, and the cold begins to increase, is found a vegetable, with a round bulbous head, which, when dried, becomes of amazing elasticity. Higher up the earth is entirely bare of vegetation, and seems covered with eternal snow. The most remarkable mountains are, that of Cotopaxi, (already described as a volcano) Chimborazo, and Pichincha, Cotopaxi is more than three geographical miles above the surface of the sea: the rest are not much inferior. On the top of the latter was my station for measuring a degree of the meridian; where I suffered particular hardships, from the intenseness of the cold, and the violence of the storms. The sky around was, in general, involved in thick fogs, which, when they cleared away, and the clouds, by their gravity, moved nearer to the surface of the earth, they appeared surrounding the foot of the mountain, at a vast distance below, like a sea, encompassing an island in the midst of it. When this happened, the horrid noises of tempests were heard from beneath, then discharging themselves

elves on Quito, and the neighbouring country. I saw the lightnings issue from the clouds, and heard the thunders roll far beneath me. All this time, while the tempest was raging below, the mountain top, where I was placed, enjoyed a delightful serenity; the wind was abated; the sky clear; and the enlivening rays of the sun moderated the severity of the cold. However, this was of no very long duration, for the wind returned with all its violence, and with such velocity as to dazzle the sight; whilst my fears were increased by the dreadful concussions of the precipice, and the fall of enormous rocks; the only sounds that were heard in this frightful situation."

Such is the animated picture of these mountains, as given us by this ingenious Spaniard. A passage over the Alps, or a journey across the Pyrenees, appear petty trips or excursions, in the comparison; and yet these are the most lofty mountains we know of in Europe.

If we compare the Alps with the mountains already described, we shall find them but little more than one half of the height of the former. The Andes, upon being measured by the barometer, are found above three thousand one hundred and thirty-six toises or fathoms above the surface of the sea. Whereas the highest point of the Alps is not above sixteen hundred. The one, in other words, is above three miles high; the other, about a mile and a half. The highest mountains in Asia are, Mount Taurus, Mount Immaus, Mount Caucasus, and the mountains of Japan.—Of these, none equals the Andes in height; although Mount Caucasus, which is the highest of them, makes very near approaches. Father Verbiest tells of a mountain in China, which he measured, and found a mile and a half high. In Africa, the mountains of the Moon, famous for giving source to the Niger, and the Nile, are rather more noted than known. Of the Pike of Teneriffe, one of the Canary Islands that lie off this coast, we have more certain information. In the year 1727, it was visited by a company of English merchants, who travelled up to the top, where they observed its height, and the volcano on its very summit. They found it an heap of mountains, the highest of which rises over the rest like a sugar-loaf, and gives a name to the whole mass. It is computed to be a mile and a half perpendicular from the surface of the sea. Kircher gives us an estimate of the heights of most of the other great mountains in the world; but as he has taken his calculations, in general, from the ancients, or from modern travellers, who had not the art of measuring them, they are quite incredible. The art of taking the heights of places by the barometer, is a new, and an ingenious invention. As the air grows lighter as we ascend, the fluid in the tube rises in due proportion: thus the instrument being properly marked, gives the height with a tolerable degree of exactness; at least enough to satisfy curiosity.

Few of our great mountains have been estimated in this manner; travellers having, perhaps, been deterred, by a supposed impossibility of breathing at the top. However, it has been invariably found, that the air in the highest that our modern travellers have ascended, is not at all too fine for respiration. At the top of the Pike of Teneriffe, there was found no other inconvenience from the air, except its coldness; at the top of the Andes there was no difficulty of breathing perceived. The accounts, therefore, of those who have asserted that they were unable to breathe, although at much less heights, are greatly to be suspected. In fact, it is very natural for mankind to paint those obstacles as insurmountable, which they themselves have not had the fortitude or perseverance to surmount.

The difficulty and danger of ascending to the tops

of mountains, proceeds from other causes, not the thinness of the air. For instance, some of the summits of the Alps have never yet been visited by man; but the reason is, that they rise with such a rugged and precipitate ascent, that they are utterly inaccessible. In some places they appear like a great wall of six or seven hundred feet high; in others, there stick out enormous rocks, that hang upon the brow of the steep, and every moment threaten destruction to the traveller below.

In this manner almost all the tops of the highest mountains are bare and pointed. And this naturally proceeds from their being so continually assaulted by thunders and tempests. All the earthy substances with which they might have been once covered, have for ages been washed away from their summits; and nothing is left remaining, but immense rocks, which no tempest has hitherto been able to destroy.

Nevertheless, time is every day, and every hour, making depredations; and huge fragments are seen tumbling down the precipice, either loosed from the summit by frost or rains, or struck down by lightning. Nothing can exhibit a more terrible picture than one of these enormous rocks, commonly larger than an house, falling from its height, with a noise louder than thunder, and rolling down the side of the mountain. Doctor Plot tells us of one in particular, which being loosened from its bed, tumbled down the precipice, and was partly shattered into a thousand pieces. Notwithstanding, one of the largest fragments of the same, still preserving its motion, travelled over the plain below, crossed a rivulet in the midst, and at last stopped on the other side of the bank! These fragments, as was said, are often struck off by lightning, and sometimes undermined by rains; but the most usual manner in which they are disunited from the mountain, is by frost: the rains insinuating between the interstices of the mountain, continue there until there comes a frost, and then, when converted into ice, the water swells with an irresistible force, and produces the same effect as gun-powder, splitting the most solid rocks, and thus shattering the summits of the mountain.

But not rocks alone, but whole mountains are, by various causes, disunited from each other. We see, in many parts of the Alps, amazing clefts, the sides of which so exactly correspond with the opposite, that no doubt can be made of their having been once joined together. At Cajeta, in Italy, a mountain was split in this manner by an earthquake; and there is a passage opened through it, that appears as if elaborately done by the industry of man. In the Andes these breaches are frequently seen. That at Thermopyle, in Greece, has been long famous. The mountain of the Troglodytes, in Arabia, has thus a passage through it: and that in Savoy, which Nature began, and which Victor Amadeus completed, is an instance of the same kind.

We have accounts of some of these disruptions, immediately after their happening. In the month of June, in the year 1714, a part of the mountain of Diableret, in the district of Valais, in France, suddenly fell down, between two and three o'clock in the afternoon, the weather being very calm and serene. It was of a conical figure, and destroyed fifty-five cottages in the fall. Fifteen persons, together with about an hundred beasts, were also crushed beneath its ruins, which covered an extent of a good league square. The dust it occasioned, instantly covered all the neighbourhood in darkness. The heaps of rubbish were more than three hundred feet high. They stopped the current of a river that ran along the plain, which is now formed into several new and deep lakes. There appeared, through the whole of this rubbish, none of those

substances that seemed to indicate that this disruption had been made by means of subterraneous fires. Most probably, the base of this rocky mountain was rotted and decayed; and thus fell without any extraneous violence. In the same manner, in the year 1618, the town of Pleurs, in France, was buried beneath a rocky mountain, at the foot of which it was situated.

These accidents, and many more that might be enumerated of the same kind, have been produced by various causes: by earthquakes, as in the mountain at Cajota; or by being decayed at the bottom, as at Diableret. But the most general way is, by the foundation of one part of the mountain being hollowed by waters, and, thus wanting a support, breaking from the other. Thus it generally has been found in the great chasms in the Alps; and thus it almost always is known in those disruptions of hills, which are known by the name of land-slips. These are nothing more than the slidings down of an higher piece of ground, disrooted from its situation by subterraneous inundations, and settling itself upon the plain below.

There is not an appearance in all nature that so much astonished our ancestors, as these land-slips. In fact, to behold a large upland, with its houses, its corn, and cattle, at once loosened from its place, and floating, as it water, upon the subjacent water; to behold it quitting its ancient situation, and travelling forward like a ship, in quest of new adventures; this is certainly one of the most extraordinary appearances that can be imagined; and to a people, ignorant of the powers of Nature, might well be considered as a prodigy. Accordingly, we find all our old historians mentioning it as an omen of approaching calamities. In this more enlightened age, however, its cause is very well known; and, instead of exciting ominous apprehensions in the populace, it only gives rise to some very ridiculous law-suits among them, about whose the property shall be; whether the land which has thus slipped, shall belong to the original possessor, or to him upon whose grounds it has encroached and settled. What has been the determination of the judges, is not so well known; but the circumstances of the slips have been minutely and exactly described.

In the lands of Slatberg, in the kingdom of Iceland, there stood a declivity, gradually ascending for near half a mile. In the year 1713, and on the 10th of March, the inhabitants perceived a crack on its side, somewhat like a furrow made with a plough, which they imputed to the effects of lightning, as there had been thunder the night before. However, on the evening of the same day, they were surpris'd to hear an hideous confused noise issuing all round from the side of the hill; and their curiosity being rais'd, they resorted to the place. There, to their amazement, they found the earth, for near five acres, all in gentle motion, and sliding down the hill upon the subjacent plain. This motion continued the remaining part of the day, and the whole night; nor did the noise cease during the whole time; proceeding, probably, from the attrition of the ground beneath. The day following, however, this strange journey down the hill ceased entirely; and above an acre of the meadow below was found covered with what before compos'd a part of the declivity.

However, these slips, when a whole mountain's side seems to descend, happen but very rarely. There are some of another kind, however, much more common; and, as they are always sudden, much more dangerous. These are snow-slips, well known, and greatly dreaded by travellers. It often happens, that when snow has long been accumulated on the tops and on the sides of mountains, it is born down the precipice, either by means of tem-

pests, or its own melting. At first, when loosened, the volume in motion is but small, but gathers as it continues to roll; and, by the time it has reached the habitable parts of the mountain, is generally grown of enormous bulk. Wherever it rolls it levels all things in its way, or buries them in unavoidable destruction. Instead of rolling, it sometimes is found to slide along from the top; yet even thus it is generally as fatal as before. Nevertheless, we have had an instance, a few years ago, of a small family in Germany, that lived for above a fortnight beneath one of these snow-slips. Although they were buried, during that whole time, in utter darkness, and under a bed of some hundred feet deep, yet they were luckily taken out alive; the weight of the snow being supported by a beam that kept up the roof; and nourishment being supplied them by the milk of an ass, that was buried under the same ruin.

But it is not the parts, alone, that are thus found to subside, whole mountains have been known totally to disappear. Pliny tells us, that in his own time, the lofty mountain of Cybotus, together with the city of Eurites, were swallowed by an earthquake. The same fate, he says, attended Phlegium, one of the highest mountains in Æthiopia; which, after one night's concussion, was never seen more. In more modern times, a very noted mountain in the Molucca islands, known by the name of the Peak, and remarkable for being seen at a very great distance from sea was swallowed by an earthquake; and nothing but a lake was left in the place where it stood. Thus, while storms and tempests are levelled against mountains above, earthquakes and waters are undermining them below. All our histories talk of their destruction; and very few new ones (if we except Mount Cenere, and one or two such heaps of cinders) are produced. If mountains, therefore, were of such great utility as some philosophers make them to mankind, it would be a very melancholy consideration that such benefits were diminished every day. But the truth is, the valleys are fertilized by that earth which is washed from their sides; and the plains become richer, in proportion as the mountains decay.

C H A P. XIII.

Of W A T E R.

IN contemplating nature, we shall often find the same substances possessed of contrary qualities, and producing opposite effects. Air, which liquifies one substance, dries up another. That fire which is seen to burn up the desert, is often found, in other places, to assist the luxuriance of vegetation: and water, which, next to fire, is the most fluid substance upon earth, nevertheless, gives all other bodies their firmness and durability; so that every element seems to be a powerful servant, capable either of good or ill, and only awaiting external direction, to become the friend or the enemy of mankind. These opposite qualities, in this substance in particular, have not failed to excite the admiration and enquiry of the curious.

That water is the most fluid penetrating body, next to fire, and the most difficult to confine, is incontestibly proved by a variety of experiments. A vessel through which water cannot pass, may be said to retain anything. It may be objected, indeed, that syrups, oils, and honey, leak through some vessels that water cannot pass through; but this is far from being the result of the greater tenuity and fineness of their parts; it is owing to the resin wherewith the wood of such vessels abounds, which oils and syrups have a power of dissolving; so that these fluids, instead of finding their way, may more properly

properly be said to eat their way through the vessels that contain them. However, water will at last find its way even through these; for it is known to escape through vessels of every substance, glass only excepted. Other bodies may be found to make their way out more readily indeed; as air, when it finds a vent, will escape at once; and quicksilver, because of its weight, quickly penetrates through whatever chinky vessel confines it: but water, though it operates more slowly, yet always finds a more certain issue. As, for instance, it is well known that air will not pass through leather; which water will very readily penetrate. Air also may be retained in a bladder; but water will quickly ooze through. And those who drive this to the greatest degree of precision, pretend to say, that it will pass through pores ten times smaller than air can do. Be this as it may, we are very certain that its parts are so small that they have been actually driven through the pores of gold. This has been proved by the famous Florentine experiment, in which a quantity of water was shut up in an hollow ball of gold, and then pressed with an huge force by screws, during which the fluid was seen to ooze through the pores of the metal, and to stand, like a dew, upon its surface.

As water is thus penetrating, and its parts thus minute, it may easily be supposed that they enter into the composition of all bodies, vegetable, animal, and fossil. This every chemist's experience convinces him of; and the mixture is the more obvious, as it can always be separated, by a gentle heat, from those substances with which it had been united. Fire, as was said, will penetrate where water cannot pass; but then it is not so easily to be separated. But there is scarce any substance from which its water cannot be divorced. The parings or filings of lead, tin, and antimony, by distillation, yield water plentifully: the hardest stones, sea-salt, nitre, vitriol, and sulphur, are found to consist chiefly of water; into which they resolve by force of fire. "All birds, beasts, and fishes," says Newton, "insects, trees, and vegetables, with their parts grow from water; and, by putrefaction, return to water again." In short, almost every substance that we see, owes its texture and firmness to the parts of water that mix with its earth; and, deprived of this fluid, becomes a mass of shapeless dust and ashes.

From hence we see, as was above hinted, that this most fluid body, when mixed with others, gives them consistence and form. Water, by being mixed with earth or ashes, and formed into a vessel, when baked before the fire, becomes a copel, remarkable for this, that it will bear the utmost force of the hottest furnace that art can contrive. So the Chinese earth, of which porcelane is made, is nothing more than an artificial composition of earth and water united by heat; and which a greater degree of heat could easily separate. Thus we see a body, extremely fluid of itself, in some measure assuming a new nature, by being united with others; we see a body, whose fluid and dissolving qualities are so obvious, giving consistence and hardness to all the substances of the earth.

From considerations of this kind, Thales, and many of the ancient philosophers, held that all things were made of water. In order to confirm this opinion, Helmont made an experiment, by divesting a quantity of earth of all its oils and salts, and then putting this earth, so prepared, into an earthen pot, which nothing but rain-water could enter, and planting a willow therein; this vegetable, so planted, grew up to a considerable height and bulk, merely from the accidental aspersion of rain-water; while the earth in which it was planted received no sensible diminution. From this experiment, he concluded, that water was the only nourishment of the

vegetable tribe; and that vegetables, being the nourishment of animals, all organized substances, therefore, owed their support and being only to water. But this has been said by Woodward to be a mistake: for he shews, that water being impregnated with earthy particles, is only the conveyer of such substances into the pores of vegetables, rather than an increaser of them, by its own bulk: and likewise, that water is ever found to afford so much less nourishment, in proportion as it is purified by distillation. A plant in distilled water will not grow so fast as in water not distilled: and if the same be distilled three or four times over, the plant will scarce grow at all, or receive any nourishment from it. So that water, as such, does not seem the proper nourishment of vegetables, but only the vehicle thereof, which contains the nutritious particles, and carries them through all parts of the plants. Water, in its pure state, may suffice to extend or swell the parts of a plant, but affords vegetable matter in a moderate proportion.

However this be, it is agreed on all sides, that water, such as we find it, is far from being a pure simple substance. The most genuine, we know, is mixed with exhalations and dissolutions of various kinds; and no expedient that has been hitherto discovered, is capable of purifying it entirely. If we filter and distil it a thousand times, according to Boerhaave, it will still depose a sediment: and by repeating the process, we may evaporate it entirely away, but can never totally remove its impurities. Some, however, assert, that water, properly distilled will have no sediment; and that the little white speck which is found at the bottom of the still, is a substance that enters from without. Kircher used to shew, in his *Musæum*, a phial of water, that had been kept for fifty years, hermetically sealed; during which time it deposited no sediment, but continued as transparent as when first it was put in. How far, therefore, it may be brought to a state of purity by distillation, is unknown; but we very well know, that all such water as we every where see, is a bed in which plants, minerals, and animals, are all found confusedly floating together.

Rain-water, which is a fluid of Nature's own distilling, and which has been raised so high by evaporation, is, nevertheless, a very mixed and impure substance. Exhalations of all kinds, whether salts, sulphurs, or metals, make a part of its substance, and tend to increase its weight. If we gather the water that falls, after a thunder clap, in a sultry summer's day, and let it settle, we shall find a real salt sticking at the bottom. In winter, however, its impure mixtures are fewer, but still may be separated by distillation. As to that which is generally caught pouring from the tops of houses, it is particularly foul, being impregnated with the smoke of the chimnies, the vapour of the slates or tiles, and with other impurities that birds and animals may have deposited there. Besides, though it should be supposed free from all these, it is mixed with a quantity of air, which, after being kept for some time, will be seen to separate.

Spring-water is next in point of purity. This, according to Dr. Halley, is collected from the air itself; which being saturated with water, and coming to be condensed by the evening's cold, is driven against the tops of the mountains, where being condensed, and collected, it trickles down by the sides, into the cavities of the earth; and running for a while under-ground, bubbles up in fountains upon the plain. This having made but a short circulation, has generally had no long time to dissolve or imbibe any foreign substances by the way.

River-water is generally more foul than the former. Wherever the stream flows, it receives a tincture from its channel. Plants, minerals, and animals,

mals, all contribute to add to its impurities: so that such as live at the mouths of great rivers, are generally subject to all those disorders which contaminated and unwholesome waters are known to produce. Of all the river-water in the world, that of the Indus and the Thames, are said to be most light and wholesome.

The most impure fresh water that we know, is that of stagnating pools and lakes, which, in summer, may be more properly considered as a jelly of floating insects, than a collection of water. In this, millions of little reptiles, undisturbed by any current, which might crush their frames to pieces, breed and engender. The whole teems with shapeless life, and only grows more fruitful by increasing putrefaction.

Of the purity of all these waters, the lightness, and not the transparency, ought to be the test. Water may be extremely clear and beautiful to the eye, and yet very much impregnated with mineral particles. In fact, sea-water is the most transparent of any, and yet is well known to contain a large mixture of salt and bitumen. On the contrary, those waters which are lightest, have the fewest dissolutions floating in them; and may, therefore, be the most useful for all the purposes of life. But, after all, though much has been said upon this subject; and although waters have been weighed with great assiduity, to determine their degree of salubrity; yet neither this, nor their curdling with soap, nor any other philosophical standard whatsoever, will answer the purposes of true information. Experience alone ought to determine the useful, or noxious qualities, of every spring; and experience assures us, that different kinds of water are adapted to different constitutions. An incontestible proof of this, are the many medicinal springs throughout the world, whose peculiar benefits are known to the natives of their respective countries. These are of various kinds, according to the different minerals with which they are impregnated; hot, saline, sulphureous, bituminous, and oily. But the account of these have been already given under that of the several minerals by which they are produced.

After all therefore, we must be contented with an impure mixture for our daily beverage: and yet, perhaps, this very mixture may often be more serviceable to our health than that of a purer kind. We know that it is so with regard to vegetables: and why not, also, in general, to man? Be this as it will, if we are desirous of having water in its greatest purity, we are ordered, by the curious in this particular, to distil it from snow, gathered upon the tops of the highest mountains, and to take none but the outer and superficial part thereof. This we must be satisfied to call pure water; but even this is far short of the pure unmixed philosophical element; which, in reality, is no where to be found.

As water is thus mixed with foreign matter, and often the repository of minute animals, or vegetable feeds, we need not be surpris'd that, when carried to sea, it is always found to putrefy. But we must not suppose that it is the element itself, which thus grows putrid, and offensive, but the substances with which it is impregnated. It is true, the utmost precautions are taken to destroy all vegetable and animal substances that may have previously been lodged in it, by boiling: but, notwithstanding this, there are some that will still survive the operation; and others, that find their way during the time of its stowage. Seamen, therefore, assure us, that their water is generally found to putrefy twice, at least, and sometimes three times, in a long voyage. In about a month after it has been at sea, when the bung is taken out of the cask, it sends up a noisome

and dangerous vapour, which would take fire upon the application of a candle. The whole body of the water then is found replete with little worm-like insects, that float, with great briskness, through all its parts. These generally live for about a couple of days, and then dying, by depositing their spoils, for a while increase the putrefaction. After a time, the heavier parts of these sinking to the bottom, the lighter float, in a scum, at the top; and this is what the mariners call, the water's purging itself. There are still, however, another race of insects, which are bred, very probably, from the spoils of the former; and produce, after some time, similar appearances: these dying, the water is then thought to change no more. However, it very often happens, especially in hot climates, that nothing can drive these nauseous insects from the ship's store of water. They often increase to a very disagreeable and frightful size, so as to deter the mariner, though parching with thirst, from tasting that cup which they have contaminated.

This water, as thus described, therefore, is a very different fluid from that simple elementary substance upon which philosophical theories have been founded; and concerning the nature of which there have been so many disputes. Elementary water is no way compounded; but is without taste, smell, or colour; and incapable of being discerned by any of the senses, except the touch. This is the famous dissolvent of the chemists, into which, as they have boasted, they can reduce all bodies; and which makes up all other substances, only by putting on a different disguise. In some forms, it is fluid, transparent, and evasive of the touch; in others, hard, firm, and elastic. In some, it is stiffened by cold; in others, dissolved by fire. According to them, it only assumes external shapes from accidental causes; but the mountain is as much a body of water as the cake of ice that melts on its brow; and even the philosopher himself is composed of the same materials with the cloud or meteor which he contemplates.

Speculation seldom rests when it begins. Others, disallowing the universality of this substance, will not allow that in a state of nature there is any such thing as water at all. What assumes the appearance, say they, is nothing more than melted ice. Ice is the real element of Nature's making; and when found in a state of fluidity, it is then in a state of violence. All substances are naturally hard; but some more readily melt with heat than others. It requires a great heat to melt iron; a smaller heat will melt copper: silver, gold, tin, and lead, melt with smaller still: ice, which is a body like the rest, melts with a very moderate warmth; and quicksilver melts with the smallest warmth of all. Water, therefore, is but ice kept in continual fusion; and still returning to its former state, when the heat is taken away. Between these opposite opinions, the controversy has been carried on with great ardour; much has been written on both sides; and yet, when we come to examine the debate, it will probably terminate in this question, whether cold or heat first began their operations upon water? This is a fact of very little importance, if known; and what is more, it is a fact we can never know.

Indeed, if we examine into the operations of cold and heat on water, we shall find that they produce somewhat similar effects. Water dilates in its bulk, by heat, to a very considerable degree; and, what is more extraordinary, it is likewise dilated by cold in the same manner.

If water be placed over a fire, it grows gradually larger in bulk, as it becomes hot, until it begins to boil; after which, no art can either increase its bulk, or its heat. By increasing the fire, indeed, it may be more quickly evaporated away; but its heat

and,

and its bulk, still continue the same. By the expanding of this fluid by heat, philosophers have found a way to determine the warmth or the coldness of other bodies: for if put into a glass tube, by its swelling and rising, it shews the quantity of heat in the body to which it is applied; and by its contracting, and sinking, it shews the absence of the same. Instead of using water in this instrument, which is called a thermometer, they now make use of spirit of wine, which is not apt to freeze, and which is endued even with a greater expansion, by heat, than water. The instrument consists of nothing more than a hollow ball of glass, with a long tube growing out of it. This being partly filled with spirits of wine, tinged red, so as to be seen when it rises, the ball is plunged into boiling water, which making the spirit within expand and rise in the tube, the water marks the greatest height to which it ascends; at this point the tube is to be broken off, and then hermetically sealed, by melting the glass with a blow-pipe: a scale being placed by the side, completes the thermometer. Now as the fluid expands or condenses with heat or cold, it will rise and fall in the tube in proportion; and the degree or quantity of ascent or descent will be seen in the scale.

No fire, as was said, can make water hotter, after it begins to boil. We can, therefore, at any time be sure of an equable certain heat; which is that of boiling water, which is invariably the same. The certainty of such an heat is not less useful than the instrument that measures it. It affords a standard, fixed, degree of heat over the whole world; boiling water being as hot in Greenland, as upon the coasts of Guinea: One fire is more intense than another: of heat there are various degrees; but boiling water is an heat every where the same, and easily procurable.

As heat thus expands water; so cold, when it is violent enough to freeze the same, produces exactly the same effect, and expands it likewise. Thus water is acted upon in the same manner by two opposite qualities; being dilated by both. As a proof that it is dilated by cold, we have only to observe the ice floating on the surface of a pond, which it would not do were it not dilated, and grown more bulky, by freezing, than the water, which remains unfrozen. Mr. Boyle, however, put the matter past a doubt, by a variety of experiments. Having poured a proper quantity of water into a strong earthen vessel, he exposed it, uncovered, to the open air, in frosty nights; and observed, that continually the ice reached higher than the water, before it was frozen. He filled also a tube with water, and stopped both ends with wax: the water, when froze, was found to push out the stopples from both ends; and a rod of ice appeared at each end of the tube, which shewed how much it was swollen by the cold within.

From hence, therefore, we may be very certain of the cold's dilating of the water; and experience also shews, that the force of this expansion has been found as great as any which heat has been found to produce. The touch-hole of a strong gun barrel being stopped, and a plug of iron forcibly driven into the muzzle, after the barrel had been filled with water, it was placed in a mixture of ice and salt: the plug, though soldered to the barrel, at first gave way, but being fixed in more firmly, within a quarter of an hour the gun-barrel burst with a loud noise, and blew up the cover of the box wherein it lay. Such is its force in an ordinary experiment. But it has been known to burst cannons, filled with water, and then left to freeze; for the cold congealing the water, and the ice swelling, it became irresistible: The bursting of rocks, by frost, which is frequent in the Northern climates, and is sometimes seen in our own, is an equal proof of the expansion of con-

gealed water; for having, by some means, insinuated itself into the body of the rock, it has remained there till the cold was sufficient to affect it by congelation. But when once frozen, no obstacle is able to confine it from dilating; and, if it cannot otherwise find room, the rock must burst asunder.

This alteration in the bulk of water, might have served as a proof that it was capable of being compressed into a narrower space than it occupied before; but, till of late, water was held to be incompressible. The general opinion was, that no art whatsoever could squeeze it into a narrower compass; that no power on earth, for instance, could force a pint of water into a vessel that held an hair's breadth less than a pint. And this, said they, appears from the famous Florentine experiment; where the water, rather than suffer compression, was seen to ooze through the pores of the solid metal; and, at length, making a cleft in the side, spun out with great vehemence. But later trials have proved that water is very compressible, and partakes of that elasticity which every other body possesses in some degree. Indeed, had not mankind been dazzled by the brilliancy of one inconclusive experiment, there were numerous reasons to convince them of its having the same properties with other substances. Ice, which is water in another state, is very elastic. A stone flung slantingly along the surface of a pond, bounds from the water several times; which shews it to be elastic also. But the trials of Mr. Canton have put this past all doubt; which being somewhat similar to those of the great Boyle, who pressed it with weights properly applied, carry sufficient conviction.

What has been hitherto related, is chiefly applicable to the element of water alone; but its fluidity is a property that it possesses in common with several other substances, in other respects greatly differing from it. That quality which gives rise to the definition of a fluid, namely, that its parts are in a continual intestine motion, seems extremely applicable to water. What the shapes of those parts are, it would be vain to attempt to discover. Every trial only shews the futility of the attempt; all we find is, that they are extremely minute; and that they roll over each other with the greatest ease. Some, indeed, from this property alone, have not hesitated to pronounce them globular; and we have, in all our hydrostatical books, pictures of these little globes in a state of sliding and rolling over each other. But all this is merely the work of imagination; we know that substances of any kind, reduced very small, assume a fluid appearance, somewhat resembling that of water. Mr. Boyle, after finely powdering and sifting a little dry powder of plaister of Paris, put it in a vessel over the fire, where it soon began to boil like water, exhibiting all the motions and appearances of a boiling liquor. Although but a powder, the parts of which we know are very different from each other, and just as accident has formed them, yet it heaved in great waves, like water. Upon agitation, an heavy body will sink to the bottom, and a light one emerge to the top. There is no reason to suppose the figure of the parts of water round, since we see their fluidity very well imitated by a composition, the parts of which are of various forms and sizes. The shape of the parts of water, therefore, we must be content to continue ignorant of. All we know is, that earth, air, and fire, conduce to separate the parts from each other.

Earthy substances divide the parts from each other, and keep them asunder. This division may be so great, that the water will entirely lose its fluidity thereby. Mud, potter's clay, and dried bricks, are so many different combinations of earth and water; each substance in which the parts of water are most separated from each other, appearing to be

the most dry. In some substances, indeed, where the parts of water are greatly divided, as in porcelain, for instance, it is no easy matter to recover and bring them together again; but they continue in a manner fixed and united to the manufactured clay. This circumstance led Doctor Cheney into a very peculiar strain of thinking. He suspected that the quantity of water, on the surface of the earth, was daily decreasing. For, says he, some parts of it are continually joined to vegetable, animal, and mineral substances, which no art can again recover. United with these, the water loses its fluidity; for if, continues he, we separate a few particles of any fluid, and fasten them to a solid body, or keep them asunder, they will be fluid no longer. To produce fluidity, a considerable number of such particles are required; but here they are close, and destitute of their natural properties. Thus, according to him, the world is growing every day harder and harder, and the earth firmer and firmer; and there may come a time when every object around us may be stiffened in universal frigidity! However, we have causes enough of anxiety in this world already, not to add this preposterous concern to the number.

That air also contributes to divide the parts of water, we can have no manner of doubt; some have even disputed whether water be not capable of being turned into air. Though this cannot be allowed, it must be granted, that it may be turned into a substance which greatly resembles air (as we have seen in the experiment of the æolipile) with all its properties; except that, by cold, this new-made air may be condensed again into water.

But of all the substances which tend to divide the parts of water, fire is the most powerful. Water, when heated into steam, acquires such force, and the parts of it tend to fly off from each other with such violence, that no earthly substance we know of, is strong enough to confine them. A single drop of water, converted into steam, has been found capable of raising a weight of twenty tons; and would have raised twenty thousand, were the vessel confining it sufficiently strong, and the fire below increased in proportion.

From this easy yielding of its parts to external pressure, arises the art of determining the specific gravity of bodies by plunging them in water; with many other useful discoveries in that part of natural philosophy, called hydrostatics. The laws of this science, which Archimedes began, and Pascal, with some other of the moderns, have improved, rather belongs to experimental than to natural history. However, we shall mention some of the most striking paradoxes in this branch of science, which are as well confirmed by experiment, as rendered universal by theory. It would, indeed, be unpardonable, while discoursing on the properties of water, to omit giving some account of the manner in which it sustains such immense bulks as we see floating upon its soft and yielding surface: how some bodies, that are known to sink at one time, swim with ease, if their surface be enlarged: how the heaviest body, even gold itself, may be made to swim upon water; and how the lightest, such as cork, shall remain sunk at the bottom: how the pouring in of a single quart of water, will burst an hoghead hooped with iron: and how it ascends, in pipes, from the valley, to travel over the mountain: these are circumstances that are at first surprising; but, upon a slight consideration, lose their wonder.

In order to conceive the manner in which all these wonders are effected, we must begin by observing that water is possessed of an invariable property, which has not hitherto been mentioned; that of always keeping its surface level and even. Winds, indeed, may raise it into waves; or art spurt it up in fountains; but ever, when left to itself, it sinks

into a smooth even surface, of which no one part is higher than another. If any one should pour water, for instance, into the arm of a pipe of the shape of the letter U, the fluid would rise in the other arm just to the same height; because, otherwise, it would not find its level, which it invariably maintains. A pipe bending from one hill down into the valley, and rising by another, may be considered as a tube of this kind, in which the water, sinking in one arm, rises to maintain its level in the other. Upon this principle all water-pipes depend; which can never raise the water higher than the fountain from which they proceed.

Again, let us suppose for a moment, that the arms of the pipe already mentioned, may be made long or short at pleasure; and let us still further suppose, that there is some obstacle at the bottom of it, which prevents the water poured into one arm, from rising in the other. Now it is evident, that this obstacle at the bottom will sustain a pressure from the water in one arm, equal to what would make it rise in the other; and this pressure will be great, in proportion as the arm filled with water is tall. We may, therefore, generally conclude, that the bottom of every vessel is pressed by a force, in proportion to the height of the water in that vessel. For instance, if the vessel filled with water be forty feet high, the bottom of that vessel will sustain such a pressure as would raise the same water forty feet high, which is very great. From hence we see how extremely apt our pipes that convey water to the city are to burst; for descending from an hill of more than forty feet high, they are pressed by the water contained in them, with a force equal to what would raise it more than forty feet high; and that this is sometimes able to burst a wooden pipe, we can have no room to doubt of.

Still recurring to our pipe, let us suppose one of its arms ten times as thick as the other; this will produce no effect whatsoever upon the obstacle below, which we supposed hindering its rise in the other arm; because, how thick soever the pipe may be, its contents would only rise to its own level; and it will, therefore, press the obstacle with an equal force. We may, therefore, universally conclude, that the bottom of any vessel is pressed by its water, not as it is broad or narrow, but in proportion as it is high. Thus the water contained in a vessel not thicker than one's finger, presses its bottom as forcibly as the water contained in an hoghead of an equal height; and, if we made holes in the bottoms of both, the water would burst out as forceful from the one as the other. Hence we may, with great ease, burst an hoghead with a single quart of water, and it has been often done. We have only, for this, to place an hoghead on one end, filled with water; we then bore an hole in its top, into which we plant a narrow tin pipe, of about thirty feet high: by pouring a quart of water into this, at the top, as it continues to rise higher in the pipe, it will press more forcibly on the bottom and sides of the hoghead below, and at last burst it.

Still returning to our simple instrument of demonstration. If we suppose the obstacle at the bottom of the pipe to be moveable, so as that the force of the water can push it up into the other arm; such a body is quicksilver, for instance. Now, it is evident, that the weight of water weighing down upon this quicksilver in one arm, will at last press it up in the other arm; and will continue to press it upwards, until the fluid in both arms be upon a par. So that here we actually see quicksilver, the heaviest substance in the world, except gold, floating upon water, which is but a very light substance.

When we see water thus capable of sustaining quicksilver, we need not be surprised that it is capable of floating much lighter substances, ships, animals,

animals, or timber. When any thing floats upon water, we always see that a part of it sinks in the same. A cork, a ship, a buoy, each buries itself a bed on the surface of the water; this bed may be considered as so much water displaced; the water will, therefore, lose so much of its own weight as is equal to the weight of that bed of water which it displaces. If the body be heavier than a similar bulk of water, it will sink; if lighter, it will swim. Universally, therefore, a body plunged in water, loses as much of its weight as is equal to the weight of a body of water of its own bulk. Some light bodies, therefore, such as cork, lose much of their weight, and therefore swim; other more ponderous bodies sink, because they are heavier than their bulk of water.

Upon this simple theorem entirely depends the art of weighing metals hydrostatically. A person has a guinea, for instance, and desires to know whether it be pure gold: it has been weighed in the usual way with another guinea, and been found exactly of the same weight, but still there is some suspicion, from its greater bulk, that it is not pure. In order to determine this, there is nothing more to be done than to weigh it in water with that same guinea that is known to be good, and of the same weight; and this will instantly shew the difference; for the true ponderous metal will sink, and the false bulky one will be sustained in proportion to the greatness of its surface. Those whose business it is to examine the purity of metals, have a balance made for this purpose, by which they can precisely determine which is most ponderous, or, as it is expressed, which has the greatest specific gravity. Seventy-one pound and an half of quicksilver is found to be equal in bulk to an hundred pound weight of gold. In the same proportion, sixty of lead, fifty-four of silver, forty-seven of copper, forty-five of brass, forty-two of iron, and thirty-nine of tin, are each equal to an hundred pound of the most ponderous of all metals.

This method of precisely determining the purity of gold, by weighing in water, was first discovered by Archimedes, to whom mankind have been indebted for many useful discoveries. Hiero, king of Sicily, having sent a certain quantity of gold to be made into a crown, the workman, it seems, kept a part for his own use, and supplied the deficiency with a baser metal. His fraud was suspected by the king, but could not be detected, till he applied to Archimedes; who weighed the crown in water; and, by this method, informed the king of the quantity of gold which was taken away.

It has been said, that all fluids endeavour to preserve their level; and, likewise, that a body pressing on the surface, tended to destroy that level. From hence it will easily be inferred, that the deeper any body sinks, the greater will be the resistance of the depressed fluid beneath. It will be asked, therefore, as the resistance increases in proportion as the body descends, how comes the body, after it is got a certain way, to sink at all? The answer is obvious. From the fluid above pressing it down with almost as great a force as the fluid beneath presses it up. Take away, by any art, the pressure of the fluid from above, and let only the resistance of the fluid from below be suffered to act, and after the body is got down very deep, the resistance will be insuperable. To give an instance: a small hole opens in the bottom of a ship at sea, forty feet we will suppose below the surface of the water; through this the water bursts up with great violence; a person attempts to stop it with his hand, but it pushes the hand violently away. Here the hand is, in fact, a body attempting to sink upon water, at a depth of forty feet, with the pressure from above taken away. The water, therefore, will overcome his strength; and will continue to burst in till it has got to its level:

if he should then dive into the hold, and clap his hand upon the opening; as before, he shall perceive no force acting against his hand at all, for the water above presses the hand as much down against the hole, as the water without presses it upward. For this reason also, when we dive to the bottom of the water, we sustain a very great pressure from above, it is true, but it is counteracted by the pressure from below; and the whole acting uniformly on the surface of the body, wraps us close round without injury.

As we have deviated thus far, we will just mention one or two properties more, which water, and all such like fluids, is found to possess. And first, their ascending in vessels which are emptied of air, as in our common pumps for instance. The air, however, being the agent in this case, we must previously examine its properties, before we undertake the explanation. The other property to be mentioned is, that of their ascending in small capillary tubes. This is one of the most extraordinary and inscrutable appearances in nature. Glass tubes may be drawn, by means of a lamp, as fine as an hair; still preserving their hollow within. If one of these be planted in a vessel of water, or spirit of wine, the liquor will immediately be seen to ascend; and it will rise higher, in proportion as the tube is smaller; a foot, two feet, and more. How does this come to pass? Is the air the cause? No: the liquor rises, although the air be taken away. Is attraction the cause? No: for quicksilver does not ascend, which it otherwise would. Many have been the theories of experimental philosophers to explain this property. Such as are fond of travelling in the regions of conjecture, may consult Hawksbee, Morgan, Jurin, or Watson, who have examined the subject with great minuteness. Hitherto, however, nothing but doubts instead of knowledge have been the result of their enquiries. It will not, therefore, become us to enter into the minuteness of the enquiry, when we have so many greater wonders to call our attention away.

C H A P. XIV.

Of the Origin of RIVERS.

THE sun riseth, and the sun goeth down, and pants for the place from whence he arose. All things are filled with labour, and man cannot utter it. All rivers run into the sea, yet the sea is not full. Unto the place whence the rivers come, thither they return again. The eye is not satisfied with seeing, nor the ear with hearing." Thus speaks the wisest of the Jews. And, at so early a period was the curiosity of man employed in observing these great circulations of nature. Every eye attempted to explain those appearances; and every philosopher who has long thought upon the subject, seems to give a peculiar solution. The enquiry whence rivers are produced; whence they derive those unceasing stores of water, which continually enrich the world with fertility and verdure; has been variously considered; and divided the opinions of mankind, more than any other topic in natural history.

In this contest, the various champions may be classed under two leaders, Mr. De La Hire, who contends that rivers must be supplied from the sea, strained through the pores of the earth; and Doctor Halley, who has endeavoured to demonstrate, that the clouds alone are sufficient for the supply. Both sides have brought in mathematics to their aid; and have shewn, that long and laborious calculations can at any time be made, to obscure both sides of a question.

De La Hire begins his proofs, that rain-water, evaporated

evaporated from the sea, is insufficient for the production of rivers; by shewing, that rain never penetrates the surface of the earth above sixteen inches. From thence he infers, that it is impossible for it, in many cases, to sink so as to be found at such considerable depths below. Rain-water, he grants, is often seen to mix with rivers, and to swell their currents; but a much greater part of it evaporates. In fact, continues he, if we suppose the earth every where covered with water, evaporation alone would be sufficient to carry off two feet nine inches of it in a year; and yet, we very well know, that scarce nineteen inches of rain-water falls in that time; so that evaporation would carry off a much greater quantity than is ever known to descend. The small quantity of rain-water that falls is therefore but barely sufficient for the purposes of vegetation. Two leaves of a fig-tree have been found, by experiment, to imbibe from the earth, in five hours and an half, two ounces of water. This implies the great quantity of fluid that must be exhausted in the maintenance of one single plant. Add to this, that the waters of the river Rungis will, by calculation, rise to fifty inches; and the whole country from whence they are supplied, never receives fifty inches, in the year, by rain. Besides this, there are many salt springs, which are known to proceed immediately from the sea, and are subject to its flux and reflux. In short, wherever we dig beneath the surface of the earth, except in a very few instances, water is to be found; and it is by this subterraneous water, that springs and rivers, nay, a great part of vegetation itself, is supported. It is this subterraneous water, which is raised into steam, by the internal heat of the earth, that feeds plants. It is this subterraneous water that distils through its interstices; and there cooling, forms fountains. It is this that, by the addition of rains, is increased into rivers; and pours plenty over the whole earth.

On the other side of the question, it is asserted, that the vapours which are exhaled from the sea, and driven by the winds upon land, are more than sufficient to supply not only plants with moisture, but also to furnish a sufficiency of water to the greatest rivers. For this purpose, an estimate has been made of the quantity of water emptied at the mouth of the greatest rivers; and of the quantity also raised from the sea by evaporation; and it has been found, that the latter by far exceeds the former. This calculation was made by Mr. Mariotte. By him it was found, upon receiving such rain as fell in a year, in a proper vessel, fitted for that purpose, that one year with another, there might fall about twenty inches of water upon the surface of the earth, throughout Europe. It was also computed, that the river Seine, from its source to the city of Paris, might cover an extent of ground, that would supply it annually with above seven millions of cubic feet of this water, formed by evaporation. But, upon computing the quantity which passed through the arches of one of its bridges in a year, it was found to amount only to two hundred and eighty millions of cubic feet, which is not above the sixth part of the former number. Hence it appears, that this river may receive a supply brought to it by the evaporated waters of the sea, six times greater than what it gives back to the sea by its current; and, therefore, evaporation is more than sufficient for maintaining the greatest rivers; and supplying the purposes also of vegetation.

In this manner the sea furnishes sufficient humidity to the air for furnishing the earth with all necessary moisture. One part of its vapours fall upon its own bosom, before they arrive upon land. Another part is arrested by the sides of mountains, and is compelled, by the rising stream of air, to mount upward towards the summits. Here it is presently

precipitated, dripping down by the crannies of the stone. In some places, entering into the caverns of the mountain, it gathers in those receptacles, which being once filled, all the rest overflows; and breaking out by the sides of the hills, forms single springs. Many of these run down by the valleys, or guts between the ridges of the mountain, and form little rivulets or brooks; many of these meeting in one common valley, and gaining the plain ground, being grown less rapid, become a river: and many of these uniting, make such vast bodies of water as the Rhine, the Rhone, and the Danube.

There is still a third part, which falls upon the lower grounds, and furnishes plants with their wonted supply. But the circulation does not rest even here; for it is again exhaled into vapour by the action of the sun; and afterwards returned to that great mass of waters whence it first arose. This, adds Doctor Halley, seems the most reasonable hypothesis; and much more likely to be true, than that of those who derive all springs from the filtering of the sea waters through certain imaginary tubes or passages within the earth; since it is well known, that the greatest rivers have their most copious fountains the most remote from the sea.

This seems the most general opinion; and yet, after all, it is still pressed with great difficulties; and there is still room to look out for a better theory. The perpetuity of many springs, which always yield the same quantity when the least rain or vapour is afforded, as well as when the greatest, is a strong objection. Derham mentions a spring at Upminster, which he could never perceive by his eye to be diminished, in the greatest droughts, even when all the ponds in the country, as well as an adjoining brook, have been dry for several months together. In the rainy seasons also, it was never overflowed; except sometimes, perhaps, for an hour or so, upon the immision of the external rains. He, therefore, justly enough concludes, that had this spring its origin from rain or vapour, there would be found an increase or decrease of its water, corresponding to the causes of its production.

Thus the reader, after having been tossed from one hypothesis to another, must at last be contented to settle in conscious ignorance. All that has been written upon this subject, affords him rather something to say, than something to think; something rather for others than for himself. Varenus, indeed, although he is at a loss for the origin of rivers, is by no means so as to their formation. He is pretty positive that all rivers are artificial. He boldly asserts, that their channels have been originally formed by the industry of man. His reasons are, that when a new spring breaks forth, the water does not make itself a new channel, but spreads over the adjacent land. Thus, says he, men are obliged to direct its course; or, otherwise, Nature would never have found one. He enumerates many rivers, that are certainly known, from history, to have been dug by men. He alledges, that no salt-water rivers are found, because men did not want salt-water; and as for salt, that was procurable at a less expence than digging a river for it. However, it costs a speculative man but a small expence of thinking to form such an hypothesis. It may, perhaps, engross the reader's patience to detain him longer upon it.

Nevertheless, though philosophy be thus ignorant, as to the production of rivers, yet the laws of their motion, and the nature of their currents, have been very well explained. The Italians have particularly distinguished themselves in this respect; and it is chiefly to them that we are indebted for the improvement.

All rivers have their source either in mountains, or elevated lakes; and it is in their descent from these,

these, that they acquire that velocity which maintains their future current. At first their course is generally rapid and headlong; but it is retarded in its journey by the continual friction against its banks, by the many obstacles it meets to divert its stream, and by the plains generally becoming more level as it approaches towards the sea.

If this acquired velocity be quite spent, and the plain through which the river passes is entirely level, it will, notwithstanding, still continue to run from the perpendicular pressure of the water, which is always in exact proportion to the depth. This perpendicular pressure is nothing more than the weight of the upper waters pressing the lower out of their places, and, consequently, driving them forward, as they cannot recede against the stream. As this pressure is greatest in the deepest parts of the river, so we generally find the middle of the stream most rapid; both because it has the greatest motion thus communicated by the pressure, and the fewest obstructions from the banks on either side.

Rivers thus set into motion are almost always found to make their own beds. When they find the bed elevated, they wear its substance away, and deposit the sediment in the next hollow, so as in time to make the bottom of their channels even. On the other hand, the water is continually gnawing and eating away the banks on each side; and this with more force as the current happens to strike more directly against them. By these means, it always has a tendency to render them more strait and parallel to its own course. Thus it continues to rectify its banks, and enlarge its bed; and, consequently, to diminish the force of its stream, till there becomes an equilibrium between the force of the water, and the resistance of its banks, upon which both will remain without any further mutation. And it is happy for man that bounds are thus put to the erosion of the earth by water; and that we find all rivers only dig and widen themselves but to a certain degree.

In those plains and large valleys where great rivers flow, the bed of the river is usually lower than any part of the valley: but it often happens, that the surface of the water is higher than many of the grounds that are adjacent to the banks of the stream. If, after inundations, we take a view of some rivers, we shall find their banks appear above water, at a time that all the adjacent valley is overflowed. This proceeds from the frequent deposition of mud, and such like substances, upon the banks, by the rivers frequently overflowing; and thus, by degrees, they become elevated above the plain; and the water is often seen higher also.

Rivers, as every body has seen, are always broadest at the mouth; and grow narrower towards their source. But what is less known, and probably more deserving curiosity, is, that they run in a more direct channel as they immediately leave their sources; and that their sinuosities and turnings become more numerous as they proceed. It is a certain sign among the savages of North America, that they are near the sea, when they find the rivers winding, and every now and then changing their direction. And this is even now become an indication to the Europeans themselves, in their journeys through those trackless forests. As those sinuosities, therefore, increase as the river approaches the sea, it is not to be wondered at, that they sometimes divide, and thus disembogue by different channels. The Danube disembogues into the Euxine by seven mouths; the Nile, by the same number; and the Wolga, by seventy.

The currents of rivers, are to be estimated very differently from the manner in which those writers, who have given us mathematical theories on this subject, represent them. They found their cal-

culations upon the surface being a perfect plain, from one bank to the other; but this is not the actual state of nature; for rivers, in general, rise in the middle; and this convexity is greatest in proportion as the rapidity is greater. Any person, to be convinced of this, need only lay his eye as nearly as he can on a level with the stream, and looking across to the opposite bank, he will perceive the river in the midst to be elevated considerably above what it is at the edges. This rising, in some rivers, is often found to be three feet high; and is ever increased, in proportion to the rapidity of the stream. In this case, the water in the midst of the current loses a part of its weight, from the velocity of its motion; while that at the sides, for the contrary reason, sinks lower. It sometimes, however, happens, that this appearance is reversed; for when tides are found to flow up with violence against the natural current of the water, the greatest rapidity is then found at the sides of the river, as the water there resists the influx from the sea. On those occasions, therefore, the river presents a concave rather than a convex surface; and, as in the former case, the middle waters rose in a ridge; in this case, they sink in a furrow.

The stream of all rivers is more rapid in proportion as its channel is diminished. For instance, it will be much swifter where it is ten yards broad, than where it is twenty; for the force behind still pushing the water forward, when it comes to the narrow part, it must make up by velocity what it wants in room.

It often happens that the stream of a river is opposed by one of its jutting banks, by an island in the midst, the arches of a bridge, or some such obstacle. This produces, not unfrequently, a back current; and the water having past the arch with great velocity, pushes the water on each side of its direct current.

This produces a side current, tending to the banks, and not unfrequently a whirlpool; in which a large body of waters are circulated in a kind of cavity, sinking down in the middle. The central point of the whirlpool is always lowest, because it has the least motion: the other parts are supported, in some measure, by the violence of theirs; and, consequently, rise higher as their motion is greater; so that towards the extremity of the whirlpool must be higher than towards the center.

If the stream of a river be stopped at the surface, and yet be free below; for instance, if it be laid over by a bridge of boats, there will then be a double current; the water at the surface will flow back, while that at the bottom will proceed with increased velocity. It often happens that the current at the bottom is swifter than at the top, when, upon violent land-floods, the weight of waters towards the source presses the waters at the bottom, before it has had time to communicate its motion to the surface. However, in all other cases, the surface of the stream is swifter than the bottom, as it is not retarded by rubbing over the bed of the river.

It might be supposed that bridges, dams, and other obstacles in the current of a river, would retard its velocity: but the difference they make is very inconsiderable. The water, by these stoppages, gets an elevation above the object; which, when it has surmounted, it gives a velocity that recompences the former delay. Islands and turnings also retard the course of the stream but very inconsiderably; any cause which diminishes the quantity of the water, most sensibly diminishes the force and the velocity of the stream.

An increase of water in the bed of the river always increases its rapidity, except in cases of inundation. The instant the river has overflowed its

banks, the velocity of its current is always turned that way, and the inundation is perceived to continue for some days; which it would not otherwise do, if, as soon as the cause was discontinued, it acquired its former rapidity.

A violent storm, that sets directly up against the course of the stream, will always retard, and sometimes entirely stop its course. We have seen an instance of this, when the bed of a large river was left entirely dry for some hours, and fish were caught among the stones at the bottom.

Inundations are generally greater towards the source of rivers, than farther down; because the current is generally swifter below than above; and that for the reason already assigned.

A little river may be received into a large one, without augmenting either its width or depth. This, which at first view seems a paradox, is yet very easily accounted for. The little river, in this case, only goes towards increasing the swiftness of the larger, and putting its dormant waters into motion. In this manner, the Venetian branch of the Po was pushed on by the Ferarrese branch and that of Panaro, without any enlargement of its breadth or depth from these accessions.

A river tending to enter another, either perpendicularly, or in an opposite direction, will be diverted, by degrees, from that direction; and be obliged to make itself a more favourable entrance downward, and more conspiring with the stream of the former.

The union of two rivers into one, makes it flow the swifter; since the same quantity of water, instead of rubbing against four shores, now only rubs against two. And, besides, the current being deeper, becomes of consequence more fitted for motion.

With respect to the places from whence rivers proceed, it may be taken for a general rule, that the largest and highest mountains supply the greatest and most extensive rivers. It may also be remarked, in whatever direction the ridge of the mountain runs, the river takes an opposite course. If the mountain, for instance, stretches from north to south, the river runs from east to west; and so contrariwise. These are some of the most generally received opinions with regard to the course of rivers; however, they are liable to many exceptions; and nothing but an actual knowledge of each particular river can furnish us with an exact theory of its current.

The largest rivers of Europe are, first, the Wolga, which is about six hundred and fifty leagues in length, extending from Reschow to Astrachan. It is remarkable of this river, that it abounds with water during the summer months of May and June; but all the rest of the year is so shallow as scarce to cover its bottom, or allow a passage for loaded vessels that trade up its stream. It was up this river that the English attempted to trade into Persia, in which they were so unhappily disappointed, in the year 1741. The next in order is the Danube. The course of this is about four hundred and fifty leagues, from the mountains of Switzerland to the Black Sea. It is so deep between Buda and Belgrade, that the Turks and Christians have fleets of men of war upon it, which frequently engaged, during the last war between the Ottomans and the Austrians: however, it is unnavigable further down, by reason of its cataracts, which prevent its commerce into the Black Sea. The Don, or Tanaïs, which is four hundred leagues from the source of that branch of it called the Sofna, to its mouth in the Euxine sea. In one part of its course it approaches near the Wolga; and Peter the Great had actually begun a canal, by which he intended joining those two rivers; but this he did not live to finish. The Nieper, or Boristhenes, which rises in the middle of Muscovy, and runs a course of

three hundred and fifty leagues, to empty itself into the Black Sea. The Old Cossacks inhabit the banks and islands of this river; and frequently cross the Black Sea, to plunder the maritime places on the coasts of Turkey. The Dwina, which takes its rise in a province of the same name in Russia, that runs a course of three hundred leagues, and disembogues into the White Sea, a little below Archangel.

The largest rivers of Asia are, the Hoanho, in China, which is eight hundred and fifty leagues in length, computing from its source at Raja Ribron, to its mouth in the Gulph of Changi. The Jenisca of Tartary, about eight hundred leagues in length, from the Lake Selinga to the Icy Sea. This river is, by some, supposed to supply most of that great quantity of drift wood which is seen floating in the seas, near the Arctic circle. The Oby, of five hundred leagues, running from the lake of Kila into the Northern sea. The Amour, in Eastern Tartary, whose course is about five hundred and seventy-five leagues, from its source to its entrance into the sea of Kamtschatka. The Kiam, in China, five hundred and fifty leagues in length. The Ganges, one of the most noted rivers in the world, and about as long as the former. It rises in the mountains which separate India from Tartary; and running through the dominions of the Great Mogul, discharges itself by several mouths into the bay of Bengal. It is not only esteemed by the Indians for the depth, and pureness of its stream, but for a supposed sanctity which they believe to be in its waters. It is visited annually by several hundred thousand pilgrims, who pay their devotions to the river as to a god; for savage simplicity is always known to mistake the blessings of the Deity for the Deity himself. They carry their dying friends from distant countries, to expire on its banks; and to be buried in its stream. The water is lowest in April or May; but the rains beginning to fall soon after, the flat country is overflowed for several miles, till about the end of September; the waters then begin to retire, leaving a prolific sediment behind, that enriches the soil, and, in a few days time, gives a luxuriance to vegetation, beyond what can be conceived by an European. Next to this may be reckoned the still more celebrated river Euphrates. This rises from two sources, northward of the city Erzerum, in Turcomania; and unites about three days journey below the same; from whence, after performing a course of five hundred leagues, it falls into the Gulph of Persia, fifty miles below the city of Bassora in Arabia. The river Indus is extended from its source to its discharge into the Arabian sea, four hundred leagues.

The largest rivers of Africa are, the Senegal, which runs a course of not less than eleven hundred leagues, comprehending the Niger, which some have supposed to fall into it. However, later accounts seem to affirm that the Niger is lost in the sands, about three hundred miles up from the western coasts of Africa. Be this as it may, the Senegal is well known to be navigable for more than three hundred leagues up the country; and how much higher it may reach is not yet discovered, as the dreadful fatality of the inland parts of Africa, not only deter curiosity, but even avarice, which is a much stronger passion. At the end of last war, of fifty Englishmen that were sent to the factory at Galam, a place taken from the French, and nine hundred miles up the river, only one returned to tell the fate of his companions, who were destroyed by the climate. The celebrated river Nile is said to be nine hundred and seventy leagues, from its source among the mountains of the Moon, in Upper Æthiopia, to its opening into the Mediterranean

terranean sea. The sources of this river were considered as inscrutable by the ancients; and the causes of its periodical inundation were equally known. They have both been ascertained by the missionaries who have travelled into the interior parts of Æthiopia. The Nile takes its rise in the kingdom of Gojam, from a small aperture on the top of a mountain, which, though not above a foot and an half over, yet was unfathomable. This fountain, when arrived at the foot of the mountain, expands into a river; and being joined by others, forms a lake thirty leagues long, and as many broad; from this, its channel, in some measure, winds back to the country where it first began; from thence, precipitating by frightful cataracts, it travels through a variety of desert regions, equally formidable, such as Amhara, Olaca, Damot, and Xaoa. Upon its arrival in the kingdom of Upper Egypt, it runs through a rocky channel, which some late travellers have mistaken for its cataracts. In the beginning of its course, it receives many lesser rivers into it; and Pliny was mistaken, in saying that it received none. In the beginning also of its course, it has many windings; but, for above three hundred leagues from the sea, runs in a direct line. Its annual overflowings arise from a very obvious cause, which is almost universal with the great rivers that take their source near the Line. The rainy season, which is periodical in those climates, flood the rivers; and as this always happens in our summer, so the Nile is at that time overflowed. From these inundations, the inhabitants of Egypt derive happiness and plenty; and, when the river does not arise to its accustomed heights, they prepare for an indifferent harvest. It begins to overflow about the seventeenth of June; it generally continues to augment for forty days, and decreases in about as many more. The time of increase and decrease, however, is much more inconsiderable now than it was among the ancients. Herodotus informs us, that it was an hundred days rising, and as many falling; which shews that the inundation was much greater at that time than at present. Mr. Buffon has ascribed the present diminution, as well to the lessening of the mountains of the Moon, by their substance having so long been washed down with the stream, as to the rising of the earth in Egypt, that has for so many ages received this extraneous supply. But we do not find, by the buildings that have remained since the times of the ancients, that the earth is much raised since then. Besides the Nile in Africa, we may reckon the Zara, and the Coanza, from the greatness of whose openings into the sea, and the rapidity of whose streams, we form an estimate of the great distance from whence they come. Their courses, however, are spent in watering deserts and savage countries, whose poverty or fierceness have kept strangers away.

But of all parts of the world, America, as it exhibits the most lofty mountains, so also it supplies the largest rivers. The foremost of these is the great river Amazons, which, from its source in the lake of Lauricocha, to its discharge into the Western Ocean, performs a course of more than twelve hundred leagues. The breadth and depth of this river is answerable to its vast length; and, where its width is most contracted, its depth is augmented in proportion. So great is the body of its waters, that other rivers, though before the objects of admiration, are lost in its bosom. It proceeds, after their junction, with its usual appearance, without any visible change in its breadth or rapidity; and, if we may so express it, remains great without ostentation. In some places it displays its whole magnificence, dividing into several large branches, and encompassing a multitude of

islands; and, at length, discharging itself into the ocean, by a channel of an hundred and fifty miles broad. Another river, that may almost rival the former, is the St. Lawrence, in Canada, which rising in the lake Assiniboils, passes from one lake to another, from Cristinaux to Alempigo; from thence to lake Superior; thence to the lake Hurons; to lake Erie; to lake Ontario; and, at last, after a course of nine hundred leagues, pours their collected waters into the Atlantic ocean. The river Mississippi is of more than seven hundred leagues in length, beginning at its source near the lake Assiniboils, and ending at its opening into the Gulf of Mexico. The river Plate runs a length of more than eight hundred leagues from its source in the river Parana, to its mouth. The river Oroonoko is seven hundred and fifty-five leagues in length, from its source near Palto, to its discharge into the Atlantic ocean.

Such is the amazing length of the greatest rivers; and even in some of these, the most remote sources very probably yet continue unknown. In fact, if we consider the number of rivers which they receive, and the little acquaintance we have with the regions through which they run, it is not to be wondered at that geographers are divided concerning the sources of most of them. As among a number of roots by which nourishment is conveyed to a stately tree, it is difficult to determine precisely that by which the tree is chiefly supplied; so among the many branches of a great river, it is equally difficult to tell which is the original. Hence it may easily happen, that a similar branch is taken for the capital stream; and its runnings are pursued, and delineated, in prejudice of some other branch that better deserved the name and the description. In this manner, in Europe, the Danube is known to receive thirty lesser rivers: the Wolga, thirty-two or thirty-three. In Asia, the Hohanno receives thirty-five; the Jenisca above sixty; the Oby as many; the Amour about forty; the Nanquin receives thirty rivers; the Ganges twenty; and the Euphrates about eleven. In Africa, the Senegal receives more than twenty rivers; the Nile receives not one for five hundred leagues upwards, and then only twelve or thirteen. In America, the river Amazons receives above sixty, and those very considerable; the river St. Lawrence about forty, counting those which fall into its lakes; the Mississippi receives forty; and the river Plate above fifty.

We mentioned the inundations of the Ganges and the Nile, but almost every other great river whose source lies within the tropics, have their stated inundations also. The river Pegu has been called, by travellers, the Indian Nile, because of the similar overflowings of its stream: this it does to an extent of thirty leagues on each side; and so fertilizes the soil, that the inhabitants send great quantities of rice into other countries, and have still abundance for their own consumption. The river Senegal has likewise its inundations, which cover the whole flat country of Negroland, beginning and ending much about the same time with those of the Nile; as, in fact, both rivers rise from the same mountains. But the difference between the effects of the inundations in each river is remarkable: in the one, it distributes health and plenty; in the other, diseases, famine, and death. The inhabitants along the torrid coasts of the Senegal can receive no benefit from any additional manure the river may carry down to their soil, which is, by nature, more than sufficiently luxuriant; or, even if they could, they have not industry to turn it to any advantage. The banks, therefore, of the rivers, lie uncultivated, overgrown with rank and noxious herbage, and infested with thousands

sands of animals of various malignity. Every new flood only tends to increase the rankness of the soil, and to provide fresh shelter for the creatures that infest it. If the flood continues but a few days longer than usual, the improvident inhabitants, who are driven up in the higher grounds, want provisions, and a famine ensues. When the river begins to return into its channel, the humidity and heat of the air are equally fatal; and the carcases of infinite numbers of animals, swept away by the inundation, putrifying in the sun, produce a stench that is almost insupportable. But even the luxuriance of the vegetation becomes a nuisance. We have been assured by persons of veracity who have been up the river Senegal, that there are some plants growing along the coast, the smell of which is so powerful, that it is hardly to be endured. It is certain, that all the sailors and soldiers who have been at any of our factories there, ascribe the unwholesomeness of the voyage up the stream, to the vegetable vapour. However this be, the inundations of the rivers in this wretched part of the globe, contribute scarce any advantage, if we except to the beauty of the prospects which they afford. These, indeed, are finished beyond the utmost reach of art: a spacious glassy river, with its banks here and there fringed to the very surface by the mangrove-tree, that grows down into the water, presents itself to view. Lofty forests of various colours, with openings between, carpeted with green plants, and the most gaudy flowers; beasts and animals, of various kinds, that stand upon the banks of the river, and, with a sort of wild curiosity, survey the mariners as they pass, contribute to heighten the scene. This is the sketch of an African prospect; which delights the eye, even while it destroys the constitution.

Beside these annually periodical inundations, there are many rivers that overflow at much shorter intervals. Thus most of those in Peru and Chili have scarce any motion by night; but upon the appearance of the morning sun, they resume their former rapidity: this proceeds from the mountain snows, which melting with the heat, increase the stream, and continue to drive on the current while the sun continues to dissolve them. Some rivers also flow with an even steady current, from their source to the sea; others flow with greater rapidity, their stream being poured down in a cataract, or swallowed by the sands, before they reach the sea.

The rivers of those countries that have been least inhabited, are usually more rocky, uneven, and broken into water-falls or cataracts, than those where the industry of man has been more prevalent. Wherever man comes, nature puts on a milder appearance: the terrible and the sublime are exchanged for the gentle and the useful; the cataract is sloped away into a placid stream; and the banks become more smooth and even. It must have required ages to render the Rhone or the Loir navigable; their beds must have been cleaned and directed; their inequalities removed; and, by a long course of industry, nature must have been taught to conspire with the desires of her controller. Every one's experience must have supplied instances of rivers thus being made to flow more evenly, and more beneficially to mankind; but there are some whose currents are so rapid, and falls so precipitate, that no art can obviate; and that must for ever remain as amazing instances of incorrigible nature.

Of this kind are the cataracts of the Rhine; one of which has been seen to exhibit a very strange appearance: it was that at Schathausen, which was frozen quite across, and the water stood in columns where the cataract had formerly fallen. The Nile, as was said, has its cataracts. The river Vologda, in Russia, has two. The river

Zara, in Africa, has one near its source. The river Velino, in Italy, has a cataract of above an hundred and fifty feet perpendicular. Near the city of Gottenburgh, in Sweden, the river rushes down from a prodigious high precipice into a deep pit, with a terrible noise, and such dreadful force, that those trees designed for the masts of ships, which are floated down the river, are usually turned upside down in their fall, and often are shattered to pieces, by being dashed against the surface of the water in the pit; this occurs if the masts fall sideways upon the water; but if they fall endways, they dive so far under water, that they disappear for a quarter of an hour, or more: the pit into which they are thus plunged, has been often sounded with a line of some hundred fathoms long, but no ground has been found hitherto. There is also a cataract at Powerscourt, in Ireland; in which the water is said to fall three hundred feet perpendicular; which is a greater descent than that of any other cataract in any part of the world. There is a cataract at Albany, in the province of New York, which pours its stream fifty feet perpendicular. But of all the cataracts in the world, that of Niagara, in Canada, if we consider the great body of water that falls, must be allowed to be the greatest, and the most astonishing.

This amazing fall of water is made by the river St. Lawrence, in its passage from the lake Erie into the lake Ontario. We have already said that St. Lawrence was one of the largest rivers in the world; and yet the whole of its waters are here poured down, by a fall of an hundred and fifty feet perpendicular. It is not easy to bring the imagination to correspond with the greatness of the scene; a river extremely deep and rapid, and that serves to drain the waters of almost all North America into the Atlantic ocean, is here poured precipitately down a ledge of rocks, that rise, like a wall, across the whole bed of its stream. The width of the river, a little above, is near three quarters of a mile broad, and the rocks, where it grows narrower, are four hundred yards over. Their direction is not straight across, but hollowing inwards like an horse-shoe; so that the cataract, which bends to the shape of the obstacle, rounding inwards, presents a kind of theatre the most tremendous in nature. Just in the middle of this circular wall of waters, a little island, that has braved the fury of the current, presents one of its points, and divides the stream at top into two; but it unites again long before it has got to the bottom. The noise of the fall is heard at several leagues distance; and the fury of the waters at the bottom of their fall is inconceivable. The dashing produces a mist that rises to the very clouds; and that produces a most beautiful rainbow, when the sun shines. It may easily be conceived, that such a cataract quite destroys the navigation of the stream: and yet some Indian canoes, as it is said, have been known to venture down it with safety.

Of those rivers that lose themselves in the sands, or are swallowed up by chasms in the earth, we have various information. What we are told by the ancients, of the river Alpheus, in Arcadia, that sinks into the ground, and rises again near Syracuse, in Sicily, where it takes the name of Arethusa, is rather more known than credited. But we have better information with respect to the river Tigris being lost in this manner under Mount Taurus; of the Guadalquivir, in Spain, being buried in the sands; of the river Greatah, in Yorkshire, running underground, and rising again, and even of the great Rhine itself, a part of which is no doubt lost in the sands, a little above Leyden. But it ought to be observed of this river, that by much the greatest part arrives at the ocean; for,

although

although the ancient channel which fell into the sea, a little to the west of that city, be now entirely choaked up, yet there are still a number of small canals, that carry a great body of waters to the sea: and, besides, it has also two very large openings, the Lech, and the Wal, below Rotterdam, by which it empties itself abundantly.

Be this as it will, nothing is more common in sultry and sandy deserts, than rivers being thus either lost in the sands, or entirely dried up by the sun. And hence we see, that under the Line, the small rivers are but few; for such little streams as are common in Europe, and which with us receive the name of rivers, would quickly evaporate, in those parching and extensive deserts. It is even confidently asserted, that the great river Niger is thus lost before it reaches the ocean; and that its supposed mouths, the Gambia, and the Senegal, are distinct rivers, that come a vast way from the interior parts of the country. It appears, that the rivers under the Line are large; but it is otherwise at the Poles, where they must necessarily be small. In that desolate region, as the mountains are covered with perpetual ice, which melts but little, or not at all, the springs and rivulets are furnished with a very small supply. Here, therefore, men and beasts would perish, and die for thirst, if Providence had not ordered that in the hardest winter, thaws should intervene, which deposit a small quantity of snow-water in pools under the ice; and from this source the wretched inhabitants drain a scanty beverage.

Thus, whatever quarter of the globe we turn to, we shall find new reasons to be satisfied with that part of it in which we reside. Our rivers furnish all the plenty of the African stream, without its inundation; they have all the coolness of the Polar rivulet, with a more constant supply; they may want the terrible magnificence of huge cataracts, or extensive lakes, but they are more navigable, and more transparent; though less deep and rapid than the rivers of the torrid zone, they are more manageable, and only wait the will of man to take their direction. The rivers of the torrid zone, like the monarchs of the country, rule with despotic tyranny, profuse in their bounties, and ungovernable in their rage. The rivers of Europe, like their kings, are the friends, and not the oppressors of the people; bounded by known limits, abridged in the power of doing ill, directed by human sagacity, and only at freedom to distribute happiness and plenty.

CHAP. XV.

Of the OCEAN in general; and its Saltness.

IN looking upon a map of the world, we find that the ocean occupies considerably more of the globe, than the land is found to do. This immense body of waters is diffused round both the Old and New Continent, to the south; and may surround them also to the north, for what we know, but the ice in those regions has stopped our enquiries. Although the ocean, properly speaking, is but one extensive sheet of waters, continued over every part of the globe, without interruption, and although no part of it is divided from the rest, yet geographers have distinguished it by different names; as the Atlantic or Western Ocean, the Northern Ocean, the Southern Ocean, the Pacific Ocean, and the Indian Ocean. Others have divided it differently, and given other names; as the Frozen Ocean, the Inferior Ocean, or the American Ocean. But all these being arbitrary distinctions, and not of Nature's making, the naturalist may consider them with indifference.

In this vast receptacle, almost all the rivers of the

No. 51.

earth ultimately terminate; nor do such great supplies seem to increase its stores; for it is neither apparently swollen by their tribute, nor diminished by their failure; it still continues the same. Indeed, what is the quantity of water of all the rivers and lakes in the world, compared to that contained in this great receptacle? If we should offer to make a rude estimate, we shall find that all the rivers in the world, flowing into the bed of the sea, with a continuance of their present stores, would take up at least eight hundred years to fill it to its present height. For, supposing the sea to be eighty-five millions of square miles in extent, and a quarter of a mile, upon an average, in depth, this, upon calculation, will give above twenty-one millions of cubic miles of water, as the contents of the whole ocean. Now, to estimate the quantity of water which all the rivers supply, take any one of them; the Po, for instance, the quantity of whose discharge into the sea, is known to be one cubic mile of water in twenty-six days. Now it will be found, upon a rude computation, from the quantity of ground the Po, with its influent streams, covers, that all the rivers of the world furnish about two thousand times that quantity of water. In the space of a year, therefore, they will have discharged into the sea about twenty-six thousand cubic miles of water; and not till eight hundred years will they have discharged as much water as is contained in the sea at present. We have not troubled our readers with the odd numbers, lest they should imagine we were giving precision to a subject that is incapable of it.

Thus great is the assemblage of waters diffused round our habitable globe; and yet, immeasurable as they seem, they are mostly rendered subservient to the necessities and the conveniencies of so little a being as man. Nevertheless, if it should be asked whether they be made for him alone, the question is not easily resolved. Some philosophers have perceived so much analogy to man in the formation of the ocean, that they have not hesitated to assert its being made for him alone. The distribution of land and water, say they, is admirable; the one being laid against the other so skilfully, that there is a just equipoise of the whole globe. Thus the Northern Ocean balances against the Southern; and the New Continent is an exact counter-weight to the Old. As to any objection from the ocean's occupying too large a share of the globe, they contend, that there could not have been a smaller surface employed to supply the earth with a due share of evaporation. On the other hand, some take the gloomy side of the question; they either magnify its apparent defects; or assert, that what seems defects to us, may be real beauties to some wiser order of beings. They observe, that multitudes of animals are concealed in the ocean, and but a small part of them are known; the rest, therefore, they sail not to say, were certainly made for their own benefit, and not for ours. How far either of these opinions be just, we will not presume to determine; but of this we are certain, that God has endowed us with abilities to turn this great extent of waters to our own advantage. He has made these things, perhaps, for other uses; but he has given us faculties to convert them to our own. This much agitated question, therefore, seems to terminate here. We shall never know whether the things of this world have been made for our use; but we very well know that we have been made to enjoy them. Let us then boldly affirm, that the earth, and all its wonders are ours; since we are furnished with powers to force them into our service. Man is the lord of all the sublunary creation; the howling savage, the winding serpent, with all the untameable and rebellious offspring of Nature, are destroyed in the contest, or driven at a distance from his habitations. The extensive and tempestuous ocean, instead of limiting or dividing his

power, only serves to assist his industry, and enlarge the sphere of his enjoyments. Its billows, and its monsters, instead of presenting a scene of terror, only call up the courage of this little intrepid being; and the greatest danger that man now fears on the deep, is from his fellow-creatures. Indeed, when we consider the human race as Nature has formed them, there is but very little of the habitable globe that seems made for them. But when we consider them as accumulating the experience of ages, in commanding the earth, there is nothing so great, or so terrible. What a poor contemptible being is the naked savage, standing on the beach of the ocean, and trembling at its tumults! How little capable is he of converting its terrors into benefits; or of saying, behold an element made wholly for my enjoyment! He considers it as an angry deity, and pays it the homage of submission. But it is very different when he has exercised his mental powers; when he has learned to find his own superiority, and to make it subservient to his commands. It is then that his dignity begins to appear, and that the true Deity is justly praised for having been mindful of man; for having given him the earth for his habitation, and the sea for an inheritance.

This power which man has obtained over the ocean, was at first enjoyed in common; and none pretended to a right in that element where all seemed intruders. The sea, therefore, was open to all till the time of the emperor Justinian. His successor Leo granted such as were in possession of the shore, the sole right of fishing before their respective territories. The Thracian Bosphorus was the first that was thus appropriated; and from that time it has been the struggle of most of the powers of Europe to obtain an exclusive right in this element. The Republic of Venice claims the Adriatic. The Danes are in possession of the Baltic. But the English have a more extensive claim to the empire of all the seas, encompassing the kingdoms of England, Scotland, and Ireland; and although these have been long contested, yet they are now considered as their indisputable property. Every one knows that the great power of the nation is exerted on this element; and that the instant England ceases to be superior upon the ocean, its safety begins to be precarious.

It is in some measure owing to our dependence upon the sea, and to our commerce there, that we are so well acquainted with its extent and figure. The bays, gulphs, currents, and shallows of the ocean, are much better known and examined than the provinces and kingdoms of the earth itself. The hopes of acquiring wealth by commerce, has carried man to much greater length than the desire of gaining information could have done. In consequence of this, there is scarce a strait or an harbour, scarce a rock or a quicksand, scarce an inflexion of the shore, or the jutting of a promontory, that has not been minutely described. But as these present very little entertainment to the imagination, or delight to any but those whose pursuits are lucrative, they need not be dwelt upon here. While the merchant and the mariner are solicitous in describing current and soundings, the naturalist is employed in observing wonders, though not so beneficial, yet to him of a much more important nature. The saltness of the sea seems to be foremost.

Whence the sea has derived that peculiar bitterish saltness which we find in it, appears, by Aristotle, to have exercised the curiosity of naturalists in all ages. He supposed (and mankind were for ages content with the solution) that the sun continually raised dry saline exhalations from the earth, and deposited them upon the sea; and hence, say his followers, the waters of the sea are more salt at top than at bottom. But, unfortunately for this opinion, neither of the facts is true. Sea salt is not

to be raised by the vapours of the sun; and sea water is not saltier at the top than at the bottom. Father Bohours is of opinion that the Creator gave the waters of the ocean their saltness at the beginning; not only to prevent their corruption, but to enable them to bear greater burthens. But their saltness does not prevent their corruption; for stagnant seawater, like fresh, soon grows putrid: and, as for their bearing greater burthens, fresh water answers all the purposes of navigation quite as well. The established opinion, therefore, is that of Boyle, who supposes, "that the sea's saltness is supplied not only from rocks or masses of salt at the bottom of the sea, but also from the salt which the rains and rivers, and other waters, dissolve in their passage through many parts of the earth, and at length carry with them to the sea." But as there is a difference in the taste of rock-salt found at land, and that dissolved in the waters of the ocean, this may be produced by the plenty of nitrous and bituminous bodies that, with the salts, are likewise washed into that great receptacle. These substances being thus once carried to the sea, must for ever remain there; for they do not rise by evaporation, so as to be returned back from whence they came. Nothing but the fresh waters of the sea rise in vapours; and all the saltness remains behind. From hence it follows, that every year the sea must become more and more salt; and this speculation Doctor Halley carries so far as to lay down a method of finding out the age of the world by the saltness of its waters. "For if it be observed," says he, "what quantity of salt is at present contained in a certain weight of water, taken up from the Caspian Sea, for example, and, after some centuries, what greater quantity of salt is contained in the same weight of water, taken from the same place; we may conclude, that in proportion as the saltness has increased in a certain time, so much must it have increased before that time; and we may thus, by the rule of proportion, make an estimate of the whole time wherein the water would acquire the degree of saltness it should be then possessed of." All this may be fine; however, an experiment, begun in this century, which is not to be completed till some centuries hence, is rather a little mortifying to modern curiosity: and, we are induced to think, the inhabitants round the Caspian Sea, will not be apt to undertake the enquiry.

This saltness is found to prevail in every part of the ocean; and as much at the surface as at the bottom. It is also found in all those seas that communicate with the ocean; but rather in a less degree.

The great lakes, likewise, that have no outlets nor communication with the ocean, are found to be salt: but some of them in less proportion. On the contrary, all those lakes through which rivers run into the sea, however extensive they be, are, notwithstanding, very fresh: for the rivers do not deposit their salts in the bed of the lake, but carry them, with their currents, into the ocean. Thus the lakes Ontario and Erie, in North America, although for magnitude they may be considered as inland seas, are, nevertheless, fresh water lakes; and kept so by the river St. Lawrence, which passes through them. But those lakes that have no communication with the sea, nor any rivers, going out, although they be less than the former, are, however, always salt. Thus, that which goes by the name of the Dead Sea, though very small, when compared to those already mentioned, is so exceedingly salt, that its waters seem scarce capable of dissolving any more. The lakes of Mexico, and of Titicaca, in Peru, though of no great extent, are, nevertheless, salt; and both for the same reason.

Those who are willing to turn all things to the best, have not failed to consider this saltness of the sea, as a peculiar blessing from Providence, in order

der to keep so great an element sweet and wholesome. What foundation there may be in the remark, we will not pretend to determine; but we shall shortly find a much better cause for its being kept sweet, namely, its motion.

On the other hand, there have been many who have considered the subject in a different light, and have tried every endeavour to make salt-water fresh, so as to supply the wants of mariners in long voyages, or when exhausted of their ordinary stores. At first it was supposed simple distillation would do; but it was soon found that the bitter part of the water still kept mixed. It was then tried by uniting salt of Tartar with sea-water, and distilling both: but here the expence was greater than the advantage. Calcined bones were next thought of; but an hoghead of calcined bones, carried to sea, would take up as much room as an hoghead of water, and was more hard to be obtained. In this state, therefore, have the attempts to sweeten sea-water rested; the chymist satisfied with the reality of his invention; and the mariner convinced of its being useless. We cannot, therefore, avoid mentioning, a kind of succedaneum which has been lately conceived to answer the purposes of fresh-water, when mariners are quite exhausted. It is well known, the persons who go into a warm bath, come out several ounces heavier than they went in; their bodies having imbibed a correspondent quantity of water. This more particularly happens, if they have been previously debarred from drinking, or go in with a violent thirst; which they quickly find quenched, and their spirits restored. It was supposed, that in case of a total failure of fresh-water at sea, a warm bath might be made of sea-water, for the use of mariners; and that their pores would thus imbibe the fluid, without any of its salts, which would be seen to crystallize on the surface of their bodies. In this manner, it is supposed, a sufficient quantity of moisture may be procured to sustain life, till time or accident furnish a more copious supply.

But, however this be, the saltness of the sea can by no means be considered as a principal cause in preserving its waters from putrefaction. The ocean has its currents, like rivers, which circulate its contents round the globe; and these may be said to be the great agents that keep it sweet and wholesome. Its saltness alone would by no means answer this purpose: and some have even imagined, that the various substances with which it is mixed, rather tend to promote putrescence than impede it. Sir Robert Hawkins, one of our most enlightened navigators, gives the following account of a calm, in which the sea continuing for some time without motion, began to assume a very formidable appearance. "Were it not," says he, "for the moving of the sea, by the force of winds, tides, and currents, it would corrupt all the world. The experiment of this I saw in the year 1590, lying with a fleet about the islands of Azores, almost six months; the greatest part of which time we were becalmed. Upon which all the sea became so replenished with several sorts of jellies, and forms of serpents, adders, and snakes, as seemed wonderful: some green, some black, some yellow, some white, some of divers colours, and many of them had life; and some there were an yard and an half and two yards long; which had I not seen, I could hardly have believed. And hereof are witnesses all the company of the ships which were then present: so that hardly a man could draw a bucket of water clear of some corruption. In which voyage, towards the end thereof, many of every ship fell sick, and began to die apace. But the speedy passage into our country, was a remedy to the crazed, and a preservative for those that were not touched."

This shews, abundantly, how little the sea's saltness was capable of preserving it from putrefaction: but, to put the matter beyond all doubt, Mr. Boyle kept a quantity of sea-water, taken up in the English channel, for some time barrelled up; and, in the space of a few weeks, it began to acquire a foetid smell: he was also assured by one of his acquaintance who was becalmed for twelve or fourteen days in the Indian sea, that the water, for want of motion, began to stink; and that had it continued much longer, the stench would probably have poisoned him. It is the motion, therefore, and not the saltness of the sea, that preserves it in its present state of salubrity; and this, very probably, by dashing and breaking in pieces the rudiments, if we may so call them, of the various animals that would otherwise breed there and putrefy.

There are some advantages, however, which are derived from the saltness of the sea. Its waters being evaporated, furnish that salt which is used for domestic purposes; and, although in some places it is made from springs, and, in others, dug out of mines, yet the greatest quantity is made only from the sea. That which is called bay-salt, (from its coming to us by the Bay of Biscay) is a stronger kind, made by evaporation in the sun: that called common salt, is evaporated in pans over the fire, and is of a much inferior quality to the former.

Another benefit arising from the quantity of salt dissolved in the sea, is, that it thus becomes heavier, and, consequently, more buoyant. Mr. Boyle, who examined the difference between sea-water and fresh, found that the former appeared to be about a forty-fifth part heavier than the latter. Those, also, who have had opportunities of bathing in the sea, pretend to have experienced a much greater ease in swimming there, than in fresh water. However, as we see they have only a forty-fifth part more of their weight sustained by it, we are apt to doubt whether so minute a difference can be practically perceivable. Be this as it may, as sea-water alters in its weight from fresh, so it is found also to differ from itself in different parts of the ocean. In general, it is perceived to be heavier, and, consequently, saltier, the nearer we approach the Line.

But there is an advantage arising from the saltness of the waters of the sea, much greater than what has been yet mentioned; which is, that their congelation is thus retarded. Some, indeed, have gone so far as to say, that sea-water never freezes: but this is an assertion contradicted by experience. However, it is certain that it requires a much greater degree of cold to freeze it than fresh water; so that, while rivers and springs are seen converted into one solid body of ice, the sea is always fit for navigation, and no way affected by the coldness of the severest winter. It is, therefore, one of the greatest blessings we derive from this element, that when at land all the stores of Nature are locked up from us, we find the sea ever open to our necessities, and patient of the hand of industry.

But it must not be supposed, because in our temperate climate we never see the sea frozen, that it is in the same manner open in every part of it. A very little acquaintance with the accounts of mariners, must have informed us, that at the polar regions it is embarrassed with mountains, and moving sheets of ice, that often render it impassable. These tremendous floats are of different magnitudes; sometimes rising more than a thousand feet above the surface of the water; sometimes diffused into plains of above two hundred leagues in length; and, in many parts, sixty or eighty broad. They are usually divided by fissures; one piece following another so close, that a person may step from one to the other. Sometimes mountains are seen rising amidst these plains, and presenting the appearance

of a variegated landscape, with hills and valleys, houses, churches, and towers. These are appearances in which all naturalists are agreed: but the great contest is respecting their formation. Mr. Buffon asserts, that they are formed from fresh water alone; which congealing at the mouths of great rivers, accumulate those huge masses that disturb navigation. However, this great naturalist seems not to have been aware that there are two sorts of ice floating in these seas; the flat ice, and the mountain ice: the one formed of sea-water only; the other, of fresh.

The flat, or driving ice, is entirely composed of sea-water; which, upon dissolution, is found to be salt; and is readily distinguished from the mountain or fresh-water ice, by its whiteness, and want of transparency. This ice is much more terrible to mariners than that which rises up in lumps: a ship can avoid the one, as it is seen at a distance; but it often gets in among the other, which sometimes closing, crushes it to pieces. This, which manifestly has a different origin from the fresh-water ice, may perhaps have been produced in the Icy Sea, beneath the Pole; or along the coasts of Spitzberg, or Nova Zembla.

The mountain-ice, as was said, is different in every respect, being formed of fresh water, and appearing hard and transparent; it is generally of a pale green colour, though some pieces are of a beautiful sky blue; many large masses, also, appear grey; and some black. If examined more nearly, they are found to be incorporated with earth, stones, and brush-wood washed from the shore. On these also are sometimes found, not only earth, but nests with bird eggs, at several hundred miles from land. The generality of these, though almost totally fresh, have, nevertheless, a thick crust of salt-water frozen upon them, probably from the power that ice has sometimes to produce ice. Such mountains as are here described, are most usually seen at spring-time, and after a violent storm, driving out to sea, where they at first terrify the mariner, and are soon after dashed to pieces by the continual washing of the waves; or driven into the warmer regions of the south, there to be melted away. They sometimes, however, strike back upon their native shores, where they seem to take root at the feet of mountains; and, as Martius tells us, are sometimes higher than the mountains themselves. Those seen by him were blue, full of clefts and cavities made by the rain, and crowned with snow, which alternately thawing and freezing every year, augmented their size. These, composed of materials more solid than that driving at sea, presented a variety of agreeable figures to the eye, that, with a little help from fancy, assumed the appearance of trees in blossom; the inside of churches, with arches, pillars, and windows; and the blue coloured rays, darting from within, presented the resemblance of a glory.

If we enquire into the origin and formation of these, which, as we see, are very different from the former, we have a very satisfactory account of them in Krantz's History of Greenland; and we will give the passage, with a very few alterations. "These mountains of ice," says he, "are not salt, like the sea-water, but sweet; and, therefore, can be formed no where except on the mountains, in rivers, in caverns, and against the hills near the sea-shore. The mountains of Greenland are so high, that the snow which falls upon them, particularly on the north-side, is, in one night's time, wholly converted into ice: they also contain clefts and cavities, where the sun seldom or never injects his rays: besides these, are projections, or landing-places, on the declivities of the steepest hills, where the rain and snow-water lodge, and quickly con-

geal. When now the accumulated flakes of snow slide down, or fall with the rain from the eminences above, on these prominences; or, when here and there a mountain-spring comes rolling down to such a lodging place, where the ice has already seated itself, they all freeze, and add their tribute to it. This, by degrees, waxes to a body of ice, that can no more be overpowered by the sun; and which, though it may indeed, at certain seasons, diminish by a thaw, yet, upon the whole, through annual acquisitions, it assumes an annual growth. Such a body of ice is often prominent far over the rocks. It does not melt on the upper surface, but underneath; and often cracks into many larger or smaller clefts, from whence the thawed water trickles out. By this it becomes, at last, so weak, that being overloaded with its own ponderous bulk, it breaks loose, and tumbles down the rocks with a terrible crash. Where it happens to overhang a precipice on the shore, it plunges into the deep with a shock like thunder; and with such an agitation of the water, as will overturn a boat at some distance, as many a poor Greenland has fatally experienced." Thus are these amazing ice mountains launched forth to sea, and found floating in the waters round both the Poles. It is these that have hindered mariners from discovering the extensive countries that lie round the South Pole; and that probably block up the passage to China by the North.

We will conclude this chapter with one effect more, produced by the saltness of the sea; which is, the luminous appearance of its waves in the night. All who have been spectators of a sea by night, a little ruffled with winds, seldom fail of observing its fiery brightness. In some places it shines as far as the eye can reach; at other times, only when the waves boom against the side of the vessel, or the oar dashes into the water. Some seas shine often; others more seldom; some, ever when particular winds blow; and others, within a narrow compass; a long tract of light being seen along the surface, whilst all the rest is hid in total darkness. It is not easy to account for these extraordinary appearances: some have supposed that a number of luminous insects produced the effect, and this is in reality sometimes the case; in general, however, they have every resemblance to that light produced by electricity; and, probably, arise from the agitation and dashing of the saline particles of the fluid against each other. But the manner in which this is done, for we can produce nothing similar by any experiments hitherto made, remains for some happier accident to discover. Our progress in the knowledge of nature is slow; and it is a mortifying consideration, that we are hitherto more indebted for success to chance than industry.

CHAP. XVI.

Of the Tides, Motion, and Currents of the Sea; with their Effects.

IT was said, in the former chapter, that the waters of the sea were kept sweet by their motion; without which they would soon putrefy, and spread universal infection. If we look for final causes, here, indeed, we have a great and an obvious one that presents itself before us. Had the sea been made without motion, and resembling a pool of stagnant water, the nobler races of animated nature would shortly be at an end. Nothing would then be left alive but swarms of ill-formed creatures, with scarce more than vegetable life; and subsisting by putrefaction. Were this extensive bed of waters entirely quiescent, millions of the

smaller reptile kinds would there find a proper retreat to breed and multiply in; they would find there no agitation, no concussion in the parts of the fluid to crush their feeble frames, or to force them from the places where they were bred: there they would multiply in security and ease, enjoy a short life; and putrifying, thus again give nourishment to numberless others, as little worthy of existence as themselves. But the motion of this great element effectually destroys the number of these viler creatures; its currents and its tides produce continual agitations, the shock of which they are not able to endure; the parts of the fluid rub against each other, destroy all viscidities; and the ocean, if we may so express it, acquires health by exercise.

The most obvious motion of the sea, and the most generally acknowledged, is that of its tides. This element is observed to flow for certain hours, from south towards the north; in which motion or flux, which lasts about six hours, the sea gradually swells; so that entering the mouths of rivers, it drives back the river waters to their heads. After a continual flux of six hours, the sea seems to rest for a quarter of an hour; and then begins to ebb, or retire back again, from north to south, for six hours more; in which time the waters sinking, the rivers resume their natural course. After a seeming pause of a quarter of an hour, the sea again begins to flow as before: and thus it has alternately risen and fallen, twice a day, since the creation.

This amazing appearance did not fail to excite the curiosity, as it did the wonder of the ancients. After some wild conjectures of the earliest philosophers, it became well known, in the times of Pliny, that the tides were entirely under the influence, in a small degree, of the sun; but in a much greater of the moon. It was found that there was a flux and reflux of the sea, in the space of twelve hours fifty minutes, which is exactly the time of a lunar day. It was observed, that whenever the moon was in the meridian, or, in other words, as nearly as possible over any part of the sea, that the sea flowed to that part, and made a tide there; on the contrary, it was found, that when the moon left the meridian, the sea began to flow back again from whence it came; and there might be said to ebb. Thus far the waters of the sea seemed very regularly to attend the motions of the moon. But as it appeared, likewise, that when the moon was in the opposite meridian, as far off on the other side of the globe, that there was a tide on this side also; so that the moon produced two tides, one by her greatest approach to us, and another by her greatest distance from us: in other words, the moon, in once going round the earth, produced two tides, always at the same time; one on the part of the globe directly under her; and the other on the part of the globe directly opposite.

Mankind continued for several ages content with knowing the general cause of these wonders, hopeless of discovering the particular manner of the moon's operation. Kepler was the first who conjectured that attraction was the principal cause; asserting that the sphere of the moon's operation extended to the earth, and drew up its waters. The precise manner in which this is done, was discovered by Newton.

The moon has been found, like all the rest of the planets, to attract, and to be attracted by the earth. This attraction prevails throughout our whole planetary system. The more matter there is contained in any body, the more it attracts: and its influence decreases in proportion as the distance, when squared, increases. This being premised, let us see what must ensue upon supposing the moon in the meridian of any tract of the sea. The surface of the water immediately under the moon, is nearer

the moon than any other part of the globe is; and, therefore, must be more subject to its attraction than the waters any where else. The waters will, therefore, be attracted by the moon, and rise in an heap; whose eminence will be the highest, where the attraction is greatest. In order to form this eminence, it is obvious that the surface, as well as the depths, will be agitated; and that wherever the water runs from one part, succeeding waters must run to fill up the space it has left. Thus the waters of the sea, running from all parts, to attend the motions of the moon, produce the flowing of the tide; and it is high tide at that part wherever the moon comes over it, or to its meridian.

But when the moon travels onward, and ceases to point over the place where the waters were just risen, the cause here of their rising ceasing to operate, they will flow back by their natural gravity, into the lower parts from whence they had travelled; and this retiring of the waters will form the ebbing of the sea.

Thus the first part of the demonstration is obvious; since, in general, it requires no great sagacity to conceive that the waters nearest the moon are most attracted, or raised highest by the moon. But the other part of the demonstration, namely, how there come to be high tides at the same time, on the opposite side of the globe, and where the waters are farthest from the moon, is not so easy to conceive. To comprehend this, it must be observed, that the part of the earth, and its waters, that are farthest from the moon, are the parts of all others that are least attracted by the moon: it must also be observed, that all the waters, when the moon is on the opposite side of the earth, must be attracted by it in the same direction that the earth itself attracts them; that is, quite through the body of the earth, towards the moon itself. This, therefore, being conceived, it is plain that those waters which are farthest from the moon, will have less weight than those of any other part, on the same side of the globe; because the moon's attraction, which conspires with the earth's attraction, is there least. Now, therefore, the waters farthest from the moon, having less weight, and being lightest, will be pressed on all sides, by those that, having more attraction, are heavier; and the heavier waters flowing in, will make them swell and rise in an eminence directly opposite to that on the other side of the globe, caused by the more immediate influence of the moon.

In this manner the moon, in one diurnal revolution, produces two tides; one raised immediately under the sphere of its influence, and the other directly opposite to it. As the moon travels, this vast body of waters rears upward, as if to watch its motions; and pursues the same constant rotation. However, in this great work of raising the tides, the sun has no small share; it produces its own tides constantly every day, just as the moon does, but in a much less degree, because the sun is at an immensely greater distance. Thus there are solar tides, and lunar tides. When the forces of these two great luminaries concur, which they always do when they are either in the same, or in opposite parts of the heavens, they jointly produce a much greater tide, than when they are so situated in the heavens, as each to make peculiar tides of their own. To express the very same thing technically; in the conjunctions and oppositions of the sun and moon, the attraction of the sun conspires with the attraction of the moon; by which means the high spring-tides are formed. But in the quadratures of the sun and moon, the water raised by the one is depressed by the other; and hence the lower neap-tides have their production. In a word, the tides are greatest in the syzgies, and least in the quadratures.

This theory well understood, and the astronomical terms previously known, it may readily be brought to explain the various appearances of the tides, if the earth were covered with a deep sea, and the waters uninfluenced by shoals, currents, straits, or tempests. But in every part of the sea, near the shores, the geographer must come in to correct the calculations of the astronomer. For, by reason of the shallowness of some places, and the narrowness of the straits in others, there arises a great diversity in the effect, not to be accounted for without an exact knowledge of all the circumstances of the place. In the great depths of the ocean, for instance, a very slow and imperceptible motion of the whole body of water will suffice to raise its surface several feet high; but if the same increase of water is to be conveyed through a narrow channel, it must rush through it with the most impetuous rapidity. Thus, in the English channel, and the German ocean, the tide is found to flow strongest in those places that are narrowest; the same quantity of water being, in this case, driven through a smaller passage. It is often seen, therefore, pouring through a strait with great force; and, by its rapidity, considerably raised above the surface of that part of the ocean into which it runs.

This shallowness and narrowness in many parts of the sea, give also rise to a peculiarity in the tides of some parts of the world. For in many places, and in our own seas in particular, the greatest swell of the tide is not while the moon is in its meridian height, and directly over the place, but some time after it has declined from thence. The sea, in this case, being obstructed, pursues the moon with what dispatch it can, but does not arrive with all its waters till long after the moon has ceased to operate. Lastly, from this shallowness of the sea, and from its being obstructed by shoals and straits, we may account for the Mediterranean, the Baltic, and the Black Sea, having no sensible tides. These, though to us they seem very extensive, are not however large enough to be affected by the influence of the moon; and as to their communication with the ocean, through such narrow inlets, it is impossible in a few hours they should receive and return water enough to raise or depress them in any considerable degree.

In general we may observe, that all tides are much higher, and more considerable in the torrid zone, than in the rest of the ocean; the sea in those parts being generally deeper, and less affected by changeable winds, or winding shores. The greatest tide we know of, is that at the mouth of the river Indus, where the water rises thirty feet in height. How great, therefore, must have been the amazement of Alexander's soldiers at so strange an appearance! They who always before had been accustomed only to the scarcely perceptible risings of the Mediterranean, or the minute intumescence of the Black Sea, when made at once spectators of a river rising and falling thirty feet in a few hours, must no doubt have felt the most extreme awe, and (as Quintus Curtius tells us) a mixture of curiosity and apprehension. The tides are also remarkably high on the coasts of Malay, in the straits of Sunda, in the Red Sea, at the mouth of the river St. Lawrence, along the coasts of China and Japan, at Panama, and in the gulph of Bengal. The tides at Tonquin, however, are the most remarkable in the world. In this part there is but one tide, and one ebb, in twenty-four hours; whereas, as we have said before, in other places there are two. Besides, there, twice in each month there is no tide at all, when the moon is near the equinoctial, the water being for some time quite stagnant. These, with some other odd appearances attending the same phæno-

mena, were considered by many as inscrutable; but Sir Isaac Newton, with peculiar sagacity, adjudged them to arise from the concurrence of two tides, one from the South Sea, and the other from the Indian Ocean. Of each of these tides there come successively two every day; two at one time greater, and two at another that are less. The time between the arrival of the two greater, is considered by him as high tide; the time between the two lesser, as ebb. In short, with this clue, that great mathematician solved every appearance, and so established his theory as to silence every opposer.

This fluctuation of the sea from the tides, produces another, and more constant rotation of its waters, from the east to the west, in this respect following the course of the moon. This may be considered as one great and general current of the waters of the sea; and although it be not every where distinguishable, it is nevertheless every where existent, except when opposed by some particular current or eddy, produced by partial and local causes. This tendency of the sea towards the west, is plainly perceivable in all the great straits of the ocean; as, for instance, in those of Magellan, where the tide running in from the east, rises twenty feet high, and continues flowing six hours; whereas the ebb continues but two hours, and the current is directed to the west. This proves that the flux is not equal to the reflux; and that from both results a motion of the sea westward, which is more powerful during the time of the flux than the reflux.

But this motion westward has been sensibly observed by navigators, in their passage back from India to Madagascar, and so on to Africa. In the great Pacific Ocean also it is very perceivable: but the places where it is most obvious are, as was said, in those straits which join one ocean to another. In the straits between the Maldivia islands, in the gulph of Mexico, between Cuba and Jucatan. In the straits of the gulph of Paria, the motion is so violent, that it hath received the appellation of the Dragon's Mouth. Northward, in the sea of Canada, in Waigat's straits, in the straits of Java, and, in short, in every strait where the ocean on one part pours into the ocean on the other. In this manner, therefore, is the sea carried with an unceasing circulation round the globe; and, at the same time that its waters are pushed back and forward with the tide, they have thus a progressive current to the west, which, though less observable, is not the less real.

Besides these two general motions of the sea, there are others which are particular to many parts of it, and are called currents. These are found to run in all directions, east, west, north, and south; being formed, as was said above, by various causes; the prominence of the shores; the narrowness of the straits, the variations of the wind, and the inequalities at the bottom. These, though no great object to the philosopher, as their causes are generally local and obvious, are nevertheless of the most material consequence to the mariner; and, without a knowledge of which, he could never succeed. It often has happened, that when a ship has unknowingly got into one of these, every thing seems to go forward with success, the mariners suppose themselves every hour approaching their wish'd-for port, the wind fills their sails, and the ship's prow seems to divide the water; but, at last, by miserable experience they find, that instead of going forward, they have been all the time receding. The business of currents, therefore, makes a considerable article in navigation; and the direction of their stream, and their rapidity, has been carefully set down. This some do by the observation of the surface of the current; or by the driving of the froth along the shore; or by throwing out what is called the log-

log-line, with a buoy made for that purpose: and by the direction and motion of this, they judge of the setting, and the rapidity of the current.

These currents are generally found to be most violent under the equator, where indeed all the motions of the ocean are most perceivable. Along the coasts of Guinea, if a ship happens to overshoot the mouth of any river it is bound to, the current prevents its return; so that it is obliged to steer out to sea, and take a very large compass, in order to correct the former mistake. These set in a contrary direction to the general motion of the sea westward; and that so strongly, that a passage which with the current is made in two days, is with difficulty performed in six weeks against it. However, they do not extend above twenty leagues from the coast; and ships going to the East-Indies, take care not to come within the sphere of their action. At Sumatra, the currents, which are extremely rapid, run from south to north: there are also strong currents between Madagascar and the Cape of Good Hope. On the western coasts of America, the current always runs from the south to the north, where a south wind, continually blowing, most probably occasions this phenomenon. But the currents that are most remarkable, are those continually flowing into the Mediterranean sea, both from the ocean by the streights of Gibraltar, and at its other extremity, from the Euxine sea by the Archipelago. This is one of the most extraordinary appearances in nature, this large sea receiving not only the numerous rivers that fall into it, such as the Nile, the Rhone, and the Po, but also a very great influx from the Euxine sea on one part, and the ocean on the other. At the same time, it is seen to return none of those waters it is thus known to receive: outlets running from it there are none; no rivers but such as bring it fresh supplies; no streights but what are constantly pouring their waters into it. It has therefore been the wonder of mankind in every age, how and by what means this vast concourse of waters are disposed of; or how this sea, which is always receiving, and never returning, is no way fuller than before. In order to account for this, some have said, that the water was re-conveyed by subterraneous passages into the Red Sea. There is a story told of an Arabian cailiff, who caught a dolphin in this sea, admiring the beauty of which, he let it go again, having previously marked it by a ring of iron. Some time after a dolphin was caught in the Red Sea, and quickly known by the ring to be the same that had been taken in the Mediterranean before. Such, however, as have not been willing to found their opinions upon a story, have attempted to account for the disposal of the waters of the Mediterranean by evaporation. For this purpose they have entered into long calculations upon the extent of its surface, and the quantity of water that would be raised from such a surface in a year. They then compute how much water runs in by its rivers and streights in that time; and find, that the quantity exhausted by evaporation greatly exceeds the quantity supplied by rivers and seas. This solution, no doubt, would be satisfactory, did not the ocean, and the Euxine, evaporate as well as the Mediterranean: and as these are subject to the same drain, it must follow, that all the seas will in this respect be upon a par; and, therefore, there must be some other cause for this unperceived drain, and continual supply. This seems to be satisfactorily enough accounted for by Doctor Smith, who supposes an under current running through the streights of Gibraltar to carry out as much water into the ocean, as the upper current continually carries in from it. To confirm this, he observes, that nearer home, between the north and south Foreland, the tide is

known to run one way at top, and the ebb another way at bottom. This double current he also confirms by an experiment communicated to him by an able seaman, who being with one of the king's frigates in the Baltic, found he went with his boat into the mid-stream, and was carried violently by the current; upon which a basket was sunk, with a large cannon-ball, to a certain depth of water, which gave a check to the boat's motion; as the basket sunk still lower, the boat was driven, by the force of the water below, against the upper current; and the lower the basket was let down, the stronger the under current was found, and the quicker was the boat's motion against the upper stream, which seemed not to be above four fathom deep. From hence we may readily infer, that the same cause may operate at the streights of Gibraltar; and that while the Mediterranean seems replenishing at top, it may be emptying at bottom.

The number of the currents at sea are impossible to be recounted, nor indeed are they always known; new ones are daily produced by a variety of causes, and as quickly disappear. When a regular current is opposed by another in a narrow streight, or where the bottom of the sea is very uneven, a whirlpool is often formed. These were formerly considered as the most formidable obstructions to navigation, and the ancient poets and historians speak of them with terror; they are described as swallowing up ships, and dashing them against the rocks at the bottom: apprehension did not fail to add imaginary terrors to the description, and placed at the center of the whirlpool a dreadful den, fraught with monsters whose howlings served to add new horrors to the dashings of the deep. Mankind at present, however, view these eddies of the sea with very little apprehension; and some have wondered how the ancients could have so much overcharged their descriptions. But all this is very naturally accounted for. In those times when navigation was in its infancy, and the slightest concussion of the waves generally sent the poor adventurer to the bottom, it is not to be wondered at that he was terrified at the violent agitations in one of these. When his little ship, but ill fitted for opposing the fury of the sea, was got within the vortex, there was then no possibility of ever returning. To add to the fatality, they were always near the shore; and along the shore was the only place where this ill provided mariner durst venture to fail. These were, therefore, dreadful impediments to his navigation; for if he attempted to pass between them and the shore, he was sometimes sucked in by the eddy; and if he attempted to avoid them, out at sea, he was often sunk by the storm. But in our time, and in our present improved state of navigation, Charybdis, and the Euripus, with all the other irregular currents of the Mediterranean, are no longer formidable. Mr. Addison, not attending to this train of thinking, upon passing through the streights of Sicily, was surpris'd at the little there was of terror in the present appearance of Sylla and Charybdis; and seems to be of opinion, that their agitations are much diminished since the times of antiquity. In fact, from the reasons above, all the wonders of the Mediterranean sea are described in much higher colours than they merit, to us who are acquainted with the more magnificent terrors of the ocean. The Mediterranean is one of the smoothest and most gentle seas in the world; its tides are scarce perceivable, except in the gulph of Venice, and shipwrecks are less known there than in any other part of the world.

It is in the ocean, therefore, that these whirlpools are particularly dangerous, where the tides are violent, and the tempests fierce. To mention only

only one, that called the Maelstrom upon the coasts of Norway, which is considered as the most dreadful and voracious in the world. The name it has received from the natives, signifies the navel of the sea, since they suppose that a great share of the water of the sea is sucked up and discharged by its vortex. A minute description of the internal parts is not to be expected, since none who were there ever returned to bring back information. The body of the waters that form this whirlpool, are extended in a circle above thirteen miles in circumference. In the midst of this stands a rock, against which the tide in its ebb is dashed with inconceivable fury. At this time it instantly swallows up all things that come within the sphere of its violence, trees, timber, and shipping. No skill in the mariner, nor strength of rowing, can work an escape: the sailor at the helm finds the ship at first go in a current opposite to his intentions: his vessel's motion, though slow in the beginning, becomes every moment more rapid; it grows round in circles still narrower and narrower, till at last it is dashed against the rocks, and instantly disappears: nor is it seen again for six hours: till the tide flowing, it is vomited forth with the same violence with which it was drawn in. The noise of this dreadful vortex still farther contributes to increase its terror, which with the dashing of the waters, and the dreadful valley, if it may be so called, caused by their circulation, makes one of the most tremendous objects in nature.

C H A P. XVII.

Of the Changes produced by the Sea upon the Earth.

FROM what has been said, as well of the earth as of the sea, they both appear to be in continual fluctuation. The earth, the common promptuary that supplies subsistence to men, animals, and vegetables, is continually furnishing its stores to their support. But the matter which is thus derived from it, is soon restored and laid down again to be prepared for fresh mutations. The transmigration of souls is no doubt false and whimsical; but nothing can be more certain than the transmigration of bodies: the spoils of the meanest reptile may go to the formation of a prince; and, on the contrary, as the poet has it, the body of Cæsar may be employed in stopping a beer-barrel. From this, and other causes, therefore, the earth is in continual change. Its internal fires, the deviation of its rivers, and the falling of its mountains, are daily altering its surface; and geography can scarce recollect the lakes and the valleys that history once described.

But these changes are nothing to the instability of the ocean. It would seem that inquietude was as natural to it as its fluidity. It is first seen with a constant and equable motion going towards the west; the tides then interrupt this progression, and for a time drive the waters in a contrary direction; beside these agitations, the currents act their part in a smaller sphere, being generally greatest where the other motions of the sea are least; namely, nearest the shore: the winds also contribute their share in this universal fluctuation; so that scarce any part of the sea is wholly seen to stagnate.

As this great element is thus changed, and continually labouring internally, it may be readily supposed that it produces correspondent changes upon its shores, and those parts of the earth subject to

its influence. In fact, it is every day making considerable alterations, either by overflowing its shores in one place, or deserting them in others; by covering over whole tracts of country, that were cultivated and peopled, at one time; or by leaving its bed to be appropriated to the purposes of vegetation, and to supply a new theatre for human industry at another.

In this struggle between the earth and the sea for dominion, the greatest number of our shores seem to defy the whole rage of the waves, both by their height, and the rocky materials of which they are composed. The coasts of Italy, for instance, are bordered with rocks of marble of different kinds, the quarries of which may easily be distinguished at a distance from sea, and appear like perpendicular columns, of the most beautiful kinds of marble, ranged along the shore. In general, the coasts of France, from Brest to Bourdeaux, are composed of rocks; as are also those of Spain and England, which defend the land, and only are interrupted, here and there, to give an egress to rivers, and to grant the conveniencies of bays and harbours to our shipping. It may be in general remarked, that wherever the sea is most violent and furious, there the boldest shores, and of the most compact materials, are found to oppose it. There are many shores several hundred feet perpendicular, against which the sea, when swollen with tides or storms, rises and beats with inconceivable fury. In the Orkneys, where the shores are thus formed, it sometimes, when agitated by a storm, rises two hundred feet perpendicular, and dashes up its spray, together with sand, and other substances that compose its bottom, upon land, like showers of rain.

From hence, therefore, we may conceive how the violence of the sea, and the boldness of the shore, may be said to have made each other. Where the sea meets no obstacles, it spreads its waters with a gentle intumescence, till all its power is destroyed, by wanting depth to aid the motion. But when its progress is checked in the midst, by the prominence of rocks, or the abrupt elevation of the land, it dashes with all the force of its depth against the obstacle, and forms, by its repeated violence, that abruptness of the shore which confines its impetuosity. Where the sea is extremely deep, or very much vexed by tempests, it is no small obstacle that can confine its rage; and for this reason we see the boldest shores projected against the deepest waters; all less impediments having long before been surmounted and washed away. Perhaps of all the shores in the world, there is not one so high as that on the west of St. Kilda, which, upon a late admeasurement, was found to be six hundred fathom perpendicular above the surface of the sea. Here also, the sea is deep, turbulent, and stormy; so that it requires great force in the shore to oppose its violence. In many parts of the world, and particularly upon the coasts of the East-Indies, the shores, though not high above water, are generally very deep, and consequently the waves roll against the land with great weight and irregularity. This rising of the waves against the shore, is called by mariners the surf of the sea; and in shipwrecks is generally fatal to such as attempt to swim on shore. In this case, no dexterity in the swimmer, no float he can use, neither swimming girdle nor cork jacket will save him; the weight of the superincumbent waves break upon him at once, and crushes him with certain ruin. Some few of the natives, however, have the art of swimming and of navigating their little boats near those shores, where an European is sure of instant destruction.

In places where the force of the sea is less violent, or its tides less rapid, the shores are generally seen to descend with a more gradual declivity. Over these, the waters of the tide steal by almost imperceptible degrees, covering them for a large extent, and leaving them bare on its recess. Upon these shores, as was said, the sea seldom beats with any great violence, as a large wave has not depth sufficient to float it onwards; so that here only are to be seen gentle surges making calmly towards land, and lessening as they approach. As the sea, in the former description, is generally seen to present prospects of tumult and uproar, here it more usually exhibits a scene of repose and tranquil beauty. Its waters, which when surveyed from the precipice, afforded a muddy greenish hue, arising from their depth and position to the eye, when regarded from a shelving shore, wear the colour of the sky, and seem rising to meet it. The deafening noise of the deep sea, is here converted into gentle murmurs; instead of the water's dashing against the face of the rock, it advances and recedes, still going forward, but with just force enough to push its weeds and shells, by insensible approaches, to the shore.

There are other shores, beside those already described, which either have been raised by art to oppose the sea's approaches, or from the sea's gaining ground, are threatened with imminent destruction. The sea's being thus seen to give and take away lands at pleasure, is, without question, one of the most extraordinary considerations in all natural history. In some places it is seen to obtain the superiority by slow and certain approaches; or to burst in at once, and overwhelm all things in undistinguished destruction; in other places it departs from its shores, and where its waters have been known to rage, it leaves fields covered with the most beautiful verdure.

The formation of new lands, by the sea's continually bringing its sediment to one place, and by the accumulation of its sands in another, is easily conceived. We have had many instances of this in England. The island of Oxney, which is adjacent to Romney-marsh, was produced in this manner. This had for a long time been a low level, continually in danger of being overflowed by the river Rother; but the sea, by its depositions, has gradually raised the bottom of the river, while it has hollowed the mouth; so that the one is sufficiently secured from inundations, and the other is deep enough to admit ships of considerable burthen. The like also may be seen at that bank called the Dogger-sands, where two tides meet, and which thus receive new increase every day, so that in time the place seems to promise fair for being habitable earth. On many parts of the coasts of France, England, Holland, Germany, and Prussia, the sea has been sensibly known to retire. Hubert Thomas asserts, in his Description of the Country of Liege, that the sea formerly encompassed the city of Tongres, which, however, is at present thirty-five leagues distant from it: this assertion he supports by many strong reasons; and among others, by the iron rings fixed in the walls of the town, for fastening the ships that came into the port. In Italy there is a considerable piece of ground gained at the mouth of the river Arno; and Ravenna, that once stood by the sea-side, is now considerably removed from it. But we need scarce mention these, when we find that the whole republic of Holland seems to be a conquest upon the sea, and in a manner rescued from its bosom. The surface of the earth, in this country, is below the level of the bed of the sea; and we remember, upon approaching the coast, to have looked down

upon it from the sea, as into a valley; however, it is every day rising higher by the depositions made upon it by the sea, the Rhine, and the Meuse; and those parts which formerly admitted large men of war, are now known to be too shallow to receive ships of very moderate burthen. The province of Jucatan, a peninsula in the gulph of Mexico, was formerly a part of the sea: this tract, which stretches out into the ocean an hundred leagues, and which is above thirty broad, is every where, at a moderate depth below the surface, composed of shells, which evince that its land once formed the bed of the sea. In France, the town of Aigues Mortes was a port in the times of St. Louis, which is now removed more than four miles from the sea. Psalmodi, in the same kingdom, was an island in the year 815, but is now more than six miles from the shore. All along the coast of Norfolk, we are well assured, that in the memory of man, the sea has gained fifty yards in some places, and has lost as much in others.

Thus numerous, therefore, are the instances of new lands having been produced from the sea, which, as we see, is brought about two different ways: first, by the waters raising banks of sand and mud where their sediment is deposited; and secondly, by their relinquishing the shore entirely, and leaving it unoccupied to the industry of man.

But as the sea has been thus known to recede from some lands, so has it, by fatal experience, been found to encroach upon others: and, probably, these depredations on one part of the shore, may account for their dereliction from another; for the current which rested upon some certain bank, having got an egress in some other place, it no longer presses upon its former bed, but pours all its stream into the new entrance, so that every inundation of the sea may be attended with some correspondent dereliction of another shore.

However this be, we have numerous histories of the sea's inundations, and its burying whole provinces in its bosom. Many countries that have been thus destroyed, bear melancholy witness to the truth of history; and shew the tops of their houses, and the spires of their steeples, still standing at the bottom of the water. One of the most considerable inundations we have in history, is that which happened in the reign of Henry I. which overflowed the estates of the Earl Godwin, and forms now that bank called the Goodwin sands. In the year 1546, a similar irruption of the sea destroyed an hundred thousand persons in the territory of Dort; and yet a greater number round Dullart. In Friezland, and Zealand, there were more than three hundred villages overwhelmed; and their remains continue still visible at the bottom of the water in a clear day. The Baltic sea has, by slow degrees, covered a large part of Pomerania; and, among others, destroyed and overwhelmed the famous port of Vineta. In the same manner, the Norwegian sea has formed several little islands from the main land, and still daily advances upon the continent. The German sea has advanced upon the shores of Holland, near Catt; so that the ruins of an ancient citadel of the Romans, which was formerly built upon this coast, are now actually under water. To these accidents several more might be added; our own historians, and those of other countries, abound with them; almost every flat shore of any extent, being able to shew something that it has lost, or something that it has gained from the sea.

There are some shores on which the sea has made temporary depredations; where it has overflowed, and after remaining perhaps some ages it has again retired of its own accord, or been driven

back by the industry of man. There are many lands in Norway, Scotland, and the Maldivia islands, that are at one time covered with water, and at another free. The country round the Isle of Ely, in the times of Bede, about a thousand years ago, was one of the most delightful spots in the whole kingdom. It was not only richly cultivated, and produced all the necessaries of life, but grapes also that afforded excellent wine. The accounts of that time are copious in the description of its verdure and fertility; its rich pastures, covered with flowers and herbage; its beautiful shades, and wholesome air. But the sea breaking in, upon the land, overwhelmed the whole country, took possession of the soil, and totally destroyed one of the most fertile vallies in the world. Its air, from being dry and healthful, from that time became most unwholesome, and clogged with vapours; and the small part of the country that, by being higher than the rest, escaped the deluge, was soon rendered uninhabitable, from its noxious vapours. Thus this country continued under water for some centuries; till, at last, the sea, by the same caprice which had prompted its invasions, began to abandon the earth in like manner. It has continued for some ages to relinquish its former conquests; and although the inhabitants can neither boast the longevity, nor the luxuries of their former pre-occupants; yet they find ample means of subsistence; and if they happen to survive the first year of their residence there, they are often known to arrive at a good old age.

But although history be silent as to many other inundations of the like kind, where the sea has overflowed the country, and afterwards retired, yet we have numberless testimonies of another nature, that prove it beyond the possibility of doubt: we mean those numerous trees that are found buried at considerable depths in places where either rivers, or the sea, has accidentally overflowed. At the mouth of the river Nefs, near Bruges, in Flanders, at the depth of fifty feet, are found great quantities of trees lying as close to each other as they do in a wood: the trunks, the branches, and the leaves, are in such perfect preservation, that the particular kind of each tree may instantly be known. About five hundred years ago, this very ground was known to have been covered with the sea; nor is there any history or tradition of its having been dry ground, which we can have no doubt must have been the case. Thus we see a country flourishing in verdure, producing large forests, and trees of various kinds, overwhelmed by the sea. We see this element depositing its sediment to an height of fifty feet; and its waters must, therefore, have risen much higher. We see the same, after it has thus overwhelmed, and sunk the land so deep beneath its slime, capriciously retiring from the same coasts, and leaving that habitable once more, which it had formerly destroyed. All this is wonderful; and perhaps, instead of attempting to enquire after the cause, which has hitherto been inscrutable, it will best become us to rest satisfied with admiration.

At the city of Modena in Italy, and about four miles round it, wherever it is dug, when the workmen arrive at the depth of sixty-three feet, they come to a bed of chalk, which they bore with an augre five feet deep: they then withdraw from the pit, before the augre is removed, and upon its extraction, the water bursts up through the aperture with great violence, and quickly fills this new-made well, which continues full, and is affected neither by rains or droughts. But that which is most remarkable in this operation, is the layers of earth as we descend. At the depth of fourteen feet, are found the ruins of an ancient city, paved streets, houses, floors, and different pieces of Mo-

saic. Under this is found a solid earth, that would induce one to think had never been removed; however, under it is found a soft oozy earth, made up of vegetables; and at twenty-six feet depth, large trees entire, such as walnut-trees, with the walnuts still sticking on the stem, and their leaves and branches in exact preservation. At twenty-eight feet deep, a soft chalk is found, mixed with a vast quantity of shells; and this bed is eleven feet thick. Under this, vegetables are found again, with leaves, and branches of trees as before; and thus alternately chalk and vegetable earth to the depth of sixty-three feet. These are the layers wherever the workmen attempt to bore; while in many of them, they also find pieces of charcoal, bones, and bits of iron. From this description, therefore, it appears, that this country has been alternately overflowed and deserted by the sea, one age after another: nor were these overflowings and retirings of trifling depth, or of short continuance. When the sea burst in, it must have been a long time in overwhelming the branches of the fallen forest with its sediments; and still longer in forming a regular bed of shells eleven feet over them. It must have, therefore, taken an age, at least, to make any one of these layers; and we may conclude, that it must have been many ages employed in the production of them all. The land, also, upon being deserted, must have had time to grow compact, to gather fresh fertility, and to be drained of its waters before it could be disposed to vegetation; or before its trees could have shot forth again to maturity.

We have instances nearer home of the same kind, given us in the Philosophical Transactions; one of them by Mr. Derham. An inundation of the sea, at Dagenham, in Essex, laying bare a part of the adjacent pasture, for above two hundred feet wide, and, in some places, twenty deep, it discovered a number of trees that had lain there for many ages before; these trees, by lying long under ground, were become black and hard, and their fibres so tough, that one might as easily break a wire, as any of them: they lay so thick in the place where they were found, that in many parts he could step from one to another: he conceived also, that not only all the adjacent marshes, for several hundred acres, were covered underneath with such timber, but also the marshes along the mouth of the Thames, for several miles. The meeting with these trees at such depths, he ascribes to the sediment of the river, and the tides, which constantly washing over them, have always left some part of their substance behind, so as, by repeated alluvions, to work a bed of vegetable earth over them, to the height at which he found it.

The levels of Hatfield-Chace, in Yorkshire, a tract of above eighteen thousand acres, which was yearly overflowed, was reduced to arable and pasture land, by one Sir Cornelius Vermuden, a Dutchman. At the bottom of this wide extent, are found millions of the roots and bodies of trees, of such as this island either formerly did, or does at present produce. The roots of all stand in their proper postures; and by them, as thick as ever they could grow, the respective trunks of each, some above thirty yards long. The oaks, some of which have been sold for fifteen pounds a piece, are as black as ebony, very lasting, and close grained. The ash-trees are as soft as earth, and are commonly cut in pieces by the workmen's spades, and as soon as flung up into the open air, turn to dust: But all the rest, even the willows themselves, which are softer than the ash, preserve their substance and texture to this very day. Some of the firs appear to have vegetated, even after they were fallen, and to have, from their branches, struck up large trees, as great as the parent trunk. It is observable, that many

many of these trees have been burnt, some quite through, some on one side, some have been found chopped and squared, others riven with great wooden wedges, all sufficiently manifesting, that the country which was deluged, had formerly been inhabited. Near a great root of one tree, were found eight coins of the Roman emperors; and, in some places, the marks of the ridge and furrow were plainly perceivable, which testified that the ground had formerly been patient of cultivation.

The learned naturalist who has given this description, has pretty plainly evinced, that this forest, in particular, must have been thus levelled by the Romans; and that the falling of the trees, must have contributed to the accumulation of the waters. "The Romans," says he, "when the Britons fled, always pursued them into the fortresses of low woods, and miry forests: in these the wild natives found shelter; and, when opportunity offered, issued out, and fell upon their invaders without mercy. In this manner, the Romans were at length so harrassed, that orders were issued out for cutting down all the woods and forests in Britain. In order to effect this, and destroy the enemy the easier, they set fire to the woods, composed of pines, and other inflammable timber, which spreading, the conflagration destroyed not only the forest, but infinite numbers of the wretched inhabitants who had taken shelter therein. When the pine-trees had thus done what mischief they could, the Romans then brought their army nearer, and, with whole legions of the captive Britons, cut down most of the trees that were yet left standing; leaving only here and there some great trees untouched, as monuments of their fury. These, unneedful of their labour, being destitute of the support of the underwood, and of their neighbouring trees, were easily overthrown by the winds, and, without interruption, remained on the places where they happened to fall. The forest, thus fallen, must necessarily have stopped up the currents, both from land and sea; and turned into great lakes, what were before but temporary streams. The working of the waters here, the consumption and decay of rotten boughs and branches, and the vast increase of water-moss which flourishes upon marshy grounds, soon formed a covering over the trunks of the fallen trees, and raised the earth several feet above its former level. The earth thus every day swelling, by a continual increase from the sediment of the waters, and by the lightness of the vegetable substances of which it was composed, soon overtopped the waters by which this intumescence was at first effected; so that it entirely got rid of its inundations, or only demanded a slight assistance from man for that purpose." This may be the origin of all bogs, which are formed by the putrefaction of vegetable substances, mixed with the mud and slime deposited by waters, and at length acquiring a sufficient consistency.

From this we see what powerful effects the sea is capable of producing upon its shores, either by overflowing some, or deserting others; by altering the direction of these, and rendering those craggy and precipitate, which before were shelving. But the influence it has upon these, is nothing to that which it has upon that great body of earth which forms its bottom. It is at the bottom of the sea that the greatest wonders are performed, and the most rapid changes are produced; it is there that the motion of the tides and the currents have their whole force, and agitate the substances of which their bed is composed. But all these are almost wholly hid from human curiosity: the miracles of the deep are performed in secret; and we have but little information from its abyfles, except what we receive by inspection at very shallow depths, or by the

plummet, or from divers, who are known to descend from twenty to thirty fathom.

The eye can reach but a very short way into the depths of the sea; and that only when its surface is glassy and serene. In many seas it perceives nothing but a bright sandy plain at bottom, extending for several hundred miles, without an intervening object. But in others, particularly in the Red Sea, it is very different: the whole bottom of this extensive bed of waters is, literally speaking, a forest of submarine plants, and corals formed by insects for their habitation, sometimes branching out to a great extent. Here are seen the madrepores, the sponges, mosses, sea-mushrooms, and other marine productions, covering every part of the bottom; so that some have even supposed the sea to have taken its name from the colour of its plants below. However, these plants are by no means peculiar to this sea, as they are found in great quantities in the Persian gulph, along the coasts of Africa, and those of Provence and Catalonia.

The bottom of many parts of the sea near America presents a very different, though a very beautiful appearance. This is covered with vegetables, which make it look as green as a meadow, and beneath are seen thousands of turtles; and other sea-animals, feeding thereon.

In order to extend our knowledge of the sea to greater depths, recourse has been had to the plummet; which is generally made of a lump of lead of about forty pounds weight, fastened to a cord. This, however, only answers in moderate depths; for when a deep sea is to be sounded, the matter of which the cord is composed being lighter than the water, floats upon it, and when let down to a considerable depth, its length so increases its surface, that it is often sufficient to prevent the lead from sinking; so that this may be the reason that some parts of the sea are said to have no bottom.

In general, we learn from the plummet, that the bottom of the sea is tolerably even where it has been examined; and that the farther from the shore, the sea is in general the deeper. Notwithstanding in the midst of a great and unfathomable ocean, we often find an island raising its head, and singly braving its fury. Such islands may be considered as the mountains of the deep; and, could we for a moment imagine the waters of the ocean removed, or dried away, we should probably find the inequalities of its bed resembling those that are found at land. Here extensive plains; there valleys; and, in many places, mountains of amazing height. M. Buache has actually given us a map of that part of its bottom, which lies between Africa and America, taken from the several soundings of mariners: in it we find the same uneven surface that we do upon land, the same eminences, and the same depressions. In such an imaginary prospect, however, there would be this difference, that, at the tops of land-mountains appear the most barren and rocky, the tops of sea-mountains would be found the most verdant and fruitful.

The plummet, which thus gives us some idea of the inequalities of the bottom, leaves us totally in the dark as to every other particular; recourse, therefore, has been had to divers: these, either being bred up in this dangerous way of life, and accustomed to remain some time under water without breathing, or assisted by means of a diving-bell, have been able to return some confused and uncertain accounts of the places below. In the great diving-bell improved by Doctor Halley, which was large enough to contain five men, and was supplied by fresh air by buckets, that alternately rose and fell, they descended fifty fathom. In this huge machine, which was let down from the mast of the ship, the doctor himself went down to
the

the bottom, where, when the sea was clear, and especially when the sun shone, he could see perfectly well to write or read, and much more to take up any thing that was underneath: at other times, when the water was troubled and thick, it was as dark as night below, so that he was obliged to keep a candle lighted at the bottom. But there is one thing very remarkable: that the water which from above was usually seen of a green colour, when looked at from below, appeared to him of a very different one, casting a redness upon one of his hands, like that of damask roses: a proof of the sea's taking its colour not from any thing floating in it, but from the different reflections of the rays of light. Upon the whole, the accounts we have received from the bottom, by this contrivance, are but few. We learn from it, and from divers in general, that while the surface of the sea may be deformed by tempests, it is usually calm and temperate below; that some divers who have gone down when the weather was calm, and came up when it was tempestuous, were surpris'd at their not perceiving the change at the bottom. This, however, must not be supposed to obtain with regard to the tides, and the currents, as they are seen constantly shifting their bottom; taking their bed with great violence from one place, and depositing it upon another. We are inform'd, also, by divers, that the sea grows colder in proportion as they descend to the bottom; that as far as the sun's rays pierce, it is influenced by their warmth; but lower, the cold becomes almost intolerable. A person of quality, who had been himself a diver, as Mr. Boyle informs us, declared, that though he seldom descended above three or four fathoms, yet he found it so much colder than near the top, that he could not well endure it; and that being let down in a great diving-bell, although the water could not immediately touch him, he found the air extremely cold upon his first arrival at the bottom.

From divers also we learn, that the sea in many places is filled with rocks at bottom: and that among their cliffs, and upon their sides, various substances sprout forward, which are either really vegetables, or the nests of insects, increased to some magnitude. Some of these assume the shape of beautiful flowers; and, though soft, when taken up, soon harden, and are kept in the cabinets of the curious.

But, of all those divers who have brought us information from the bottom of the deep, the famous Nicola Pesce, whose performances are told us by Kircher, is the most celebrated. We will not pretend to vouch for the veracity of Kircher's account, which he assures us he had from the archives of the kings of Sicily; but it may serve to enliven an heavy chapter. "In the times of Frederic, king of Sicily, there lived a celebrated diver, whose name was Nicolas, and who from his amazing skill in swimming, and his perseverance under water, was surnamed the fish. This man had, from his infancy, been us'd to the sea; and earned his scanty subsistence by diving for corals and oysters, which he sold to the villagers on shore. His long acquaintance with the sea, at last, brought it to be almost his natural element. He frequently was known to spend five days in the midst of the waves, without any other provisions than the fish which he caught there, and ate raw. He often swam over from Sicily to Calabria, a tempestuous and dangerous passage, carrying letters from the king. He was frequently known to swim among the gulphs of the Lipari islands, no way apprehensive of danger.

"Some mariners out at sea one day observed something at some distance from them, which they regarded as a sea-monster; but upon its approach,

it was known to be Nicolas, whom they took into their ship. When they asked him whither he was going in so stormy and rough a sea, and at such a distance from land, he shew'd them a packet of letters, which he was carrying to one of the towns of Italy, exactly done up in a leather bag, in such a manner as that they could not be wetted by the sea. He kept them thus company for some time on their voyage, conversing and asking questions; and after eating an hearty meal with them, he took his leave, and jumping into the sea, pursued his voyage alone.

"In order to aid these powers of enduring in the deep, nature seem'd to have assist'd him in a very extraordinary manner; for the spaces between his fingers and toes were webbed, as in a goose; and his chest became so very capacious, that he could take in at one inspiration, as much breath as would serve him for a whole day.

"The account of so extraordinary a person did not fail to reach the king himself; who actuated by the general curiosity, order'd that Nicolas should be brought before him. It was no easy matter to find Nicolas, who generally spent his time in the solitudes of the deep; but at last, however, after much searching, he was found, and brought before his majesty. The curiosity of this monarch had been long excited by the accounts he had heard of the bottom of the gulph of Charybdis; he therefore conceiv'd that it would be a proper opportunity to have more certain information; and command'd our poor diver to examine the bottom of this dreadful whirlpool: as an incitement to his obedience, he order'd a golden cup to be flung into it. Nicolas was not insensible of the danger to which he was expos'd; dangers best known only to himself; and he therefore presum'd to remonstrate; but the hopes of the reward, the desire of pleasing the king, and the pleasure of shewing his skill, at last prevail'd. He instantly jumped into the gulph, and was swallow'd as instantly up in its bosom. He continued for three quarters of an hour below; during which time the king and his attendants remained upon shore anxious for his fate; but he at last appear'd, buffeting upon the surface, holding the cup in triumph in one hand, and making his way good among the waves with the other. It may be supposed he was received with applause, upon his arrival on shore; the cup was made the reward of his adventure; the king order'd him to be taken proper care of; and, as he was somewhat fatigued and debilitated by his labour, after an hearty meal, he was put to bed, and permitted to refresh himself by sleeping.

"When his spirits were thus restored, he was again brought to satisfy the king's curiosity with a narrative of the wonders he had seen; and his account was to the following effect. He would never, he said, have obeyed the king's commands, had he been appriz'd of half the dangers that were before him. There were four things, he said, that render'd the gulph dreadful, not only to men, but even to the fishes themselves: first, the force of the water bursting up from the bottom, which requires great strength to resist; secondly, the abruptness of the rocks, that on every side threaten destruction; thirdly, the force of the whirlpool, dashing against those rocks; and fourthly, the number and magnitude of the polypus fish, some of which appear'd as large as a man, and which every where sticking against the rocks, project'd their fibrous arms to entangle him. Being ask'd how he was able so readily to find the cup that had been thrown in, he repli'd, that it happen'd to be flung by the waves into the cavity of a rock, against which he himself was urg'd in his descent. This account, however, did not satisfy the king's curiosity: being request'd

to venture once more into the gulph for further discoveries, he at first refused; but the king, desirous of having the most exact information possible of all things to be found in the gulph, repeated his solicitations; and, to give them still greater weight, produced a larger cup than the former, and added also a purse of gold. Upon these considerations, the unfortunate Pessacola once again plunged into the whirlpool, and was never heard of more."

CHAP. XVIII.

A particular Account of the Mechanical Properties of AIR.

HAVING described the earth and the sea, we now ascend into that fluid which surrounds them both; and which, in some measure, supports and supplies all animated nature. As upon viewing the bottom of the ocean from its surface, we see an infinity of animals moving therein, and seeking food; so were some superior being to regard the earth at a proper distance, he might consider us in the same light: he might, from his superior station, behold a number of busy little beings, immersed in the ærial fluid, that every where surrounds them, and sedulously employed in procuring the means of subsistence. This fluid, though too fine for the gross perception of its inhabitants, might, to his nicer organs of sight, be very visible; and, while he at once saw into its operations, he might smile at the varieties of human conjecture concerning it: he might readily discern, perhaps, the height above the surface of the earth to which this fluid atmosphere reaches: he might exactly determine that peculiar form of its parts which gives it the spring or elasticity with which it is endued: he might distinguish which of its parts were pure incorruptible air, and which only made for a little time to assume the appearance, so as to be quickly returned back to the element from whence it came. But as for us, who are immersed at the bottom of this gulph, we must be contented with a more confined knowledge; and, wanting a proper point of prospect, remain satisfied with a combination of the effects.

One of the first things that our senses inform us of is, that although the air is too fine for our sight, it is very obvious to our touch. Although we cannot see the wind contained in a bladder, we can very readily feel its resistance; and though the hurricane may want colour, we often fatally experience that it does not want force. We have equal experience of the air's spring or elasticity; the bladder, when pressed, returns again, upon the pressure being taken away; a bottle, when filled, often bursts, from the spring of air which is included.

So far the slightest experience reaches; but, by carrying experiment a little farther, we learn, that air also is heavy: a round glass vessel being emptied of its air, and accurately weighed, has been found lighter than when it was weighed with the air in it. Upon computing the superior weight of the full vessel, a cubic foot of air is found to weigh something more than an ounce.

From this experiment, therefore, we learn, that the earth, and all things upon its surface, are every where covered with a ponderous fluid, which rising very high over our heads, must be proportionably heavy. For instance, as in the sea, a man at the depth of twenty feet, sustains a greater weight of water than a man at the depth of but ten feet; so will a man at the bottom of a valley

have a greater weight of air over him, than a man on the top of a mountain.

From hence we may conclude, that we sustain a very great weight of air; and although, like men walking at the bottom of the sea, we cannot feel the weight which presses equally round us, yet the pressure is not the less real. As in morals, we seldom know the blessings that surround us till we are deprived of them, so here we do not perceive the weight of the ambient fluid till a part of it is taken away. If, by any means, we contrive to take away the pressure of the air from any one part of our bodies, we are soon made sensible of the weight upon the other parts. If we clap our hand upon the mouth of a vessel from whence the air has been taken away, there will thus be air on one side, and none on the other; upon which, we shall instantly find the hand violently sucked inwards, which is nothing more than the weight of the air upon the back of the hand that forces it into the space which is empty below.

As by this experiment we perceive that the air presses with great weight upon every thing on the surface of the earth, so by other experiments we learn the exact weight with which it presses. First, if the air be exhausted out of any vessel, a drinking-vessel for instance, and this vessel be set with the mouth downwards in water, the water will rise up into the empty space, and fill the inverted glass; for the external air will, in this case, press up the water, where there is no weight to resist; as, one part of a bed being pressed, makes the other parts, that have no weight upon them, rise. In this case, as was said, the water being pressed without, will rise in the glass; and would continue to rise (if the empty glass were tall enough) thirty-two feet high. In fact, there have been pipes made purposely for this experiment of above thirty-two feet high; in which, upon being exhausted, the water has always risen to the height of thirty-two feet: there it has always rested, and never ascended higher. From this, therefore, we learn, that the weight of the air which presses up the water, is equal to a pillar or column of water, which is thirty-two feet high; as it is just able to raise such a column, and no more. In other words, the surface of the earth is every where covered with a weight of air, which is equivalent to a covering of thirty-two feet deep of water; or to a weight of twenty-nine inches and an half of quicksilver, which is known to be just as heavy as the former.

Thus we see that the air at the surface of the earth is just as heavy as thirty-two feet of water, or twenty-nine inches and an half of quicksilver; and it is easily found, by computation, that to raise water thirty-two feet, will require a weight of fifteen pounds upon every square inch. Now, if we are fond of computations, we have only to calculate how many square inches are in the surface of an ordinary human body, and allowing every inch to sustain fifteen pounds, we may amaze ourselves at the weight of air we sustain. It has been computed, and found, that our ordinary load of air amounts to within a little of forty thousand pounds: this is wonderful! but wondering is not the way to grow wise.

Notwithstanding this be our ordinary load, and our usual supply, there are at different times very great variations. The air is not, like water, equally heavy at all seasons; but sometimes is lighter, and sometimes more heavy. It is sometimes more compressed, and sometimes more elastic or springy, which produces the same effects as an increase of its weight. The air which at one time raises water thirty-two feet in the tube, and quick-

silver twenty-nine inches, will not at another raise the one to thirty feet, or the other to twenty-six inches. This makes, therefore, a very great difference in the weight we sustain; and we are actually known, by computation, to carry at one time four thousand pounds of air more than at another.

The reason of this surprising difference in the weight of air, is either owing to its pressure from above, or to an increase of vapour floating in it. Its increased pressure is the consequence of its spring or elasticity, which cold and heat sensibly affect, and are continually changing.

This elasticity of the air is one of its most amazing properties; and to which it should seem nothing can set bounds. A body of air that may be contained in a nut-shell, may easily, with heat, be dilated into a sphere of unknown dimensions. On the contrary, the air contained in an house, may be compressed into a cavity not larger than the eye of a needle. In short, no bounds can be set to its confinement or expansion; at least, experiment has hitherto found its attempts indefinite. In every situation, it retains its elasticity; and the more closely we compress it, the more strongly does it resist the pressure. If to the increasing the elasticity on one side by compression, we increase it on the other side by heat, the force of both soon becomes irresistible; and a certain French philosopher supposed, that air thus confined, and expanding, was sufficient for the explosion of a world.

Many instruments have been formed to measure and determine these different properties of the air; and which serve several useful purposes. The barometer serves to measure its weight; to tell us when it is heavier, and when lighter. It is composed of a glass tube or pipe, of about thirty inches in length, closed up at one end; this tube is then filled with quicksilver; this done, the maker clapping his finger upon the open end, inverts the tube, and plunges the open end, finger and all, into a basin of quicksilver, and then takes his finger away: now the quicksilver in the tube will, by its own weight, endeavour to descend into that in the basin; but the external air, pressing on the surface of the quicksilver in the basin without, and no air being in the tube at top, the quicksilver will continue in the tube, being pressed up, as was said, by the air, on the surface of the basin below. The height at which it is known to stand in the tube, is usually about twenty-nine inches, when the air is heavy; but not above twenty-six, when the air is very light. Thus, by this instrument we can, with some exactness, determine the weight of the air; and, of consequence, tell before-hand the changes of the weather. Before the fine dry weather, the air is charged with a variety of vapours, which float in it unseen, and render it extremely heavy, so that it presses up the quicksilver; or, in other words, the barometer rises. In moist, rainy weather, the vapours are washed down, or there is not heat sufficient for them to rise, so that the air is then sensibly lighter, and presses up the quicksilver with less force; or, in other words, the barometer is seen to fall. Our constitutions seem also to correspond with the changes of the weather-glass; they are braced, strong, and vigorous, with a large body of air upon them; they are languid, relaxed, and feeble, when the air is light, and refuses to give our fibres their proper tone.

But although the barometer thus measures the weight of the air with exactness enough for the general purposes of life, yet it is often affected with a thousand irregularities, that no exactness in the instrument can remedy, nor no theory account for. When high winds blow, the quicksilver generally is low; it rises higher in cold weather than in warm; and is usually higher at morning and even-

ing than at mid-day: it generally descends lower after rain than it was before it. There are also frequent changes in the air, without any sensible alteration in the barometer.

As the barometer is thus used in predicting the changes of the weather, so it is also serviceable in measuring the heights of mountains, which mathematicians cannot so readily do: for, as the higher we ascend from the surface of the earth, the air becomes lighter, so the quicksilver in the barometer will descend in proportion. It is found to sink at the rate of the tenth part of an inch for every ninety feet we ascend; so that in going up a mountain, if we find the quicksilver fallen an inch, we conclude, that we are got upon an ascent of near nine hundred feet high. In this there has been found some variation; into a detail of which, it is not the business of a natural historian to enter.

In order to determine the elasticity of air, the wind-gun has been invented, which is an instrument variously made; but in all upon the principle of compressing a large quantity of air into a tube, in which there is an ivory ball, and then giving the compressed elastic air free power to act, and drive the ball as directed. The ball thus driven will pierce a thick board: and will be as fatal, at small distances, as if driven with gunpowder. Perhaps the force of this instrument has never been assisted by means of heat; this, which could be very easily contrived by means of phosphorus, or any other hot substance applied to the barrel, would produce a greater force than gunpowder itself.

The air pump is an instrument contrived to exhaust the air from round a vessel adapted to that purpose, called a receiver. This method of exhausting, is contrived in the simple instrument, by a piston, like that of a syringe, going down into the vessel, and thus pushing out its air; which, by means of a valve, is prevented from returning into the vessel again.

But this, like all other complicated instruments, will be better understood by a minute inspection, than an hour's description: it may suffice here to observe, that by depriving animals, and other substances, of all air, it shews us what the benefits and effects of air are in sustaining life, or promoting vegetation.

The digester is an instrument of still more extraordinary effects than any of the former; and sufficiently discovers the amazing force of air, when its elasticity is augmented by fire. A common tea-kettle, if the spout were closed up, and the lid put firmly down, would serve to become a digester, if strong enough. But the instrument used for this purpose, is a strong metal pot, with a lid to screw close on, so that, when down, no air can get in or return: into this pot meat and bones are put, with a small quantity of water, and then the lid screwed close: a lighted lamp is put underneath, and, what is very extraordinary (yet equally true), in six or eight minutes the whole mass, bones and all, are dissolved into a jelly; so great is the force and elasticity of the air contained within, struggling to escape, and breaking in pieces all the substances with which it is mixed. Care, however, must be taken not to heat this instrument too violently; for then, the inclosed air would become irresistible, and burst the whole, with perhaps a fatal explosion.

There are numberless other useful instruments made to depend on the weight, the elasticity, or the fluidity of the air, which do not come within the plan of the present work; the design of which is not to give an account of the inventions that have been made for determining the nature and properties of air, but a mere narrative of its effects. The description of the pump, the forcing-pump, the fire-engine, the steam-engine, the syphon, and

many others, belong not to the naturalist, but the experimental philosopher: the one gives an history of Nature, as he finds she presents herself to him; and he draws the obvious picture: the other pursues her with close investigation, tortures her by experiment to give up her secrets, and measures her latent qualities with laborious precision. Much more, therefore, might be said of the mechanical effects of air, and of the conjectures that have been made respecting the form of its parts; how some have supposed them to resemble little hoops, coiled up in a spring; others, like fleeces of wool; others, that the parts are endued with a repulsive quality, by which, when squeezed together, they endeavour to fly off, and recede from each other. We might have given the disputes relative to the height to which this body of air extends above us, and concerning which there is no agreement. We might have enquired how much of the air we breathe is elementary, and not reducible to any other substance; and of what density it would become, if it were supposed to be continued down to the center of the earth. At that place we might, with the help of figures, and a bold imagination, have shewn it twenty thousand times heavier than its bulk of gold. We might also prove it millions of times purer than upon earth, when raised to the surface of the atmosphere. But these speculations do not belong to natural history; and they have hitherto produced no great advantages in that branch of science to which they more properly appertain.

C H A P. XIX.

NATURAL HISTORY of the AIR.

OUR atmosphere has been considered by a late eminent philosopher, as one large chemical vessel, in which a great number of various operations are constantly performing. In it all the bodies of the earth are continually sending up a part of their substance by evaporation, to mix in this great alembic, and to float a-while in common. Here minerals, from their lowest depths, ascend in noxious, or in warm vapours, to make a part of the general mass; seas, rivers, and subterraneous springs, furnish their copious supplies; plants receive and return their share; and animals, that by living upon, consume this general store, are found to give it back in greater quantities, when they die. The air, therefore, that we breathe, and upon which we subsist, bears very little resemblance to that pure elementary body which was described in the last chapter; and which is rather a substance that may be conceived, than experienced to exist. Air, such as we find it, is one of the most compounded bodies in all nature. Water may be reduced to a fluid every way resembling air, by heat; which, by cold, becomes water again. Every thing we see gives off its parts to the air, and has a little floating atmosphere of its own round it. The rose is encompassed with a sphere of its own odorous particles; while the night-shade infects the air with scents of a more ungrateful nature. The perfume of musk flies off in such abundance, that the quantity remaining becomes sensibly lighter by the loss. A thousand substances that escape all our senses, we know to be there; the powerful emanations of the load-stone, the effluvia of electricity, the rays of light, and the insinuations of fire. Such are the various substances through which we move, and which we are constantly taking in at every pore, and returning again with imperceptible discharge!

This great solution, or mixture of all earthly bodies, is continually operating upon itself; which, perhaps, may be the cause of its unceasing motion:

but it operates still more visibly upon such grosser substances as are exposed to its influence; for scarce any substance is found capable of resisting the corroding qualities of the air. The air, say the chemists, is a chaos, furnished with all kinds of salts and menstrooms; and, therefore, it is capable of dissolving all kinds of bodies. It is well known, that copper and iron are quickly covered, and eaten with rust; and that in the climates near the equator, no art can keep them clean. In those dreary countries, the instruments, knives and keys, that are kept in the pocket, are nevertheless quickly encrusted; and the great guns, with every precaution, after some years, become useless. Stones, as being less hard, may be readily supposed to be more easily soluble. The marble of which the noble monuments of Italian antiquity are composed, although in one of the finest climates in the world, shew the impressions which have been made upon them by the air. In many places they seem worm eaten by time; and, in others, they appear crumbling into dust. Gold alone seems to be exempted from this general state of dissolution; it is never found to contract rust, though exposed never so long: the reason of this seems to be, that sea-salt, which is the only menstruum capable of acting upon, and dissolving gold, is but very little mixed with the air; for salt being a very fixed body, and not apt to volatilize, and rise with heat, there is but a small proportion of it in the atmosphere. In the laboratories, and shops, however, where salt is much used, and the air is impregnated with it, gold is found to rust as well as other metals.

Bodies of a softer nature are obviously destroyed by the air. Mr. Boyle says, that silks brought to Jamaica, will, if there exposed to the air, rot even while they preserve their colour; but if kept therefrom, they both retain their strength and gloss. The same happens in Brasil, where their cloaths, which are black, soon turn of an iron colour; though, in the shops, they preserve their proper hue. In these tropical climates also, such are the putrescent qualities of the air, that white sugar will sometimes be full of maggots. Drugs and plasters lose their virtue, and become verminous. In some places they are obliged to expose their sweetmeats by day in the sun, otherwise the night air would quickly cause them to putrify. On the contrary, in the cold arctic regions, animal substances, during their winter, are never known to putrify; and meat may be kept for months, without any salt whatsoever. This experiment happily succeeded with the eight Englishmen that were accidentally left upon the inhospitable coasts of Greenland, at a place where seven Dutchmen had perished but a few years before; for killing some rein-deer for their subsistence, and having no salt to preserve the flesh, to their great surprize, they soon found it did not want any, as it remained sweet during their eight months continuance upon that shore.

These powers with which air is endued over unorganized substances, are exerted in a still stronger manner over plants, animals of an inferior nature, and, lastly, over man himself. Most of the beauty, and the luxuriance of vegetation, is well known to be derived from the benign influence of the air: and every plant seems to have its favourite climate, not less than its proper soil. The lower ranks of animals also, seem formed for their respective climates, in which only they can live. Man alone seems the child of every climate, and capable of existing in all. However, this peculiar privilege does not exempt him from the influences of the air; he is as much subject to its malignity, as the meanest insect or vegetable.

With regard to plants, air is so absolutely necessary for their life and preservation, that they will not
vegetate

vegetate in an exhausted receiver. All plants have within them a quantity of air, which supports and agitates their juices. They are continually imbibing fresh nutriment from the air, to increase this store, and to supply the wants which they sustain from evaporation. When, therefore, the external air is drawn from them, they are no longer able to subsist. Even that quantity of air which they before were possessed of, escapes through their pores, into the exhausted receiver; and as this continues to be pumped away, they become languid, grow flaccid, and die. However, the plant or flower thus ceasing to vegetate, is kept, by being secured from the external air, a much longer time sweet than it would have continued, had it been openly exposed.

That air which is so necessary to the life of vegetables, is still more so to that of animals; there are none found, how seemingly torpid soever, that do not require their needful supply. Fishes themselves will not live in water from whence the air is exhausted; and it is generally supposed that they die in frozen ponds, from the want of this necessary to animal existence. Many have been the animals that idle curiosity has tortured in the prison of a receiver, merely to observe the manner of their dying. We shall, from a thousand instances, produce that of the viper, as it is known to be one of the most vivacious reptiles in the world; and as we shall feel but little compassion for its tortures. Mr. Boyle took a new-caught viper, and shutting it up into a small receiver, began to pump away the air. At first, upon the air's being drawn away, it began to swell; some time after he had done pumping, it began to gape, and open its jaws; being thus compelled to open its jaws, it once more resumed its former lankness; it then began to move up and down within, as if to seek for air, and after a while foamed a little, leaving the foam sticking to the inside of the glass; soon after the body and neck grew prodigiously tumid, and a blister appeared upon its back; an hour and an half after the receiver was exhausted, the distended viper moved, and gave manifest signs of life; the jaws remained quite distended; as it were from beneath the epiglottis, came the black tongue, and reached beyond it; but the animal seemed, by its posture, not to have any life: the mouth also was grown blackish within; and in this situation it continued for twenty-three hours. But upon the air's being re-admitted, the viper's mouth was presently closed, and soon after opened again; and for some time those motions continued, which argued the remains of life. Such is the fate of the most insignificant or minute reptile that can be thus included. Mites, fleas, and even the little eels that are found swimming in vinegar, die for want of air. Not only these, but the eggs of these animals, will not produce in vacuo, but require air to bring them to perfection.

As in this manner air is necessary to their subsistence, so also it must be of a proper kind, and not impregnated with foreign mixtures. That factitious air which is pumped from plants or fluids, is generally, in a short time, fatal to them. Mr. Boyle has given us many experiments to this purpose. After having shewn that all vegetable, and most mineral substances, properly prepared, may afford air, by being placed in an exhausted receiver, and this in such quantities, that some have thought it a new substance, made by the alteration which the mineral or plant has undergone by the texture of its parts being loosened in the operation—having shewn, that this air may be drawn in great quantities from vegetable, animal, or mineral substances, such as apples, cherries, amber burnt, or hartshorn—he included a frog in artificial air, produced from paste; in seven minutes space it suf-

fered convulsions, and at last lay still, and being taken out, recovered no motion at all, but was dead. A bird enclosed in artificial air, from raisins, died in a quarter of a minute, and never stirred more. A snail was put into the receiver, with air of paste; in four minutes it ceased to move, and was dead, although it had survived in vacuo for several hours: so that factitious air proved a greater enemy to animals than even a vacuum itself.

Air also may be impregnated with fumes that are instantly fatal to animals. The fumes of hot iron, copper, or any other heated metal, blown into the place where an animal is confined, instantly destroy it. We have already mentioned the vapours in the grotto Del Cane suffocating a dog. The ancients even supposed, that these animals, as they always ran with their noses to the ground, were the first that felt any infection. In short, it should seem that the predominance of any one vapour, from any body, how wholesome soever in itself, becomes infectious; and that we owe the salubrity of the air to the variety of its mixture.

But there is no animal whose frame is more sensibly affected by the changes of the air than man. It is true, he can endure a greater variety of climates than the lower orders generally are able to do; but it is rather by the means which he has discovered of obviating their effects, than by the apparent strength of his constitution. Most other animals can bear cold or hunger better, endure greater fatigues in proportion, and are satisfied with shorter repose. The variations of the climate, therefore, would probably affect them less, if they had the same means or skill in providing against the severities of the change. However this be, the body of man is an instrument much more nicely sensible of the variations of the air, than any of those which his own art has produced; for his frame alone seems to unite all their properties, being invigorated by the weight of the air, relaxed by its moisture, enfeebled by its heat, and stiffened by its frigidty.

But it is chiefly by the predominance of some peculiar vapour, that the air becomes unfit for human support. It is often found by dreadful experience, to enter into the constitution, to mix with its juices, and to putrify the whole mass of blood. The nervous system is not less affected by its operations; palsies and vertigoes are caused by its damps; and a still more fatal train of distempers by its exhalations. In order that the air should be wholesome, it is necessary, as we have seen, that it should not be of one kind, but the compound of several substances; and the more various the composition, to all appearance the more salubrious. A man, therefore, who continues in one place, is not so likely to enjoy this wholesome variety, as he who changes his situation; and, if we may so express it, instead of waiting for a renovation of air, walks forward to meet his arrival. This mere motion, independent even of the benefits of exercise, becomes wholesome, by thus supplying a great variety of that healthful fluid by which we are sustained.

A thousand accidents are found to increase these bodies of vapour, that make one place more or less wholesome than another. Heat may raise them in too great quantities; and cold may stagnate them. Minerals may give off their effluvia in such proportion as to keep away all other kind of air; vegetables may render the air unwholesome by their supply; and animal putrefaction seems to furnish a quantity of vapour, at least as noxious as any of the former. All these united, generally make up the mass of respiration, and are, when mixed together, harmless; but any one of them, for a long

long time singly predominant, becomes at length fatal.

The effects of heat in producing a noxious quality in the air, are well known. Those torrid regions under the Line, are always unwholesome. At Senegal the natives consider forty as a very advanced time of life, and generally die of old age at fifty. At Carthageña, in America, where the heat of the hottest day ever known in Europe is continual; where, during their winter season, these dreadful heats are united with a continual succession of thunder, rain, and tempests; arising from their intenseness, the wan and livid complexions of the inhabitants might make strangers suspect that they were just recovered from some dreadful distemper; the actions of the natives are conformable to their colour; in all their motions there is somewhat relaxed and languid; the heat of the climate even affects their speech, which is soft and slow, and their words generally broken. Travellers from Europe retain their strength and ruddy colour in that climate, possibly for three or four months; but afterwards suffer such decays in both, that they are no longer to be distinguished from the inhabitants by their complexion. However, this languid and spiritless existence is frequently drawled on sometimes even to eighty. Young persons are generally most affected by the heat of climate, which spares the more aged; but all, upon their arrival on the coasts, are subject to the same train of fatal disorders. Few nations have experienced the mortality of these coasts, so much as our own: in our unsuccessful attack upon Carthageña, more than three parts of our army were destroyed by the climate alone; and those that returned from that fatal expedition, found their former vigour irretrievably gone. In our more fortunate expedition, which gave us the Havana, we had little reason to boast of our success; instead of a third, not a fifth part of the army were left survivors of their victory, the climate being an enemy that even heroes cannot conquer.

The distempers that thus proceed from the cruel malignity of those climates are many; that, for instance, called the Chapotonadas, carries off a multitude of people; and extremely thins the crews of European ships, whom gain tempts into those inhospitable regions. The nature of this distemper is but little known, being caused in some persons by cold, in others by indigestion. But its effects are far from being obscure; it is generally fatal in three or four days: upon its seizing the patient, it brings on what is there called the black vomit, which is the sad symptom after which none are ever found to recover. Some, when the vomit attacks them, are seized with a delirium, that, were they not tied down, they would tear themselves to pieces, and thus expire in the midst of this furious paroxysm. This disorder, in milder climates, takes the name of the bilious fever, and is attended with milder symptoms, but very dangerous in all.

There are many other disorders incident to the human body, that seem the offspring of heat; but to mention no other, that very lassitude which prevails in all the tropical climates, may be considered as a disease. The inhabitants of India, says a modern philosopher, sustain an unceasing languor, from the heats of their climate; and are torpid in the midst of profusion. For this reason, the great Disposer of Nature has clothed their country with trees of an amazing height, whose shade might defend them from the beams of the sun; and whose continual freshness might, in some measure, temperate their fierceness. From these shades, therefore, the air receives refreshing moisture, and animals a cooling protection. The whole race of

savage animals retire, in the midst of the day, to the very center of the forests; not so much to avoid their enemy man, as to find a defence against the raging heats of the season. This advantage which arises from shade in torrid climates, may probably afford a solution for that extraordinary circumstance related by Boyle, which he imputes to a different cause. In the island of Ternate, belonging to the Dutch, a place that had been long celebrated for its beauty and healthfulness, the clove-trees grew in such plenty, that they in some measure lessened their own value: for this reason, the Dutch resolved to cut down the forests, and thus to raise the price of the commodity: but they had soon reason to repent of their avarice; for such a change ensued, by cutting down the trees, that the whole island, from being healthy and delightful, having lost its charming shades, became extremely sickly, and has actually continued so to this day. Boerhaave considered heat so prejudicial to health, that he was never seen to go near a fire.

An opposite set of calamities are the consequence, in climates where the air is condensed by cold. In such places, all that train of distempers which are known to arise from obstructed perspiration, are very common; eruptions, boils, scurvy, and a loathsome leprosy, that covers the whole body with a scurf, and white putrid ulcers. These disorders also are infectious; and, while they thus banish the patient from society, they generally accompany him to the grave. The men of those climates seldom attain to the age of fifty; but the women, who do not lead such laborious lives, are found to live longer.

The autumnal complaints which attend a wet summer, indicate the dangers of a moist air. The long continuance of an east wind also, shews the prejudice of a dry one. Mineral exhalations, when copious, are every where known to be fatal; and although we probably owe the increase and luxuriance of vegetation to a moderate degree of their warmth, yet the natives of those countries where there are mines in plenty, but too often experience the noxious effects of their vicinity. Those trades also that deal in the preparations of metals of all kinds, are always unwholesome; and the workmen, after some time, are generally seen to labour under palsies, and other nervous complaints. The vapours from some vegetable substances, are well known to be attended with dangerous effects. The shade of the machinet-tree, in America, is said to be fatal; as was that of the juniper, if we may credit the ancients. Those who walk through fields of poppies, or in any manner prepare those flowers, for making opium, are very sensibly affected with the drowsiness they occasion. A physician of Mr. Boyle's acquaintance, causing a large quantity of black hellebore to be pounded in a mortar, most of the persons who were in the room, and especially the person who pounded it, were purged by it; and some of them strongly. He also gathered a certain plant in Ireland, which the person who beat in a mortar, and the physician who was standing near, were so strongly affected by, that their hands and faces swelled to an enormous size, and continued tumid for a long time after.

But neither mineral nor vegetable steams are so dangerous to the constitution, as those proceeding from animal substances, putrifying either by disease or death. The effluvia that comes from diseased bodies, propagate that frightful catalogue of disorders which are called infectious. The parts which compose vegetable vapours; and mineral exhalations, seem gross and heavy, in comparison of these volatile vapours, that go to great distances, and have been described as spreading desolation

defolation over the whole earth. They fly every where; penetrate every where; and the vapours that fly from a single disease, soon render it epidemic.

The plague is the first upon the list in this class of human calamities. From whence this scourge of man's presumption may have its beginning, is not well known; but we well know that it is propagated by infection. Whatever be the general state of the atmosphere, we learn from experience, that the noxious vapours, though but singly introduced at first, taints the air by degrees: every person infected, tends to add to the growing malignity; and, as the disorder becomes more general, the putrescence of the air becomes more noxious, so that the symptoms are aggravated by continuance. When it is said that the origin of this disorder is unknown, it implies, that the air seems to be but little employed in first producing it. There are some countries, even in the midst of Africa, that we learn have never been infected with it; but continue, for centuries, unmolested. On the contrary, there are others, that are generally visited once a year, as in Egypt, which, nevertheless, seems peculiarly blessed with the serenity and temperature of its climate. In the former countries, which are of vast extent, and many of them very populous, every thing should seem to dispose the air to make the plague continual among them. The great heats of the climate, the unwholesomeness of the food, the sloth and dirt of the inhabitants, but, above all, the bloody battles which are continually fought among them, after which heaps of dead bodies are left unburied, and exposed to putrefaction. All these one might think would be apt to bring the plague among them; and yet, nevertheless, we are assured by Leo Africanus, that in Numidia the plague is not known once in an hundred years; and that in Negroland, it is not known at all. This dreadful disorder, therefore, must have its rise, not from any previous disposition of the air, but from some particular cause, beginning with one individual, and extending the malignity, by communication; till at last the air becomes actually tainted by the generality of the infection.

The plague which spread itself over the whole world, in the year 1346, as we are told by Mezeray, was so contagious, that scarce a village, or even an house, escaped being infected by it. Before it had reached Europe, it had been for two years travelling from the great kingdom of Cathay, where it began by a vapour most horridly foetid; this broke out of the earth like a subterranean fire, and upon the first instant of its eruption, consumed and desolated above two hundred leagues of that country, even to the trees and stones.

In that great plague which desolated the city of London, in the year 1665, a pious and learned schoolmaster of Mr. Boyle's acquaintance, who ventured to stay in the city, and took upon him the humane office of visiting the sick and the dying, who had been deserted by better physicians, averred, that being once called to a poor woman who had buried her children of the plague, he found the room where she lay so little that it scarce could hold any more than the bed whereon she was stretched. However, in this wretched abode, beside her, in an open coffin, her husband lay, who had some time before died of the same disease; and whom she, poor creature, soon followed. But what shewed the peculiar malignity of the air, thus suffering from animal putrefaction, was, that the contagious steams had produced spots on the very wall of their wretched apartment: and Mr. Boyle's own study, which was contiguous to a pest-house, was also spotted in the same frightful manner. Happily for mankind, this disorder, for more than a century,

has not been known in our island; and, for this last age, has abated much of its violence, even in those countries where it is most common. Diseases, like empires, have their revolutions; and those which for a while were the scourge of mankind, sink unheard of, to give place to new ones, more dreadful, as being less understood.

For this revolution in disorders, which has employed the speculation of many, Mr. Boyle accounts in the following manner: "Since," says he, "there want not causes in the bowels of the earth, to make considerable changes amongst the materials that nature has plentifully treasured up in those magazines, and as those noxious steams are abundantly supplied to the surface, it may not seem improbable, that in this great variety, some may be found capable of particularly affecting the human frame in a particular manner, and thus of producing new diseases. The duration of these may be greater or less, according to the lastingness of those subterraneous causes that produced them. On which account, it need be no wonder that some diseases have but a short duration, and vanish not long after they appear; whilst others may continue longer, as having under ground more settled and durable causes to maintain them."

From the recital of this train of mischiefs produced by the air, upon minerals, plants, animals, and man himself, a gloomy mind may be apt to dread this indulgent nurse of nature as a cruel and an inexorable step-mother: but it is far otherwise; and, although we are sometimes injured, yet almost all the comforts and blessings of life spring from its propitious influence. It would be needless to observe, that it is absolutely necessary for the support of our lives; for of this, every moment's experience assures us. But how it contributes to this support, is not so readily comprehended. All allow it to be a friend; to whose benefits we are constantly obliged: and yet, to this hour, philosophers are divided as to the nature of the obligation. The dispute is, whether the air is only useful by its weight to force our juices into circulation; or, whether, by containing a peculiar spirit, it mixes with the blood in our vessels, and acts like a spur to their industry. Perhaps it may exert both these useful offices at the same time. Its weight may give the blood its progressive motion, through the larger vessels of the body; and its admixture with it, cause those contractions of all the vessels, which serve to force it still more strongly forward, through the minutest channels of the circulation. Be this as it may, it is well known, that that part of our blood which has just received the influx of the air in our bodies, is of a very different colour from that which has almost performed its circuit. It has been found, that the arterial blood which has been immediately mixed with the air in the lungs, and, if we may so express it, is just beginning its journey through the body, is of a fine florid scarlet colour; while, on the contrary, the blood of the veins that is returning from having performed its duty, is of a blackish crimson hue. Whence this difference of colour should proceed, is not well understood; we only know the fact, that this florid colour is communicated by the air; and we are well convinced, that this air has been admitted into the blood for very useful purposes.

Besides this vital principle in animals, the air also gives life and body to flame. A candle quickly goes out in an exhausted receiver; for having soon consumed the quantity of air, it then expires, for want of a fresh supply. There has been a flame contrived that will burn under water; but none yet has been found, that will continue to burn without air. Gunpowder, which is the most catching and powerful fire we know, will not go off in an exhausted

hausted receiver; nay, if a train of gunpowder be laid, so as that one part may be fired in the open air, yet the other part in vacuo will remain untouched, and unconsumed. Wood also set on fire, immediately goes out; and its flame ceases upon removing the air; for something is then wanting to press the body of the fire against that of the fuel, and to prevent the too speedy diffusion of the flame. We frequently see cooks, and others, whose business it is to keep up strong fires, take proper precautions to exclude the beams of the sun from shining upon them, which effectually puts them out. This they are apt to ascribe to a wrong cause; namely, the operation of the light: but the real fact is, that the warmth of the sun-beams lessen and dissipate the body of the air that goes to feed the flame; and the fire, of consequence, languishes for want of a necessary supply.

The air, while it thus kindles fire into flame, is notwithstanding found to moderate the rays of light, to dissipate their violence, and to spread an uniform lustre over every object. Were the beams of the sun to dart directly upon us, without passing through this protecting medium, they would either burn us up at once, or blind us with their effulgence. But by going through the air, they are reflected, refracted, and turned from their direct course, a thousand different ways; and thus are more evenly diffused over the face of nature.

Among the other necessary benefits the air is of to us, one of the principal is its conveyance of sound. Even the vibrations of a bell, which have the loudest effect that we know of, ceases to be heard, when under the receiver of an air-pump. Thus all the pleasures we receive from conversation with each other, or from music, depend entirely upon the air.

Odours likewise are diffused only by the means of air; without this fluid to swim in, they would for ever remain torpid in their respective substances; and the rose would affect us with as little sensations of pleasure, as the thorn on which it grew.

Those who are willing to augment the catalogue of the benefits we receive from this element, assert also, that tastes themselves would be insipid, were it not that the air presses their parts upon the nerves of the tongue and palate, so as to produce their grateful effects. Thus, continue they, upon the tops of high mountains, as on the Pike of Teneriff, the most poignant bodies, as pepper, ginger, salt, and spice, have no sensible taste, for want of their particles being thus sent home to the sensory. But we owe the air sufficient obligations, not to be studious of admitting this among the number: in fact, all substances have their taste, as well on the tops of mountains, as in the bottom of the valley; and several have been known to eat a good dinner on the Alps.

It is sufficient, therefore, that we regard the air as the parent of health and vegetation; as a kind dispenser of light and warmth; and as the conveyer of sounds and odours. This is an element of which avarice will not deprive us; and which power cannot monopolize. The treasures of the earth, the verdure of the fields, and even the refreshments of the stream, are too often seen going only to assist the luxuries of the great; while the less fortunate part of mankind stand humble spectators of their encroachments. But the air no limitations can bound, nor any land-marks restrain. In this benign element, all mankind can boast an equal possession; and for this we all have equal obligations to Heaven. We consume a part of it, for our own sustenance, while we live; and, when we die, our putrifying bodies give back the supply, which, during life, we had accumulated from the general mass.

CHAP. XX.

Of Regular and Irregular WINDS.

WIND is a current of air. Experimental philosophers produce an artificial wind, by an instrument called an æolipyle. This is nothing more than an hollow copper ball, with a long pipe; a tea-kettle might be readily made into one, if it were entirely closed at the lid, and the spout left open; through this spout it is to be filled with water, and then set upon the fire, by which means it produces a violent blast, like wind, which continues while there is any water remaining in the instrument. In this manner water is converted into a rushing air; which, if caught as it goes out, and left to cool, is again quickly converted into its former element. Besides this, as was mentioned in the former chapter, almost every substance contains some portions of air. Vegetables, or the bodies of animals left to putrify, produce it in a very copious manner. But it is not only seen thus escaping from bodies, but it may be very easily made to enter into them. A quantity of air may be compressed into water, so as to be intimately blended with it. It finds a much easier admission into wine, or any fermented liquor; and an easier still, into spirits of wine. Some salts suck up the air in such quantities, that they are made sensibly heavier thereby, and often are melted by its moisture. In this manner, most bodies, being found either capable of receiving or affording it, we are not to be surprized at those streams of air that are continually fleeting round the globe. Minerals, vegetables, and animals, contribute to increase the current; and are sending off their constant supplies. These, as they are differently affected by cold or heat, by mixture or putrefaction, all yield different quantities of air at different times; and the loudest tempests, and most rapid whirlwinds, are formed for their united contributions.

The sun is the principal instrument in rarefying the juices of plants, so as to give an escape to their imprisoned air; it is also equally operative in promoting the putrefaction of animals. Mineral exhalations are more frequently raised by subterranean heat. The moon, the other planets, the seasons, are all combined in producing these effects in a smaller degree. Mountains give a direction to the courses of the air. Fires carry a current of air along their body. Night and day alternately chill and warm the earth, and produce an alternate current of its vapours. These, and many other causes, may be assigned for the variety, and the activity of the winds, their continual change, and uncertain duration.

With us on land, as the wind proceeds from so many causes, and meets such a variety of obstacles, there can be but little hopes of ever bringing its motions to conform to theory; or of foretelling how it may blow a minute to come. The great Bacon, indeed, was of opinion, that by a close and regular history of the winds, continued for a number of ages together, and the particulars of each observation reduced to general maxims, we might at last come to understand the variations of this capricious element; and that we could foretell the certainty of a wind, with as much ease as we now foretell the return of an eclipse. Indeed, his own beginnings in this arduous undertaking, seem to speak the possibility of success; but, unhappily for mankind, this investigation is the work of ages, and we want a Bacon to direct the process.

To be able, therefore, with any plausibility, to account for the variations of the wind upon land, is not to be at present expected; and to understand any thing of their nature, we must have recourse to those

those places where they are more permanent and steady. This uniformity and steadiness we are chiefly to expect upon the ocean. There, where there is no variety of substances to furnish the air with various and inconstant supplies; where there are no mountains to direct the course of its current, but where all is extensively uniform and even; in such a place, the wind arising from a simple cause, must have but one simple motion. In fact, we find it so. There are many parts of the world where the winds, that with us are so uncertain, pay their stated visits. In some places, they are found to blow one way by day, and another by night; in others, for one half of the year, they go in a direction contrary to their former course: but what is more extraordinary still, there are some places where the winds never change, but for ever blow the same way. This is particularly found to obtain between the tropics in the Atlantic and Æthiopic oceans; as well as in the great Pacific sea.

Few things can appear more extraordinary to a person who has never been out of our variable latitudes, than this steady wind, that for ever sits in the sail, sending the vessel forward; and as effectually preventing its return. He who has been taught to consider that nothing in the world is so variable as the winds, must certainly be surpris'd to find a place where there is nothing more uniform. With us their inconstancy has become a proverb; with the natives of those distant climates, they may talk of a friend or a mistress as fixed and unchangeable as the winds, and mean a compliment by the comparison. When our ships are once arriv'd into the proper latitudes of the great Pacific ocean, the mariner forgets the helm, and his skill becomes almost useless: neither storms nor tempests are known to deform the glassy bosom of that immense sheet of waters; a gentle breeze, that for ever blows in the same direction, rests upon the canvas, and speeds the navigator. In the space of six weeks, ships are thus known to cross an immense ocean, that takes more than so many months to return. Upon returning, the trade-wind, which has been propitious, is then avoided; the mariner is generally oblig'd to steer into the northern latitudes, and to take the advantage of every casual wind that offers, to assist him into port. This wind, which blows with such constancy one way, is known to prevail not only in the Pacific ocean, but also in the Atlantic, between the coasts of Guinea and Brazil; and, likewise, in the Æthiopic ocean. This seems to be the great universal wind, blowing from the east to the west, that prevails in all the extensive oceans, where the land does not frequently break the general current. Were the whole surface of the globe an ocean, there would probably be but this one wind, for ever blowing from the east, and pursuing the motions of the sun westward. All the other winds seem subordinate to this; and many of them are made from the deviations of its current. To form, therefore, any conception relative to the variations of the wind in general, it is proper to begin with that which never varies.

There have been many theories to explain this invariable motion of the winds; among the rest, we cannot omit that of Doctor Lyster, for its strangeness: "The sea," says he, "in those latitudes, is generally covered over with green weeds, for a great extent; and the air produced from the vegetable perspiration of these, produces the trade-wind." The theory of Cartesius was not quite so absurd. He alledged, that the earth went round faster than its atmosphere at the equator; so that its motion, from west to east, gave the atmosphere an imaginary one from east to west; and thus an east wind was eternally seen to prevail. Rejecting those arbitrary opinions, conceived without force,

and asserted without proof, Doctor Halley has given one more plausible; which seems to be the reigning system of the day.

To conceive his opinion clearly, let us for a moment suppose the whole surface of the earth to be an ocean, and the air encompassing it on every side, without motion. Now it is evident, that that part of the air which lies directly under the beams of the sun, will be rarefied; and if the sun remained for ever in the same place, there would be a great vacuity in the air (if it may be so expressed) beneath the place where the sun stood. The sun, moving forward, from east to west, this vacuity will follow too, and still be made under it. But while it goes on to make new vacuities, the air will rush in to fill up those the sun has already made; in other words, as it is still travelling forward, the air will continually be rushing in behind, and pursue its motions from east to west. In this manner, the air is put into motion by day; and by night, the parts continue to impel each other, till the next return of the sun, that gives a new force to the circulation.

In this manner is explained the constant east wind that is found blowing round the globe, near the equator. But it is also known, that as we recede from the equator on either side, we come into a trade-wind, that continually blows from the poles, from the north on one side, or the south on the other, both directing towards the equator. This also proceeds from a similar cause with the former; for the air being more rarefied in those places over which the sun more directly daats its rays, the currents will come both from the north and the south to fill up the intermediate vacuity.

These two motions, namely, the general one from east to west, and the more particular one from both the poles, will account for all the phenomena of trade-winds; which, if the whole surface of the globe were sea, would undoubtedly be constant, and for ever continue to blow in one direction. But there are a thousand circumstances to break these air-currents into smaller ones; to drive them back against their general course; to raise or depress them; to condense them into storms; or to whirl them in eddies. In consequence of this, regard must be often had to the nature of the soil, the position of the high mountains, the course of the rivers, and even to the luxuriance of vegetation.

If a country lying directly under the sun, be very flat and sandy, and if the land be low and extensive, the heats occasioned by the reflection of the sun-beams, produces a very great rarefaction of the air. The deserts of Africa, which are conformable to this description, are scarce ever fanned by a breath of wind by day; but the burning sun is continually seen blazing in intolerable splendor above them. For this reason, all along the coasts of Guinea, the wind is always perceived blowing in upon land, in order to fill up the vacuity caused by the sun's operation. In those shores, therefore, the wind blows in a contrary direction to that of its general current; and is constantly found setting in from the west.

From the same cause it happens, that those constant calms, attended with deluges of rain, are found in the same part of the ocean. For this tract being placed in the middle, between the westerly winds blowing on the coast of Guinea, and the easterly trade-winds that move at some distance from shore, in a contrary direction, the tendency of that part of the air that lies between these two opposite currents, is indifferent to either, and so rests between both in torpid serenity; and the weight of the incumbent atmosphere, being diminished by the continual contrary winds blowing from hence,

it is unable to keep the vapours suspended that are copiously borne thither; so that they fall in continual rains.

But it is not to be supposed, that any theory can account for all the phaenomena of even those winds that are known to be most regular. Instead of a complete system of the trade-winds, we must rather be content with an imperfect history. These, as was said, being the result of a combination of effects, assume as great a variety, as the causes producing them are various.

Besides the great general wind above mentioned; in those parts of the Atlantic that lie under the temperate zone, a north wind prevails constantly during the months of October, November, December, and January. These, therefore, are the most favourable months for embarking for the East-Indies, in order to take the benefit of these winds, for crossing the line: and it has been often found, by experience, that those who had set sail five months before, were not in the least farther advanced in their voyage, than those who waited for the favourable wind. During the winter of Nova Zembla, and the other arctic countries, a north wind reigns almost continually. In the Cape de Verde islands, a south wind prevails during the month of July. At the Cape of Good Hope, a north-west wind blows during the month of September. There are also regular winds, produced by various causes, upon land. The ancient Greeks were the first who observed a constant breeze, produced by the melting of the snows, in some high neighbouring countries. This was perceived in Greece, Thrace, Macedonia, and the Aegean sea. The same kind of winds are now remarked in the kingdom of Congo, and the most southern parts of Africa. The flux and reflux of the sea also produces some regular winds, that serve the purposes of trade; and, in general, it may be observed, that wherever there is a strong current of water, there is a current of air that seems to attend it.

Besides these winds that are found to blow in one direction, there are, as was said before, others that blow for certain months of the year one way, and the rest of the year the contrary way: these are called the Monsoons, from a famous pilot of that name, who first used them in navigation with success. In all that part of the ocean that lies between Africa and India, the east winds begin at the month of January, and continue till about the commencement of June. In the month of August, or September, the contrary direction takes place; and the west winds prevail for three or four months. The interval between these winds, that is to say, from the end of June to the beginning of August, there is no fixed wind; but the sea is usually tossed by violent tempests, proceeding from the north. These winds are always subject to their greatest variations, as they approach the land; so that on one side of the great peninsula of India, the coasts are, for near half the year, harrassed by violent hurricanes, and northern tempests; while, on the opposite side, and all along the coasts of Coromandel, these dreadful tempests are wholly unknown. At Java, and Ceylon, a west wind begins to reign in the month of September; but at fifteen degrees of south latitude, this wind is found to be lost, and the great general trade wind from the east, is perceived to prevail. On the contrary, at Cochin, in China, the west wind begins at March; so that these Monsoons prevail, at different seasons, throughout the Indies. So that the mariner takes one part of the year to go from Java to the Moluccas; another from Cochin to Molucca; another from Molucca to China; and still another to direct him from China to Japan.

There are winds also that may be considered as peculiar to certain coasts; for example, the south-

wind is almost constant upon the coasts of Chili and Peru; western winds almost constantly prevail on the coast of Terra Magellanica; and in the environs of the Streights le Maire. On the coasts of Malabar, north and north-west winds prevail continually; along the coast of Guinea, the north-west wind is also very frequent; and, at a distance from the coasts, the north-east is always found prevailing. From the beginning of November to the end of December, a west wind prevails on the coasts of Japan; and, during the whole winter, no ships can leave the port of Cochin, on account of the impetuosity of the winds that set upon the coast. These blow with such vehemence, that the ports are entirely choaked up with sand, and even boats are not able to enter. However, the east winds that prevail for the other half of the year, clear the mouths of the harbours from the accumulations of the preceding winter, and set the confined ships at liberty. At the Streights of Babelmandel there is a south wind that periodically returns, and which is always followed by a north-east.

Besides winds thus peculiar to certain coasts, there are others found to prevail on all the coasts, in warm climates; which, during one part of the day, blow from the shore, and, during another part of it, blow from the sea. The sea-breeze, in those countries, as Dampier observes, commonly rises in the morning, about nine, proceeding slowly, in a fine small black curl, upon the surface of the water, and making its way to refresh the shore. It is gentle at first, but increases gradually till twelve, then insensibly sinks away, and is totally hushed at five. Upon its ceasing, the land breeze begins to take its turn, which increases till twelve at night, and is succeeded, in the morning, by the sea breeze again. Without all doubt nothing could have been more fortunate, for the inhabitants of the warm countries, where those breezes blow, than this alternate refreshment, which they feel at those seasons when it is most wanted. The heat, on some coasts, would be insupportable, were it not for such a supply of air, when the sun has rarefied all that which lay more immediately under the coast. The sea-breeze temperates the heat of the sun by day; and the land-breeze corrects the malignity of the dews, and vapours, by night. Where these breezes, therefore, prevail, and they are very common, the inhabitants enjoy a share of health and happiness, unknown to those that live much farther up the country, or such as live in similar latitudes without this advantage. The cause of these obviously seems to arise from the rarefaction of the air by the sun, as their duration continues with its appearance, and alters when it goes down. The sun, it is observed, equally diffusing his beams upon land and sea, the land, being a more solid body than the water, receives a greater quantity of heat, and reflects it more strongly. Being thus, therefore, heated to a greater degree than the waters, it, of consequence, drives the air from land out to sea; but, its influence being removed, the air returns to fill up the former vacuity. Such is the usual method of accounting for this phaenomenon; but, unfortunately, these sea and land breezes are visitants that come at all hours. On the coasts of Malabar, the land-breezes begin at midnight, and continue till noon; then the sea-breezes take their turn, and continue till midnight. While, again, at Congo, the land-breezes begin at five, and continue till nine the next day.

But, if the cause of these be so inscrutable, that are, as we see, tolerably regular in their visitations, what shall we say to the winds of our own climate, that are continually shifting, and incapable of rest? Some general causes may be assigned, which nothing but particular experience can apply. And, in the first place, it may be observed, that clouds,

and heat, and, in short, whatever either increases the density or the elasticity of the air, in any one place, will produce a wind there: for the increased activity of the air thus pressing more powerfully on the parts of it that are adjacent, will drive them forward; and thus go on, in a current, till the whole comes to an equality.

In this manner, as a denser air produces a wind, on the one hand; so will any accident, that contributes to lighten the air, produce it on the other: for a lighter air may be considered as a vacuity, into which the neighbouring air will rush: and hence it happens, that when the barometer marks a peculiar lightness in the air, it is no wonder that it foretells a storm.

The winds upon large waters are generally more regular than those upon land. The wind at sea generally blows with an even steady gale; the wind at land puffs by intervals, increasing its strength, and remitting it, without any apparent cause. This, in a great measure, may be owing to the many mountains, towers, or trees, that it meets in its way, all contributing either to turn it from its course, or interrupt its passage.

The east wind blows more constantly than any other, and for an obvious reason: all other winds are, in some measure, deviations from it, and partly may owe their origin thereto. It is generally, likewise, the most powerful, and for the same reason.

There are often double currents of the air. While the wind blows one way, we frequently see the clouds move another. This is generally the case before thunder; for it is well known that the thunder cloud always moves against the wind: the cause of this surprising appearance has hitherto remained a secret. From hence we may conclude, that weathercocks only inform us of that current of the air, which is near the surface of the earth; but are often erroneous with regard to the upper regions; and, in fact, Derham has often found them erroneous.

Winds are generally more powerful on elevated situations than on the plain, because their progress is interrupted by fewer obstacles. In proportion as we ascend the heights of a mountain, the violence of the weather seems to increase, until we have got above the region of storms, where all is usually calm and serene. Sometimes, however, the storms rise even to the tops of the highest mountains; as we learn from those who have been on the Andes, and as we are convinced by the deep snows that crown even the highest.

Winds blowing from the sea are generally moister, and more attended with rains, than those which blow over extensive tracts of land: for the sea gives off more vapours to the air, and these are rolled forward upon land, by the winds blowing from thence. For this reason our easterly winds, that blow from the continent, are dry, compared with those that blow from the surface of the ocean, with which we are surrounded on every other quarter.

In general the winds are more boisterous in spring and autumn, than at other seasons: for, that being the time of high tides, the sea may communicate a part of its motions to the winds. The sun and moon, also, which then have a greater effect upon the waters, may also have some influence upon the winds; for, there being a great body of air surrounding the globe, which, if condensed into water, would cover it to the depth of thirty-two feet, it is evident that the sun and moon will, to a proportionable degree, affect the atmosphere, and make a tide of air. This tide will be scarce perceivable, indeed; but, without doubt, it actually exists; and may contribute to increase the vernal

and autumnal storms, which are then known to prevail.

Upon narrowing the passage through which the air is driven; both the density and the swiftness of the wind is increased. For as currents of water flow with greater force and rapidity by narrowing their channels, so also will a current of air, driven through a contracted space, grow more violent and irresistible. Hence we find those dreadful storms that prevail in the defiles of mountains, where the wind, pushing from behind through a narrow channel, at once increases in speed and density, levelling, or tearing up, every obstacle that rises to obstruct its passage.

Winds reflected from the sides of mountains and towers, are often found to be more forceful than those in direct progression. This we frequently perceive near lofty buildings, such as churches or steeples, where winds are generally known to prevail, and that much more powerful than at some distance. The air, in this case, by striking against the side of the building, acquires additional density, and therefore blows with more force.

These differing degrees of density, which the air is found to possess, sufficiently shew that the force of the winds do not depend upon their velocity alone; so that those instruments called anemometers, which are made to measure the velocity of the wind, will by no means give us certain information of the force of the storm. In order to estimate this with exactness, we ought to know its density; which also these are not calculated to discover. For this reason we often see storms, with very powerful effects, that do not seem to shew any great speed; and on the contrary, we see these wind measurers go round, with great swiftness, when scarce any damage has followed from the storm.

Such is the nature, and the inconstancy of the irregular winds with which we are best acquainted. But their effects are much more formidable in those climates, near the tropics, where they are often found to break in upon the steady course of the trade winds, and to mark their passage with destruction. With us the tempest is but rarely known, and its ravages are registered as an uncommon calamity; but, in the countries that lie between the tropics, and for a good space beyond them, its visits are frequent, and its effects anticipated. In these regions the winds vary their terrors, sometimes involving all things in a suffocating heat; sometimes mixing all the elements of fire, air, earth, and water together; sometimes, with a momentary swiftness, passing over the face of the country, and destroying all things in their passage; and sometimes raising whole sandy deserts in one country, to deposit them upon some other. We have little reason, therefore, to envy these climates the luxuriance of their soil, or the brightness of their skies. Our own muddy atmosphere, that wraps us round in obscurity, though it fails to gild our prospects with sun-shine, or our groves with fruitage, nevertheless answers the calls of industry. They may boast of a plentiful, but precarious harvest; while, with us, the labourer toils in a certain expectation of a moderate, but an happy return.

In Egypt, a kingdom so noted for its fertility, and the brightness of its atmosphere, during summer, the south winds are so hot, that they almost stop respiration; besides which, they are charged with such quantities of sand, that they sometimes darken the air, as with a thick cloud. These sands are so fine, and driven with such violence, that they penetrate every where; even into chests, be they shut never so closely. If these winds happen to continue for any length of time, they produce epidemic diseases; and are often followed by a great mortality.

mortality. It is also found to rain but very seldom in that country; however, the want of showers is richly compensated by the copiousness of their dews, which greatly tend to promote vegetation.

In Persia, the winter begins in November, and continues till March. The cold at that time is intense enough to congeal the water; and snow falls in abundance upon their mountains. During the months of March and April, winds arise, that blow with great force, and seem to usher in the heats of summer. These return again, in autumn, with some violence; without, however, producing any dreadful effects. But, during their summer, all along the coasts of the Persian Gulph, a very dangerous wind prevails, which the natives call the Sameyel, still more dreadful and burning than that of Egypt, and attended with instant and fatal effects. This terrible blast, which was, perhaps, the pestilence of the ancients, instantly kills all those that it involves in its passage. What its malignity consists in, none can tell, as none have ever survived its effects, to give information. It frequently assumes a visible form; and darts, in a kind of bluish vapour, along the surface of the country. The natives not only of Persia, but Arabia, talk of its effects with terror; and their poets have not failed to heighten them, with the assistance of imagination. They have described it as under the conduct of a minister of vengeance, who governs its terrors, and raises, or depresses it, as he thinks proper. These deadly winds are also known along the coasts of India, at Necapatan, Masulipatan, and Petaoli. But, luckily for mankind, the shortness of their duration diminishes the injuries that might ensue from their malignity.

The Cape of Good Hope, as well as many islands in the West-Indies, are famous for their hurricanes, and that extraordinary kind of cloud, which is said to produce them. This cloud, which is the forerunner of an approaching hurricane, appears, when first seen, like a small black spot on the verge of the horizon; and is called, by sailors, the bull's eye, from being seen so minute at a vast distance. All this time, a perfect calm reigns over the sea and land, while the cloud grows gradually broader as it approaches. At length, coming to the place where its fury is to fall, it invests the whole horizon with darkness. During all the time of its approach, an hollow murmur is heard in the cavities of the mountains: and beasts and animals, sensible of its approach, are seen running over the fields, to seek for shelter. Nothing can be more terrible than its violence when it begins. The houses in those countries, which are made of timber, the better to resist its fury, bend to the blast like osiers, and again recover their rectitude. The sun, which, but a moment before, blazed with meridian splendor, is totally shut out; and a midnight darkness prevails, except that the air is incessantly illuminated with gleams of lightning, by which one can easily see to read. The rain falls, at the same time, in torrents; and its descent has been resembled to what pours from the spouts of our houses after a violent shower. These hurricanes are not less offensive to the sense of smelling also; and never come without leaving the most noisome stench behind them. If the seamen also lay by their wet cloaths, for twenty-four hours, they are all found swarming with little white maggots, that were brought with the hurricane. Our first mariners, when they visited those regions, were ignorant of its effects, and the signs of its approach; their ships, therefore, were dashed to the bottom at the first onset; and numberless were the wrecks which the hurricane occasioned. But, at present, being fore-warned of its approach, they strip their masts of all their sails, and thus patiently abide its fury. These hurricanes are com-

mon in all the tropical climates. On the coasts of Guinea they have frequently three or four in a day, that thus shut out the heavens for a little space; and when past leave all again in former splendor. They chiefly prevail, on that coast, in the intervals of the trade-winds; the approach of which clears the air of its meteors, and gives these mortal showers that little degree of wholesomeness, which they possess. They chiefly obtain there during the months of April and May; they are known at Loango, from January to April; on the opposite coast of Africa, the hurricane season begins at May; and, in general, whenever a trade-wind begins to cease, these irregular tempests are found to exert their fury.

All this is terrible; but there is a tempest, known in those climates, more formidable than any we have hitherto been describing, which is called, by the Spaniards, a Tornado. As the former was seen arriving from one part of the heavens, and making a line of destruction; so the winds in this seem to blow from every quarter, and settle upon one destined place, with such fury, that nothing can resist their vehemence. When they have all met, in their central spot, then the whirlwind begins with circular rapidity. The sphere every moment widens as it continues to turn, and catches every object that lies within its attraction. This, also, like the former, is preceded by a flattering calm; the air is every where hushed; and the sea is as smooth as polished glass: however, as its effects are more dreadful than those of the ordinary hurricane, the mariner tries all the power of his skill to avoid it; which, if he fails of doing, there is the greatest danger of his going to the bottom. All along the coasts of Guinea, beginning about two degrees north of the line, and so downward, lengthwise, for about a thousand miles, and as many broad, the ocean is unnavigable, upon account of these tornados. In this torpid region there reigns unceasing tornados, or continual calms; among which, whatever ship is so unhappy as to fall, is totally deprived of all power of escaping. In this dreadful repose of all the elements, the solitary vessel is obliged to continue, without a single breeze to assist the mariner's wishes, except those whirlwinds, which only serve to increase his calamity. At present, therefore, this part of the ocean is totally avoided; and, although there may be much gold along the coasts of that part of Africa, to tempt avarice, yet there is something, much more dreadful than the fabled dragon of antiquity, to guard the treasure. As the internal parts of that country are totally unknown to travellers, from their burning sand and extensive deserts, so here we find a vast tract of ocean, lying off its shores, equally unvisited by the mariner.

But of all these terrible tempests that deform the face of Nature, and repress human presumption, the sandy tempests of Arabia and Africa, are the most terrible, and strike the imagination most strongly. To conceive a proper idea of these, we are by no means to suppose them resembling those whirlwinds of dust that we sometimes see scattering in our air, and sprinkling their contents upon our roads or meadows. The sand-storm of Africa exhibits a very different appearance. As the sand of which the whirlwind is composed is excessively fine, and almost resembles the parts of water, its motion entirely resembles that of a fluid; and the whole plain seems to float onward, like a slow inundation. The body of sand thus rolling, is deep enough to bury houses and palaces in its bosom: travellers who are crossing those extensive deserts, perceive its approach at a distance; and, in general, have time to avoid it, or turn out of its way, as it generally extends but to a moderate breadth. However,

ever, when it is extremely rapid, or very extensive, as sometimes is the case, no swiftness, no art, can avail; nothing then remains, but to meet death with fortitude, and submit to be buried alive with resignation.

It is happy for us of Britain, that we have no such calamity to fear; for, from this, even some parts of Europe are not entirely free. We have an account given us, in the History of the French Academy, of a miserable town in France, that is constantly in danger of being buried under a similar inundation. "In the neighbourhood of St. Paul de Leon, in Lower Brittany, there lies a tract of country along the sea-side, which before the year 1666 was inhabited, but now lies deserted, by reason of the sands which cover it, to the height of twenty feet; and which every year advance more and more inland, and gain ground continually. From the time mentioned above, the sand has buried more than six leagues of the country inward; and it is now but half a league from the town of St. Paul; so that, in all appearance, the inhabitants must be obliged to abandon it entirely. In the country that has been overwhelmed, there are still to be seen the tops of some steeples peeping through the sand, and many chimnies that still remain above this sandy ocean. The inhabitants, however, had sufficient time to escape; but being deprived of their little all, they had no other resource but begging for their subsistence. This calamity chiefly owes its advancement to a north, or an east wind, raising the sand, which is extremely fine, in such great quantities, and with such velocity, that M. Deslands, who gave the account, says, that while he was walking near the place, during a moderate breeze of wind, he was obliged, from time to time, to shake the sand from his cloaths and hat, on which it was lodged in great quantities, and made them too heavy to be easily borne. Still further, when the wind was violent, it drove the sand across a little arm of the sea, into the town of Roscoff, and covered the streets of that place two feet deep; so that they have been obliged to carry it off in carts. It may also be observed, that there are several particles of iron mixed with the sand, which are readily affected by the loadstone. The part of the coast that furnishes these sands, is a tract of about four leagues in length; and is upon a level with the sea at high-water. The shore lies in such a manner as to leave its sands subject only to the north and east winds, that bear them farther up the shore. It is easy to conceive how the same sand that has at one time been borne a short way in land, may, by some succeeding and stronger blast, be carried up much higher; and thus the whole may continue advancing forward, deluging the plain, and totally destroying its fertility. At the same time, the sea, from whence this deluge of sand proceeds, may furnish it in inexhaustible quantities. This unhappy country, thus overwhelmed in so singular a manner, may well justify what the antients and the moderns have reported concerning those tempests of sand in Africa, that are said to destroy villages, and even armies in their bosom."

C H A P. XXI.

Of METEORS, and such Appearances as result from a Combination of the Elements.

IN proportion as the substances of nature are more compounded and combined, their appearances become more inexplicable and amazing. The properties of water have been very nearly ascertained. Many of the qualities of air, earth, and fire, have been discovered, and estimated; but when these come to be united by Nature, they often

produce a result which no artificial combinations can imitate: and we stand surpris'd, that although we are possess'd of all those substances which Nature makes use of, she shews herself a much more various operator than the most skilful chemist ever appeared to be. Every cloud that moves, and every shower that falls, serves to mortify the philosopher's pride; and to shew him hidden qualities in air and water; that he finds it difficult to explain. Dews, hail, snow, and thunder, are not less difficult for being more common. Indeed, when we reflect on the manner in which Nature performs any one of these operations, our wonder increases. To see water, which is heavier than air, rising in air, and then falling in a form so very different from that in which it rose; to see the same fluid at one time descending in the form of hail, at another in that of snow; to see two clouds, by dashing against each other, producing an electrical fire, which no watery composition that we know of, can effect—these serve sufficiently to excite our wonder; and still the more, in proportion as the objects are ever pressing on our curiosity. Much, however, has been written concerning the manner in which nature operates in these productions; as nothing is so ungrateful to mankind as hopeless ignorance.

And first, with regard to the manner in which water evaporates, and rises to form clouds, much has been advanced, and many theories devised. All water, say some, has a quantity of air mixed with it; and the heat of the sun darting down, disengages the particles of this air from the grosser fluid: the sun's rays being reflected back from the water, carry back with them those bubbles of air and water which, being lighter than the condensed air, will ascend till they meet with a more rarefied air; and they will then stand suspended. Experience, however, proves nothing of all this. Particles of air or fire, are not thus known to ascend with a thin coat of water; and, in fact, we know that the little particles of steam are solid drops of water. But besides this, water is known to evaporate more powerfully in the severest frost, than when the air is moderately warm. Doctor Hamilton, therefore, of the university of Dublin, rejecting this theory, has endeavoured to establish another. According to him, as aqua fortis is a menstruum that dissolves iron, and keeps it mixed in the fluid; as aqua regia is a menstruum that dissolves gold; or as water dissolves salts to a certain quantity; so air is a menstruum that corrodes and dissolves a certain quantity of water, and keeps it suspended above. But however ingenious this may be, it can hardly be admitted; as we know, by Mariotte's experiment, that if water and air be enclosed together, instead of the air's acting as a menstruum upon the water, the water will act as a menstruum upon the air, and take it all up. We know also, that of two bodies, that which is most fluid and penetrating, is most likely to be the menstruum of the other; but water is more fluid and penetrating than air, and therefore, the most likely of the two to be the menstruum. We know that all bodies are more speedily acted upon, the more their parts are brought into contact with the menstruum that dissolves them; but water, enclosed with compressed air, is not the more diminished thereby. In short, we know, that cold, which diminishes the force of other menstrua, is often found to promote evaporation. In this variety of opinion, and uncertainty of conjecture, we cannot avoid thinking that a theory of evaporation may be formed upon very simple and obvious principles, and embarrassed with very few objections.

We know that a repelling power prevails in nature, not less than an attractive one. This repulsion prevails strongly between the body of fire and that

that of water. If the end of a red hot bar of iron be plunged into a vessel of water, the fluid rises, and large drops of it fly up in all manner of directions, every part bubbling and steaming until the iron be cold. Why may we not, for a moment, compare the rays of the sun, darted directly upon the surface of the water, to so many bars of red hot iron; each bar, indeed, infinitely small; but not the less powerful? In this case, wherever a ray of fire darts, the water, from its repulsive quality, will be driven on all sides; and, of consequence, as in the case of the bar of iron, a part of it will rise. The parts thus rising, however, will be extremely small; as the ray that darts is extremely so. The assemblage of the rays darting upon the water in this manner, will cause it to rise in a light thin steam above the surface; and as the parts of this steam are extremely minute, they will be lighter than air, and, consequently, float upon it. There is no need for supposing them bubbles of water, filled with fire; for any substance, even gold itself, will float on air, if its parts be made small enough; or, in other words, if its surface be sufficiently increased. This water, thus disengaged from the general mass, will be still farther attenuated and broken by the reflected rays, and consequently more adapted for ascending.

From this plain account, every appearance in evaporation may be easily deduced. The quantity of heat increases evaporation, because it raises a greater quantity of steam. The quantity of wind increases evaporation; for, by waving the surface of the water, it thus exposes a greater surface to the evaporating rays. A dry frost, in some measure, assists the quantity of evaporation; as the quantity of rays are found to be no way diminished thereby. Moist weather alone prevents evaporation; for the rays being absorbed, refracted, and broken, by the intervening moisture, before they arrive at the surface, cannot produce the effect; and the vapour will rise in a small proportion.

Thus far we have accounted for the ascent of vapours; but to account for their falling again, is attended with rather more difficulty. We have already observed, that the particles of vapour, disengaged from the surface of the water, will be broken and attenuated in their ascent, by the reflected, and even the direct rays, that happen to strike upon their minute surfaces. They will, therefore, continue to ascend, till they rise above the operation of the reflected rays, which reaches but to a certain height above the surface of the earth. Being arrived at this region, which is cold for want of reflected heat, they will be condensed, and suspended in the form of clouds. Some vapours that ascend to great heights, will be frozen into snow; others, that are condensed lower down, will put on the appearance of a mist, which we find the clouds to be, when we ascend among them, as they hang along the sides of a mountain. These clouds of snow and rain, being blown about by winds, are either entirely scattered and dispersed above, or they are still more condensed by motion, like a snow-ball, that grows more large and solid as it continues to roll. At last, therefore, they will become too weighty for the air which first raised them, to sustain; and they will descend, with their excess of weight, either in snow or rain. But as they will fall precipitately, when they begin to descend, the air, in some measure, will resist the falling; for, as the descending fluid gathers velocity in its precipitation, the air will increase its resistance to it, and the water will, therefore, be thus broken into rain; as we see, that water which falls from the tops of houses, though it begins in a spout, separates into drops before it has got to the bottom. Were it not for this happy interposition of the air, between us

and the water falling from a considerable height above us, a drop of rain might fall with dangerous force, and an hail-stone might strike us with fatal rapidity.

In this manner, evaporation is produced by day; but when the sun goes down, a part of that vapour which his rays had excited, being no longer broken, and attenuated by the reflecting rays, it will become heavier than the air, even before it has reached the clouds; and it will, therefore, fall back in dews, which differ only from rain in descending before they have had time to condense into a visible form.

Hail, the Cartesians say, is a frozen cloud, half melted, and frozen again in its descent. An hoar-frost is but a frozen dew. Lightning we know to be an electrical flash, produced by the opposition of two clouds: and thunder to be the sound proceeding from the same, continued by an echo reverberated among them. It would be to very little purpose, to attempt explaining exactly how these wonders are effected: we have as yet but little insight into the manner in which these meteors are found to operate upon each other; and, therefore, we must be contented with a detail rather of their effects than their causes.

In our own gentle climate, where Nature wears the mildest and kindest aspect, every meteor seems to befriend us. With us, rains fall in refreshing showers, to enliven our fields; and to paint the landscape with a more vivid beauty. Snows cover the earth, to preserve its tender vegetables from the inclemency of the departing winter. The dews descend with such an imperceptible fall as no way injures the constitution. Even thunder is seldom injurious; and it is often wished by the husbandman, to clear the air, and to kill numberless insects that are noxious to vegetation. Hail is the most injurious meteor that is known in our climate; but it seldom visits us with violence, and then its fury is but transient.

One of the most dreadful storms we hear of, was that of Hertfordshire, in the year 1697. It began by thunder and lightning, which continued for some hours, when suddenly a black cloud came forward, against the wind, and marked its passage with devastation. The hail-stones which it poured down, being measured, were found to be many of them fourteen inches round, consequently, as large as a bowling-green ball. Wherever it came, every plantation fell before it; it tore up the ground, split great oaks, and other trees, without number; the fields of ye were cut down, as if levelled with a scythe; wheat, oats, and barley, suffered the same damage. The inhabitants found but a precarious shelter, even in their houses, their tiles and windows being broke by the violence of the hail-stones, which, by the force with which they came, seemed to have descended from a great height. The birds, in this universal wreck, vainly tried to escape by flight; pigeons, crows, rooks, and many more of the smaller and feebler kinds, were brought down. An unhappy young man, who had not time to take shelter, was killed; one of his eyes was struck out of his head, and his body was all over black with the bruises: another had just time to escape, but not without the most imminent danger, his body being bruised all over. But what is most extraordinary, all this fell within the compass of a mile.

Mezeray, in his History of France, tells us of a shower of hail much more terrible, which happened in the year 1510, when the French monarch invaded Italy. There was, for a time, an horrid darkness, thicker than that of midnight, which continued till the terrors of mankind were changed to still more terrible objects, by thunder and lightning breaking the gloom, and bringing on such a shower of hail, as no history of human calamities

could equal. These hail-stones were of a bluish colour; and some of them weighed not less than an hundred pounds. A noisome vapour of sulphur attended the storm. All the birds and beasts of the country were entirely destroyed. Numbers of the human race suffered the same fate. But what is still more extraordinary, the fishes found no protection from their native element; but were equal sufferers in the general calamity.

These, however, are terrors that are seldom exerted in our mild climates. They only serve to mark the page of history with wonder; and stand as admonitions to mankind, of the various stores of punishment in the hands of the Deity, which his power can treasure up, and his mercy can suspend.

In the temperate zones, therefore, meteors are rarely found thus terrible; but between the tropic, and near the poles, they assume very dreadful and various appearances. In those inclement regions, where cold and heat exert their chief power, meteors seem peculiarly to have fixed their residence. They are seen there in a thousand terrifying forms, astonishing to Europeans, yet disregarded by the natives, from their frequency. The wonders of air, fire, and water, are there combined, to produce the most tremendous effects; and to sport with the labours and apprehensions of mankind. Lightnings, that flash without noise; hurricanes, that tear up the earth; clouds, that all at once pour down their contents, and produce an instant deluge; mock suns, northern lights, that illuminate half the hemisphere; circular rainbows; halos; fleeting balls of fire; clouds, reflecting back the images of things on earth, like mirrors; and water-spouts, that burst from the sea, to join with the mists, that hang immediately above them. These are but a part of the phænomena that are common in those countries; and from many of which, our own climate is, in a great measure, exempted.

The meteors of the torrid zone are different from those that are found near the polar circles: and it may readily be supposed, that in those countries where the sun exerts the greatest force in raising vapours of all kinds, there should be the greatest quantity of meteors. Upon the approach of the winter months, as they are called, under the line, which usually begin about May, the sky, from a fiery brightness, begins to be overcast, and the whole horizon seems wrapt in a muddy cloud. Mists and vapours still continue to rise; and the air, which so lately before was clear and elastic, now becomes humid, obscure, and stifling: the fogs become so thick, that the light of the sun seems in a manner excluded; nor would its presence be known, but for the intense and suffocating heat of its beams, which dart through the gloom, and, instead of dissipating, only serve to increase the mist. After this preparation, there follows an almost continual succession of thunder, rain, and tempests. During this dreadful season, the streets of cities flow like rivers; and the whole country wears the appearance of an ocean. The inhabitants often make use of this opportunity to lay in a stock of fresh water, for the rest of the year; as the same cause which pours down the deluge at one season, denies the kindly shower at another. The thunder which attends the fall of these rains, is much more terrible than that we are generally acquainted with. With us, the flash is seen at some distance, and the noise shortly after ensues; our thunder generally rolls on one quarter of the sky, and one stroke pursues another. But here it is otherwise; the whole sky seems illuminated with unremitted flashes of lightning; every part of the air seems productive of its own thunders; and every cloud produces its own shock. The strokes come so thick, that the inhabitants can scarce mark the intervals; but all is one unremitted roar of elementary

confusion. It should seem, however, that the lightning of those countries is not so fatal, or so dangerous, as with us; since, in this case, the torrid zone would be uninhabitable.

When these terrors have ceased, with which, however, the natives are familiar, meteors of another kind begin to make their appearance. The intense beams of the sun, darting upon stagnant waters, that generally cover the surface of the country, raise vapours of various kinds. Floating bodies of fire, which assume different names, rather from their accidental forms, than from any real difference between them, are seen without surprize. The draco volans, or flying dragon, as it is called; the ignis fatuus, or wandering fire; the fires of St. Helmo, or the mariner's light, are every where frequent; and of these we have numberless descriptions. "As I was riding in Jamaica," says Mr. Barham, "one morning from my habitation, situated about three miles north-west from Jago-de-la-Vega, I saw a ball of fire, appearing to me of the bigness of a bomb, swiftly falling down with a great blaze. At first I thought it fell into the town; but when I came nearer, I saw many people gathered together, a little to the southward, in the Savannah, to whom I rode up, to enquire the cause of their meeting: they were admiring, as I found, the ground's being strangely broke up and ploughed by a ball of fire; which, as they said, fell down there. I observed there were many holes in the ground; one in the middle of the bigness of a man's head, and five or six smaller round about it, of the bigness of one's fist, and so deep as not to be fathomed by such implements as were at hand. It was observed, also, that all the green herbage was burnt up, near the holes; and there continued a strong smell of sulphur near the place, for some time after."

Ulloa gives an account of one of a similar kind, at Quito. "About nine at night," says he, "a globe of fire appeared to rise from the side of the mountain Pichinca, and so large, that it spread a light over all the part of the city facing that mountain. The house where I lodged looking that way, I was surprized with an extraordinary light, darting through the crevices of the window-shutters. On this appearance, and the bustle of the people in the street, I hastened to the window, and came time enough to see it, in the middle of its career; which continued from west to south, till I lost sight of it, being intercepted by a mountain, that lay between me and it. It was round; and its apparent diameter about a foot. I observed it to rise from the sides of Pichinca; although, to judge from its course, it was behind that mountain where this congeries of inflammable matter was kindled. In the first half of its visible course it emitted a prodigious effulgence; then it began gradually to grow dim; so that, upon its disappearing behind the intervening mountain, its light was very faint."

Meteors, of this kind, are very frequently seen between the tropics; but they sometimes, also, visit the more temperate regions of Europe. We have the description of a very extraordinary one, given us by Montanari, that serves to shew to what great heights, in our atmosphere, these vapours are found to ascend. In the year 1676, a great globe of fire was seen at Bononia, in Italy, about three quarters of an hour after sun-set. It passed westward, with a most rapid course, and at the rate of not less than a hundred and sixty miles in a minute, which is much swifter than the force of a cannon-ball, and, at last, stood over the Adriatic sea. In its course it crossed over all Italy; and, by computation, it could not have been less than thirty-eight miles above the surface of the earth. In the whole line of its course, wherever it approached, the inhabitants below could distinctly hear it, with a hissing noise, resembling

resembling that of a fire-work. Having passed away to sea, towards Corfica, it was heard, at last, to go off with a most violent explosion, much louder than that of a cannon; and, immediately after, another noise was heard, like the rattling of a great cart upon a stony pavement; which was, probably, nothing more than the echo of the former sound. Its magnitude, when at Bononia, appeared twice as long as the moon, one way; and as broad the other; so that, considering its height, it could not have been less than a mile long, and half a mile broad. From the height at which this was seen, and there being no volcano, on that quarter of the world, from whence it came, it is more than probable that this terrible globe was kindled on some part of the contrary side of the globe, in those regions of vapours, which we have been just describing; and thus rising above the air, and passing, in a course opposite to that of the earth's motion, in this manner it acquired its amazing rapidity.

To these meteors, common enough southward, we will add one more of a very uncommon kind, which was seen by Ulloa, at Quito, in Peru; the beauty of which will, in some measure, serve to relieve us, after the description of those hideous ones preceding. "At day-break," says he, "the whole mountain of Pambamarca, where we then resided, was encompassed with very thick clouds; which the rising of the sun dispersed so far, as to leave only some vapours, too fine to be seen. On the side opposite to the rising sun, and about ten fathoms distant from the place where we were standing, we saw, as in a looking-glass, each his own image; the head being, as it were, the center of three circular rainbows, one without the other, and just near enough to each other as that the colours of the internal verged upon those more external; while round all was a circle of white, but with a greater space between. In this manner these circles were erected, like a mirror, before us; and as we moved, they moved, in disposition and order. But, what is most remarkable, though we were six in number, every one saw the phænomenon, with regard to himself, and not that relating to others. The diameter of the arches gradually altered, as the sun rose above the horizon; and the whole, after continuing a long time insensibly faded away. In the beginning, the diameter of the inward iris, taken from its last colour, was about five degrees and a half; and that of the white arch, which surrounded the rest, was not less than sixty-seven degrees. At the beginning of the phænomenon, the arches seemed of an oval or elliptical figure, like the disk of the sun; and afterwards became perfectly circular. Each of these was of a red colour, bordered with an orange; and the last bordered by a bright yellow, which altered into a straw colour, and this turned to a green; but, in all, the external colour remained red." Such is the description of one of the most beautiful illusions that has been ever seen in nature. This alone seems to have combined all the splendours of optics in one view. To understand the manner, therefore, how this phænomenon was produced, would require a perfect knowledge of optics; which it is not our present province to enter upon. It will be sufficient, therefore, only to observe, that all these appearances arise from the density of the cloud, together with its uncommon and peculiar situation, with respect to the spectator and the sun. It may be observed, that but one of these three rainbows was real, the rest being only reflections thereof. It may also be observed, that whenever the spectator stands between the sun and a cloud of falling rain, a rainbow is seen, which is nothing more than the reflection of the different coloured rays of light from the bosom of the cloud. If, for instance, we

take a glass globe, filled with water, and hang it up before us, opposite the sun, in many situations, it will appear transparent; but if it is raised higher, or sideways, to an angle of forty-five degrees, it will at first appear red; altered a very little higher, yellow; then green; then blue, then violet colour; in short, it will assume successively all the colours of the rainbow; but, if raised higher, still it will become transparent again. A falling shower may be considered as an infinite number of these little transparent globes, assuming different colours, by being placed at the proper heights. The rest of the shower will appear transparent, and no part of it will seem coloured; but such as are at angles of forty-five degrees from the eye, forty-five degrees upward, forty-five degrees on each side, and forty-five degrees downward, did not the plain of the earth prevent us. We, therefore, see only an arch of the rainbow, the lower part being cut off from our sight by the earth's interposition. However, upon the tops of very high mountains, circular rainbows are seen, because we can see to an angle of forty-five degrees downward, as well as upward, or sideways, and therefore we take in the rainbow's complete circle.

In those forlorn regions, round the poles, the meteors though of another kind, are not less numerous and alarming. When the winter begins, and the cold prepares to set in, the same misty appearance which is produced in the southern climates by the heat, is there produced by the contrary extreme. The sea smokes like an oven, and a fog arises, which mariners call the frost smoke. This cutting mist, commonly raises blisters on several parts of the body; and, as soon as it is wafted to some colder part of the atmosphere, it freezes to little icy particles, which are driven by the wind, and create such an intense cold on land, that the limbs of the inhabitants are sometimes frozen, and drop off.

There also, halos, or luminous circles round the moon, are oftener seen than in any other part of the earth, being formed by the frost smoke; although the air otherwise seems to be clear. A lunar rainbow also is often seen there, though somewhat different from that which is common with us; as it appears of a pale white, striped with grey. In these countries also the aurora borealis streams, with peculiar lustre, and variety of colours. In Greenland it generally arises in the east, and darts its sportive fires, with variegated beauty, over the whole horizon. Its appearance is almost constant in winter; and, at those seasons when the sun departs, to return no more for half a year, this meteor kindly rises to supply its beams, and affords sufficient light for all the purposes of existence. However, in the very midst of their tedious night, the inhabitants are not entirely forsaken. The tops of the mountains are often seen painted with the red rays of the sun; and the poor Greenlander from thence begins to date his chronology. It would appear whimsical to read a Greenland calendar, in which we might be told, that one of their chiefs, having lived forty days, died, at last, of a good old age; and that his widow continued for half a day to deplore his loss, with great fidelity, before she admitted a second husband.

The meteors of the day, in these countries, are not less extraordinary than those of the night; mock suns are often reflected upon an opposite cloud; and the ignorant spectator fancies that there are often three or four real suns in the firmament at the same time. In this splendid appearance the real sun is always readily known by its superior brightness, every reflection being seen with diminished splendour. The solar rainbow there is often seen different from ours. Instead of a pleasing variety of colours,

lours, it appears of a pale white, edged with a stripe of dusky yellow; the whole being reflected from the bosom of a frozen cloud.

But, of all the meteors which mock the imagination with an appearance of reality, those strange illusions that are seen there, in fine serene weather, are the most extraordinary and entertaining. "Nothing," says Krantz, "ever surprised me more, than, on a fine warm summer's day, to perceive the islands that lie four leagues west of our shore, putting on a form quite different from what they are known to have. As I stood gazing upon them, they appeared, at first, infinitely greater than what they naturally are; and seemed as if I viewed them through a large magnifying glass. They were not thus only made larger, but brought nearer to me. I plainly descried every stone upon the land, and all the furrows filled with ice, as if I stood close by. When this illusion had lasted for a while, the prospect seemed to break up, and a new scene of wonder to present itself. The islands seemed to travel to the shore, and represented a wood, or a tall cut hedge. The scene then shifted, and shewed the appearance of all sorts of curious figures; as ships with sails, streamers and flags; antique elevated castles, with decayed turrets; and a thousand forms, for which fancy found a resemblance in nature. When the eye had been satisfied with gazing, the whole groupe of riches seemed to rise in air, and at length vanish into nothing. At such times the weather is quite serene and clear; but compressed with such subtle vapours, as it is in very hot weather; and these appearing between the eye and the object, give it all that variety of appearances which glasses of different refrangibilities would have done." Mr. Krantz observes, that commonly a couple of hours afterwards, a gentle west wind and a visible mist follows, which puts an end to this *lusus naturæ*.

It were easy to swell this catalogue of meteors with the names of many others, both in our own climate and in other parts of the world. Such as falling stars, which are thought to be no more than unctuous vapours, raised from the earth to small heights, and continuing to shine till that matter which first raised and supported them, being burnt out, they fall back again to the earth, with extinguished flame. Burning spears, which are a peculiar kind of aurora borealis; bloody rains, which are said to be the excrements of an insect, that at that time has been raised into the air. Showers of stones, fishes, and ivy-berries, at first, no doubt, raised into the air by tempests in one country, and falling at some considerable distance, in the manner of rain, to astonish another. But omitting these, of which we know little more than what is thus briefly mentioned, we will give a description of a water-spout; a most surprising phenomenon; not less dreadful to mariners, than astonishing to the observers of nature.

These spouts are seen very commonly in the tropical seas, and sometimes in our own. Those seen by Tournefort, in the Mediterranean, he has described as follows. "The first of these," says this great botanist, "that we saw, was about a musket-shot from our ship. There we perceived the water began to boil, and to rise about a foot above its level. The water was agitated and whitish; and above its surface there seemed to stand a smoke, such as might be imagined to come from wet straw before it begins to blaze. It made a sort of a murmuring sound, like that of a torrent, heard at a distance, mixed, at the same time, with an hissing noise, like that of a serpent: shortly after we perceived a column of this smoke rise up to the clouds, at the same time whirling about with great rapidity. It appeared to be as thick as one's finger; and the

former found still continued. When this disappeared, after lasting for about eight minutes, upon turning to the opposite quarter of the sky, we perceived another, which began in the manner of the former; presently after a third appeared in the west; and instantly beside it still another arose. The most distant of these three could not be above a musket-shot from the ship. They all continued like so many heaps of wet straw set on fire, that continued to smoke, and to make the same noise as before. We soon after perceived each, with its respective canal, mounting up in the clouds, and spreading where it touched; the cloud, like the mouth of a trumpet, making a figure, to express it intelligibly, as if the tail of an animal were pulled at one end by a weight. These canals were of a whitish colour, and so tinged, as I suppose, by the water which was contained in them; for, previous to this, they were apparently empty, and of the colour of transparent glass. These canals were not straight, but bent in some parts, and far from being perpendicular, but rising in their clouds with a very inclined ascent. But what is very particular, the cloud to which one of them was pointed happening to be driven by the wind, the spout still continued to follow its motion, without being broken; and passing behind one of the others, the spouts crossed each other, in the form of a St. Andrew's cross. In the beginning they were all about as thick as one's finger, except at the top, where they were broader, and two of them disappeared; but shortly after, the last of the three increased considerably; and its canal, which was at first so small, soon became as thick as a man's arm, then as his leg, and at last thicker than his whole body. We saw distinctly, through this transparent body, the water, which rose up with a kind of spiral motion; and it sometimes diminished a little of its thickness, and again resumed the same; sometimes widening at top, and sometimes at bottom; exactly resembling a gut filled with water, pressed with the fingers, to make the fluid rise or fall; and I am well convinced, that this alteration in the spout was caused by the wind, which pressed the cloud, and impelled it to give up its contents. After some time its bulk was so diminished as to be no thicker than a man's arm again; and thus, swelling and diminishing, it at last became very small. In the end, I observed the sea which was raised about it to resume its level by degrees, and the end of the canal that touched it to become as small as if it had been tied round with a cord; and this continued till the light, striking through the cloud, took away the view. I still, however, continued to look, expecting that its parts would join again, as I had before seen in one of the others, in which the spout was more than once broken, and yet again came together; but I was disappointed, for the spout appeared no more."

Many have been the solutions offered for this surprising appearance. Mr. Buffon supposes the spout, here described, to proceed from the operation of fire, beneath the bed of the sea; as the waters at the surface are thus seen agitated. However, the solution of Dr. Stuart is not divested of probability; who thinks it may be accounted for by suction, as in the application of a cupping-glass to the skin.

Wherever spouts of this kind are seen they are extremely dreaded by mariners; for if they happen to fall upon a ship they most commonly dash it to the bottom. But, if the ship be large enough to sustain the deluge, they are at least sure to destroy its sails and rigging, and render it unfit for sailing. It is said that vessels of any force usually fire their guns at them, loaden with a bar of iron; and, if so happy as to strike them, the water is instantly seen

to fall from them, with a dreadful noise, though without any further mischief.

The more the sky is obscured with clouds, water-spouts, and the phænomena which accompany them, are the more easily observed.

M. de la Nux thinks, and perhaps with reason, that water-spouts are nothing but viscous portions of a cloud driven off by different whirlwinds, i. e. by the whirlings of the superior air sinking into the mass of vapours of which the whole cloud is composed.

What seems to prove that these water-spouts are composed of viscous parts, is the tenaciousness of their cohesion; for they make inflexions and curvatures in every direction, without breaking: If the matter of water-spouts was not viscous, how can we conceive that they should, without breaking, bend and obey the motion of the winds? If all the parts did not firmly adhere, the wind would dissipate them, or, at least, make them change their form. But, as the form, both of the large and small water-spouts, is uniformly the same, this is almost a certain indication of the viscous tenacity of the matter of which they are composed.

Thus the basis of the matter of water-spouts is a viscous substance contained in the clouds, and every water-spout is formed by a whirlwind of air pressing through the mass of vapours, and, by blowing up the inferior part of the cloud, pierces it, and descends with its covering of viscous matter. And, as complete water-spouts descend from the cloud to the surface of the sea, the water must boil and whirl at the place to which the end of the water-spout is directed; because the air blows from the extremity of the water-spout like the tube of a pair of bellows. The effects of this blowing upon the sea will augment, in proportion as the cylinder approaches the surface of the water; and, when the orifice of the tube enlarges, a greater quantity of air is permitted to escape, and the agitation of the water is, of course, increased.

M. de la Nux has seen water-spouts around the isle of Bourbon in the months of January, May, June, and October, i. e. in all seasons of the year. He has seen them in calm weather, and during the highest winds. These phænomena, however, may be said to be rare, and seldom appear but upon the sea; because the viscosity of the clouds can only proceed from the bituminous and greasy particles raised, by the heat of the sun and the winds, from the waters of the sea; and collected in the clouds near its surface. It is for this reason that water-spouts seldom appear on land, where there is not, as on the surface of the sea, a sufficient quantity of bituminous and oily particles to be exhaled by the action of the sun. They are sometimes, however, observed on land, and even at great distances from the sea; this effect may be produced, when viscous clouds have been rapidly driven by a violent wind from the sea toward the land. M. Grignon, in the month of June 1768, saw a well formed water-spout in Lorraine near Vauvillier, among the hills which are a continuation of the Vosges. It was about fifty fathoms high. Its form was that of a column, and it communicated with a large thick cloud. It was impelled by one or several winds, which made the water-spout turn rapidly; and it produced lightning and thunder. This water-spout continued seven or eight minutes only, and broke upon the base of the hill, which is from five to six hundred feet high.

We are at a loss whether we ought to reckon these spouts called typhons, which are sometimes seen at land, of the same kind with those so often described by mariners, at sea, as they seem to differ in several respects. That, for instance, observed at Hatfield, in Yorkshire, in 1687, as it is described

No. 54.

by a person who saw it, seems rather to have been a whirlwind than a water-spout. The season in which it appeared was very dry; the weather extremely hot, and the air very cloudy. After the wind had blown for some time, with considerable force; and condensed the black clouds one upon another, a great whirling of the air ensued; upon which the center of the clouds, every now and then, darted down, in the shape of a thick long black pipe; in which the relator could distinctly view a motion, like that of a screw, continually screwing up to itself, as it were, whatever it happened to touch. In its progress it moved slowly over a grove of young trees, which it violently bent, in a circular motion: Going forward to a barn, it in a minute stripped it of all the thatch, and filled the whole air with the same. As it came near the relator, he perceived that its blackness proceeded from a gyration of the clouds, by contrary winds, meeting in a point, or a center; and where the greatest force was exerted, there darting down, like an Archimedes's screw, to suck up all that came in its way. Another which he saw, some time after, was attended with still more terrible effects; levelling, or tearing up great oak trees, catching up the birds in its vortex, and dashing them against the ground. In this manner it proceeded, with an audible whirling noise, like that of a mill; and, at length, dissolved, after having done much mischief.

But we must still continue to suspend our assent as to the nature even of these land spouts; since they have been sometimes found to drop, in a great column of water, at once upon the earth, and produce an instant inundation, which could not readily have happened had they been caused by the gyration of a whirlwind only. Indeed, every conjecture regarding these meteors, seems to be entirely unsatisfactory. They sometimes appear in the calmest weather at sea; and, therefore, these are not caused by a whirlwind. They are always capped by a cloud: and, therefore, are not likely to proceed from fires at the bottom. They change place; and, therefore, suction seems impracticable. In short, we still want facts, upon which to build a rational theory; and, instead of knowledge, we must be contented with admiration. To be well acquainted with the appearances of Nature, even though we are ignorant of their causes, often constitutes the most useful wisdom.

Having thus gone through a particular description of the earth, let us now pause for a moment, to contemplate the great picture before us. The universe may be considered as the palace in which the Deity resides; and this earth as one of its apartments. In this, all the meaner races of animated nature mechanically obey him; and stand ready to execute his commands, without hesitation. Man alone is found refractory; he is the only being endowed with a power of contradicting these mandates: The Deity was pleased to exert superior power in creating him a superior being; a being endowed with a choice of good and evil; and capable, in some measure, of co-operating with his own intentions. Man, therefore, may be considered as a limited creature, endowed with powers imitative of those residing in the Deity. He is thrown into a world that stands in need of his help; and has been granted a power of producing harmony from partial confusion.

If, therefore, we consider the earth as allotted for our habitation, we shall find, that much has been given us to enjoy, and much to amend; that we have ample reasons for our gratitude, and still more for our industry. In those great outlines of nature,

to which art cannot reach, and where our greatest efforts must have been ineffectual, God himself has finished these with amazing grandeur and beauty. Our beneficent Father has considered these parts of nature as peculiarly his own; as parts which no creature could have skill or strength to amend: and therefore, made them incapable of alteration, or of more perfect regularity. The heavens, and the firmament, shew the wisdom, and the glory of the Workman. Astronomers, who are best skilled in the symmetry of systems, can find nothing there that they can alter for the better. God made these perfect, because no subordinate being could correct their defects.

When, therefore, we survey nature on this side, nothing can be more splendid, more correct, or amazing. We there behold a Deity residing in the midst of an universe, infinitely extended every way, animating all, and cheering the vacuity with his presence! We behold an immense and shapeless mass of matter, formed into worlds by his power, and dispersed at intervals, to which even the imagination cannot travel! In this great theatre of his glory, a thousand suns, like our own, animate their respective systems, appearing and vanishing at divine command. We behold our own bright luminary, fixed in the center of its system, wheeling its planets in times proportioned to their distances, and at once dispensing light, heat, and action. The earth also is seen with its twofold motion; producing, by the one, the change of seasons; and, by the other, the grateful vicissitudes of day and night. With what silent magnificence is all this performed! with what seeming ease! The works of art are exerted with interrupted force; and their noisy progress discovers the obstructions they receive: but the earth, with a silent steady rotation, successively presents every part of its bosom to the sun; at once imbibing nourishment and light from that parent of vegetation and fertility.

But not only provisions of heat and light are thus supplied, but its whole surface is covered with a transparent atmosphere, that turns with its motion, and guards it from external injury. The rays of the sun are thus broken into a genial warmth; and, while the surface is assisted, a gentle heat is produced in the bowels of the earth, which contributes to cover it with verdure. Waters also are supplied in healthful abundance, to support life,

and assist vegetation. Mountains arise, to diversify the prospect, and give a current to the stream. Seas extend from one continent to the other, replenished with animals, that may be turned to human support; and also serving to enrich the earth with a sufficiency of vapour. Breezes fly along the surface of the fields, to promote health and vegetation. The coolness of the evening invites to rest; and the freshness of the morning renews for labour.

Such are the delights of the habitation that has been assigned to man; without any one of these he must have been wretched; and none of these could his own industry have supplied. But while many of his wants are thus kindly furnished, on the one hand, there are numberless inconveniencies to excite his industry on the other. This habitation, though provided with all the conveniencies of air, pasturage, and water, is but a desert place, without human cultivation. The lowest animal finds more conveniencies in the wilds of nature, than he who boasts himself their lord. The whirlwind, the inundation, and all the asperities of the air, are peculiarly terrible to man, who knows their consequences, and, at a distance, dreads their approach. The earth itself, where human art has not pervaded, puts on a frightful gloomy appearance. The forests are dark and tangled; the meadows over-grown with rank weeds; and the brooks stray without a determined channel. Nature, that has been kind to every lower order of beings, has been quite neglectful with regard to him; to the savage uncontriving man the earth is an abode of desolation, where his shelter is insufficient, and his food precarious.

A world thus furnished with advantages on one side, and inconveniencies on the other, is the proper abode of reason, is the fittest to exercise the industry of a free and a thinking creature. These evils, which art can remedy, and prescience guard against, are a proper call for the exertion of his faculties; and they tend still more to assimilate him to his Creator. God beholds with pleasure, that being which he has made, converting the wretchedness of his natural situation into a theatre of triumph; bringing all the headlong tribes of nature into subjection to his will; and producing that order and uniformity upon earth, of which his own heavenly fabric is so bright an example.

A

NEW, COMPLETE, and UNIVERSAL BODY, or SYSTEM of
NATURAL HISTORY;

Being a Grand, Accurate and Extensive

Display of Animated Nature.

B O O K VII.

Containing the NATURAL HISTORY *of* MAN.

C H A P. I.

Of the Nature of M A N.

HAVING given an account of the Earth in general, and the advantages and inconveniencies with which it abounds, we shall now proceed to give the Natural History of Man. Though it is so much our interest to acquire an exact and thorough knowledge of ourselves, yet we are often less acquainted with the human, than with any other existence. Provided by nature with organs, calculated solely for our preservation, we never employ those organs but to receive foreign impressions; our only study is, to acquire a familiarity with external objects, and to exist out of ourselves. Too intent on multiplying the functions of our senses, and on enlarging the external bounds of our being, rarely do we make any use of that internal sense which reduces us to our true dimensions, and which abstracts from us whatever does not constitute a part of ourselves. It is by an exertion of this sense alone, however, that we can form a proper judgment of ourselves. But how shall it receive its full activity and extent? How shall the soul, in which it resides, be disengaged from all the illusions of the mind? Having lost the habit of employing it, it has remained inactive amidst the tumult of our corporeal sensations; it has been, as it were, dried up by the fire of our passions; the heart, the mind, the senses, have all co-operated against it.

Unalterable in its substance, and impassible by its essence, it still, however, continues the same. The splendor of its light has been overcast, but its power has not been diminished. It is less luminous; but its guidance is not the less certain. Let us then collect those rays, of which we are not yet deprived. The obscurity with which we are surrounded will decrease; and though the road may not be every where equally filled with light, we yet

shall have a torch that will prevent us from going astray.

The first, and indeed the most difficult step, which leads to the knowledge of ourselves, is, a distinct conception of the nature of the two substances that constitute our being. To say simply, that the one is unextended, immaterial and immortal; and that the other is extended, material and mortal, is only to deny of one thing, what we affirm of another. What knowledge is to be acquired from this mode of negation? Such private expressions can exhibit no real and positive idea; but to say, that we are certain of the existence of the former, and that the existence of the latter is less evident; that the substance of the one is simple, indivisible, and of one form, since it only manifests itself by a single modification, which is thought; that the other is less a substance than a subject, capable of receiving different forms, which bear a relation to those of our senses, but all as uncertain, all as variable, as the nature of the organs themselves: That is to say something; it is to ascribe to each such distinct and positive properties, as may lead us to an elemental knowledge of both, and to a comparison between them.

From the smallest reflection on the origin of our knowledge, it is easy, indeed, to perceive, that by comparison alone, we can acquire it. What is absolutely incomparable, is utterly incomprehensible; of this, God is the only instance we can adduce; he exceeds all comprehension, because he is above all comparison. But whatever is capable of being compared, whatever we can contemplate in different lights, whatever we can consider relatively, may always conclude to come within the sphere of our understanding. The more subjects of comparison, the more different views, or particular appearances, we have for examining any object, the more methods there are for obtaining a knowledge of it, and the greater facility there is to combine those ideas which ought to direct our judgment.

The existence of the soul is demonstrated to us; or rather that existence and ourselves form but one and the same thing. To be and to think, are with us identical. This truth is within us, and it is more than intuitive; it is independent of our senses, of our imagination, of our memory, and of all our other relative faculties. The existence of our body, and of other external objects, is held in uncertainty by every unprejudiced reasoner; for what is that extension of length, breadth and depth, which we call our body, and which seems to be so much our own, but as it relates to our senses? What are even the material organs of those senses, but so many conformities with what affects them? And, with regard to our internal sense, our soul, has it any thing similar, any thing in common, with the nature of these external organs? Does the sensation excited in our soul by light or sound, resemble that tenuous matter, which seems to diffuse light, or even that tremulous undulation, which sound produces in the air? Our eyes and our ears have every necessary conformity with these matters, because those organs and matter itself, are, in effect, of the same nature. The sensation, however, which the soul experiences, has nothing similar, nothing analogous to it; and is not this a sufficient proof, that the nature of the soul is in reality different from that of matter?

It is a certain truth, then, that the internal sensation is altogether different from its cause; as also, that, if there are things which exist without us, they are in themselves totally different from what we conceive them to be. As the sensation therefore, bears no kind of resemblance to the thing which is the cause of it; does it not follow, that what excites our sensations is necessarily, and of its own nature, quite another thing than we imagine it? The extension which we perceive by our eyes, the impenetrability, of which we receive an idea by the touch, all those qualities, whose various combinations constitute matter, are of a doubtful existence; since our inward sensation, and what it represents to us as extension, impenetrability, &c. are no wise extended or impenetrable, and have not even the smallest affinity with those qualities.

If it is observed, that the soul is often affected with sensations, during sleep, and the absence of every object; and that these sensations are sometimes very different from those, which it has experienced by the presence of the same objects, through the channel of the senses; does it not lead to a belief, that this presence of objects is not necessary to the existence of our sensations; and that, of consequence, our soul and we may exist singly, and independently of those objects? During sleep, and after death, for example, our body exists; it has even all that kind of existence of which it is susceptible, and is the same as it was before; yet the soul no longer perceives this existence of the body; it has ceased to be with regard to us. The question is therefore, whether a thing which can exist, and afterwards not exist; whether a thing, which affects us in a manner altogether different from what it is, or what it has been, may yet be a reality of indubitable existence.

That something exists without us, we may believe, though not with a positive assurance; whereas of the real existence of every thing within us, we have a certainty. That of our soul therefore, is incontestible, and that of our body seems doubtful; because matter may be only a mode of the soul, one of its methods of perception. Our soul perceives by this method, when we are awake; it perceives by another method, when we are asleep; after death, it will perceive by a method far more different still: and whatever is, in the present state, the cause of its sensations, matter in general may well cease to exist,

with respect to it, when all communication with its own body is cut off.

But let us admit this existence of matter; let us, though it is impossible to demonstrate it, adopt the common opinion, and say, that it even exists as it appears to our senses, by comparing the soul with any material object, we shall then find differences so great, and contrarieties so strongly marked, that every doubt will instantly vanish of its being of a nature totally different, and of an order infinitely superior.

Our soul has but one form, which is very simple, very general, and very permanent. Thought is this form; otherwise than by thought, it is impossible for us to perceive the soul. This form has nothing in it of division and extension, nothing of impenetrability, or matter; of consequence, therefore, our soul, the subject of this form, is indivisible, and immaterial. Our body on the contrary, and all other bodies, have many forms. Every one of these is compounded, divisible, variable, perishable, and has a relation to the different organs, through which we perceive them. Our body, therefore, any things material, having nothing permanent, nothing real, nothing general, by which we may fix our researches, and attain a certain knowledge of them. A blind man has no idea of that part of a material object, which represents to us the form of bodies; a leper, whose skin has lost the sense of feeling, is denied all the ideas which arise from the touch; and a deaf man has no knowledge of sounds. Let these three modes of sensation be successively destroyed, in a man whom nature has provided with them, and the soul will exist in its wonted vigour; its internal functions will subsist, and thought will still manifest itself within him. On the other hand, divest matter of all its qualities; strip it of colour, of strength, of solidity, and of every other property which has any relation to our senses, and the consequence will be its annihilation. Our soul therefore, is unperishable, but matter may, and will perish.

Thus it is with all the other faculties of our soul, compared with those of our body, and with the most essential properties of any kind of matter. As the soul wills and commands, so the body obeys in every thing within its power. The soul forms, at pleasure, an intimate union with any object: neither distance, nor magnitude, nor figure, can obstruct this union, when the soul inclines to it; it is effected, and effected in an instant. The body can form no union: whatever touches it too closely injures it; it requires a long time in order to approach another body; it every where meets with some resistance, with some obstacle; from the smallest shock, its motion ceases. Is will then nothing more than a corporeal movement; and is contemplation but a simple contact? How could this contact take place upon a remote object, upon an abstracted subject? How could this movement be accomplished in an indivisible instant? Is it possible to have a conception of motion, without having a conception of space, and of time? Will, therefore, if it be a motion, is not a material one; and if the union of the soul to a particular object be a touch, a contact, is not this touch effected at a distance; is not this contact a penetration; qualities which are absolutely opposite to those of matter, and which of consequence cannot belong to an immaterial being?

But we have already dwelt too long on a subject, which by many will perhaps be considered as foreign to our purpose. Ought Considerations on the Soul to find a place in a system of Natural History? Why, after all, retrench from the Natural History of Man, the history of the noblest part of his being? Why thus preposterously debase him, and, as it were, force us to consider him merely as an animal; while
in

in reality, he is of a nature so different and distinguished, so superior to that of the brutes, that he who confounds them must be immersed in ignorance as themselves?

In comparing man with an animal, we find in both a body, an organized substance, senses, flesh, blood, motion, and a multitude of other resemblances. But these resemblances, are all external, and not sufficient to justify a decision, that the human and the animal natures are similar. In order to form a proper judgment of the nature of each, we ought to have as distinct a knowledge of the internal qualities of an animal, as we have of our own. As the knowledge, however, of what passes within an animal is impossible to be attained; as we know not of what order and kind its sensations may be, in relation to those of man; we may judge solely from a comparison of the effects of the natural operations of both.

Let us, then, take a view of these effects; and, while we admit of all the particular resemblances, limit our investigation to the most general differences. It will be allowed, that the most stupid man is able to manage the most acute animal: he governs it, and renders it subservient to his purposes; and this, not so much on account of his strength or skill, as of the superiority of his nature, and of his having a rational scheme, system of action, and method by which he compels the animals to obey him. We do not find, that the strongest and most expert animals give law to the others, and hold them in servitude. The stronger, it is true, devour the weaker; but this action implies no more than an urgent necessity, or a rage of appetite; a quality very different from that which is capable of producing a series of actions, all tending to the same end. Did animals enjoy this faculty, should we not see some of them assume dominion over others, and oblige them to furnish them with food, to watch over them and to attend them when sick or wounded? Now, throughout the creation of animals, there is no vestige of such subordination; no appearance that one of them knows, or is sensible of, the superiority of his own nature over that of others. It follows, then, that they must all be considered as of one nature; as also, that the nature of man is not only highly superior to that of any animal, but also entirely different from it.

Man, by an outward sign, indicates what passes within him; he communicates his sentiments by speech, which is a sign common to the whole human species. The savage and the civilized man have the same power of utterance; they both speak naturally, and speak so as to be understood. No animal is endowed with this expression of thought; nor is it a defect owing, as is commonly imagined, to the want of proper organs. Anatomists have found the tongue of an ape to be as perfect as that of a man. The ape, therefore, if he had thought, it would have speech; and if its thought had aught analogous to ours, this speech would have an analogy to ours also. Supposing its thoughts were only the thoughts of an ape, it still would hold some kind of discourse with other apes; a circumstance, of which we should certainly have heard, had it been endowed with the powers of speech. So far, then, is the ape from having any thought like ours, that it has not even any order or series of thoughts of its own. Nothing regular, nothing connected, passes within it; for as it expresses nothing by combined and settled signs, so it is, of consequence, void of thought, even in the lowest degree.

So true it is, that it is from no organical defect, animals are denied the gift of speech, that we know several species of them which may be taught to pronounce words, and even repeat sentences of some length. Perhaps, were we to take the trouble to

teach them, many others might be found capable of articulating particular sounds; but to make them conceive the idea which such sounds denote, is an impracticable task. They seem to repeat and even to articulate them, merely as an echo, or an artificial machine, would repeat or articulate. It is not in the mechanical powers, or the material organs, but in the intellectual faculty, in thought, that they are deficient.

As all language supposes a chain of thought, it is on this account that animals have none; for, even allowing something in them which resembles our first apprehensions, our most gross and mechanical sensations, they still will be found incapable of forming that association of ideas, which can alone produce reflection; and in this, be it remarked, consists the essence of thought. To this inability of connecting ideas, it is owing, that they are destitute of thought and speech; as also, that they neither can invent nor improve any thing. Were they endowed with the power of reflection, even in the most subordinate degree, they would be capable of making some kind of proficiency, and would acquire more industry: the modern beaver would build with more art and solidity than the ancient; and the bee would daily be adding new improvements to its cell. If we suppose this cell as perfect already as it can be, we ascribe to the insect an intelligence superior to our own; an intelligence whereby it could discern at once the last degree of perfection to which its work might be carried; while we ourselves are for ever in the dark as to this degree, and stand in need of much reflection, time and practice, in order to perfect even one of our most trivial arts.

Whence can arise that uniformity we observe in all the works of animals? Why does each species invariably perform the same actions in the same manner? And why does not one individual perform them better or worse than another? Can there be a stronger proof that their operations are merely the effects of mechanism and materiality; evidently as it follows, that if they possessed the smallest spark of that light which is inherent in us, their works would display variety at least, if they did not display perfection; and that one individual of the same species would, in some of its performances, do something a little different from what another had done? But this is far from being the case. One plan of action is common to the whole species, and whoever would attribute a soul to animals, must of necessity, allow but one to each species. Of this soul each individual would be an equal partaker; and as thereby it would be divisible, it would consequently be material, and of a nature widely different from ours.

Why, on the other hand, are our productions and performances so various and so diversified? Why is a servile imitation more troublesome to us than an original design? It is because our soul is our own; because it is independent on that of another; because we have nothing in common with our species, but the substance of our body; and because, in effect, our resemblance to animals is confined to the lowest of our faculties.

Were internal sensations annexed to matter, and dependent on the corporeal organs, should we not see as remarkable differences in the works of animals of the same species, as in those of men? Would not those which were the most happily organized, build their nests, contrive their cells, or lay their eggs, in a manner more solid, more elegant and more commodious? And would not some individual, possessed of a superior genius, take an opportunity to manifest that superiority in this very mode? Now nothing of this very kind has ever happened; and therefore the corporeal organs, however perfect or imperfect, have no influence on the nature of

the internal sensations. Hence may we conclude, that animals have no sensations of this kind; that such sensations have no connection with matter, no dependence, in their nature, on the corporeal organs; and that, of consequence, there must be a substance within us, different from matter, which is at once the subject and the cause that produces and receives those sensations.

But these proofs of the immateriality of the soul may be carried farther still. In all the works of nature, there are imperceptible gradations maintained. This truth, which in no other instance admits of exception, is here expressly contradicted; between the faculties of man, and those of the most perfect animal, the distance is infinite; an evident proof, that man is of a different nature, and that of himself he forms a distinct class, between which and that of animals, there is an immense chasm. If man belonged to the class of animals, there would be a certain number of beings in nature less perfect than the former, and more perfect than the latter, in order to complete the gradation of man to the monkey. But this is not the case; the transition is immediate from the thinking being to the material being; from intellectual power to mechanical force; from order and design to blind motion; from reflection to appetite.

To the ingenuous enquirer after truth more than enough has been here advanced, as demonstrative of the excellency of our nature, and of the immense distance which the Creator has placed between man and the brute. The former is a rational being, the latter a being devoid of reason. And as there is no medium between the positive and the negative; as there are no intermediate beings between the rational being, and the being devoid of reason; it is evident, that man is of a nature entirely different from that of the animal; that all the resemblance he bears to it is merely external; and that to judge of him by this resemblance, is to allow ourselves to be deceived by appearance, and wilfully to shut our eyes against that light, by which we ought to distinguish it from reality.

Having thus considered man as to his internal properties, we shall now proceed to examine his external ones, and to give the history of his body. After taking a view of the different stages of his life, we shall conduct him to the period when he must be separated from that body, and then resign him to the common mass of matter to which he belongs.

CHAP. II.

The Infancy of MAN.

IN surveying the various classes of animals, and examining their strength, their beauty, or their structure, we find man possesses most of those advantages united, which the rest enjoy partially. Infinitely superior to all others in the powers of the understanding, he is also superior to them in the fitness and proportions of his form. He would, indeed, have been one of the most miserable beings upon earth, if with a sentient mind he was so formed as to be incapable of obeying its impulse; but Nature has otherwise provided; as with the most extensive intellects to command, she has furnished him with a body the best fitted for obedience.

In infancy, however, that mind, and this body, form the most helpless union in all animated nature; and, if any thing can give us a picture of complete imbecillity, it is a man when just come into the world. The infant just born stands in need of all things, without the power of procuring any.

The lower races of animals, upon being produced, are active, vigorous, and capable of self-support; but the infant is obliged to wait in helpless expectation; and its cries are its only aid to procure subsistence.

An infant just born may be said to come from one element into another; for from the watery fluid in which it was surrounded, it now immerses into air; and its first cries seem to imply how greatly it regrets the change. How much longer it could have continued in a state of almost total insensibility, in the womb, is impossible to tell; but it is very probable that it could remain there some hours more. In order to throw some light upon this subject, Mr. Buffon so placed a pregnant bitch as that her puppies were brought forth in warm water, in which he kept them above half an hour at a time. However, he saw no change in the animals, thus newly brought forth; they continued the whole time vigorous; and, during the whole time, it is very probable that the blood circulated through the same channels through which it passed while they continued in the womb.

Almost all animals have their eyes closed, for some days after being brought into the world. The infant opens them the instant of its birth. However, it seems to keep them fixed and idle; they want that lustre which they acquire by degrees; and if they happen to move, it is rather an accidental gaze than an exertion of the act of seeing. The light alone seems to make the greatest impression upon them. The eyes of infants are sometimes found turned to the place where it is strongest; and the pupil is seen to dilate and diminish, as in grown persons, in proportion to the quantity it receives. But still, the infant is incapable of distinguishing objects; the sense of seeing, like the rest of the senses, requires an habit before it becomes any way serviceable. All the senses must be compared with each other, and must be made to correct the defects of one another, before they can give just information. It is probable, therefore, that if the infant could express its own sensations, it would give a very extraordinary description of the illusions which it suffers from them. The sight might, perhaps, be represented as inverting objects, or multiplying them; the hearing, instead of conveying one uniform tone, might be said to bring up an interrupted succession of noises; and the touch apparently would divide one body into as many as there are fingers that grasped it. But all these errors are lost in one common confused idea of existence; and it is happy for the infant, that it then can make but very little use of its senses, when they could serve only to bring it false information.

If there be any distinct sensations, those of pain seem to be much more frequent and stronger than those of pleasure. The infant's cries are sufficient indications of the uneasinesses it must at every interval endure; while, in the beginning, it has got no external marks to testify its satisfactions. It is not till after forty days that it is seen to smile; and not till that time also, the tears begin to appear, its former expressions of uneasiness being always without them. As to any other marks of the passions, the infant being as yet almost without them, it can express none of them in its visage; which, except in the act of crying and laughing, is fixed in a settled serenity. All the other parts of the body seem equally relaxed and feeble: its motions are uncertain, and its postures without choice; it is unable to stand upright; its hams are yet bent, from the habit which it received from its position in the womb; it has not strength enough in its arms to stretch them forward, much less to grasp any thing with its hands; it rests just in the posture it is laid; and, if abandoned, must continue in the same position.

Never-

Nevertheless, though this be the description of infancy among mankind in general, there are countries, and races, among whom infancy does not seem marked with such utter imbecillity, but where the children, not long after they are born, appear possessed of a greater share of self-support. The children of Negroes have a surprising degree of this premature industry: they are able to walk at two months; or, at least, to move from one place to another: they also hang to the mother's back without any assistance, and seize the breast over her shoulder, continuing in this posture till she thinks proper to lay them down. This is very different in the children of our countries, that seldom are able to walk under a twelvemonth.

The skin of children newly brought forth, is always red, proceeding from its transparency, by which the blood beneath appears more conspicuous. Some say that this redness is greatest in those children that are afterwards about to have the finest complexions; and it appears reasonable that it should be so, since the thinnest skins are always the fairest. The size of a new-born infant is generally about twenty inches, and its weight about twelve pounds. The head is large, and all the members delicate, soft, and puffy. These appearances alter with its age; as it grows older, the head becomes less in proportion to the rest of the body; the flesh hardens: the bones that before birth grew very thick in proportion, now lengthen by degrees, and the human figure more and more acquires its due dimensions. In such children, however, as are but feeble or sickly, the head always continues too big for the body; the heads of dwarfs being extremely large in proportion.

Infants, when newly born, pass most of their time in sleeping, and awake with crying, excited either by sensations of pain, or of hunger. Man, when come to maturity, but rarely feels the want of food, as eating twice or thrice in the four and twenty hours is known to suffice the most voracious: but the infant may be considered as a little glutton, whose only pleasure consists in its appetite; and this, except when it sleeps, it is never easy without satisfying. Thus Nature has adapted different desires to the different periods of life; each as it seems most necessary for human support or succession. While the animal is yet forming, hunger excites it to that supply which is necessary for its growth; when it is completely formed, a different appetite takes place, that incites it to communicate existence. These two desires take up the whole attention at different periods, but are very seldom found to prevail strongly together in the same age; one pleasure ever serving to repress the other: and, if we find a person of full age, placing a principal part of his happiness in the nature and quantity of his food, we have strong reasons to suspect, that with respect to his other appetites, he still retains a part of the imbecillity of his childhood.

It is extraordinary, however, that infants, who are thus more voracious than grown persons, are nevertheless more capable of sustaining hunger. We have several instances, in accidental cases of famine, in which the child has been known to survive the parent; and seen clinging to the breast of their dead mother. Their little bodies also, are more patient of cold; and we have similar instances of the mother's perishing in the snow, while the infant has been found alive beside her. However, if we examine the internal structure of infants, we shall find an obvious reason for both these advantages. Their blood-vessels are known to be much larger than in adults; and their nerves much thicker and softer: thus, being furnished with a more copious quantity of juices, both of the nervous and sanguinary kinds, the infant finds a temporary sustenance

in this superfluity, and does not expire till both are exhausted. The circulation also being larger and quicker, supplies it with proportionable warmth, so that it is more capable of resisting the accidental rigours of the weather.

The first nourishment of infants is well known to be the mother's milk; and, what is remarkable, the infant has milk in its own breasts, which may be squeezed out by compression: this nourishment becomes less grateful as the child gathers strength; and perhaps, also, more unwholesome. However, in cold countries, which are unfavourable to propagation, and where the female has seldom above three or four children at the most, during her life, she continues to suckle the child for four or five years together. In this manner the mothers of Canada and Greenland are often seen suckling two or three children, of different ages, at a time.

The life of infants is very precarious, till the age of three or four, from which time it becomes more secure; and when a child arrives at its seventh year, it is then considered as a more certain life, as Mr. Buffon asserts, than at any other age whatever. It appears, from Simpson's Tables, that of a certain number of children born at the same time, a fourth part are found dead, at the end of the first year; more than two thirds at the end of the second; and, at least, half, at the end of the third: so that those who live to be above three years old, are indulged a longer term than half the rest of their fellow-creatures. Nevertheless, life, at that period, may be considered as mere animal existence; and rather a preparation for, than an enjoyment of, those satisfactions, both of mind and body, that make life of real value: and hence it is more natural for mankind to deplore a fellow-creature, cut off in the bloom of life, than one dying in early infancy. The one, by living up to youth, and thus wading through the disadvantageous parts of existence, seems to have earned a short continuance of its enjoyments; the infant, on the contrary, has served but a short apprenticeship to pain; and, when taken away, may be considered as rescued from a long continuance of misery.

There is something very remarkable in the growth of the human body. The embryo in the womb continues to increase still more and more, till it is born. On the other hand, the child's growth is less every year till the time of puberty, when it seems to start up of a sudden. Thus, for instance, the embryo, which is an inch long, in the first month, grows but one inch and a quarter in the second; it then grows one and a half in the third; two and a half in the fourth; and in this manner it keeps increasing, till in the last month of its continuance, it is actually found to grow four inches; and, in the whole, about eighteen inches long. But it is otherwise with the child when born: if we suppose it eighteen inches at that time, it grows, in the first year, six or seven inches; in the second year, it grows but four inches; in the third year about three; and so on, at the rate of about an inch and a half or two inches, each year, till the time of puberty, when Nature seems to make one great last effort, to complete her work, and unfold the whole animal machine.

The growth of the mind in children seems to correspond with that of the body. The comparative progress of the understanding is greater in infants than in children of three or four years old. If we only reflect a moment on the amazing acquisitions that an infant makes in the first and second years of life, we shall have much cause for wonder. Being sent into a world where every thing is new and unknown, the first months of life are spent in a kind of torpid amazement; an attention distracted by the multiplicity of objects that press to

be known. The first labour, therefore, of the little learner is, to correct the illusions of the senses, to distinguish one object from another, and to exert the memory, so as to know them again. In this manner a child of a year old has already made a thousand experiments; all which it has properly ranged, and distinctly remembers. Light, heat, fire, sweets, and bitters, sounds soft or terrible, are all distinguished at the end of a very few months. Besides this, every person the child knows, every individual object it becomes fond of, its rattles, or its bells, may be all considered as so many new lessons to the young mind, with which it has not become acquainted, without repeated exertions of the understanding. At this period of life, the knowledge of every individual object cannot be acquired without the same effort which, when grown up, is employed upon the most abstract idea: every thing the child hears or sees, all the marks and characters of nature, are as much unknown, and require the same attention to attain, as if the reader were set to understand the characters of an Ethiopic manuscript: and yet we see in how short a time the little student begins to understand them all, and to give evident marks of early industry.

It is very amusing to pursue the young mind, while employed in its first attainments. At about a year old, the same necessities that first engaged its faculties, increase, as its acquaintance with nature enlarges. Its studies, therefore, if we may so express it, are no way relaxed; for having experienced what gave pleasure at one time, it desires a repetition of it from the same object; and, in order to obtain this, that object must be pointed out: here, therefore, a new necessity arises, which, very often, neither its little arts nor importunities can remove; so that the child is at last obliged to set about naming the objects it desires to possess or avoid. In beginning to speak, which is usually about a year old, children find a thousand difficulties. It is not without repeated trials that they come to pronounce any one of the letters; nor without an effort of the memory, that they can retain them. For this reason, we frequently see them attempting a sound which they had learned, but forgot; and when they have failed, their attempt is often attended with apparent confusion. The letters soonest learned, are those which are most easily formed; thus A and B require an obvious disposition of the organs, and their pronunciation is consequently soon attained. Z and R, which require a more complicated position, are learned with greater difficulty. And this may, perhaps, be the reason why the children in some countries speak sooner than in others; for the letters mostly occurring in the language of one country, being such as are of easy pronunciation, that language is of course more easily attained. In this manner the children of the Italians are said to speak sooner than those of the Germans; the language of the one being smooth and open; that of the other, crowded with consonants, and extremely guttural.

But be this as it will, in all countries, children are found able to express the greatest part of their wants by the time they arrive at two years old; and from the moment the necessity of learning new words ceases, they relax their industry. It is then that the mind, like the body, seems every year to make slow advances; and, in order to spur up attention, many systems of education have been contrived.

Almost every philosopher who has written on the education of children, has been willing to point out a method of his own, chiefly professing to advance the health, and improve the intellects at the same time. These are usually found to begin with finding nothing right in the common practice; and

by urging a total reformation. In consequence of this, nothing can be more wild or imaginary than their various systems of improvement. Some will have the children every day plunged in cold water, in order to strengthen their bodies; they will have them converse with the servants in nothing but the Latin language, in order to strengthen their minds; every hour of the day must be appointed for its own studies, and the child must learn to make these very studies an amusement; till about the age of ten or eleven it becomes a prodigy of premature improvement. Quite opposite to this, we have others, whom the courtesy of mankind also calls philosophers: and they will have the child learn nothing till the age of ten or eleven; at which the former has attained so much perfection; with them the mind is to be kept empty, until it has a proper distinction of some metaphysical ideas about truth; and the promising pupil is debarred the use of even his own faculties, lest they should conduct him into prejudice and error. In this manner, some men; whom fashion has celebrated for profound and fine thinkers, have given their hazarded and untried conjectures, upon one of the most important subjects in the world, and the most interesting to humanity. When men speculate at liberty upon innate ideas, or the abstracted distinctions between will and power, they may be permitted to enjoy their systems at pleasure, as they are harmless, although they may be wrong; but when they alledge that children are to be every day plunged in cold water, and, whatever be their constitution, indiscriminately inured to cold and moisture; that they are to be kept wet in the feet, to prevent their catching cold; and never to be corrected when young, for fear of breaking their spirits when old; these are such noxious errors, that all reasonable men should endeavour to oppose them. Many have been the children whom these opinions began in speculation, have injured or destroyed in practice.

If any system be therefore necessary, it is one that would serve to shew, a very plain point; that very little system is necessary. The natural and common course of education is in every respect the best: We mean that in which the child is permitted to play among its little equals; from whose similar instructions it often gains the most useful stores of knowledge. A child is not idle because it is playing about the fields, or pursuing a butterfly; it is all this time storing its mind with objects, upon the nature, the properties, and the relations of which future curiosity may speculate.

It is a vain task to try to make a child's learning its amusement; nor would it answer any good end were it actually attained. The child, as was said, ought to have its share of play, and it will be benefited thereby; and for every reason also, it ought to have its share of labour. The mind, by early labour, will be thus accustomed to fatigues and subordination; and whatever be the person's future employment in life, he will be better fitted to endure it: he will be thus enabled to support the drudgeries of office, with content; or to fill up the vacancies of life with variety. The child, therefore, should by times be put to its duty; and be taught to know, that the task is to be done, or the punishment to be endured. We do not object against alluring it to duty by reward; but we well know, that the mind will be more strongly stimulated by pain; and both may, upon some occasions, take their turn to operate. In this manner, a child, by playing with its equals abroad, and labouring with them at school, will acquire more health and knowledge than by being bred up under the wing of any speculative system-maker; and will be thus qualified for a life of activity and obedience. It is true, indeed, that when educated in this manner, the boy may not be

so seemingly sensible and forward as one bred up under solitary instruction; and, perhaps, this early forwardness is more engaging than useful. It is well known, that many of those children who have been such prodigies of literature before ten, have not made an adequate progress to twenty. It should seem, that they only began learning manly things before their time; and, while others were busied in picking up that knowledge adapted to their age and curiosity, these were forced upon subjects unsuited to their years; and, upon that account alone, appearing extraordinary. The stock of knowledge in both may be equal; but with this difference, that each is yet to learn what the other knows.

But whatever may have been the acquisitions of children at ten or twelve, their greatest, and most rapid progress, is made when they arrive near the age of puberty. It is then that all the powers of nature seem at work in strengthening the mind, and completing the body; the youth acquires courage, and the virgin modesty; the mind, with new sensations, assumes new powers; it conceives with greater force, and remembers with greater tenacity. About this time, therefore, which is various in different countries, more is learned in one year than in any two of the preceding: and on this age, in particular, the greatest weight of instruction ought to be thrown.

CHAP. IV. Of PUBERTY.

IT is a common saying, that the season of youth is the season of pleasures: but this can only be true in savage countries, where but little preparation is made for the perfection of human nature; and where the mind has but a very small part in the enjoyment. It is otherwise in those places where nature is carried to the highest pitch of refinement, in which this season of the greatest sensual delight is wisely made subservient to the succeeding, and more rational one of manhood. Youth, with us, is but a scene of preparation; a drama, upon the right conduct of which all future happiness is to depend. The youth who follows his appetites, too soon seizes the cup, before it has received its best ingredients; and, by anticipating his pleasures, robs the remaining parts of life of their share; so that his eagerness only produces a manhood of imbecility, and an age of pain.

The time of puberty is different in various countries, and always more late in men than in women. In the warm countries, of India, the women are marriageable at nine or ten, and the men at twelve or thirteen. It is also different in cities where the inhabitants lead a more soft, luxurious life, from the country where they work harder, and fare less delicately. Its symptoms are seldom alike in different persons; but it is usually known by a swelling of the breasts in one sex, and a roughness of the voice in the other. At this season also, the women seem to acquire new beauty, while the men lose all that delicate effeminacy of countenance which they had when boys.

All countries, in proportion as they are civilized, or barbarous, improve, or degrade the nuptial satisfaction. In those miserable regions, where strength makes the only law, the stronger sex exerts its power, and becomes the tyrant over the weaker: while the inhabitant of Negroland is indolently taking his pleasure in the fields, his wife is obliged to till the grounds, that serve for their mutual support. It is thus in all barbarous countries, where the men throw all the laborious duties of life upon the

women; and, regardless of beauty, put the softer sex to those employments that must effectually destroy it.

But, in countries that are half barbarous, particularly wherever Mahometanism prevails, the men run into the very opposite extreme. Equally brutal with the former, they exert their tyranny over the weaker sex, and consider that half of the human creation as merely made to be subservient to the depraved desires of the other. The chief, and indeed the only aim of an Asiatic, is to be possessed of many women; and to be able to furnish a seraglio is the only tendency of his ambition. As the savage was totally regardless of beauty, he on the contrary, prizes it too highly; he excludes the person who is possessed of such personal attractions, from any share in the duties, or employments of life; and, as if willing to engross all beauty to himself, increases the number of his captives in proportion to the progress of his fortune. In this manner he vainly expects to augment his satisfactions, by seeking from many that happiness which he ought to look for in the society of one alone. He lives a gloomy tyrant, amidst wretches of his own making; he feels none of those endearments which spring from affection, none of those delicacies which arise from knowledge. His mistresses, being shut out from the world, and totally ignorant of all that passes there, have no arts to entertain his mind, or calm his anxieties; the day passes with them in fullen silence, or languid repose; appetite can furnish but few opportunities of varying the scene; and all that falls beyond it must be irksome expectation.

From this avarice of women, if we may so express it, has proceeded that jealousy and suspicion which ever attends the miser: hence those low and barbarous methods of keeping the women of those countries guarded, and of making, and procuring eunuchs to attend them. These unhappy creatures are of two kinds, the white and the black. The white are generally made in the country where they reside, being but partly deprived of the marks of virility; the black are generally brought from the interior parts of Africa, and are made entirely bare. These are chiefly chosen for their deformity: the thicker the lips, the flatter the nose, and the more black the teeth, the more valuable the eunuch; so that the vile jealousy of mankind here inverts the order of Nature; and the poor wretch finds himself valued in proportion to his deficiencies. In Italy, where this barbarous custom is still retained, and eunuchs are made, in order to improve the voice, the laws are severely aimed against such practice; so that being entirely prohibited, none but the poorest, and most abandoned of the people, still secretly practice it upon their children. Of those served in this manner, not one in ten is found to become a singer; but such is the luxurious folly of the times, that the success of one amply compensates for the failure of the rest. It is very difficult to account for the alterations which castration make in the voice, and the other parts of the body. The eunuch is shaped differently from others. His legs are of an equal thickness above and below; his knees weak; his shoulders narrow; and his beard thin and downy. In this manner his person is rendered more deformed; but his desires, as we are told, still continue the same; and actually, in Asia, some of them are found to have their seraglios, as well as their masters. Even in our country, we have an instance of a very fine woman's being married to one of them, whose appearance was the most unpromising; and, what is more extraordinary still, this couple continue perfectly happy in each other's society.

The mere necessities of life seem the only aim of
6 Z the

the savage; the sensual pleasures are the only study of the semi-barbarian; but the refinement of sensuality, by reason, is the boast of real politeness. Among the merely barbarous nations, such as the natives of Madagascar, or the inhabitants of Congo, nothing is desired so ardently as to prostitute their wives, or daughters, to strangers, for the most trifling advantages; they will account it a dishonour not to be among the foremost who are thus received into favour; on the other hand, the Mahometan keeps his wife faithful, by confining her person; and would instantly put her to death if he but suspected her chastity. With the politer inhabitants of Europe both these barbarous extremes are avoided; the woman's person is left free, and no constraint is imposed but upon her affections. The passion of love, which may be considered as the nice conduct of ruder desire, is only known, and practised in this part of the world; so that what other nations guard as their right, the more delicate European is contented to ask as a favour. In this manner, the concurrence of mutual appetite contributes to increase mutual satisfaction; and the power on one side of refusing, makes every blessing more grateful when obtained by the other. In barbarous countries, woman is considered merely as an useful slave; in such as are somewhat more refined, she is regarded as a desirable toy; in countries entirely polished, she enjoys juster privileges; the wife being considered as an useful friend, and an agreeable mistress. Her mind is still more prized than her person; and without the improvement of both, she can never expect to become truly agreeable; for her good sense alone can preserve what she has gained by her beauty.

Female beauty, as was said, is always seen to improve about the age of puberty; but, if we should attempt to define in what this beauty consists or what constitutes its perfection, we should find nothing more difficult to determine. Every country has its peculiar way of thinking, in this respect; and even the same country thinks differently, at different times. The ancients had a very different taste from what prevails at present. The eye-brows joining in the middle was considered as a very peculiar grace, by Tibullus, in the enumeration of the charms of his mistress. Narrow foreheads were approved of, and scarce any of the Roman ladies that are celebrated for their other perfections, but are also praised for the redness of their hair. The nose also of the Grecian Venus, was such as would appear at present an actual deformity; as it fell in a straight line from the forehead, without the smallest sinking between the eyes; without which we never see a face at present.

Among the moderns, every country seems to have peculiar ideas of beauty. The Persians admire large eye-brows, joining in the middle; the edges and corners of the eyes are tintured with black, and the size of the head is increased by a great variety of bandages, formed into a turban. In some parts of India, black teeth and white hair, are desired with ardour; and one of the principal employments of the women of Thibet, is to redden the teeth with herbs, and to make their hair white by a certain preparation. The passion for coloured teeth obtains also in China, and Japan; where, to complete their idea of beauty, the object of desire must have little eyes, nearly closed, feet extremely small, and a waist far from being shapely. There are some nations of the American Indians, that flatten the head of their children, by keeping them, while young, squeezed between two boards, so as to make the visage much larger than it would naturally be. Others flatten the head at top; and others make it as round as they possibly can. The inhabitants along the western coasts of Africa, have

a very extraordinary taste for beauty. A flat nose, thick lips, and a jet black complexion, are these the most indulgent gifts of Nature. Such, indeed, they are all, in some degree, found to possess. However, they take care, by art, to increase the natural deformities, as they should seem to us; and they have many additional methods of rendering the persons still more frightfully pleasing. The whole body and visage is often scarred with the variety of monstrous figures; which is not done without great pain, and repeated incision; and even sometimes, parts of the body are cut away. But it would be endless to remark the various arts which caprice, or custom, has employed to distort and disfigure the body, in order to render it more pleasing: in fact, every nation, how barbarous soever, seems unsatisfied with the human figure, as Nature has left it, and has its peculiar arts of heightening beauty. Painting, powdering, cutting, boring the nose, and the ears, lengthening the one, and depressing the other, are arts practised in many countries; and, in some degree, admired in all. These arts might have been at first introduced to hide epidemic deformities; custom, by degrees, reconciles them to the view; till, from looking upon them with indifference, the eye at length begins to gaze with pleasure.

CHAP. V.

Of the Age of MANHOOD.

THE human body attains its full height during the age of puberty; or, at least a short time after. Some young people cease growing at fourteen, or fifteen; while others continue their growth till two or three and twenty. During this period they are mostly of slender make, their thighs and legs small, and the muscular parts as yet unfilled: but, by degrees, the fleshy fibres augment; the muscles swell, and assume their figure; the limbs become more proportioned; and more round; and, before the age of thirty, the body, in men, has acquired its most perfect symmetry.

In women, the body attains this symmetry much sooner, as with them the age of maturity is much earlier: the muscles, and all the other parts being less strong, less compact, and less solid than those of men, they require less time in coming to perfection; and, as they are less in size, that size is sooner completed. Hence it is, that the persons of women are found to be as complete at twenty, as those of men are found to be at thirty.

The body of a well-shaped man ought to be square, the muscles expressed with boldness, and the lines of the face distinctly marked. In women superior elegance prevails; her form is more delicate and more smooth. Strength and majesty belong to the former, grace and softness are the peculiar embellishments of the latter.

In both, does each part even of their form declare their sovereignty over every living creature. Man supports his body erect; his attitude is that of command; and his face, which is turned towards the heavens, displays the dignity of his station. The image of his soul is painted in his countenance; and the excellence of his nature penetrates through the material form in which it is inclosed. His majestic port, his sedate, and resolute step, announce the superiority of his rank. He touches the earth only with his extremity; and beholds it as if at a disdainful distance. His arms are not given to him for pillars of support; nor, by rendering his hands callous against the ground, does he lose the delicacy of which the hand is the principal organ. The arms and hands are formed for very different purposes; they

they are formed to second every intention of his will, and to perfect the gifts of Nature.

When the soul is at rest, all the features of the visage seem settled in a state of profound tranquility. Their proportion, their union, their harmony, seem to mark the sweet serenity of the mind, and to give a true information of what passes within. When the soul, however, is excited, the human visage becomes a living picture; where the passions are expressed with as much delicacy as energy, where every motion is designed by some correspondent feature, where every impression anticipates the will, and betrays those hidden agitations, that he would often wish to conceal.

It is particularly in the eyes that the passions are painted; and in which we may most readily discover their beginning. The eye seems to belong to the soul more than any other organ; it seems to participate of all its emotions; as well the most soft and tender, as the most violent and tumultuous. These it not only receives, but transmits by sympathy; the observing the eye of one catches the secret fire from another; and thus the passion often becomes general.

Such persons as are short-sighted, labour under a particular disadvantage, in this respect. They are, in a manner, entirely cut off from the language of the eyes; and this gives an air of stupidity to the face, which often produces very unfavourable prepossessions. However intelligent we may find such persons, it is with difficulty that we renounce our former prejudices against them. In this manner, we are too much induced to judge of men by their physiognomy; and having perhaps, at first, caught up our judgments prematurely, they mechanically influence us all our lives after. This extends even to the very colour, or the cut of people's cloaths; and we should for this reason be careful, even in such trifling particulars, since an article so paltry as dress go to make up a part of the total judgment which those we converse with may form to our advantage.

The vivacity, or the languid motion of the eyes, gives the strongest marks to physiognomy; and their colour contributes still more to enforce the expression. The different colours of the eye are the dark-hazle, the light-hazle, the green, the blue, the grey, the whitish-grey, and also the red. These different colours arise from the different colours of the little muscles that serve to contract the pupils, and they are very often found to change colour with disorder, and with age.

Those most frequent are, the hazle and the blue, and very often, both these colours are found in the eyes of the same person. Those eyes which are called black, are only of the dark-hazle, which may be easily seen upon closer inspection; however, those eyes are reckoned the most beautiful where the shade is the deepest; and either in these, or the blue eyes, the fire, which gives to the eye its finest expression, is more distinguishable in proportion to the darkness of the tint. For this reason, the black eyes, as they are called, have the greatest vivacity; but, probably, the blue have the most powerful effects in beauty, as they reflect a greater variety of lights, being composed of more various colours.

This variety, which is found in the colour of the eyes, is peculiar to man, and one or two of the brute-creation: but, in general, the colour in any one individual is the same in all the rest. The eyes of oxen are brown; those of sheep of a water colour; those of goats are grey, &c. and it may also be, in general remarked, that the eyes of most white animals are red; thus the rabbit, the ferret, and, even in the human race, the white Moor, all have their eyes of a red colour.

Though the eye, when put into motion, seems to

be drawn on one side, yet it only moves round its centre; by which its coloured part moves nearer, or farther from the angle of the eye-lids, or is elevated or depressed. The distance between the eyes is less in man than in any other animal; and in some of these it is so great, that it is impossible that they should ever view the same object with both eyes at once, unless it be at a great distance.

Next to the eyes, the features, which most give a character to the face, are the eye-brows; which being in some measure, more apparent than the other features, are most readily distinguished at a distance.

The eye-lashes have an effect, in giving expression to the eye, particularly when long and close; they soften its glances, and improve its sweetness. Man and apes are the only animals that have eye-lashes both upon the upper and lower lids; all other animals want them on the lid below.

The eye-lids serve to guard the ball of the eyes and to furnish it with a proper moisture. The upper lids rise and fall; the lower has scarce any motion; and though their being moved depends on the will, yet it often happens that the will is unable to keep them open, when sleep, or fatigue, oppresses the mind. In birds, and amphibious quadrupeds, the lower lid alone has motion; fishes and insects have no eye-lids whatsoever.

The forehead makes a large part of the face, and a part which chiefly contributes to its beauty. It ought to be justly proportioned; neither too round nor too flat, neither too narrow nor too low, and the hair should come thick upon its extremities. It is known to every body how much the hair tends to improve the face; and how much the being bald serves to take away from beauty. The highest part of the head is that which becomes bald the soonest, as well as that part which lies immediately above the temples; and as for the hair under the temples, and at the back of the head, it is seldom known to fail.

Of all parts, or appendages of the body, the hair is that which is found most different, in different climates; and often, it not only contributes to mark the country, but also the disposition of the man. It is in general thickest where the constitution is strongest; and more glossy and beautiful where the health is most permanent. The ancients held the hair to be a sort of excrement, produced like the nails; the part next the root pushing out that immediately contiguous. But the moderns have found that every hair may be truly said to live, to receive nutriment, to fill and distend itself like the other parts of the body. The roots, they observe, do not turn grey sooner than the extremities, but the whole hair changes colour at once; and we have many instances of persons who have grown grey in one night's time.

The nose is the most prominent feature in the face; but, as it has scarce any motion, and that only in the strongest passions, it rather adds to the beauty, than to the expression of the countenance.

The form of this feature, and its advanced position, are peculiar to the human visage alone. Other animals, for the most part, have nostrils, with a partition between them; but none of them have an elevated nose. Apes themselves have scarce any thing else of this feature, but the nostrils; the rest of the feature lying flat upon the visage, and scarce higher than the cheek-bones.

The mouth and lips, next to the eyes, are found to have the greatest expression. The passions have great power over this part of the face; and the mouth marks its different degrees, by its different forms. The organ of speech still more animates this part, and give it more life than any other feature in the countenance. The ruby colour of the lips, and the
white

white enamel of the teeth, give it such a superiority over every other feature, that it seems to make the principal object of our regards. In fact, the whole attention is fixed upon the lips of the speaker; however rapid his discourse, however various the subject, the mouth takes correspondent situations; and deaf men have been often found to see the force of those reasonings which they could not hear, understanding every word as it was spoken.

The under-jaw in man possesses a great variety of motions; while the upper has been thought, by many, to be quite immoveable. However, that it moves in man, a very easy experiment will suffice to convince us. If we keep the head fixed with any thing between our teeth, the edge of a table for instance, and then open our mouths, we shall find that both jaws recede from it at the same time; the upper jaw rises, the lower falls, and the table remains untouched between them. The upper jaw has motion as well as the under; and, what is remarkable, it has its proper muscles behind the head, for thus raising and depressing it. Whenever, therefore, we eat, both jaws move at the same time, though very unequally; for the whole head moving with the upper jaw, of which it makes a part, its motions are thus less observable. In the human embryo, the under jaw is very much advanced before the upper. In the adult, it hangs a good deal more backward; and those whose upper and under row of teeth are equally prominent, and strike directly against each other, are what the painters call under-hung; and they consider this as a great defect in beauty. The under jaw in a Chinese face falls greatly more backward than with us; and the difference is half an inch, when the mouth is shut naturally. In instances of the most violent passion, the under jaw has often an involuntary quivering motion; and often also, a state of languor produces another, which is that of yawning. Every one knows how very sympathetic this kind of languid motion is; and that for one person to yawn, is sufficient to set all the rest of the company a yawning. A ridiculous instance of this was commonly practised upon the famous M'Laurin, one of the professors at Edinburgh. He was very subject to have his jaw dislocated; so that when he opened his mouth wider than ordinary, or when he yawned, he could not shut it again. In the midst of his harangues, therefore, if any of his pupils began to be tired of his lecture, he had only to gape or yawn, and the professor instantly caught the sympathetic affection; so that he thus continued to stand speechless, with his mouth wide open, till his servant, from the next room, was called in to set his jaw again.

When the mind reflects with regret upon some good unattained or lost, it feels an internal emotion, which acting upon the diaphragm, and that upon the lungs, produces a sigh; this when the mind is strongly affected, is repeated; sorrow succeeds these first emotions; and tears are often seen to follow: sobbing is the sigh still more invigorated; and lamentation, or crying, proceeds from the continuance of the plaintive tone of the voice, which seems to implore pity. There is yet a silent agony, in which the mind appears to disdain all external help, and broods over its distresses with gloomy reserve. This is the most dangerous state of mind; accidents or friendship may lessen the louder kinds of grief; but all remedies for this, must be had from within: and there, despair too often finds the most deadly enemy.

Laughter is a sound of the voice, interrupted and pursued for some continuance. The muscles of the belly, and the diaphragm, are employed in the slightest exertions; but those of the ribs are strongly agitated in the louder: and the head sometimes is thrown backward, in order to raise them with greater

ease. The smile is often an indication of kindness and good-will: it is also often used as a mark of contempt and ridicule.

Blushing proceeds from different passions; being produced by shame, anger, pride, and joy. Paleness is often also the effect of anger; and almost ever attendant on fright and fear. These alterations in the colour of the countenance, are entirely involuntary; all the other expressions of the passions, are, in some small degree, under controul; but blushing and paleness, betray our secret purposes; and we might as well attempt to stop them, as the circulation of the blood, by which they are caused.

The whole head, as well as the features of the face, takes peculiar attitudes from its passions: it bends forward, to express humility, shame, or sorrow; it is turned to one side, in languor, or in pity; it is thrown with the chin forward, in arrogance and pride; erect, in self-conceit, and obstinacy; it is thrown backwards in astonishment; and combines its motion to the one side, and the other, to express contempt, ridicule, anger, and resentment. Painters, whose study leads to the contemplation of external forms, are much more adequate judges of these, than any naturalist can be; and it is with these a general remark, that no one passion is regularly expressed on different countenances in the same manner; but that grief often sits upon the face like joy; and pride assumes the air of passion. It would be vain, therefore, in words, to express their general effect, since they are often as various as the countenances they sit upon; and in making this distinction nicely, lies all the skill of the physiognomist. In being able to distinguish what part of the face is marked by nature, and what by the mind; what part has been originally formed, and what is made by habit, constitutes this science, upon which the ancients so much valued themselves, and which we at present so little regard. Some, however, of the most acute men among us, have paid great attention to this art; and, by long practice, have been able to give some character of every person whose face they examined. Montaigne is well known to have disliked those men who shut one eye in looking upon any object; and Fielding asserts, that he never knew a person with a steady glavering smile, but he found him a rogue. However, most of these observations, tending to a discovery of the mind by the face, are merely capricious; and Nature has kindly hid our hearts from each other to keep us in good humour with our fellow creatures.

The parts of the head which give the least expression to the face, are the ears; and they are generally found hidden under the hair. These, which are immoveable, and make so small an appearance in man, are very distinguishable features in quadrupeds. They serve in them as the principal marks of the passion; the ears discover their joys or their terrors, with tolerable precision; and denote all their internal agitations. The smallest ears, in men, are said to be most beautiful; but the largest are found the best for hearing. There are some savage nations who bore their ears, and so draw that part down, that the tip of the ears are seen to rest upon their shoulders.

The strange variety in the different customs of men, appears still more extravagant in their manner of wearing their beards. Some, and among others the Turks, cut the hair off their heads, and let their beards grow. The Europeans, on the contrary, shave their beards, and wear their hair. The Negroes shave their heads in figures at one time, in stars at another, in the manner of friars; and still more commonly in alternate stripes; and their little boys are shaved in the same manner. The Talapoints, of Siam, shave the heads and the eye-brows of such children as are committed to their care.

Every nation seems to have entertained different prejudices, at different times, in favour of one part or another of the beard. Some have admired the hair upon the cheeks on each side; as we see with some low-bred men among ourselves, who want to be fine. Some like the hair lower down; some chuse it curled; and others like it strait. Some have cut it into a peak; and others shave all but the whisker. This particular part of the beard was highly prized among the Spaniards; till of late, a man without whiskers was considered as unfit for company; and where Nature had denied them, Art took care to supply the deficiency. We are told of a Spanish general who, when he borrowed a large sum of money from the Venetians, pawned his whisker, which he afterwards took proper care to release. Kingston assures us, that a considerable part of the religion of the Tartars consists in the management of their whiskers; and that they waged a long and bloody war with the Persians, declaring them infidels, merely because they would not give their whiskers the orthodox cut. The kings of Persia carried the care of their beards to a ridiculous excess, when they chose to wear them matted with gold thread; and even the kings of France of the first race, had them knotted and buttoned with gold. But of all nations, the Americans take the greatest pains in cutting their hair, and plucking their beards. The under part of the beard, and all but the whisker, they take care to pluck up by the roots, so that many have supposed them to have no hair naturally growing on that part: and even Linnæus has fallen into that mistake. Their hair is also cut into bands; and no small care employed in adjusting the whisker. In fact, we have a very wrong idea of savage finery; and are apt to suppose that, like the beasts of the forest, they rise, and are dressed with a shake: but the reverse is true; for no birth-night beauty takes more time or pains in the adorning her person, than they. When the Cherokee kings were over here, they were often three hours in dressing. They never would venture to make their appearance till they had gone through the tedious ceremonies of the toilet; they had their boxes of oil and ochre, their fat, and their perfumes, like the most effeminate beau, and generally took up four hours in dressing, before they considered themselves as fit to be seen. We must not, therefore, consider a delicacy in point of dress, as a mark of refinement, since savages are much more difficult in this particular, than the most fashionable or tawdry European. The more barbarous the people, the sonder of finery. In Europe, the lustre of jewels, and the splendor of the most brilliant colours, are generally given up to women, or to the weakest part of the other sex, who are willing to be contemptibly fine: but in Asia, these trifling fineries are eagerly sought after by every condition of men; and, as the proverb has it, we find the richest jewels in an Ethiop's ear. The passion for glittering ornaments, is still stronger among the absolute barbarians, who often exchange their whole stock of provisions, and whatever else they happen to be possessed of, with our seamen, for a glass bead, or a looking-glass.

Although fashions have arisen in different countries from fancy and caprice, these, when they become general, deserve examination. Mankind have always considered it as a matter of moment, and they will ever continue desirous of drawing the attention of each other, by such ornaments as mark the riches, the power, or the courage of the wearer. The value of those shining stones which have at all times been considered as precious ornaments, is entirely founded upon their scarceness or their brilliancy. It is the same likewise, with respect to those shining metals, the weight of which is so little regarded, when spread over our cloaths. These orna-

ments are rather designed to draw the attention of others, than to add to any enjoyments of our own; and few there are that these ornaments will not serve to dazzle, and who can coolly distinguish between the metal and the man.

All things rare and brilliant, will, therefore, ever continue to be fashionable, while men derive greater advantage from opulence than virtue; while the means of appearing considerable are more easily acquired, than the title to be considered. The first impression we generally make, arises from our dress; and this varies, in conformity to our inclinations, and the manner in which we desire to be considered. The modest man, or he who would wish to be thought so, desires to shew the simplicity of his mind, by the plainness of his dress; the vain man, on the contrary, takes a pleasure in displaying his superiority, and is willing to incur the spectator's dislike, so he does but excite his attention.

Another point of view which men have in dressing, is to increase the size of their figure; and to take up more room in the world than Nature seems to have allotted them. We desire to swell out our cloaths by the stiffness of art, and raise our heels, while we add to the largeness of our heads. How bulky soever our dress may be, our vanities are still more bulky. The largeness of the doctor's wig arises from the same pride with the smallness of the beau's queue. Both want to have the size of their understanding measured by the size of their heads.

There are some modes that seem to have a more reasonable origin, which is to hide or to lessen the defects of Nature. To take men altogether, there are many more deformed and plain, than beautiful and shapely. The former, as being the most numerous, give law to fashion; and their laws are generally such as are made in their own favour. The women begin to colour their cheeks with red, when the natural roses are faded; and the younger are obliged to submit, though not compelled by the same necessity. In all parts of the world, this custom prevails more or less; and powdering and frizzing the hair, though not so general, seems to have arisen from a similar controul.

But leaving the draperies of the human picture let us return to the figure, unadorned by art. Man's head, whether considered externally or internally, is differently formed from that of all other animals, the monkey-kind only excepted, in which there is a striking similitude. There are some differences, however, which we shall take notice of in another place. The bodies of all quadrupede animals are covered with hair; but the head of man seems the part most adorned; and that more abundantly than in any other animal.

There is a very great variety in the teeth of all animals; some have them above and below; others have them in the under jaw only: in some they stand separate from each other; while in some they are continued and united. The palate of some fishes is nothing else but a bony plate studded with points, which perform the offices of teeth. All these substances, in every animal, derive their origin from the nerves, the substance of the nerves hardens by being exposed to the air; and the nerves that terminate in the mouth, being thus exposed, acquire a bony solidity. In this manner, the teeth and nails are formed in man; and in this manner also, the beak, the hoofs, the horns, and the talons of other animals, are found to be produced.

The neck supports the head, and unites it to the body. This part is much more considerable in the generality of quadrupeds, than in man. But fishes, and other animals that want lungs similar to ours, have no neck whatsoever. Birds, in general, have the neck longer than any other kind of animals: those

those of them, which have short claws, have also short necks; those, on the contrary, that have them long, are found to have the neck in proportion. In men, there is a lump upon the wind-pipe, formed by the thyroid cartilage, which is not to be seen in women; an Arabian fable says, that this is a part of the original apple, that has stuck in the man's throat by the way, but that the woman swallowed her part of it down.

The human breast is outwardly formed in a very different manner from that of other animals. It is larger in proportion to the size of the body; and none but man, and such animals as make use of their fore feet as hands, such as monkeys, bats, and squirrels, are found to have those bones called the clavicles, or, as we usually term them, the collar-bones. The breasts in women are larger than in men; however, they seem formed in the same manner; and, sometimes, milk is found in the breasts of men, as well as in those of women. Among animals, there is a great variety in this part of the body. The teats of some, as in the ape and elephant, are like those of men, being but two, and placed on each side of the breast. The teats of the bear amount to four. The sheep has but two, placed between the hinder legs. Other animals; such as the bitch, and the sow, have them all along the belly; and, as they produce many young, they have a great many teats for their support. The form also of the teats varies in different animals; and, in the same animal, at different ages. The bosom in females, seems to unite all our ideas of beauty; where the outline is continually changing, and the gradations are soft and regular.

The graceful fall of the shoulders, both in man and woman, constitute no small part of beauty. In apes, though otherwise made like us, the shoulders are high, and drawn up on each side towards the ears. In man they fall by a gentle declivity; and the more so, in proportion to the beauty of his form. In fact, being high-shouldered, is not without reason considered as a deformity, for we find very sickly persons are always so; and people, when dying, are ever seen with their shoulders drawn up in a surprising manner. The muscles that serve to raise the ribs, mostly rise near the shoulders; and the higher we raise the shoulders, we the more easily raise the ribs likewise. It happens, therefore, in the sickly and the dying, who do not breathe without labour, that to raise the ribs they are obliged to call in the assistance of the shoulders; and thus their bodies assume, from habit, that form which they are so frequently obliged to assume. Women with child also are usually seen to be high-shouldered; for the weight of the inferior parts drawing down the ribs, they are obliged to use every effort to elevate them, and thus they raise the shoulders of course.

The arms of men but very little resemble the fore-feet of quadrupeds, and much less the wings of birds. The ape is the only animal that is possessed of hands and arms; but these are much more rudely fashioned, and with less exact proportion than in men; the thumb not being so well opposed to the rest of the fingers, in their hands, as in ours.

The form of the back is not much different in man from that of other quadrupede animals, only that the reins are more muscular in him, and stronger. The buttock, however, in man, is different from that of all other animals whatsoever. What goes by that name, in other creatures, is only the upper part of the thigh: man being the only animal that supports himself perfectly erect; the largeness of this part is owing to the peculiarity of his position.

Man's feet also are different from those of all other animals, those even of apes not excepted. The

foot of the ape is rather a kind of aukward hand; its toes, or rather fingers, are long, and that of the middle longest of all. This foot also wants the heel, as in man; the sole is narrower, and less adapted to maintain the equilibrium of the body in walking, dancing or running.

The nails are less in man than in any other animal. If they were much longer than the extremities of the fingers, they would rather be prejudicial than serviceable, and obstruct the management of the hand. Such savages as let them grow long, make use of them in slaying animals, in tearing their flesh, and such like purposes; however, though their nails are considerably larger than ours, they are by no means to be compared to the hoofs, or the claws of other animals. They may sometimes be seen longer indeed than the claws of any animal whatsoever; as we learn that the nails of some of the learned men in China are longer than their fingers. But these want that solidity which might give force to their exertions; and could never, in a state of nature, have served them for annoyance, or defence.

There is little known exactly with regard to the proportion of the human figure; and the beauty of the best statues is better conceived by observing than by measuring them. The statues of antiquity, which were at first copied after the human form, are now become the models of it; nor is there one man found whose person approaches to those inimitable performances that have thus, in one figure, united the perfections of many. It is sufficient to say that, from being at first models, they are now become originals; and are used to correct the deviations in that form from whence they were taken. We will not, however, pretend to give the proportions of the human body as taken from these, there being nothing more arbitrary, and which good painters themselves so much contemn. Some, for instance, who have studied after these, divide the body into ten times the length of the face, and others into eight. Some pretend to tell us that there is a similitude of proportion in different parts of the body. Thus, that the hand is the length of the face; the thumb the length of the nose; the space between the eyes is the breadth of an eye; that the breadth of the thigh, at thickest, is double that of the thickest part of the leg, and treble the smallest; that the arms extended are as long as the figure is high; that the legs and thighs are half the length of the figure. All this, however, is extremely arbitrary; and the excellence of a shape, or the beauty of a statue, results from the attitude and position of the whole, rather than any established measurements; begun without experience, and adopted by caprice. In general, it may be remarked that the proportions alter in every age, and are obviously different in the two sexes. In woman, the shoulders are narrower, and the neck proportionably longer than in men. The hips also are considerably larger, and the thighs much shorter than in men. These proportions, however, vary greatly at different ages. In infancy the upper parts of the body are much larger than the lower; the legs and thighs do not constitute any thing like half the height of the whole figure; in proportion as the child increases in age, the inferior parts are found to lengthen; so that the body is not equally divided until it has acquired its full growth.

The size of men varies considerably. Men are said to be tall who are from five feet eight inches to six feet high. The middle stature is from five feet five to five feet eight, and these are said to be of small stature who fall under these measures. However, it ought to be remarked, that the same person is always taller when he arises in the morning; than upon going to bed at night; and sometimes there is an inch difference, and often more. Few persons are sensible of this remarkable variation; and, some

some say, it was first perceived, in England, by a recruiting officer. He often found that those men whom he had enlisted for soldiers, and answered to the appointed standard at one time, fell short of it when they came to be measured before the colonel, at the head quarters. This diminution in their size proceeded from the different times of the day, and the different states of the body when they happened to be measured. If, as was said; they were measured in the morning, after the night's refreshment, they were found to be commonly half an inch, and very often a whole inch taller than if measured after the fatigues of the day; if they were measured when fresh, in the country, and before a long fatiguing march to the regiment, they were found to be an inch taller than when they arrived at their journey's end. All this is now well known among those who recruit for the army; and the reason of this difference of stature is obvious. Between all the joints of the back-bone, which is composed of several pieces, there is a glutinous liquor deposited, which serves, like oil in a machine, to give the parts an easy play upon each other. This lubricating liquor, or synovia, as the anatomists call it, is poured in during the season of repose, and is consumed by exercise and employment; so that in a body, after hard labour, there is scarce any of it remaining; but all the joints grow stiff; and their motion becomes hard and painful. It is from hence, therefore, that the body diminishes in stature. For this moisture being drained away, from between the numerous joints of the back-bone, they lie closer upon each other; and their whole length is thus very sensibly diminished; but sleep, by restoring the fluid, again swells the spaces between the joints, and the whole is extended to its former dimensions.

As the human body is thus often found to differ from itself in size, so it is found to differ in its weight also; and the same person, without any apparent cause, is found to be heavier at one time than another. If, after having eaten an hearty dinner, or having drank hard, the person should find himself thus heavier, it would appear no way extraordinary; but the fact is, the body is very often found heavier some hours after eating an hearty meal, then immediately succeeding it. If, for instance, a person, fatigued by a day's hard labour, should eat a plentiful supper, and then get himself weighed upon going to bed; after sleeping soundly, if he is again weighed, he will find himself considerably heavier than before; and this difference is often found to amount to a pound, or sometimes to a pound and a half. From whence this adventitious weight is derived is not easy to conceive; the body, during the whole night, appears rather plentifully perspiring than imbibing any fluid, rather losing than gaining moisture: however, we have no reason to doubt but that either by the lungs, or, perhaps, by a peculiar set of pores, it is all this time inhaling a quantity of fluid, which thus increases the weight of the whole body, upon being weighed the next morning.

Although the human body is externally more delicate than any of the quadrupede kind, it is, notwithstanding, extremely muscular: and, perhaps, for its size, stronger than that of any other animal. If we should offer to compare the strength of the lion with that of man, we should consider that the claws of this animal give us a false idea of its power; we ascribe to its force what is only the effects of its arms. Those which man has received from Nature are not offensive; happy had art never furnished him with any more terrible than those which arm the paws of the lion!

But there is another manner of comparing the strength of man with that of other animals; namely,

by the weights which either can carry. We are assured that the porters of Constantinople, carry burdens of nine hundred pounds weight: Mr. Desaguliers tells us of a man, who, by distributing weights in such a manner as that every part of his body bore its share, he was thus able to raise a weight of two thousand pounds. An horse, which is about seven times our bulk, would be thus able to raise a weight of fourteen thousand pounds, if its strength were in the same proportion. But, the truth is, an horse will not carry upon its back, above a weight of two or three hundred pounds; while a man, of confessedly inferior strength, is thus able to support two thousand. Whence comes this seeming superiority? The answer is obvious. Because the load upon man's shoulder is placed to the greatest advantage; while upon the horse's back, it is placed at the greatest disadvantage. Let us suppose, for a moment, the man standing as upright as possible, under the great load abovementioned. It is obvious that all the bones of his body may be compared to a pillar supporting a building, and that his muscles have scarce any share in this dangerous duty. However, they are not entirely inactive; as man, let him stand never so upright, will have some bending in the different parts of his body. The muscles, therefore, give the bones some assistance, and that with the greatest possible advantage. In this manner, a man has been found to support two thousand weight; but may be capable of supporting a still greater. The manner in which this is done, is by strapping the load round the shoulders of the person, who is to bear it by a machine, something like that by which milk-vessels, or water-buckets are carried. The load being thus placed on a scaffold, on each side, contrived for that purpose, and the man standing erect in the midst, all parts of the scaffold, except that where the man stands, are made to sink; and thus the man maintaining his position, the load, whatever it is, becomes suspended, and the column of his bones may be fairly said to support it. If, however, he should but ever so little give way, he must inevitably drop; and no power of his can raise the weights again. But the case is very different with regard to a load laid upon an horse. The column of the bones there lies a different way; and a weight of five hundred pounds, as we are told, would break the back of the strongest horse that could be found. The great force of an horse and other quadrupedes, is exerted when the load is in such a position as that the column of the bones can be properly applied; which is lengthwise. When, therefore, we are to estimate the comparative strength of an horse, we are not to try what he can carry, but what he can draw; and, in this case, his amazing superiority over man is easily discerned; for one horse can draw a load that ten men cannot move. And in some cases it happens that a draft horse draws the better for being somewhat loaded; for, as the peasants say, the load upon the back keeps him the better to the ground.

There is still another way of estimating human strength by the perseverance and agility of our motions. Men, who are exercised in running, outstrip horses; or at least hold their speed for a longer continuance. In a journey, also, a man will walk down a horse; and, after they have both continued to proceed for several days, the horse will be quite tired, and the man will be fresher than in the beginning. The king's messengers of Isaphan, who are runners by profession, go thirty-six leagues in fourteen hours. Travellers assure us that the Hottentots outstrip lions in the chase; and that the savages, who hunt the elk, pursue with such speed, that they at last tire down, and take it. We are told many very surprising things of the great swiftness

of the savages, and of the long journeys they undertake, on foot, through the most craggy mountains, where there are no paths to direct, nor houses to entertain them. They are said to perform a journey of twelve hundred leagues in less than six weeks. But, notwithstanding what travellers report of this matter, we have been assured, from many of our officers and soldiers, who compared their own swiftness with that of the native Americans, during the last war, that although the savages held out, and, as the phrase is, had better bottoms, yet, for a spurt, the Englishmen were more nimble and speedy.

Nevertheless, in general, civilized man is ignorant of his own powers; he is ignorant how much he loses by effeminacy; and what might be acquired by habit and exercise. Here and there, indeed, men are found among us of extraordinary strength; but that strength, for want of opportunity, is seldom called into exertion. Among the ancients it was a quality of much greater use than at present; as in war the same man that had strength sufficient to carry the heaviest armour, had strength sufficient also to strike the most fatal blow. In this case, his strength was at once his protection and his power. We ought not to be surprised, therefore, when we hear of one man terrible to an army, and irresistible in his career, as we find some generals represented in ancient history. But we may be very certain that this prowess was exaggerated by flattery, and exalted by terror. An age of ignorance is ever an age of wonder. At such times, mankind, having no just ideas of the human powers, are willing rather to represent what they wish than what they know; and exalt human strength, to fill up the whole sphere of their limited conceptions. Great strength is an accidental thing; two, or three, in a country, may possess it; and these may have a claim to heroism. But what may lead us to doubt of the veracity of these accounts is, that the heroes of antiquity are represented as the sons of heroes; their amazing strength is delivered down from father to son; and this we know to be contrary to the course of nature. Strength is not hereditary; although titles are: and we are induced to believe, that this great tribe of heroes who are all represented as the descendants of heroes, are more obliged to their titles than to their strength, for their characters. With regard to the shining characters in Homer, they are all represented as princes, and as the sons of princes; while we are told of scarce any share of prowess in the meaner men of the army; who are only brought into the field for these to protect, or to slaughter. But nothing can be more unlikely than that those men, who were bred in the luxury of courts, should be strong; while the whole body of the people, who received a plainer and simpler education, should be comparatively weak. Nothing can be more contrary to the general laws of nature, than that all the sons of heroes should thus inherit not only the kingdoms, but the strength of their forefathers; and we may conclude, that they owe the greatest share of their imputed strength rather to the dignity of their stations than the force of their arms; and, like all fortunate princes, their flatterers happened to be believed. In later ages, indeed, we have some accounts of amazing strength, which we can have no reason to doubt of. But in these, nature is found to pursue her ordinary course; and we find their strength accidental. We find these strong men among the lowest of the people, and gradually rising into notice, as this superiority had more opportunity of being seen. Of this number was the Roman tribune, who went by the name of the second Achilles; who, with his own hand is said to have killed, at different times, three hundred of the enemy; and when treacherously set upon, by twenty-five of his own coun-

trymen, although then past his sixtieth year, killed fourteen of them before he was slain. Of this number was Milo, who, when he stood upright, could not be forced out of his place. Pliny, also, tells us of one Athanatus, who walked across the stage at Rome, loaded with a breast-plate weighing five hundred pounds, and buskins of the same weight. But of all the prodigies of strength; of whom we have any accounts in Roman history, Maximin, the emperor, is to be reckoned the foremost. Whatever we are told relative to him is well attested; his character was too exalted not to be thoroughly known; and that very strength, for which he was celebrated, at last procured him no less a reward than the empire of the world. Maximin was above nine feet in height, and the best proportioned man in the whole empire. He was by birth a Thracian; and, from being a simple herdsman, rose through the gradations of office, until he came to be Emperor of Rome. The first opportunity he had of exerting his strength, was in the presence of all the citizens, in the theatre, where he overthrew twelve of the strongest men, in wrestling, and outstript two of the fleetest horses, in running, all in one day. He could draw a chariot loaden, that two strong horses could not move; he could break a horse's jaw with a blow of his fist; and its thigh with a kick. In war he was always foremost, and invincible; happy had it been for him, and his subjects, if, from being formidable to his enemies, he had not become still more so to his subjects; he reigned, for some time, with all the world his enemy; all mankind wishing him dead, yet none daring to strike the blow. As if fortune had resolved that through life he should continue unconquerable, he was killed at last by his own soldiers, while he was sleeping. We have many other instances, in later ages, of very great strength, and not fewer of amazing swiftness; but these, merely corporeal perfections, are now considered as of small advantage, either in war or in peace. The invention of gunpowder has, in some measure, levelled all force to one standard; and has wrought a total change in martial education through all parts of the world. In peace also, the invention of new machines every day, and the application of the strength of the lower animals to the purposes of life, have rendered human strength less valuable. The boast of corporeal force is therefore consigned to savage nations, where those arts not being introduced, it may still be needful; but, in more polite countries, few will be proud of that strength which other animals can be taught to exert to as useful purposes as they.

If we compare the largeness and thickness of our muscles with those of any other animal, we shall find that, in this respect, we have the advantage: and if strength, or swiftness, depended upon the quantity of the muscular flesh alone, in this respect we should be more active and powerful than any other. But this is not the case; a great deal more than the size of the muscles goes to constitute activity, or force; and it is not he who has the thickest legs that can make the best use of them. Those, therefore, who have written elaborate treatises on muscular force, and have estimated the strength of animals by the thickness of their muscles, have been employed to very little purpose. It is, in general, observed that thin and raw-boned men are always stronger and more powerful than such as are seemingly more muscular; as in the former all the parts have better room for their exertions.

Women want much of the strength of men; and, in some countries, the stronger sex have availed themselves of this superiority, in cruelly and tyrannically enslaving those who were made with equal pretensions to a share in all the advantages life can bestow. Savage nations oblige their women to a life

life of continual labour; upon them rest all the drudgeries of domestic duty; while the husband, indolently reclined in his hammock, is first served from the fruits of her industry. From this negligent situation he is seldom roused, except by the calls of appetite, when it is necessary, either by fishing or hunting, to make a variety in his entertainments. A savage has no idea of taking pleasure in exercise; he is surpris'd to see an European walk forward for his amusement, and then return back again. As for his part, he could be contented to remain for ever in the same situation, perfectly satisfied with sensual pleasures and undisturbed repose. The women, of these countries, are the greatest slaves upon earth; sensible of their weakness, and unable to resist, they are obliged to suffer those hardships which are naturally inflicted by such as have been taught that nothing but corporeal force ought to give pre-eminence. It is not, therefore, till after some degree of refinement, that women are treated with lenity; and not till the highest degree of politeness, that they are permitted to share in all the privileges of man. The first impulse of savage nature is to confirm their slavery; the next, of half barbarous nations, is to appropriate their beauty; and that, of the perfectly polite, to engage their affections. In civilized countries, therefore, women have united the force of modesty to the power of their natural charms; and thus obtain that superiority over the mind, which they are unable to extort by their strength.

When we come to treat of the different senses, we shall be able to determine what stress is to be laid on the ideas of beauty in general, which we receive from the eyes. In the mean time, and that our description of Man may not be found imperfect, let us examine the human countenance, as it appears among ourselves, when agitated by the Passions.

DESIRE may be represented, by the eyebrows being pressed and advanced over the eyes, which shall be more open than ordinary, with the eyeball in the middle full of fire; the nostrils drawn closest next the eyes, the mouth also is more open, than in the foregoing action, the corners drawn back; the tongue may approach upon the edge of the lips, the colour more inflamed than in love; all these motions shewing the agitation of the soul caused by the spirits, which dispose it to desire a good, as convenient for it.

FEAR. But if there be no appearance of obtaining what we desire, then instead of hope comes fear or despair; the motion of fear is expressed by the eyebrows a little raised next the nose, the eyebrows sparkling in an unquiet manner, situated in the middle of the eye; the mouth open, and drawn back, and more open at the corners than in the middle, having the under lip more drawn back than the upper; the complexion redder than in love or desire, but not so beautifully inclined to livid; with the lips of the same colour, and dry when love changes fear into jealousy.

HOPE. When there is an appearance of obtaining what we desire, that brings forth hope: but the motions of this passion being not so much external as internal, we shall speak but little of them, and only remark, that this passion keeps all the parts of the body suspended, between fear and assurance; in such a manner, that if one part of the eyebrow makes fear, the other makes security; and, in all the parts of the face and body, the motions of these two passions are particularly intermixed.

SORROW. As we have said, that sorrow is a disagreeable faintness, by which the soul receives the inconveniency or defect, which presents itself to it by the impression of the brain; so this passion is represented, by motions which seem to mark the

inquietude of the brain, and the dejection of the heart, the eyebrows being more raised in the middle of the forehead than next the temples. He that is troubled with this passion, has his eyeballs dull, the white of the eye inclining to yellow, the eyelids hanging down something swoln, and a livid look round them; the nostrils drawing downwards, the mouth open, the corners thereof drawn down; the head appears carelessly hanging on one of the shoulders, the complexion of a kind of lead colour, and the lips pale and wan.

SIMPLE LOVE. The motions of this passion, when it is simple, are very soft and sweet, for the forehead will be smooth, the eyebrows will be a little elevated over the place where the eyeballs shall be turned, the head inclined towards the object of the passion; the eyes may be moderately open, the white very lively and sparkling, and the eyeball being greatly turned toward the object, will appear a little sparkling and elevated; the nose receives no alteration, nor any of the parts of the face, which being only filled with spirits that warm and enliven it, render the complexion fresh and lively, and particularly the cheeks and lips; the mouth may be a little open, the corner a little turned up, the lips will appear moist, and this moistness may be caused by vapours arising from the heart.

RAGE hath the same motions as despair, but yet more violent; for the face will be almost black, covered with a cold sweat, the hair at an end, the eyes wandering in a contrary motion, the eyeballs sometimes rolling towards the nose, sometimes back towards the ear, all the parts of the face will be extremely marked and swoln.

WEeping. He that weeps, hath his eyebrows hanging down in the middle of the forehead, the eyes almost closed, very wet, and cast down towards the cheeks; the nostrils swelled, all the muscles of the forehead being apparent; the mouth shall be half open, the corners hanging down, and making wrinkles in the cheek; the under lip will appear turned down and pouting out, all the face will appear drawn together and wrinkled, the colour very red, especially about the eyes, eyebrows, nose, mouth, and cheeks.

ADMIRATION. As we have said, that admiration is the first and most temperate of all the passions, wherein the heart feels the least disturbance, so the face receives very little alteration; if any, it will be only in the raising of the eyebrows, the ends being parallel, the eye will be a little more open than ordinary, and the ball even between the lids, without motion, being fixed on the object which causes the admiration. The mouth will be open, but will appear without alteration, any more than the other parts of the face: this passion produces only a suspension of motion, to give time to the soul to consider what she has to do; and to consider attentively the object before her, if it be extraordinary. Out of this simple motion of admiration is engendered esteem.

CHAP. VI.

Of SLEEP and HUNGER.

AS man, in all the privileges he enjoys, and the powers he is invested with, has a superiority over all other animals, so, in his necessities, he seems inferior to the meanest of them all. Nature has brought him into life with a greater variety of wants and infirmities, than the rest of her creatures, unarmed in the midst of enemies. The lion has natural arms; the bear natural cloathing; but man is destitute of all such advantages; and, from the superiority of his mind alone, he is to supply

the deficiency. The number of his wants, however, were merely given, in order to multiply the number of his enjoyments; since the possibility of being deprived of any good, teaches him the value of its possession. Were man born with those advantages which he learns to possess by industry, he would very probably enjoy them with a blunter relish: it is by being naked, that he knows the value of a covering; it is by being exposed to the weather that he learns the comforts of an habitation. Every want thus becomes a means of pleasure, in the redressing; and the animal that has most desires, may be said to be capable of the greatest variety of happiness.

Besides the thousand imaginary wants peculiar to man, there are two, which he has in common with all other animals; and which he feels in a more necessary manner than they. These are the wants of sleep and hunger. Every animal that we are acquainted with, seems to endure the want of these with much less injury to health, than man; and some are most surprisingly patient in sustaining both. The little domestic animals that we keep about us, may often set a lesson of calm resignation, in supporting want and watchfulness, to the boasted philosopher. They receive their pittance at uncertain intervals, and wait its coming with cheerful expectation. We have instances of the dog, and the cat, living, in this manner, without food for several days; and yet still preserving their attachment to the tyrant that oppresses them; still ready to exert their little services for his amusement or defence. But the patience of these is nothing to what the animals of the forest endure. As these mostly live upon accidental carnage, so they are often known to remain without food for several weeks together. Nature, kindly sollicitous for their support, has also contracted their stomachs, to suit them for their precarious way of living; and kindly, while it abridges the banquet, lessens the necessity of providing for it. But the meaner tribes of animals are made still more capable of sustaining life without food, many of them remaining in a state of torpid indifference till their prey approaches, when they jump upon and seize it. In this manner, the snake, or the spider, continue, for several months together, to subsist upon a single meal; and some of the butterfly kinds live upon little or nothing. But it is very different with man: his wants daily make their importunate demands; and it is known, that he cannot continue to live many days without eating, drinking, and sleeping.

Hunger is a much more powerful enemy to man, than watchfulness, and kills him much sooner. It may be considered as a disorder that food removes; and that would quickly be fatal, without its proper antidote. In fact, it is so terrible to man, that to avoid it he would even encounter certain death; and, rather than endure its tortures, exchanges them for immediate destruction. However, by all accounts, it is much more dreadful in its approaches, than in its continuance; and the pains of a famishing wretch, decrease as his strength diminishes. In the beginning, the desire of food is dreadful indeed, as we know by experience, for there are few who have not in some degree felt its approaches. But, after the first or second day, its tortures become less terrible, and a total insensibility at length come kindly in to the poor wretch's assistance. A captain of a ship, who was one of six that endured it in its extremities, was the only person that had not lost his senses, when they received accidental relief. His pains at first were so great, as to be often tempted to eat a part of one of the men who died; and which the rest of his crew actually for some time lived upon: he said that, during the continuance of this paroxysm, he found his pains

insupportable; and was desirous, at one time, of anticipating that death which he thought inevitable: but his pains, he said, gradually decreased, after the sixth day, (for they had water in the ship, which kept them alive so long) and then he was in a state rather of languor than desire; nor did he much wish for food, except when he saw others eating; and that for a while revived his appetite, though with diminished importunity. The latter part of the time, when his health was almost destroyed, a thousand strange images rose upon his mind; and every one of his senses began to bring him wrong information. The most fragrant perfumes appeared to him to have a foetid smell; and every thing he looked at took a greenish hue, and sometimes a yellow. When he was presented with food by the ship's company that took him and his men up, four of whom died shortly after, he could not help looking upon it with loathing, instead of desire; and it was not till after four days, that his stomach was brought to its natural tone; when the violence of his appetite returned, with a sort of canine eagerness.

Thus dreadful are the effects of hunger; and yet, when we come to assign the cause that produces them, we find the subject involved in doubt and intricacy. This longing eagerness is, no doubt, given for a very obvious purpose; that of replenishing the body, wasted by fatigue and perspiration. Were not men stimulated by such a pressing monitor, they might be apt to pursue other amusements, with a perseverance beyond their power; and forget the useful hours of refreshment, in those more tempting ones of pleasure. But hunger makes a demand that will not be refused; and, indeed, the generality of mankind seldom await the call.

Hunger has been supposed by some to arise from the rubbing of the coats of the stomach against each other, without having any intervening substance to prevent their painful attrition. Others have imagined, that its juices, wanting their necessary supply, turn acrid, or, as some say, pungent; and thus fret its internal coats, so as to produce a train of the most uneasy sensations. Boerhaave, who established his reputation in physic, by uniting the conjectures of all those that preceded him, ascribes hunger to the united effect of both these causes; and asserts, that the pungency of the gastric juices, and the attrition of its coats against each other, cause those pains, which nothing but food can remove. These juices continuing still to be separated in the stomach, and every moment becoming more acrid, mix with the blood, and infect the circulation: the circulation being thus contaminated, becomes weaker, and more contracted; and the whole nervous frame sympathizing, an hectic fever and sometimes madness is produced; in which state the faint wretch expires. In this manner, the man who dies of hunger, may be said to be poisoned by the juices of his own body; and is destroyed less by the want of nourishment, than by the vitiated qualities of that which he had already taken.

However this may be, we have but few instances of men dying, except at sea, of absolute hunger; the decline of those unhappy creatures who are destitute of food, at land, being more slow and unperceived. These, from often being in need; and as often receiving an accidental supply, pass their lives between surfeiting and repining; and their constitution is impaired by insensible degrees. Man is unfit for a state of precarious expectation. That share of provident precaution which incites him to lay up stores for a distant day, becomes his torment, when totally unprovided against an immediate call. The lower race of animals, when satisfied, for the instant moment, are perfectly happy:

but it is otherwise with man; his mind anticipates distress, and feels the pangs of want even before it arrests him. Thus the mind, being continually harassed by the situation, it at length influences the constitution, and unfits it for all its functions. Some cruel disorder, but no way like hunger, seizes the unhappy sufferer; so that almost all those men who have thus long lived by chance, and whose every day may be considered as an happy escape from famine, are known at last to die in reality, of a disorder caused by hunger; but which, in the common language, is often called a broken-heart. The number of such as die in London for want, is much greater than one would imagine, about two thousand in a year.

But how numerous soever those who die of hunger may be, many times greater, on the other hand, are the number of those who die by repletion. It is not the province of the present page to speculate, with the physician, upon the danger of surfeits; or, with the moralist, upon the nauseousness of gluttony: it will only be proper to observe, that as nothing is so prejudicial to health as hunger by constraint, so nothing is more beneficial to the constitution than voluntary abstinence. It was not without reason that religion enjoined this duty; since it answered the double purpose of restoring the health oppressed by luxury, and diminished the consumption of provisions; so that a part might come to the poor. It should be the business of the legislature, therefore, to enforce this divine precept; and thus, by restraining one part of mankind in the use of their superfluities, to consult for the benefit of those who want the necessaries of life. The injunctions for abstinence are strict over the whole Continent; and were rigorously observed, even among ourselves, for a long time after the Reformation. Queen Elizabeth, by giving her commands, upon this head, the air of a political injunction, lessened, in a great measure, and very unwisely, the religious force of the obligation. She enjoined that her subjects should fast from flesh on Fridays and Saturdays; but at the same time declared, that this was not commanded from motives of religion, as if there were any differences in meats, but merely to favour the consumption of fish, and thus to multiply the number of mariners; and also to spare the stock of sheep, which might be more beneficial in another way. In this manner the injunction defeated its own force; and this most salutary law became no longer binding, when it was supposed to come purely from man. How far it may be enjoined in the Scriptures, we will not pretend to say; but this may be asserted, that if the utmost benefit to the individual, and the most extensive advantage to society, serve to mark any institution as of Heaven, this of abstinence may be reckoned among the foremost.

Were we to give an history of the various benefits that have arisen from this command, and how conducive it has been to long life, the instances would fatigue with their multiplicity. It is surprising to what a great age the primitive Christians of the East, who retired from persecution in the deserts of Arabia, continued to live in all the bloom of health, and yet all the rigours of abstemious discipline. Their common allowance, as we are told, for four and twenty hours, was twelve ounces of bread, and nothing but water. On this simple beverage, St. Anthony is said to have lived an hundred and five years; James, the hermit, an hundred and four; Arsenius, tutor to the emperor Arcadius, an hundred and twenty; St. Epiphanius, an hundred and fifteen; Simeon, an hundred and twelve; and Rombold, an hundred and twenty. In this manner did these holy temperate men live to an extreme old age, kept chearful by strong hopes, and healthful by moderate labour.

Abstinence which is thus voluntary, may be much more easily supported than constrained hunger. Man is said to live without food for seven days; which is the usual limit assigned him: and, perhaps, in a state of constraint, this is the longest time he can survive the want of it. But, in cases of voluntary abstinence, of sickness, or sleeping, he has been known to live much longer.

In the records of the Tower, there is an account of a Scotchman, imprisoned for felony, who, for the space of six weeks, took not the least sustenance, being exactly watched during the whole time; and for this he received the king's pardon.

When the American Indians undertake long journies, and when, consequently, a stock of provisions sufficient to support them the whole way, would be more than they could carry, in order to obviate this inconvenience, instead of carrying the necessary quantity, they contrive a method of palliating their hunger, by swallowing pills, made of calcined shells and tobacco. These pills take away all appetite, by producing a temporary disorder in the stomach; and, no doubt, the frequent repetition of this wretched expedient, must at last be fatal. By these means, however, they continue several days without eating, chearfully bearing such extremes of fatigue and watching, as would quickly destroy men bred up in a greater state of delicacy. For those arts by which we learn to obviate our necessities, do not fail to unfit us for their accidental encounter.

Upon the whole, therefore, man is less able to support hunger than any other animal; and he is not better qualified to support a state of watchfulness. Indeed, sleep seems much more necessary to him, than to any other creature; as, when awake, he may be said to exhaust a greater proportion of the nervous fluid; and, consequently, to stand in need of an adequate supply. Other animals, when most awake, are but little removed from a state of slumber; their feeble faculties, imprisoned in matter, and rather exerted by impulse than deliberation, require sleep rather as a cessation from motion, than from thinking. But it is otherwise with man; his ideas, fatigued with their various excursions, demand a cessation, not less than the body, from toil; and he is the only creature that seems to require sleep from double motives; not less for the refreshment of the mental than of the bodily frame.

There are some lower animals, indeed, that seem to spend the greatest part of their lives in sleep; but, properly speaking, the sleep of such may be considered as a kind of death; and their waking, a resurrection. Flies, and insects, are said to be asleep, at a time that all the vital motions have ceased; without respiration, without any circulation of their juices, if cut in pieces, they do not awake, nor does any fluid ooze out at the wound. These may be considered rather as congealed than as sleeping animals; and their rest, during winter, rather as a cessation from life, than a necessary refreshment: but in the higher races of animals, whose blood is not thus congealed, and thawed by heat, these all bear the want of sleep much better than man; and some of them continue a long time without seeming to take any refreshment from it whatsoever.

But man is more feeble; he requires its due return; and if it fails to pay the accustomed visit, his whole frame is in a short time thrown into disorder; his appetite ceases; his spirits are dejected; his pulse becomes quicker and harder; and his mind, abridged of its slumbering visions, begins to adopt waking dreams. A thousand strange phantoms arise, which come and go without his will: these, which are transient in the beginning, at last take firm possession of the mind, which yields to their

dominion,

dominion, and after a long struggle, runs into confirmed madness. In that horrid state, the mind may be considered as a city without walls, open to every insult, and paying homage to every invader: every idea that then starts with any force, becomes a reality; and the reason, over fatigued with its former importunities, makes no head against the tyrannical invasion, but submits to it from mere imbecillity.

But it is happy for mankind, that this state of inquietude is seldom driven to an extreme; and that there are medicines which seldom fail to give relief. However, man finds it more difficult than any other animal to procure sleep: and some are obliged to court its approaches for several hours together, before they incline to rest. It is in vain that all light is excluded; that all sounds are removed; that warmth and softness conspire to invite it; the restless and busy mind still retains its former activity; and reason that wishes to lay down the reins, in spite of herself, is obliged to maintain them. In this disagreeable state, the mind passes from thought to thought, willing to lose the distinctness of perception, by increasing the multitude of images. At last, when the approaches of sleep are near, every object of the imagination begins to mix with that next it; their outlines become, in a manner, rounder; a part of their distinctions fade away; and sleep, that ensues, fashions out a dream from the remainder.

If then it should be asked from what cause this state of repose proceeds, or in what manner sleep thus binds us for several hours together, we must fairly confess our ignorance, although it is easy to tell what philosophers say upon the subject. Sleep, says one of them, consists in a scarcity of spirits, by which the orifices or pores of the nerves in the brain, through which the spirits used to flow into the nerves, being no longer kept open by the frequency of the spirits, shut of themselves; thus the nerves, wanting a new supply of spirits, become lax, and unfit to convey any impression to the brain. All this, however, is explaining a very great obscurity by somewhat more obscure: leaving, therefore, those spirits to open and shut the entrances to the brain, let us be contented with simply enumerating the effects of sleep upon the human constitution.

In sleep, the whole nervous frame is relaxed, while the heart and the lungs seem more forcibly exerted. This fuller circulation produces also a swelling of the muscles, as they always find who sleep with ligatures on any part of their body. This increased circulation also, may be considered as a kind of exercise, which is continued through the frame; and, by this, the perspiration becomes more copious, although the appetite for food is entirely taken away. Too much sleep dulls the apprehension, weakens the memory, and unfits the body for labour. On the contrary, sleep too much abridged, emaciates the frame, produces melancholy, and consumes the constitution. It requires some care, therefore, to regulate the quantity of sleep, and just to take as much as will completely restore Nature, without oppressing it. The poor, as Otway says, sleep little; forced, by their situation, to lengthen out their labour to their necessities, they have but a short interval for this pleasing refreshment; and we are of opinion, that bodily labour demands a less quantity of sleep than mental. Labourers and artizans are generally satisfied with about seven hours; but we have known some scholars who usually slept nine, and perceived their faculties no way impaired by over-sleeping.

The famous Philip Barrettiere, who was considered as a prodigy of learning at the age of fourteen, was known to sleep regularly twelve hours in

the twenty-four; the extreme activity of his mind, when awake, in some measure called for an adequate alternation of repose: and, we are apt to think, that when students stint themselves in this particular, they lessen the waking powers of the imagination, and weaken its most strenuous exertions. Animals, that seldom think, as was said, can very easily dispense with sleep; and of men, such as think least, will very probably be satisfied with the smallest share. A life of study, it is well known, unfits the body for receiving this gentle refreshment; the approaches of sleep are driven off by thinking: when, therefore, it comes at last, we should not be too ready to interrupt its continuance.

Sleep is, indeed, to some, a very agreeable period of their existence: and it has been a question in the schools, which was most happy, the man who was a beggar by night, and a king by day; or he was a beggar by day, and a king by night? It is given in favour of the nightly monarch, by him who first started the question: for the dream, says he, gives the full enjoyment of the dignity, without its attendant inconveniencies; while, on the other hand, the king, who supposes himself degraded, feels all the misery of his fallen fortune, without trying to find the comforts of his humble situation. Thus, by day, both states have their peculiar distresses: but, by night, the exalted beggar is perfectly blessed, and the king completely miserable. All this, however, is rather fanciful than just; the pleasure dreams can give us, seldom reaches to our waking pitch of happiness: the mind often, in the midst of its highest visionary satisfactions, demands of itself, whether it does not owe them to a dream; and frequently awakes with the reply.

But it is seldom, except in cases of the highest delight, or the most extreme uneasiness, that the mind has power thus to disengage itself from the dominion of fancy. In the ordinary course of its operations, it submits to those numberless fantastic images that succeed each other; and which, like many of our waking thoughts, are generally forgotten. Of these, however, if any, by their oddity, or their continuance, affect us strongly, they are then remembered; and there have been some who felt their impressions so strongly, as to mistake them for realities, and to rank them among the past actions of their lives.

There are others, upon whom dreams seem to have a very different effect; and who, without seeming to remember their impressions the next morning, have yet shewn, by their actions during sleep, that they were very powerfully impelled by their dominion. We have numberless instances of such persons, who, while asleep, have performed many of the ordinary duties to which they had been accustomed when waking; and with a ridiculous industry, have completed by night, what they failed doing by day. We are told, in the German ephemerides, of a young student, who being enjoined a severe exercise by his tutor, went to bed, despairing of accomplishing it. The next morning, awaking, to his great surprize he found the task fairly written out, and finished in his own hand-writing. He was at first, as the account has it, induced to ascribe this strange production to the operations of an infernal agent; but his tutor, willing to examine the affair to the bottom, set him another exercise, still more severe than the former; and took precautions to observe his conduct the whole night. The young gentleman, upon being so severely tasked, felt the same inquietude that he had done on the former occasion; went to bed gloomy and pensive, pondering on the next day's duty, and, after some time, fell asleep. But shortly after, his tutor, who continued to observe him from a place that was concealed, was surprized to see

him get up, and very deliberately go to the table; there he took out pen, ink, and paper, drew himself a chair, and sat very methodically to thinking: it seems, that his being asleep only served to strengthen the powers of his imagination; for he very quickly and easily went through the task assigned him, put his chair aside, and then returned to bed to take out the rest of his nap. What credit we are to give to this account, we will not pretend to determine: but this may be said, that the book from whence it is taken, has some good marks of veracity; for it is very learned, and very dull, and is written in a country noted, if not for truth, at least for want of invention.

The ridiculous history of Arlotto is well known, who has had a volume written, containing a narrative of the actions of his life, not one of which was performed while he was awake: He was an Italian Franciscan friar, extremely rigid in his manners, and remarkably devout and learned in his daily conversation. By night, however, and during his sleep, he played a very different character from what he did by day, and was often detected in very atrocious crimes. He was at one time detected in actually attempting a rape, and did not awake till the next morning, when he was surprised to find himself in the hands of justice. His brothers of the convent often watched him while he went very deliberately into the chapel, and there attempted to commit sacrilege. They sometimes permitted him to carry the chalice and the vestments away into his own chamber, and the next morning amused themselves at the poor man's consternation for what he had done. But of all his sleeping transgressions, that was the most ridiculous, in which he was called to pray for the soul of a person departed: Arlotto, after having very devoutly performed his duty, retired to a chamber which was shewn him, to rest; but there he had no sooner fallen asleep, than he began to reflect that the dead body had got a ring upon one of the fingers, which might be useful to him: accordingly, with a pious resolution of stealing it, he went down, undressed as he was, in a room full of women, and, with great composure, endeavoured to seize the ring. The consequence was, that he was taken before the inquisition for witchcraft; and the poor creature had like to have been condemned, till his peculiar character accidentally came to be known: however, he was ordered to remain for the rest of life in his own convent, and upon no account whatsoever to stir abroad.

What are we to say to such actions as these; or how account for this operation of the mind in dreaming? It should seem, that the imagination, by day, as well as by night, is always employed; and that often, against our wills, it intrudes where it is least commanded or desired. While awake, and in health, this busy principle cannot much delude us: it may build castles in the air, and raise a thousand phantoms before us; but we have every one of the senses alive, to bear testimony to its falsehood. Our eyes shew us that the prospect is not present; our hearing, and our touch, depose against its reality; and our taste and smelling are equally vigilant in detecting the impostor. Reason, therefore, at once gives judgment upon the cause; and the vagrant intruder, imagination, is imprisoned, or banished from the mind. But in sleep it is otherwise; having, as much as possible, put our senses from their duty, having closed the eyes from seeing, and the ears, taste, and smelling, from their peculiar functions, and having diminished even the touch itself, by all the arts of softness, the imagination is then left to riot at large, and to lead the understanding without an opposer. Every incurative idea then becomes a reality; and the mind, not

having one power that can prove the illusion, takes them for truths. As in madness, the senses, from struggling with the imagination, are at length forced to submit, so, in sleep, they seem for a while soothed into the like submission: the smallest violence exerted upon any one of them, however, rouses all the rest in their mutual defence; and the imagination, that had for a while told its thousand falsehoods, is totally driven away, or only permitted to pass under the custody of such as are every moment ready to detect its imposition.

C H A P. VII.

Of S E E I N G.

HAVING mentioned the senses as correcting the errors of the imagination, and as forcing it, in some measure, to bring us just information, it will naturally follow that we should examine the nature of those senses themselves: we shall thus be enabled to see how far they also impose on us, and how far they contribute to correct each other. Let it be observed, however, that in this we are neither giving a treatise of optics, or phonics, but an history of our own perceptions; and to those we chiefly confine ourselves.

The eyes very soon begin to be formed in the human embryo, and in the chicken also. Of all the parts which the animal has double, the eyes are produced the soonest, and appear the most prominent. It is true, indeed, that in viviparous animals, and particularly in man, they are not so large in proportion, at first, as in the oviparous kinds; nevertheless, they are more speedily developed, when they begin to appear, than any other parts of the body. It is the same with the organ of hearing; the little bones that compose the internal parts of the ear, are entirely formed before the other bones, though much larger, have acquired any part of their growth, or solidity. Hence it appears, that those parts of the body which are furnished with the greatest quantity of the nerves, are the first in forming. Thus the brain, and the spinal marrow, are the first seen begun in the embryo; and in general, it may be said, that wherever the nerves go, or send their branches in great numbers, there the parts are soonest begun, and the most completely finished.

If we examine the eyes of a child some hours, or even some days after its birth, it will be easily discerned that it, as yet, makes no use of them. The humours of the organ not having acquired a sufficient consistence, the rays of light strike but confusedly upon the retina, or expansion of nerves at the back of the eye. It is not till about a month after they are born, that children fix them upon objects; for, before that time, they turn them indiscriminately every where, without appearing to be affected by any. At six, or seven weeks old, they plainly discover a choice in the objects of their attention; they fix their eyes upon the most brilliant colours, and seem peculiarly desirous of turning them towards the light. Hitherto, however, they only seem to fortify the organ for seeing distinctly; but they have still many illusions to correct.

The first great error in vision is, that the eye inverts every object; and it in reality appears to the child, until the touch has served to undeceive it, turned upside down. A second error in vision is, that every object appears double. The same object forms itself distinctly upon each eye; and is consequently seen twice. This error, also, can only be corrected by the touch; and although, in reality, every object we see appears inverted, and double, yet the judgment, and habit, have so often corrected the sense, that we no longer submit to its imposition,

position, but see every object in its just position, the very instant it appears. Were we, therefore, deprived of feeling, our eyes would not only misrepresent the situation, but also the number of all things round us.

To convince us that we see objects inverted, we have only to observe the manner in which images are represented, coming through a small hole, in a darkened room. If such a small hole be made in a dark room so that no light can come in, but through it, all the objects without will be painted on the wall behind, but in an inverted position, their heads downwards. For as all the rays which pass from the different parts of the object without, cannot enter the hole in the same extent which they had in leaving the object, since, if so, they would require the aperture to be as large as the object; and, as each part, and every point of the object, sends forth the image of itself on every side, and the rays, which form these images, pass from all points of the object as from so many centres; so such only can pass through the small aperture as come in opposite directions. Thus the little aperture becomes a centre for the entire object; through which the rays from the upper parts, as well as from the lower parts of it, pass in converging directions; and, consequently, they must cross each other in the central point, and thus paint the objects behind, upon the wall, in an inverted position.

It is, in like manner, easy to conceive, that we see all objects double, whatever our present sensations may seem to tell us to the contrary. For, to convince us of this, we have only to compare the situation of any one object on shutting one eye, and then compare the same situation by shutting the other. If, for instance, we hold up a finger, and shut the right eye, we shall find it hide a certain part of the room; if again reshutting the other eye, we shall find that part of the room visible, and the finger seeming to cover a part of the room that had been visible before. If we open both eyes, however, the part covered will appear to lie between the two extremes. But, the truth is, we see the object our finger had covered, one image of it to the right, and the other to the left; but, from habit, suppose that we see but one image placed between both; our sense of feeling having corrected the errors of sight. And thus, also, if instead of two eyes we had two hundred, we should, at first, fancy the objects increased in proportion, until one sense had corrected the errors of another.

The having two eyes might thus be said to be rather an inconvenience than a benefit, since one eye would answer the purposes of sight as well, and be less liable to illusion. But it is otherwise; two eyes greatly contribute, if not to distinct, at least to extensive vision. When an object is placed at a moderate distance, by the means of both eyes we see a larger share of it than we possibly could with one; the right eye seeing a greater portion of its right side, and the left eye of its correspondent side. Thus both eyes, in some measure, see round the object; and it is this that gives it, in nature, that bold relief, or swelling, with which they appear; and which no painting, how exquisite soever, can attain to. The painter must be contented with shading on a flat surface; but the eyes, in observing nature, do not behold the shading only, but a part of the figure also, that lies behind these very shadings, which gives it that swelling, which painters so ardently desire, but can never fully imitate.

There is another defect, which either of the eyes, taken singly, would have, but which is corrected, by having the organ double. In either eye there is a point, which has no vision whatsoever; so that if one of them only is employed in seeing, there is a part of the object to which it is always totally blind.

This is that part of the optic nerve where its vein and artery run; which being insensible, that point of the object that is painted there must continue unseen. To be convinced of this we have only to try a very easy experiment. If we take three black patches, and stick them upon a white wall, about a foot distant from each other, each about as high as the eye that is to observe them; then retiring six or seven feet back, and shutting one eye, by trying for some time we shall find, that while we distinctly behold the black spots that are to the right and left, that which is in the middle remains totally unseen. Or, in other words, when we bring that part of the eye, where the optic artery runs, to fall upon the object, it will then become invisible. This defect, however, in either eye, is always corrected by both, since the part of the object that is unseen by one, will be very distinctly perceived by the other.

Beside the former defects we can have no idea of distances from the sight, without the help of touch. Naturally every object we see appears to be within our eyes; and a child, who has as yet made but little use of the sense of feeling, must suppose that every thing it sees makes a part of itself. Such objects are only seen more or less bulky as they approach or recede from its eyes; so that a fly that is near will appear larger than an ox at a distance. It is experience alone that can rectify this mistake; and a long acquaintance with the real size of every object, quickly assures us of the distance at which it is seen. The last man in a file of soldiers appears in reality much less, perhaps ten times more diminutive, than the man next to us; however, we do not perceive this difference, but continue to think him of equal stature; for the numbers we have seen thus lessened by distance, and have found, by repeated experience, to be of the natural size, when we come closer, instantly corrects the sense, and every object is perceived with nearly its natural proportion. But it is otherwise, if we observe objects in such situations as we have not had sufficient experience to correct the errors of the eye; if, for instance, we look at men from the top of an high steeple, they, in that case appear very much diminished, as we have not had an habit of correcting the sense in that position.

Although a small degree of reflection will serve to convince us of the truth of these positions, it may not be amiss to strengthen them by an authority which cannot be disputed. Mr. Cheselden having couched a boy of thirteen for a cataract, who had hitherto been blind, and thus at once having restored him to sight, curiously marked the progress of his mind, upon that occasion. This youth, though he had been till then incapable of seeing, yet was not totally blind, but could tell day from night, as persons in his situation always may. He could also, with a strong light, distinguish black from white, and either from the vivid colour of scarlet; however, he saw nothing of the form of bodies; and, without a bright light, not even colours themselves. He was, at first, couched only in one of his eyes; and, when he saw for the first time, he was so far from judging of distances, that he supposed his eyes touched every object that he saw, in the same manner as his hands might be said to feel them. The objects that were most agreeable to him were such as were of plain surfaces and regular figures; though he could as yet make no judgment whatever of their different forms, nor give a reason why one pleased him more than another. Although he could form some idea of colours during his state of blindness, yet that was not sufficient to direct him at present; and he could scarcely be persuaded that the colours he now saw were the same with those he had formerly conceived such erroneous ideas of. He delighted most in green; but black objects, as if giving

ing him an idea of his former blindness, he regarded with horror. He had, as was said, no idea of forms; and was unable to distinguish one object from another, though never so different. When those things were shown him, which he had been formerly familiarized to, by his feeling, he beheld them with earnestness, in order to remember them a second time; but, as he had too many to recollect at once, he forgot the greatest number; and for one he could tell, after seeing, there was a thousand he was totally unacquainted with. He was very much surprised to find that those things and persons he loved best were not the most beautiful to be seen; and even testified displeasure in not finding his parents so handsome as he conceived them to be. It was near two months before he could find that a picture resembled a solid body. Till then he only considered it as a flat surface, variously shadowed; but, when he began to perceive that these kind of shadings actually represented human beings, he then began to examine, by his touch, whether they had not the usual qualities of such bodies, and was greatly surprised to find, what he expected a very unequal surface to be smooth and even. He was then shewn a miniature picture of his father, which was contained in his mother's watch-case, and he readily perceived the resemblance; but asked, with great astonishment, how so large a face could be contained in so small a compass? It seemed as strange to him as if a bushel was contained in a pint vessel. At first, he could bear but a very small quantity of light, and he saw every object much greater than the life; but in proportion as he saw objects that were really large, he seemed to think the former were diminished; and although he knew the chamber where he was contained in the house, yet until he saw the latter, he could not be brought to conceive how an house could be larger than a chamber. Before the operation he had no great expectations from the pleasure he should receive from a new sense; he was only excited by the hopes of being able to read and write; he said, for instance, that he could have no greater pleasure in walking, in the garden, with his sight than he had without it, for he walked there at his ease, and was acquainted with all the walks. He remarked also, with great justice, that his former blindness gave him one advantage over the rest of mankind, which was that of being able to walk in the night, with confidence and security. But, when he began to make use of his new sense, he seemed transported beyond measure. He said that every new object was a new source of delight, and that his pleasure was so great as to be past expression. About a year after, he was brought to Epsom, where there is a very fine prospect, with which he seemed greatly charmed; and he called the landscape before him a new method of seeing. He was couched in the other eye, a year after the former, and the operation succeeded equally well: when he saw with both eyes, he said that objects appeared to him twice as large as when he saw but with one; however, he did not see them doubled, or at least he shewed no marks as if he saw them so. Mr. Cheselden mentions instances of many more that were restored to sight in this manner; they all seemed to concur in their perceptions with this youth; and they all seemed particularly embarrassed in learning how to direct their eyes to the objects they wished to observe.

In this manner it is that our feeling corrects the sense of seeing, and that objects which appear of very different sizes, at different distances, are all reduced, by experience, to their natural standard. But not the feeling only, but also the colour, and brightness of the object, contributes, in some measure, to assist us in forming an idea of the distance at which it appears. Those which we see most

strongly marked with light and shade, we readily know to be nearer than those on which the colours are more faintly spread, and that, in some measure, take a part of their hue from the air between us and them. Bright objects also, are seen at a greater distance than such as are obscure, and, most probably, for this reason, that, being less similar in colour to the air which interposes, their impressions are less effaced by it, and they continue more distinctly visible. Thus a black and distant object is not seen so far off as a bright and glittering one; and a fire by night is seen much farther off than by day.

The power of seeing objects at a distance is very rarely equal in both eyes. When this inequality is in any great degree, the person so circumstanced then makes use only of one eye, shutting that which sees the least, and employing the other with all its power. And hence proceeds that aukward look which is known by the name of strabism.

There are many reasons to induce us to think that such as are near-sighted see objects larger than other persons; and yet the contrary is most certainly true, for they see them less. Mr. Buffon informs us that he himself is short-sighted, and that his left eye is stronger than his right. He has very frequently experienced, upon looking at any object, such as the letters of a book, that they appear less to the weakest eye; and that when he places the book, so as that the letters appear double, the images of the left eye, which is strongest, are greater than those of the right, which is the most feeble. He has examined several others, who were in similar circumstances, and has always found that the best eye saw every object the largest. This he ascribes to habit; for near-sighted people being accustomed to come close to the object, and view but a small part of it at a time, the habit ensues, when the whole of an object is seen, and it appears less to them than to others.

Infants having their eyes less than those of adults, must see objects also smaller in proportion. For the image formed on the back of the eye will be large, as the eye is capacious; and infants, having it not so great, cannot have so large a picture of the object. This may be a reason also why they are unable to see so distinctly, or at such distances as persons arrived at maturity.

Old men, on the contrary, see bodies close to them very indistinctly, but bodies at a great distance from them with more precision; and this may happen from an alteration in the coats, or, perhaps, humours of the eye; and not, as is supposed, from their diminution. The cornea, for instance, may become too rigid to adapt itself, and take a proper convexity for seeing minute objects; and its very flatness will be sufficient to fit it for distant vision.

When we cast our eyes upon an object extremely brilliant, or when we fix and detain them too long upon the same object, the organ is hurt and fatigued, its vision becomes indistinct, and the image of the body, which has thus too violently, or too perseveringly employed us, is painted upon every thing we look at, and mixes with every object that occurs. And this is an obvious consequence of the eye taking in too much light, either immediately, or by reflection. Every body exposed to the light, for a time, drinks in a quantity of its rays, which, being brought into darkness, it cannot instantly discharge. Thus the hand, if it be exposed to broad day-light, for some time, and then immediately snatched into a dark room, will appear still luminous; and it will be some time before it is totally darkened. It is thus with the eye; which, either by an instant gaze at the sun, or a steady continuance, upon some less brilliant object, has taken in too much light; its humours are, for a while, unfit

unfit for vision, until that be discharged, and room made for rays of a mild nature. How dangerous the looking upon bright and luminous objects is to the sight, may be easily seen, from such as live in countries, covered for most part of the year with snow, who become generally blind before their time. Travellers who cross these countries, are obliged to wear a crape before their eyes, to save them, which would otherwise be rendered totally unserviceable; and it is equally dangerous in the sandy plains of Africa. The reflection of the light is there so strong that it is impossible to sustain the effect, without incurring the danger of losing one's sight entirely. Such persons, therefore, as read, or write for any continuance, should chuse a moderate light, in order to save their eyes; and, although it may seem insufficient at first, the eye will accustom itself to the shade, by degrees, and be less hurt by the want of light than the excess.

It is, indeed, surprising how far the eye can accommodate itself to darkness, and make the best of a gloomy situation. When first taken from the light, and brought into a dark room, all things disappear; or, if any thing is seen, it is only the remaining radiations that still continue in the eye. But, after a very little time, when these are spent, the eye takes the advantage of the smallest ray that happens to enter; and this alone would, in time, serve for many of the purposes of life. There was a gentleman of great courage and understanding, who was a major under King Charles the First. This unfortunate man sharing in his master's misfortunes, and being forced abroad, ventured at Madrid to do his king a signal service; but, unluckily, failed in the attempt. In consequence of this, he was instantly ordered to a dark and dismal dungeon, into which the light never entered, and into which there was no opening but by a hole at the top; down which the keeper put his provisions, and presently closed it again on the other side. In this manner the unfortunate loyalist continued for some weeks, distressed and disconsolate; but, at last, began to think he saw some little glimmering of light. This internal dawn seemed to increase from time to time, so that he could not only discover the parts of his bed, and such other large objects, but, at length, he even began to perceive the mice that frequented his cell; and saw them as they ran about the floor, eating the crumbs of bread that happened to fall. After some months confinement he was at last set free; but, such was the effect of the darkness upon him, that he could not for some days venture to leave his dungeon, but was obliged to accustom himself by degrees to the light of the day.

C H A P. VIII.

Of HEARING.

AS the sense of hearing, as well as of sight, gives us notice of remote objects, so like that, it is subject to similar errors, being capable of imposing on us upon all occasions, where we cannot rectify it by the sense of feeling. We can have from it no distinct intelligence of the distance from whence a sounding body is heard; a great noise far off, and a small one very near, produces the same sensation; and, unless we receive information from some other sense, we can never distinctly tell whether the sound be a great or a small one. It is not till we have learned, by experience, that the particular sound which is heard, is of a peculiar kind; then we can judge of the distance from whence we hear it. When we know the tone of the bell, we can then judge how far it is from us.

Every body that strikes against another produces

a sound, which is simple, and but one in bodies which are not elastic, but which is often repeated in such as are. If we strike a bell, or a stretched string, for instance, which are both elastic, a single blow produces a sound, which is repeated by the undulations of the sonorous body, and which is multiplied as often as it happens to undulate, or vibrate. These undulations each strike their own peculiar blow; but they succeed so fast, one behind the other, that the ear supposes them one continued sound; whereas in reality, they make many. A person who should, for the first time, hear the toll of the bell, would very probably, be able to distinguish these breaks of sound; and, in fact, we can readily ourselves perceive an intension and remission in the sound.

In this manner, sounding bodies are of two kinds; those unelastic ones, which being struck, return but a single sound; and those more elastic returning a succession of sound; which uniting together form a tone. This tone may be considered as a great number of sounds, all produced one after the other, by the same body, as we find in a bell, or the string of an harpsichord, which continues to sound for some time after it is struck. A continuing tone may be also produced from a nonelastic body, by repeating the blow quick and often, as when we beat a drum, or when we draw a bow along the string of a fiddle.

Considering the subject in this light, if we should multiply the number of blows, or repeat them at quicker intervals upon the sounding body, as upon the drum, for instance, it is evident that this will have no effect in altering the tone; it will only make it either more even or more distinct. But it is otherwise, if we increase the force of the blow; if we strike the body with double weight, this will produce a tone twice as loud as the former. If, for instance, we strike a table with a switch, this will be very different from the sound produced by striking it with a cudgel. From hence, therefore, we may infer, that all bodies give a louder and graver tone, not in proportion to the number of times they are struck, but in proportion to the force that strikes them. And, if this be so, those philosophers who make the tone of a sonorous body, of a bell, or the string of an harpsichord, for instance, to depend upon the number only of its vibrations, and not the force, have mistaken what is only an effect for a cause. A bell, or an elastic string can only be considered as a drum beaten; and the frequency of the blows can make no alteration whatever in the tone. The largest bells, and the longest and thickest strings, have the most forceful vibrations; and, therefore, their tones are the most loud and the most grave.

To know the manner in which sounds thus produced become pleasing, it must be observed, no one continuing tone, how loud or swelling soever, can give us satisfaction; we must have a succession of them, and those in the most pleasing proportion. The nature of this proportion may be thus conceived. If we strike a body incapable of vibration with a double force, or, what amounts to the same thing, with a double mass of matter, it will produce a sound that will be doubly grave. Music has been said, by the ancients, to have been first invented from the blows of different hammers on an anvil. Suppose then we strike an anvil with an hammer of one pound weight, and again with an hammer of two pounds, it is plain that the two pound hammer will produce a sound twice as grave as the former. But if we strike with a two pound hammer, and then with a three pound, it is evident that the latter will produce a sound one third more grave than the former. If we strike an anvil with a three pound hammer, and then with a four pound,

it will likewise follow that the latter will be a quarter part more grave than the former. Now, in the comparing between all those sounds, it is obvious that the difference between one and two is more easily perceived than between two and three, three and four, or any numbers succeeding in the same proportion. The succession of sounds will be, therefore, pleasing in proportion to the ease with which they may be distinguished. That sound which is double the former, or, in other words, the octave to the preceding tone, will of all others be the most pleasing. The next to that, which is as two to three, or, in other words, the third, will be most agreeable. And thus universally, those sounds whose difference may be most easily compared are the most agreeable.

Musicians, therefore, have contented themselves with seven different proportions of sound, which are called notes, and which sufficiently answer all the purposes of pleasure. Not but that they might adopt a greater diversity of proportions; and some have actually done so; but, in these, the differences of the proportion are so imperceptible, that the ear is rather fatigued than pleased in making the distinction. In order, however, to give variety, they have admitted half tones; but, in all the countries where music is yet in its infancy, they have rejected such; and they can find music in none but the obvious. The Chinese, for instance, have neither flats nor sharps in their music; but the intervals between their other notes, are in the same proportion with ours.

Many more barbarous nations have their peculiar instruments of music; and, what is remarkable, the proportion between their notes is in all the same as in ours. This is not the place for entering into the nature of these sounds, their effects upon the air, or their consonances with each other. We are not now giving an history of sound, but of human perception.

All countries are pleased with music; and, if they have not skill enough to produce harmony, at least they seem willing to substitute noise. Without all question, noise alone is sufficient to operate powerfully on the spirits; and, if the mind be already predisposed to joy, we have seldom found noise fail of increasing it into rapture. The mind feels a kind of distracted pleasure in such powerful sounds; braces up every nerve, and riots in the excess. But, as in the eye, an immediate gaze upon the sun will disturb the organ, so, in the ear, a loud, unexpected noise, disorders the whole frame, and sometimes disturbs the sense ever after. The mind must have time to prepare for the expected shock, and to give its organs the proper tension for its arrival.

Musical sounds, however, seem of a different kind. These are generally most pleasing, which are most unexpected. It is not from bracing up the nerves, but from the grateful succession of the sounds, that these become so charming. There are few, how indifferent soever, but have at times felt their pleasing impression; and, perhaps, even those who have stood out against the powerful persuasion of sounds, only wanted the proper tune, or the proper instrument to allure them.

The ancients give us a thousand strange instances of the effects of music, upon men and animals. The story of Arion's harp, that gathered the dolphins to the ship's side, is well known; and, what is remarkable, Schotteus assures us, that he saw a similar instance of fishes being allured by music. They tell us of diseases that have been cured; unchastity corrected, seditions quelled, passions removed, and sometimes excited even to madness. Doctor Wallis has endeavoured to account for these surprising effects, by ascribing them to the novelty

of the art; but we can scarce hesitate to impute them to the exaggeration of their writers. They are as hyperbolic in the effects of their oratory; and yet, we well know, there is nothing in the orations which they have left us, capable of exciting madness, or of raising the mind to that ungovernable degree of fury which they describe. As they have exaggerated, therefore, in one instance, we may naturally suppose, that they have done the same in the other: and, indeed, from the few remains we have of their music, collected by Meibomius, one might be apt to suppose, there was nothing very powerful in what is lost. Nor does any one of the ancient instruments, such as we see them represented in statues, appear comparable to our fiddle.

However this be, we have many odd accounts, not only among them, but the moderns, of the power of music; and it must not be denied, but that, on some particular occasions, musical sounds may have a very powerful effect. We have seen all the horses and cows in a field, where there were above an hundred, gather round a person that was blowing the French horn, and seeming to testify an awkward kind of satisfaction. Dogs are well known to be very sensible of different tones in music; and we have sometimes heard them sustain a very ridiculous part in a concert, where their assistance was neither expected nor desired.

We are told, of Henry IV. of Denmark, that being one day desirous of trying in person whether a musician who boasted that he could excite men to madness, was not an impostor, he submitted to the operation of his skill: but the consequence was much more terrible than he expected; for, becoming actually mad, he killed four of his attendants in the midst of his transports. A contrary effect of music we have, in the cure of a madman of Alais, in France, by music. This man, who was a dancing-master, after a fever of five days grew furious, and so ungovernable that his hands were obliged to be tied to his sides: what at first was rage, in a short time was converted into silent melancholy, which no arts could exhilarate, nor no medicines remove. In this sullen and dejected state, an old acquaintance accidentally came to enquire after his health; he found him sitting up in bed, tied, and totally regardless of every external object round him. Happening, however, to take up a fiddle that lay in the room, and touching a favourite air, the poor madman instantly seemed to brighten up at the sound; from a recumbent posture, he began to sit up; and as the musician continued playing, the patient seemed desirous of dancing to the sound: but he was tied, and incapable of leaving his bed, so that he could only humour the tune with his head, and that part of his arms which were at liberty. Thus the other continued playing, and the dancing-master practised his own art, as far as he was able, for about a quarter of an hour, when suddenly falling into a deep sleep, in which his disorder came to a crisis, he awaked perfectly recovered.

A thousand other instances might be added, equally true: let it suffice to add one more, which is not true; we mean that of the tarantula. Every person who has been in Italy, now well knows, that the bite of this animal, and its being cured by music, is all a deception. When strangers come into that part of the country, the country people are ready enough to take money for dancing to the tarantula. A gentleman had a servant who suffered himself to be bit; the wound, which was little larger than the puncture of a pin, was uneasy for a few hours, and then became well without any farther assistance. Some of the country people, however, still make a tolerable livelihood of the credulity

lity of strangers, as the musician finds his account in it not less than the dancer.

Sounds, like light, are not only extensively diffused, but are frequently reflected. The laws of this reflection, it is true, are not as well understood as those of light; all we know is, that sound is principally reflected by hard bodies; and their being hollow also, sometimes increases the reverberation. No art, however, can make an echo; and some, who have bestowed great labour and expence upon such a project, have only erected shapeless buildings whose silence was a mortifying lecture upon their presumption.

The internal cavity of the ear seems to be fitted up for the purposes of echoing sound with the greatest precision. This part is fashioned out in the temporal bone, like a cavern cut into a rock. In this the sound is repeated and articulated; and, as some anatomists tell us, (for we have as yet but very little knowledge on this subject) is beaten against the tympanum, or drum of the ear, which moves four little bones joined thereto; and these move and agitate the internal air which lies on the other side; and lastly, this air strikes and affects the auditory nerves, which carry the sound to the brain.

One of the most common disorders in old age is deafness; which probably proceed from the rigidity of the nerves in the labyrinth of the ear. This disorder also, sometimes proceeds from a stoppage of the wax, which art may easily remedy. In order to know whether the defect be an internal or an external one, let the deaf person put a repeating watch into his mouth; and if he hears it strike, he may be assured that his disorder proceeds from an external cause, and is, in some measure, curable: for there is a passage for the ears into the mouth, by what anatomists call the eustachian tube; and, by this passage, people often hear sounds, when they are utterly without hearing through the larger channel: and this also is the reason that we often see persons who listen with great attention, hearken with their mouths open, in order to catch all the sound at every aperture.

It often happens, that persons hear differently with one ear from the other; and it is generally found that these have what is called, by musicians, a bad ear. Mr. Buffon, who has made many trials upon persons, of this kind, always found that their defect in judging properly of sounds, proceeded from the inequality of their ears; and receiving by both, at the same, unequal sensations, they form an unjust idea. In this manner, as those people hear false, they also, without knowing it, sing false. Those persons also frequently deceive themselves with regard to the side from whence the sound comes, generally supposing the noise to come on the part of the best ear.

Such as are hard of hearing find the same advantage in the trumpet made for this purpose, that short-sighted persons do from glasses. These trumpets might be easily improved, so as to increase sounds, in the same manner that the telescope does objects: however, they could be used to advantage only in a place of solitude and stillness, as the neighbouring sounds would mix with the more distant, and the whole would produce in the ear nothing but tumult and confusion.

Hearing is a much more necessary sense to man than to animals. With these it is only a warning against danger, or an encouragement to mutual assistance. In man, it is the source of most of his pleasures; and without which, the rest of his senses would be of little benefit. A man born deaf, must necessarily be dumb; and his whole sphere of knowledge must be bounded only by sensual objects. We have an instance of a young man who, being

born deaf, was restored, at the age of twenty-four, to perfect hearing: the account is given in the Memoirs of the Academy of Sciences, 1793, page 18.

A young man of the town of Chartres, between the age of twenty-three and twenty-four, the son of a tradesman, and deaf and dumb from his birth, began to speak all of a sudden, to the great astonishment of the whole town. He gave them to understand that, about three or four months before he had heard the sound of bells for the first time, and was greatly surpris'd at this new and unknown sensation. After some time a kind of water issued from his left ear, and he then heard perfectly well with both. During these three months, he was sedulously employed in listening, without saying a word, and accustoming himself to speak softly, so as not to be heard, the words pronounced by others. He laboured hard also in perfecting himself in the pronunciation, and in the ideas attached to every sound. At length, having supposed himself qualified to break silence, he declared, that he could now speak, although as yet but imperfectly. Soon after, some able divines questioned him concerning his ideas of his past state; and principally with respect to God, his soul, the morality or turpitude of actions. The young man, however, had not driven his solitary speculations into that channel. He had gone to mass indeed with his parents, had learned to sign himself with the cross, to kneel down and assume all the grimaces of a man that was praying; but he did all this without any manner of knowledge of the intention or the cause; he saw others do the like, and that was enough for him; he knew nothing even of death, and it never entered into his head; he led a life of pure animal instinct; entirely taken up with sensible objects, and such as were present, he did not seem even to make as many reflections upon these, as might reasonably be expected from his improving situation: and yet, the young man was not in want of understanding; but the understanding of a man deprived of all commerce with others, is so very confined, that the mind is in some measure totally under the controul of its immediate sensations.

Notwithstanding, it is very possible to communicate ideas to deaf men, which they previously wanted, and even give them very precise notions of some abstract subjects, by means of signs, and of letters. A person born deaf, may, by time, and sufficient pains, be taught to write and read, to speak, and, by the motions of the lips, to understand what is said to him: however, it is probable that, as most of the motions of speech are made within the mouth by the tongue, the knowledge from the motion of the lips, is but very confined: nevertheless, a gentleman thus taught has been conversed with, and in all the commonly occurring questions, and the usual salutations, he was ready enough, merely by attending to the motion of the lips alone; but when he was spoke to for a short continuance, he was totally at a loss, although he understood the subject, when written, extremely well. Persons taught in this manner, were at first considered as prodigies; but there have been so many instances of success of late, and so many are skilful in the art of instructing in this way, that, though still a matter of some curiosity, it ceases to be an object of wonder.

CHAP. IX.

Of SMELLING, FEELING, and TASTING.

AN animal may be said to fill up that sphere which he can reach by his senses; and is actually large in proportion to the sphere to which its organ

organ extends. By sight, man's enjoyments are diffused into a wide circle; that of hearing, though less widely diffused, nevertheless extends his powers; the sense of smelling is more contracted still; and the taste and touch are the most confined of all. Thus man enjoys very distant objects, but with one sense only; more nearly he brings two senses at once to bear upon them; his sense of smelling assists the other two, at its own distance; and of such objects, as a man, he may be said to be in perfect possession.

Each sense, however, the more it acts at a distance, the more capable it is of making combinations; and is, consequently, the more improveable: Refined imaginations, and men of strong minds, take more pleasure, therefore, in improving the delights of the distant senses, than in enjoying such as are scarce capable of improvement.

By combining the objects of the extensive senses, all the arts of poetry, painting, and harmony, have been discovered; but the closer senses, if we may so call them, such as smelling, tasting, and touching, are, in some measure, as simple as they are limited, and admit of little variety. The man of imagination makes a great and an artificial happiness, by the pleasure of altering and combining; the sensualist just stops where he began, and cultivates only those pleasures which he cannot improve. The sensualist is contented with those enjoyments that are already made to his hand; but the man of pleasure is best pleased with growing happiness.

Of all the senses, perhaps, there is not one in which man is more inferior to other animals than in that of smelling. With man, it is a sense that acts in a narrow sphere, and disgusts almost as frequently as it gives him pleasure. With many other animals it is diffused to a very great extent; and never seems to offend them. Dogs not only trace the steps of other animals, but also discover them by the scent, at a very great distance; and, while they are thus exquisitely sensible of all smells, they seem no way disgusted by any.

But, although this sense is, in general, so very inferior in man, it is much stronger in those nations that abstain from animal food, than among Europeans. The Bramins of India have a power of smelling equal to what it is in most other creatures. They can smell the water which they drink, that to us seems quite inodorous; and have a word, in their language, which denotes a country of fine water. We are told, also, that the Negroes of the Antilles, by the smell alone, can distinguish between the footsteps of a Frenchman and a Negro. It is possible, therefore, that we may dull this organ by our luxurious way of living; and sacrifice to the pleasures of taste those which might be received from perfume.

However, it is a sense that we can, in some measure, dispense with; and we have known many that wanted it entirely, with but very little inconvenience from its loss. In a state of nature it is said to be useful in guiding us to proper nourishment, and deterring us from that which is unwholesome; but, in our present situation, such information is but little wanted; and, indeed, but little attended to. In fact, the sense of smelling gives us very often false intelligence. Many things that have a disagreeable odour are, nevertheless, wholesome, and pleasant to the taste; and such as make eating an art, seldom think a meal fit to please the appetite till it begins to offend the nose. On the other hand, there are many things that smell most gratefully, and yet are noxious, or fatal to the constitution. Some physicians think that perfumes, in general, are unwholesome; that they relax the nerves, produce head-aches, and even retard digestion. The machinel apple, which

is known to be deadly poison, is possessed of the most grateful odour. Some of those mineral vapours that are often found fatal, in the stomach, smell like the sweetest flowers, and continue thus to flatter till they destroy. This sense, therefore, as it should seem, was never meant to direct us in the choice of food, but appears rather as an attendant than a necessary pleasure.

Indeed, if we examine the natives of different countries, or even different natives of the same, we shall find no pleasure in which they differ so widely as that of smelling. Some persons are pleased with the smell of a rose; while we have known others that could not abide to have it approach them. The savage nations are highly delighted with the smell of assafœtida, which is to us the most nauseous stink in nature. It would in a manner seem that our delight in perfumes was made by habit; and that a very little industry could bring us totally to invert the perception of odours.

Thus much is certain, that many bodies which at one distance are an agreeable perfume, when nearer are a most ungrateful odour. Musk, and amber-grease, in small quantities, are considered by most persons as highly fragrant; and yet, when in larger masses, their scent is insufferable. From a mixture of two bodies, each whereof is, of itself, void of all smell, a very powerful smell may be drawn. Thus, by grinding quick-lime with sal-ammoniac, may be produced a very foetid mixture. On the contrary, from a mixture of two bodies, that are separately disagreeable, a very pleasant aromatic odour may be gained. A mixture of aqua fortis with spirit of wine produces this effect. But not only the alterations of bodies, by each other, but the smallest change in us, makes a very great alteration in this sense, and frequently deprives us of it totally. A slight cold often hinders us from smelling; and as often changes the nature of odours. Some persons, from disorder, retain an incurable aversion to those smells which most pleased them before; and many have been known to have an antipathy to some animals, whose presence they instantly perceive by the smell. From all this, therefore, the sense of smelling appears to be an uncertain monitor, easily disordered, and not much missed when totally wanting.

The sense most nearly allied to smelling is that of tasting. This, some have been willing to consider merely as a nicer kind of touch, and have undertaken to account, in a very mechanical manner, for the difference of flavours. Such bodies, say they, as are pointed, happening to be applied to the papillæ of the tongue, excite a very powerful sensation, and give us the idea of saltness. Such, on the contrary, as are of a rounder figure, slide smoothly along the papillæ, and are perceived to be sweet. In this manner they have, with minute labour, gone through the variety of imagined forms in bodies, and have given them as imaginary effects. All we can precisely determine upon the nature of tastes is, that the bodies to be tasted must be either somewhat moistened, or, in some measure, dissolved by the saliva before they can produce a proper sensation: when both the tongue itself, and the body to be tasted, are extremely dry, no taste whatever ensues. The sensation is then changed; and the tongue, instead of tasting can only be said, like any other part of the body, to feel the object.

It is for this reason, that children have a stronger relish of tastes than those who are more advanced in life. This organ with them, from the greater moisture of their bodies, is kept in greater perfection; and is, consequently, better adapted to perform its functions. Every person remembers how great a pleasure he found in sweets while a child; but his taste growing more obtuse, with age, he is obliged to

to use artificial means to excite it. It is then that he is found to call in the assistance of poignant sauces, and strong relishes, of salts and aromatics; all which the delicacy of his tender organ, in childhood, were unable to endure. His taste grows callous to the natural relishes; and is artificially formed to others more unnatural; so that the highest epicure may be said to have the most depraved taste; as it is owing to the bluntness of his organs that he is obliged to have recourse to such a variety of expedients, to gratify his appetite.

As smells are often rendered agreeable by habit, so also tastes may be. Tobacco, and coffee, so pleasing to many, are yet, at first, very disagreeable to all. It is not without perseverance that we begin to have a relish for them; we force nature so long, that what was constraint, in the beginning, at last becomes inclination.

The grossest, and yet the most useful of all the senses, is that of feeling. We are often seen to survive under the loss of the rest; but of this we can never be totally deprived, but with life. Although this sense is diffused over all parts of the body, yet it most frequently happens that those parts which are most exercised in touching, acquire the greatest degree of accuracy. Thus the fingers, by long habit, become greater masters in the art than any others, even where the sensation is more delicate and fine. It is from this habit, therefore, and their peculiar formation, and not, as is supposed, from their being furnished with a greater quantity of nerves, that the fingers are thus perfectly qualified to judge of forms. Blind men, who are obliged to use them much oftner, have this sense much finer; so that the delicacy of the touch arises rather from the habit of constantly employing the fingers, than from any fancied nervousness in their conformation.

All animals that are furnished with hands, seem to have more understanding than others. Monkeys have so many actions, like those of men, that they appear to have similar ideas of the form of bodies. All other creatures, deprived of hands, can have no distinct ideas of the shape of the objects, by which they are surrounded, as they want this organ, which serves to examine and measure their forms; their risings and depressions. A quadrupede probably conceives as erroneous an idea of any thing near him, as a child would of a rock, or a mountain, that it beheld at a distance. It may be for this reason, that we often see them frightened at things with which they ought to be better acquainted. Fishes, whose bodies are covered with scales, and who have no organs for feeling, must be the most stupid of all animals. Serpents, that are likewise destitute, are yet, by winding round several bodies, better capable of judging of their form. All these, however, can have but very imperfect ideas from feeling; and we have already seen, when deprived of this sense, how little the rest of the senses are to be relied on.

The feeling therefore, is the guardian, the judge, and the examiner of all the rest of the senses. It establishes their information, and detects their errors. All the other senses are altered by time, and contradict their former evidence; but the touch still continues the same; and though extremely confined in its operations, yet it is never found to deceive. The universe, to a man who had only used the rest of his senses, would be but a scene of illusion; every object misrepresented, and all its properties unknown. Mr. Buffon has imagined a man just newly brought into existence, describing the illusion of his first sensations, and pointing out the steps by which he arrived at reality. He considers him as just created, and awaking amidst the productions of Nature; and to animate the narrative still more strongly, has made his philosophical man a speaker.

The reader will, no doubt, recollect Adam's speech in Milton, as being similar. One treats the subject more as a poet, the other more as a philosopher. The philosopher's man describes his first sensation in the following manner:

"I well remember that joyful anxious moment when I first became acquainted with my own existence. I was quite ignorant of what I was, how I was produced, or from whence I came. I opened my eyes: what an addition to my surprize! the light of the day, the azure vault of heaven, the verdure of the earth, the chrystal of the waters, all employed me at once, and animated and filled me with inexpressible delight. I at first imagined that all those objects were within me, and made a part of myself.

"Impressed with this idea, I turned my eyes to the sun; its splendor dazzled and overpowered me: I shut them once more; and, to my great concern, I supposed that, during this short interval of darkness, I was again returning to nothing.

"Afflicted, seized with astonishment, I pondered a moment on this great change, when I heard a variety of unexpected sounds. The whistling of the wind, and the melody of the grove, formed a concert, the soft cadence of which sunk upon my soul. I listened for some time, and was persuaded that all this music was within me.

"Quite occupied with this new kind of existence, I had already forgotten the light which was my first inlet into life; when I once more opened my eyes, and found myself again in possession of my former happiness. The gratification of the two senses at once, was a pleasure too great for utterance.

"I turned my eyes upon a thousand various objects: I soon found that I could lose them, and restore them at will; and amused myself more at leisure with a repetition of this new-made power.

"I now began to gaze without emotion, and to hearken with tranquillity, when a light breeze, the freshness of which charmed me, wafted its perfumes to my sense of smelling; and gave me such satisfaction as even increased my self-love.

"Agitated, roused by the various pleasures of my new existence, I instantly arose, and perceived myself moved along, as if by some unknown and secret power.

"I had scarce proceeded forward, when the novelty of my situation once more rendered me immoveable. My surprize returned; I supposed that every object around me had been in motion: I gave to them that agitation which I produced by changing place; and the whole creation seemed once more in disorder.

"I lifted my hand to my head; I touched my forehead; I felt my whole frame: I then supposed that my hand was the principal organ of my existence; all its informations were distinct and perfect; and so superior to the senses I had yet experienced, that I employed myself for some time in repeating its enjoyments: every part of my person I touched, seemed to touch my hand in turn; and gave back sensation for sensation.

"I soon found, that this faculty was expanded over the whole surface of my body; and I now first began to perceive the limits of my existence, which I had in the beginning supposed spread over all the objects I saw.

"Upon casting my eyes upon my body, and surveying my own form, I thought it greater than all the objects that surrounded me. I gazed upon my person with pleasure; I examined the formation of my hand, and all its motions; it seemed to me large or little in proportion as I approached it to my eyes; I brought it very near, and it then hid almost every other object from my sight. I began soon, however,

ever,

ever, to find that my sight gave me uncertain information, and resolved to depend upon my feeling for redress.

“ This precaution was of the utmost service; I renewed my motions, and walked forward with my face turned towards the heavens. I happened to strike lightly against a palm-tree, and this renewed my surprize: I laid my hand on this strange body; it seemed replete with new wonders, for it did not return me sensation for sensation, as my former feelings had done. I perceived that there was something external, and which did not make a part of my own existence.

“ I now, therefore, resolved to touch whatever I saw, and vainly attempted to touch the sun; I stretched forth my arm, and felt only yielding air: at every effort, I fell from one surprize into another, for every object appeared equally near me; and it was not till after an infinity of trials, that I found some objects further removed than the rest.

“ Amazed with the illusions, and the uncertainty of my state, I sat down beneath a tree; the most beautiful fruits hung upon it, within my reach; I stretched forth my hand, and they instantly separated from the branch. I was proud of being able to grasp a substance without me; I held them up, and their weight appeared to me like an animated power that endeavoured to draw them to the earth. I found a pleasure in conquering their resistance.

“ I held them near my eye; I considered their form and beauty; their fragrance still more allured me to bring them nearer; I approached them to my lips, and drank in their odours; the perfume invited my sense of tasting, and I soon tried a new sense—How new! how exquisite! Hitherto I had tasted only of pleasure; but now it was luxury. The power of tasting gave me the idea of possession.

“ Flattered with this new acquisition, I continued its exercise, till an agreeable languor stealing upon my mind, I felt all my limbs become heavy, and all my desires suspended. My sensations were now no longer vivid and distinct; but seemed to lose every object, and presented only feeble images, confusedly marked. At that instant I sunk upon the flowery bank, and slumber seized me. All now seemed once more lost to me. It was then as if I was returning into my former nothing. How long my sleep continued, I cannot tell; as I yet had no perception of time. My awaking appeared like a second birth; I then perceived that I had ceased for a time to exist. This produced a new sensation of fear; and from this interruption in life, I began to conclude that I was not formed to exist for ever.

“ In this state of doubt and perplexity, I began to harbour new suspicions; and to fear that sleep had robbed me of some of my late powers: when, turning on one side, to resolve my doubts, what was my amazement, to behold another being, like myself, stretched by my side! New ideas now began to arise; new passions, as yet unperceived, with fears, and pleasures, all took possession of my mind, and prompted my curiosity: love served to complete that happiness which was begun in the individual; and every sense was gratified in all its varieties.”

C H A P. X.

Of old AGE and DEATH.

EVERY thing in nature has its improvement and decay. The human form is no sooner arrived at its state of perfection than it begins to decline. The alteration is, at first, insensible; and, often, several years are elapsed before we find our-

elves grown old. The news of this disagreeable change, too generally, comes from without, and we learn from others that we grow old, before we are willing to believe the report.

When the body has come to its full height, and is extended into its just dimensions; it then also begins to receive an additional bulk, which rather loads than assists it. This is formed from fat; which generally, at the age of thirty-five, or forty, covers all the muscles, and interrupts their activity: Every action is then performed with greater labour, and the increase of size only serves as a forerunner of decay.

The bones, also, become every day more solid. In the embryo they are as soft almost as the muscles and the flesh; but, by degrees, they harden, and acquire their natural vigour; but still, however, the circulation is carried on through them; and, how hard soever the bones may seem, yet the blood holds its current through them as through all other parts of the body. Of this we may be convinced, by an experiment, which was first accidentally discovered, by our ingenious countryman Mr. Belcher. Perceiving, at a friend's house, that the bones of hogs, which were fed upon madder, were red, he tried it upon various animals, by mixing this root with their usual food; and he found that it tintured the bones in all: an evident demonstration that the juices of the body had a circulation through the bones. He fed some animals alternately upon madder and their common food, for some time, and he found their bones tintured with alternate layers, in conformity to their manner of living. From all this, he naturally concluded, that the blood circulated through the bones as it does through every other part of the body; and that, how solid soever they seemed, yet, like the softest parts, they were furnished, through all their substance, with their proper canals. Nevertheless, these canals are of very different capacities, during the different stages of life. In infancy they are capacious; and the blood flows almost as freely through the bones as through any other part of the body; in manhood their size is greatly diminished; the vessels are almost imperceptible; and the circulation through them is proportionably slow. But, in the decline of life, the blood, which flows through the bones, no longer contributing to their growth, must necessarily serve to increase their hardness. The channels, that every where run through the human frame, may be compared to those pipes that we every where see crusted on the inside, by the water, for a long continuance, running through them. Both, every day grow less and less, by the small rigid particles which are deposited within them. Thus as the vessels are by degrees diminished, the juices, also, which were necessary for the circulation through them, are diminished in proportion; till, at length, in old age, those props of the human frame are not only more solid but more brittle.

The cartilages, or gristles, which may be considered as bones beginning to be formed, grow also more rigid. The juices circulating through them, for there is a circulation through all parts of the body, every day contributes to render them harder; so that these substances, which in youth are elastic and pliant, in age become hard and bony. As these cartilages are generally placed near the joints, the motion of the joints also must, of consequence, become more difficult. Thus, in old age, every action of the body is performed with labour; and the cartilages, formerly so supple, will now sooner break than bend.

As the cartilages acquire hardness, and unfit the joints for motion, so also that mucous liquor, which is always separated between the joints, and which serves, like oil to an hinge, to give them an easy

and ready play, is now grown more scanty. It becomes thicker, and more clammy, more unfit for answering the purposes of motion; and from thence, in old age, every joint is not only stiff, but awkward. At every motion, this clammy liquor is heard to crack; and it is not without the greatest effort of the muscle, that its resistance is overcome.

The membranes that cover the bones, the joints, and the rest of the body, become, as we grow old, more dense and more dry. These which surround the bones, soon cease to be ductile. The fibres, of which the muscles or flesh is composed, become every day more rigid; and, while to the touch the body seems, as we advance in years, to grow softer, it is, in reality, increasing in hardness. It is the skin, and not the flesh, that we feel upon such occasions. The fat, and the flabbiness of that, seems to give an appearance of softness, which the flesh itself is very far from having. There are few can doubt this after trying the difference between the flesh of young and old animals. The first is soft and tender, the last is hard and dry.

The skin is the only part of the body that age does not contribute to harden. That stretches to every degree of tension; and we have horrid instances of its pliancy, in many disorders incident to humanity. In youth, therefore, while the body is vigorous and increasing, it still gives way to its growth. But, although it thus adapts itself to our increase, it does not in the same manner conform to our decay. The skin, which in youth was filled, and glossy, when the body begins to decline, has not elasticity enough to shrink entirely with its diminution. It hangs, therefore, in wrinkles, which no art can remove. The wrinkles of the body, in general, proceed from this cause. But those of the face seem to proceed from another; namely, from the many varieties of positions into which it is put by the speech, the food, or the passions. Every grimace, and every passion wrinkles up the visage into different forms. These are visible enough in young persons; but what at first was accidental, or transitory, becomes unalterably fixed in the visage as it grows older. From hence we may conclude, that a freedom from passions not only adds to the happiness of the mind, but preserves the beauty of the face; and the person that has not felt their influence, is less strongly marked by the decays of nature.

Hence, therefore, as we advance in age, the bones, the cartilages, the membranes, the flesh, the skin, and every fibre of the body, becomes more solid, more brittle, and more dry. Every part shrinks, every motion becomes more slow; the circulation of the fluids is performed with less freedom; perspiration diminishes; the secretions alter; the digestion becomes slow and laborious; and the juices, no longer serving to convey their accustomed nourishment, those parts may be said to live no longer when the circulation ceases. Thus the body dies by little and little: all its functions are diminished by degrees; life is driven from one part of the frame to another; universal rigidity prevails; and death at last seizes upon the little that is left.

As the bones, the cartilages, the muscles, and all other parts of the body are softer in women than in men, these parts must, of consequence, require a longer time to come to that hardness which hastens death. Women, therefore, ought to be a longer time in growing old than men; and this is actually the case. If we consult the tables which have been drawn up respecting human life, we shall find, that after a certain age they are more long lived than men, all other circumstances the same. A woman of sixty has a better chance than a man of the same age to live till eighty. Upon the whole we may infer, that such persons as have been slow in coming up to maturity, will also be slow in growing old; and

this holds as well with regard to other animals as to man.

The whole duration of the life of either vegetables, or animals, may be, in some measure, determined from their manner of coming to maturity. The tree, or the animal, which takes but a short time to increase to its utmost pitch, perishes much sooner than such as are less premature. In both, the increase upwards is first accomplished; and not till they have acquired their greatest degree of height do they begin to spread in bulk. Man grows in stature till about the age of seventeen; but his body is not completely developed till about thirty. Dogs, on the other hand, are at their utmost size, in a year, and become as bulky as they usually are in another. However, man who is so long in growing, continues to live for fourscore, or an hundred years; but the dog seldom above twelve, or thirteen. In general, also, it may be said that large animals live longer than little ones, as they usually take a longer time to grow. But in all animals one thing is equally certain, that they carry the causes of their own decay about them; and that their deaths are necessary and inevitable. The prospects which some visionaries have formed of perpetuating life by remedies, have been often enough proved false by their own example. Such unaccountable schemes would, therefore, have died with them, had not the love of life always augmented our credulity.

When the body is naturally well formed, it is possible to lengthen out the period of life for some years by management. Temperance in diet is often found conducive to this end. The famous Cornaro, who lived to above an hundred years although his constitution was naturally feeble, is a strong instance of the benefit of an abstemious life. Moderation in the passions, also many contribute to extend the term of our existence. Fontenelle, the celebrated writer, was naturally of a very weak and delicate habit of body. He was affected by the smallest irregularities; and had frequently suffered severe fits of illness from the slightest causes. But the remarkable equality of his temper, and his seeming want of passion, lengthened out his life to above an hundred. It was remarkable of him, that nothing could vex or make him uneasy; every occurrence seemed equally pleasing; and no event, however unfortunate, seemed to come unexpected. However, the term of life can be prolonged but for a very little time by any art we can use. We are told of men who have lived beyond the ordinary duration of human existence; such as Par, who lived to an hundred and forty-four; and Jenkins to an hundred and sixty-five; yet these men used no peculiar arts to prolong life; on the contrary, it appears that these, as well as some others, remarkable for their longevity, were peasants, accustomed to the greatest fatigues, who had no settled rules of diet, but who often indulged in accidental excesses. Indeed, if we consider that the European, the Negro, the Chinese, and the American, the civilized man, and the savage, the rich and the poor, the inhabitants of the city, and of the country, though all so different in other respects, are yet entirely similar in the period allotted them for living; if we consider that neither the difference of race, of climate, of nourishment, of convenience, or of soil, makes any difference in the term of life; if we consider that those men who live upon raw flesh, or dried fishes, upon seago, or rice, upon cassava, or upon roots, nevertheless live as long as those who are fed upon bread and meat, we shall readily be brought to acknowledge, that the duration of life depends neither upon habit, customs, or the quantity of food; we shall confess, that nothing can change the laws of that mechanism which regulates the number of our years, and which can chiefly be affected only by long fasting, or great excess.

If there be any difference in the different periods of man's existence, it ought principally to be ascribed to the quality of the air. It has been observed, that in elevated situations there have been found more old people than in those that were low. The mountains of Scotland, Wales, Auvergne, and Switzerland, have furnished more instances of extreme old age than the plains of Holland, Flanders, Germany, or Poland. But, in general, the duration of life is nearly the same in most countries. Man, if not cut off by accidental diseases, is often found to live to ninety or an hundred years. Our ancestors did not live beyond that date; and, since the time of David, this term has undergone little alteration.

If we be asked how in the beginning men lived so much longer than at present, and by what means their lives were extended to nine hundred and thirty, or even nine hundred and sixty years, it may be answered, that the productions of the earth, upon which they fed, might be of a different nature at that time, from what they are at present. It may be answered, that the term was abridged by Divine command, in order to keep the earth from being over-stocked with human inhabitants; since, if every person were now to live and generate for nine hundred years, mankind would be increased to such a degree, that there would be no room for subsistence: so that the plan of Providence would be altered; which is seen not to produce life, without providing a proper supply.

But, to whatever extent life may be prolonged, or however some may have delayed the effects of age, death is the certain goal to which all are hastening. All the causes of decay which have been mentioned, contribute to bring on this dreaded dissolution. However, nature approaches to this awful period, by slow and imperceptible degrees; life is consuming day after day; and some one of our faculties, or vital principles, is every hour dying before the rest; so that death is only the last shade in the picture: and it is probable, that man suffers a greater change in going from youth to age, than from age into the grave. When we first begin to live, our lives may scarcely be said to be our own; as the child grows, life increases in the same proportion: and is at its height in the prime of manhood. But as soon as the body begins to decrease, life decreases also; for, as the human frame diminishes, and its juices circulate in smaller quantity, life diminishes and circulates with less vigour; so that as we begin to live by degrees, we begin to die in the same manner.

Why then should we fear death, if our lives have been such as not to make eternity dreadful! Why should we fear that moment which is prepared by a thousand other moments of the same kind! the first pangs of sickness being probably greater than the last struggles of departure. Death, in most persons, is as calmly endured as the disorder that brings it on. If we enquire from those whose business it is to attend the sick and the dying, we shall find that, except in a very few acute cases, where the patient dies in agonies, the greatest number die quietly, and seemingly without pain; and even the agonies of the former, rather terrify the spectators, than torment the patient; for how many have we not seen who have been accidentally relieved from this extremity, and yet had no memory of what they then endured? In fact, they had ceased to live, during that time when they ceased to have sensation; and their pains were only those of which they had an idea.

The greatest number of mankind die, therefore, without sensation; and of those few that still preserve their faculties entire to the last moment, there is scarce one of them that does not also preserve the hopes of still out-living his disorder. Nature, for

the happiness of man, has rendered this sentiment stronger than his reason. A person dying of an incurable disorder, which he must know to be so, by frequent examples of his case; which he perceives to be so, by the inquietude of all around him, by the tears of his friends, and the departure or the face of the physician, is, nevertheless, still in hopes of getting over it. His interest is so great that he only attends to his own representations; the judgment of others is considered as an hasty conclusion; and while death every moment makes new inroads upon his constitution, and destroys life in some part, hope still seems to escape the universal ruin, and is the last that submits to the blow.

Cast your eyes upon a sick man, who has an hundred times told you that he felt himself dying, that he was convinced he could not recover, and that he was ready to expire; examine what passes on his visage, when, through zeal or indiscretion, any one comes to tell him that his end is at hand. You will see him change, like one who is told an unexpected piece of news. He now appears not to have thoroughly believed what he had been telling you himself; he doubted much; and his fears were greater than his hopes: but he still had some feeble expectations of living, and would not have seen the approaches of death, unless he had been alarmed by the mistaken assiduity of his attendants.

Death, therefore, is not that terrible thing which we suppose it to be. It is a spectre which frights us at a distance, but which disappears when we come to approach it more closely. Our ideas of its terrors are conceived in prejudice, and dressed up by fancy; we regard it not only as the greatest misfortune, but also as an evil accompanied with the most excruciating tortures: we have even increased our apprehensions, by reasoning on the extent of our sufferings. It must be dreadful, say some, since it is sufficient to separate the soul from the body; it must be long, since our sufferings are proportioned to the succession of our ideas; and these being painful, must succeed each other with extreme rapidity. In this manner has false philosophy laboured to augment the miseries of our nature; and to aggravate that period, which Nature has kindly covered with insensibility. Neither the mind, nor the body, can suffer these calamities; the mind is, at that time, mostly without ideas; and the body too much enfeebled to be capable of perceiving its pain. A very acute pain produces either death, or fainting, which is a state similar to death: the body can suffer but to a certain degree; if the torture becomes excessive, it destroys itself; and the mind ceases to perceive, when the body can no longer endure.

In this manner, excessive pain admits of no reflection; and wherever there are any signs of it, we may be sure that the sufferings of the patient are no greater than what we ourselves may have remembered to endure.

But, in the article of death, we have many instances in which the dying person has shewn that very reflection which pre-supposes an absence of the greatest pain; and, consequently, that pang which ends life, cannot even be so great as those which have preceded. Thus, when Charles XII. was shot at the siege of Frederickshall, he was seen to clap his hand on the hilt of his sword; and although the blow was great enough to terminate one of the boldest and bravest lives in the world, yet it was not painful enough to destroy reflection. He perceived himself attacked; he reflected that he ought to defend himself, and his body obeyed the impulse of his mind, even in the last extremity. Thus it is the prejudice of persons in health, and not the body in pain, that makes us suffer from the approach of death: we have, all our lives, contracted an habit of making out excessive pleasures
and

and pains; and nothing but repeated experience shews us, how seldom the one can be suffered, or the other enjoyed to the utmost.

If there be any thing necessary to confirm what we have said, concerning the gradual cessation of life, or the insensible approaches of our end, nothing can more effectually prove it, than the uncertainty of the signs of death. If we consult what Winslow or Bruhier have said upon this subject, we shall be convinced, that between life and death, the shade is so very undistinguishable, that even all the powers of art can scarcely determine where the one ends, and the other begins. The colour of the visage, the warmth of the body, the suppleness of the joints, are but uncertain signs of life still subsisting; while on the contrary, the paleness of the complexion, the coldness of the body, the stiffness of the extremities, the cessation of all motion, and the total insensibility of the parts, are but uncertain marks of death begun. In the same manner also, with regard to the pulse, and the breathing, these motions are often so kept under, that it is impossible to perceive them. By approaching a looking-glass to the mouth of the person supposed to be dead, people often expect to find whether he breathes or not. But this is a very uncertain experiment: the glass is frequently sullied by the vapour of the dead man's body; and often the person is still alive, although the glass is no way tarnished. In the same manner, neither burning, nor scarifying, neither noises in the ears, nor pungent spirits applied to the nostrils, give certain signs of the discontinuance of life; and there are many instances of persons who have endured them all, and afterwards recovered, without any external assistance, to the astonishment of the spectators. How careful, therefore, should we be, before we commit those who are dearest to us to the grave, to be well assured of their departure? Experience, justice, humanity, all persuade us not to hasten the funerals of our friends, but to keep their bodies unburied, until we have certain signs of their real decease.

C H A P. XI.

Of the Varieties in the HUMAN Race.

WE have hitherto considered man as an individual, endowed with excellencies above the rest of the creation; we now come to consider the advantages which men have over men, and the various kinds with which our earth is inhabited.

If we compare the minute differences of mankind, there is scarce one nation upon the earth that entirely resembles another; and there may be said to be as many different kinds of men as there are countries inhabited. One polished nation does not differ more from another, than the merest savages do from those savages that lie even contiguous to them; and it frequently happens that a river, or a mountain, divides two barbarous tribes that are unlike each other in manners, customs, features, and complexion. But these differences, however perceivable, do not form such distinctions as come within a general picture of the varieties of mankind. Custom, accident, or fashion, may produce considerable alterations in neighbouring nations; their being derived from ancestors of a different climate, or complexion, may contribute to make accidental distinctions, which every day grow less; and it may be said, that two neighbouring nations, how unlike to each other at first, will assimilate by degrees; and, by long continuance, the difference between them will at last become almost imperceptible. It is not, therefore, between contiguous nations we are to look for any strong marked varieties in the human species;

it is by comparing the inhabitants of opposite climates, and distant countries; those who live within the polar circle with those beneath the equator; those that live on one side of the globe with those that occupy the other.

Of all animals, the differences between mankind are the smallest. Of the lower races of creatures, the changes are so great as often entirely to disguise the natural animal, and to distort, or to disfigure its shape. But the chief differences in man are rather taken from the tincture of his skin than the variety of his figure; and in all climates he preserves his erect deportment, and the marked superiority of his form. If we look round the world there seem to be not above six distinct varieties in the human species, each of which is strongly marked, and speaks the kind seldom to have mixed with any other. But there is nothing in the shape, nothing in the faculties, that shews their coming from different originals; and the varieties of climate, of nourishment, and custom, are sufficient to produce every change.

The first distinct race of men is found round the polar regions. The Laplanders, the Esquimaux Indians, the Samœid Tartars, the inhabitants of Nova Zembla, the Borandians, the Greenlanders, and the natives of Kamtschatka, may be considered as one peculiar race of people, all greatly resembling each other in their stature, their complexion, their customs, and their ignorance. These nations being under a rigorous climate, where the productions of nature are but few, and the provisions coarse and unwholesome, their bodies have shrunk to the nature of their food; and their complexions have suffered, from cold, almost a similar change to what heat is known to produce; their colour being a deep brown, in some places inclining to actual blackness. These, therefore, in general, are found to be a race of short stature, and odd shape, with countenances as savage as their manners are barbarous. The visage, in these countries, is large and broad, the nose flat and short, the eyes of a yellowish brown inclining to blackness, the eye-lids drawn towards the temples, the cheek-bones extremely high, the mouth very large, the lips thick and turned outwards, the voice thin and squeaking, the head large, the hair black and straight, the colour of the skin of a dark greyish. They are short in stature, the generality not being above four feet high, and the tallest not above five. Among all these nations the women are as deformed as the men, and resemble them so nearly that one cannot, at first, distinguish the sexes among them.

These nations not only resemble each other in their deformity, their dwarfishness, the colour of their hair and eyes, but they have, in a great measure, the same inclinations, and the same manners, being all equally rude, superstitious, and stupid. The Danish Laplanders have a large black cat, to which they communicate their secrets, and consult in all their affairs. Among the Swedish Laplanders there is in every family a drum for consulting the devil; and, although these nations are robust, and nimble, yet they are so cowardly, that they never can be brought into the field. Gustavus Adolphus attempted to form a regiment of Laplanders; but he found it impossible to accomplish his design; for it should seem that they can live only in their own country, and in their own manner. They make use of skates, which are made of fir, of near three feet long, and half a foot broad; these are pointed, and raised before, and tied to the foot by straps of leather. With these they skate upon the icy snow with such velocity, that they very easily overtake the swiftest animals. They make use also of a pole, pointed with iron at one end, and rounded at the other. This pole serves to push them along, to direct

rect their course, to support them from falling, to stop the impetuosity of their motion, and to kill that game which they have overtaken. Upon these skates they descend the steepest mountains, and scale the most craggy precipices; and, in these exercises, the women are not less skilful than the men. They have all the use of the bow and arrow, which seems to be a contrivance common to all barbarous nations; and which, however, at first, required no small skill to invent. They launch a javelin also, with great force; and some say that they can hit a mark, no larger than a crown, at thirty yards distance, and with such force as would pierce a man through. They are all hunters; and particularly pursue the ermine, the fox, the ounce, and the martin, for the sake of their skins. These they barter, with their southern neighbours, for brandy and tobacco; both which they are fond of to excess. Their food is principally dried fish, the flesh of rein-deer and bears. Their bread is composed of the bones of fishes, pounded and mixed with the inside bark of the pine-tree. Their drink is train-oil, or brandy, and, when deprived of these, water, in which juniper berries have been infused. With regard to their morals, they have all the virtues of simplicity, and all the vices of ignorance. They offer their wives and daughters to strangers; and seem to think it a particular honour if their offer be accepted. They have no idea of religion, or a Supreme Being; the greatest number of them are idolaters; and their superstition is as profound as their worship is contemptible. Wretched and ignorant as they are, yet they do not want pride; they set themselves far above the rest of mankind; and Krantz assures us, that when the Greenlanders are got together, nothing is so customary among them as to turn the Europeans into ridicule. They are obliged, indeed, to yield them the pre-eminence in understanding, and mechanic arts; but they do not know how to set any value upon these. They therefore count themselves the only civilized and well-bred people in the world; and it is common with them, when they see a quiet, or a modest stranger, to say that he is almost as well bred as a Greenlander.

From this description, therefore, this whole race of people may be considered as distinct from any other. Their long continuance in a climate the most inhospitable, their being obliged to subsist on food the most coarse and ill prepared, the savageness of their manners, and their laborious lives, all have contributed to shorten their stature, and to deform their bodies. In proportion as we approach towards the north pole, the size of the natives appears to diminish, growing less and less as we advance higher, till we come to those latitudes that are destitute of all inhabitants whatsoever.

The wretched natives of these climates seem fitted by nature to endure the rigours of their situation. As their food is but scanty and precarious, their patience in hunger is amazing. A man, who has ate nothing for four days, can manage his little canoe, in the most furious waves, and calmly subsist in the midst of a tempest, that would quickly dash an European boat to pieces. Their strength is not less amazing than their patience; a woman among them will carry a piece of timber, or a stone, near double the weight of what an European can lift. Their bodies are of a dark grey all over; and their faces brown, or olive. The tincture of their skins partly seems to arise from their dirty manner of living, being generally daubed with train-oil; and partly from the rigours of climate, as the sudden alterations of cold and raw air in winter, and of burning heats in summer, shade their complexions by degrees, till, in a succession of generations, they at last become almost black. As the countries in

which these reside are the most barren, so the natives seem the most barbarous of any part of the earth. Their more southern neighbours of America, treat them with the same scorn that a polished nation would treat a savage one; and we may readily judge of the rudeness of those manners, which even a native of Canada can think more barbarous than his own.

But the gradations of nature are imperceptible; and, while the north is peopled with such miserable inhabitants, there are here and there to be found, upon the edges of these regions, people of larger stature, and completer figure. A whole race of the dwarfish breed is often found to come down from the north, and settle more to the southward; and, on the contrary, it sometimes happens that southern nations are seen higher up, in the midst of these diminutive tribes, where they have continued for time immemorial. Thus the Ostiac Tartars seem to be a race that have travelled down from the north, and to be originally sprung from the minute savages we have been describing. There are also Norwegians, and Finlanders, of proper stature, who are seen to inhabit in latitudes higher even than Lapland. These, however, are but accidental migrations, and serve as shades to unite the distinct varieties of mankind.

The second great variety, in the human species, seems to be that of the Tartar race; from whence, probably, the little men we have been describing originally proceeded. The Tartar country, taken in general, comprehends the greatest part of Asia; and is, consequently, a general name given to a number of nations, of various forms and complexions. But, however they seem to differ from each other, they all agree in being very unlike the people of any other country. All these nations have the upper part of the visage very broad, and wrinkled even while yet in their youth. Their noses are short and flat, their eyes little and sunk in their heads; and, in some of them, they are seen five or six inches asunder. Their cheek-bones are high, the lower part of their visage narrow, the chin long and advanced forward, their teeth of an enormous size and growing separate from each other, their eyebrows thick, large, and covering their eyes, their eye-lids thick, the face broad and flat, the complexion olive coloured, and the hair black. They are of a middle size, extremely strong, and very robust. They have but little beard, which grows stragglingly on the chin. They have large thighs, and short legs. The ugliest of all are the Calmoucks, in whose appearance there seems to be something frightful. They all lead an erratic life, remaining under tents of hair, or skins. They live upon horse-flesh and that of camels, either raw or a little sodden between the horse and the saddle. They eat also fish dried in the sun. Their most usual drink is mares milk fermented with millet ground into meal. They all have the head shaven, except a lock of hair, on the top, which they let grow sufficiently long to form into tresses, on each side of the face. The women, who are as ugly as the men, wear their hair, which they bind up with bits of copper and other ornaments of a like nature. The majority of these nations have no religion, no settled notions of morality, no decency of behaviour. They are chiefly robbers; and the natives of Dagestan, who live near their more polished neighbours, make a traffic of Tartar slaves who have been stolen, and sell them to the Turks and the Persians. Their chief riches consist in horses, of which perhaps there are more in Tartary, than in any other part of the world. The natives are taught by custom to live in the same place with their horses; they are continually employed in managing them,

and at last bring them to such great obedience, that the horse seems actually to understand the rider's intention.

To this race of men also, we must refer the Chinese and the Japanese, however different they seem in their manners and ceremonies. It is the form of the body we are now principally considering; and there is, between these countries, a surprising resemblance. It is in general allowed that the Chinese have broad faces, small eyes, flat noses, and scarce any beard; that they are broad and square-shouldered, and rather less in stature than Europeans. These are marks common to them and the Tartars, and they may, therefore, be considered as being derived from the same original. "I have observed," says Chardin, "that in all the people from the east and the north of the Caspian sea, to the peninsula of Malacca, that the lines of the face, and the formation of the visage, is the same. This has induced me to believe, that all these nations are derived from the same original, however different either their complexions or their manners may appear: for as to the complexion, that proceeds entirely from the climate and the food; and as to the manners, these are generally the result of their different degrees of wealth or power." That they come from one stock, is evident also, from this; that the Tartars who settle in China, quickly resemble the Chinese; and, on the contrary, the Chinese who settle in Tartary, soon assume the figure, and the manners of the Tartars.

The Japanese so much resemble the Chinese, that one cannot hesitate to rank them in the same class. They only differ in being rather browner, as they inhabit a more southern climate. They are, in general, described, as of a brown complexion, a short stature, a broad flat face, a very little beard, and black hair. Their customs and ceremonies are nearly the same; their ideas of beauty similar; and their artificial deformities of blackening the teeth, and bandaging the feet, entirely alike in both countries. They both, therefore, proceed from the same stock; and although they differ very much from their brutal progenitors, yet they owe their civilization wholly to the mildness of the climate in which they reside, and to the peculiar fertility of the soil. To this tribe also, we may refer the Cochinchinese, the Siamese, the Tonquinese, and the inhabitants of Aracan, Laos, and Pegu, who, though all differing from the Chinese, and each other, nevertheless, have too strong a resemblance, not to betray their common original.

Another, which makes the third variety in the human species, is that of the southern Asiatics; the form of whose features and persons may be easily distinguished from those of the Tartar races. The nations that inhabit the peninsula of India, seem to be the principal stock from whence the inhabitants of the islands that lie scattered in the Indian ocean, have been peopled. They are, in general, of a slender shape, with long straight black hair, and often with Roman noses. Thus they resemble the Europeans in stature and features; but greatly differ in colour and habit of body. The Indians are of an olive colour, and, in the more southern parts, quite black; although the word Mogul, in their language, signifies a white man. The women are extremely delicate, and bathe very often: they are of an olive colour, as well as the men; their legs and thighs are long, and their bodies short, which is the opposite to what is seen among the women of Europe. They are, it is said, by no means so fruitful as the European women; but they feel the pains of child-birth with much less sensibility, and are generally up and well the day following. In fact, these pains seem greatest in all countries where the women are most delicate, or the constitution enfee-

bled by luxury or indolence. The women of savage nations seem, in a great measure, exempt from painful labours; and even the hard-working wives of the peasants among ourselves, have this advantage, from a life of industry, that their child-bearing is less painful. Over all India, the children arrive sooner at maturity, than with us of Europe. They often marry, and consummate, the husband at ten years old, and the wife at eight; and they frequently have children at that age. However, the women who are mothers so soon, cease bearing before they are arrived at thirty; and, at that time, they appear wrinkled, and seem marked with all the deformities of age. The Indians have long been remarkable for their cowardice and effeminacy; every conqueror that has attempted the invasion of their country, having succeeded. The warmth of the climate entirely influences their manners; they are slothful, submissive and luxurious: satisfied with sensual happiness alone, they find no pleasure in thinking; and contented with slavery, they are ready to obey any master. Many tribes among them eat nothing that has life; they are fearful of killing the meanest insect; and have even erected hospitals for the maintainance of all kinds of vermin. The Asiatic dress is a loose flowing garment, rather fitted for the purposes of peace and indolence, than of industry or war. The vigour of the Asiatics is in general conformable to their dress and nourishment; fed upon rice, and cloathed in effeminate silk vestments, their soldiers are unable to oppose the onset of an European army; and, from the times of Alexander to the present day, we have scarce any instances of their success in arms. Upon the whole, therefore, they may be considered as a feeble race of sensualists, too dull to find rapture in any pleasures, and too indolent to turn their gravity into wisdom. To this class we may refer the Persians and Arabians, and, in general, the inhabitants of the islands that lie scattered in the Indian ocean.

The fourth striking variety in the human species, is to be found among the Negroes of Africa. This gloomy race of mankind is found to blacken all the southern parts of Africa, from eighteen degrees north of the line, to its extreme termination, at the Cape of Good Hope. It is said, that the Caffres, who inhabit the southern extremity of that large continent, are not to be ranked among the Negroe race; however, the difference between them, in point of colour and features, is so small, that they may very easily be grouped in this general picture. Each of the Negroe nations, it must be owned, differ from each other; they have their peculiar countries for beauty, like us; and different nations, as in Europe, pride themselves upon the regularity of their features. Those of Guinea, for instance, are extremely ugly, and have an insupportable scent; those of Mosambique are reckoned beautiful, and have no ill smell whatsoever. The Negroes, in general, are of a black colour, with a smooth soft skin. This smoothness proceeds from the downy softness of the hair which grows upon it; the strength of which gives a roughness to the feel, in those of a white complexion. Their skins, therefore, have a velvet smoothness, and seem less braced upon the muscles than ours. The hair of their heads differs entirely from what we are accustomed to, being soft, woolly, and short. The beard also, partakes of the same qualities; but in this it differs, that it soon turns grey, which the hair is seldom found to do; so that several are seen with white beards, and black hair, at the same time. Their eyes are generally of a deep hazle; their noses flat and short; their lips thick and tumid; and their teeth of an ivory whiteness. This their only beauty, however, is set off by the colour of their skin; the contrast between the

black and white being the more observable. It is false to say that their features are deformed by art; since, in the Negroe children born in European countries, the same deformities are seen to prevail; the same flatness in the nose; and the same prominence in the lips. They are, in general, said to be well shaped; but there is seldom found one that might be justly called so; their legs being mostly ill formed, and commonly bending outward on the shin-bone. But it is not only in those parts of their bodies that are obvious, that they are disproportioned; those parts which among us are usually concealed by dress, with them are large and languid. The women's breasts, after bearing one child, hang down below the navel; and it is customary, with them, to suckle the child at their backs, by throwing the breast over the shoulder. As their persons are thus naturally deformed, at least to our imaginations, their minds are equally incapable of strong exertions. The climate seems to relax their mental powers still more than those of the body; they are, therefore, in general, found to be stupid, indolent, and mischievous. The Arabians themselves, many colonies of whom have migrated southward into the most inland parts of Africa, seem to have degenerated from their ancestors; forgetting their ancient learning, and losing their beauty, they have become a race scarce any way distinguishable from the original natives. Nor does it seem to have fared otherwise with the Portuguese, who, about two centuries ago, settled along this coast. They also are become almost as black as the Negroes; and are said, by some, to be even more barbarous.

The inhabitants of America make a fifth race, as different from all the rest in colour, as they are distinct in habitation. The natives of America (except in the northern extremity, where they resemble the Laplanders) are of a red or copper colour; and although, in the old world, different climates produce a variety of complexions and customs, the natives of the new continent seem to resemble each other in almost every respect. They are all nearly of one colour; all have black thick straight hair, and thin black beards; which, however, they take care to pluck out by the roots. They have, in general, flat noses, with high cheek bones, and small eyes; and these deformities of nature they endeavour to increase by art; they flatten the nose, and often the whole head of their children, while the bones are yet susceptible of every impression. They paint the body and face of various colours, and consider the hair upon any part of it, except the head, as a deformity which they are careful to eradicate. Their limbs are generally slighter made than those of the Europeans; and they are far from being so strong. All these savages seem to be cowardly; they seldom are known to face their enemies in the field, but fall upon them at an advantage; and the greatness of their fears serves to increase the rigours of their cruelty. The wants which they often sustain, makes them surprisngly patient in adversity; distress, by being grown familiar, becomes less terrible; so that their patience is less the result of fortitude than of custom. They have all a serious air, although they seldom think; and, however cruel to their enemies, are kind and just to each other. In short, the customs of savage nations in every country are almost the same; a wild, independent, and precarious life, produces a peculiar train of virtues and vices: and patience and hospitality, indolence and rapacity, content and sincerity, are found not less among the natives of America, than all the barbarous nations of the globe.

The sixth and last variety of the human species, is that of the Europeans, and the nations bordering on them. In this class we may reckon the Georgians, Circassians, and Mingrelians, the inha-

bitants of Asia Minor, and the northern parts of Africa, together with a part of those countries which lie north-west of the Caspian sea. The inhabitants of these countries differ a good deal from each other; but they generally agree in the colour of their bodies, the beauty of their complexions, the largeness of their limbs, and the vigour of their understandings. Those arts which might have had their invention among the other races of mankind, have come to perfection there. In barbarous countries, the inhabitants go either naked, or are awkwardly clothed in furs or feathers; in countries semi-barbarous, the robes are loose and flowing; but here the cloathing is less made for shew than expedition, and unites, as much as possible, the extremes of ornament and dispatch.

To one or other of these classes, we may refer the people of every country; and as each nation has been less visited by strangers, or has had less commerce with the rest of mankind, we find their persons, and their manners, more strongly impressed with one or other of the characters mentioned above. On the contrary, in those places where trade has long flourished, or where enemies have made many incursions, the races are usually found blended, and properly fall beneath no one character. Thus, in the islands of the Indian ocean, where a trade has been carried on for time immemorial, the inhabitants appear to be a mixture of all the nations upon the earth; white, olive, brown, and black men, are all seen living together in the same city, and propagate a mixed breed, that can be referred to none of the classes into which naturalists have thought proper to divide mankind.

Of all the colours by which mankind is diversified, it is easy to perceive, that ours is not only the most beautiful to the eye, but the most advantageous. The fair complexion seems, if we may so express it, as a transparent covering to the soul; all the variations of the passions, every expression of joy or sorrow, flows to the cheek, and, without language, marks the mind. In the slightest change of health also, the colour of the European face is the most exact index, and often teaches us to prevent those disorders that we do not as yet perceive; not but that the African black, and the Asiatic olive complexions, admit of their alterations also; but these are neither so distinct, nor so visible, as with us; and, in some countries, the colour of the visage is never found to change; but the face continues in the same settled shade in shame, and in sickness, in anger, and despair.

The colour, therefore, most natural to man, ought to be that which is most becoming; and it is found, that, in all regions, the children are born fair, or at least red; and that they grow more black or tawny, as they advance in age. It should seem, consequently, that man is naturally white; since the same causes that darken the complexion in infants, may have originally operated, in slower degrees, in blackening whole nations. We could, therefore, readily account for the blackness of different nations, did we not see the Americans, who live under the line, as well as the natives of Negroeland, of a red colour, and but a very small shade darker than the natives of the northern latitudes, in the same continent. For this reason, some have sought for other causes of blackness than the climate; and have endeavoured to prove that the blacks are a race of people, bred from one man, who was marked with accidental blackness. This, however, is but mere ungrounded conjecture; and, although the Americans are not so dark as the Negroes, yet we must still continue in the ancient opinion, that the deepness of the colour proceeds from the excessive heat of the climate: for, if we compare the heats of Africa with those of America, we shall find they bear no proportion

proportion to each other. In America, all that part of the continent which lies under the line, is cool and pleasant, either shaded by mountains, or refreshed by breezes from the sea; but, in Africa, the wide tract of country that lies under the line is very extensive, and the soil sandy: the reflection of the sun, therefore, from so large a surface of the earth, is almost intolerable; and it is not to be wondered at, that the inhabitants should bear, in their looks, the marks of the inhospitable climate. In America, the country is but thinly inhabited; and the more torrid tracts are generally left desert by the inhabitants; for which reason they are not so deeply tinged by the beams of the sun. But in Africa the whole face of the country is fully peopled; and the natives are obliged to endure their situation, without a power of migration. It is there, consequently, that they are in a manner tied down to feel all the severity of the heat; and their complexions take the darkest hue they are capable of receiving. We need not, therefore, have recourse to any imaginary propagation, from persons accidentally black, since the climate is a cause obvious, and sufficient to produce the effect.

In fact, if we examine the complexion of different countries, we shall find them darken in proportion to the heat of their climate; and the shades gradually to deepen as they approach the line. Some nations, indeed, may be found not so much tinged by the sun as others, although they lie nearer the line. But this ever proceeds from some accidental causes; either from the country lying higher, and consequently being colder; or from the natives bathing oftener, and leading a more civilized life. In general, it may be asserted, that as we approach the line, we find the inhabitants of each country grow browner until the colour deepens into perfect blackness. Thus taking our standard from the whitest race of people, and beginning with our own country, which certainly bids fairest for the pre-eminence, we shall find the French, who are more southern, a slight shade deeper than we; going farther down, the Spaniards are browner than the French; the inhabitants of Fez darker than they; and the natives of Negroeland the darkest of all. In what manner the sun produces this effect, and how the same luminary which whitens wax and linen, should darken the human complexion, is not easy to conceive. Sir Thomas Brown first supposed that a mucous substance, which had something of a vitriolic quality, settled under the reticular membrane, and grew darker with heat. Others have supposed that the blackness lay in the epidermis, or scarf skin, which was burnt up like leather. But nothing has been satisfactorily discovered upon the subject; it is sufficient that we are assured of the fact; and that we have no doubt of the sun's tinging the complexion in proportion to its vicinity.

But we are not to suppose that the sun is the only cause of darkening the skin; the wind, extreme cold, hard labour, or coarse and sparing nourishment, are all found to contribute to this effect. We find the peasants of every country, who are most exposed to the weather, a shade darker than the higher ranks of people. The savage inhabitants of all places are exposed still more, and, therefore, contract a still deeper hue; and this will account for the tawny colour of the North American Indians. Although they live in a climate the same, or even more northerly than ours, yet they are found to be of complexions very different from those of Europe. But it must be considered that they live continually exposed to the sun; that they use many methods to darken their skins by art, painting them with red ochre, and anointing them with the fat of bears. Had they taken, for a succession of several generations, the same precautions to brighten their co-

lour that an European does, it is very probable that they would in time come to have similar complexions; and, perhaps, dispute the prize of beauty.

The extremity of cold is not less productive of a tawny complexion than that of heat. The natives of the arctic circle, as was observed, are all brown; and those that lie most to the north are almost entirely black. In this manner both extremes are unfavourable to the human form and colour, and the same effects are produced under the poles that are found at the line.

With regard to the stature of different countries, that seems chiefly to result from the nature of the food, and the quantity of the supply. Not but that the severity of heat or cold, may, in some measure, diminish the growth, and produce a dwarfishness of make. But, in general, the food is the great agent in producing this effect; where that is supplied in large quantities, and, where its quality is wholesome and nutrimental, the inhabitants are generally seen above the ordinary stature. On the contrary, where it is afforded in a sparing quantity, or very coarse, and void of nourishment in its kind, the inhabitants degenerate, and sink below the ordinary size of mankind. In this respect they resemble other animals, whose bodies, by proper feeding, may be greatly augmented. An ox, on the fertile plains of India, grows to a size four times as large as the diminutive animal of the same kind bred in the Alps. The horses bred in the plains are larger than those of the mountain. So it is with man; the inhabitants of the valley are usually found taller than those of the hill: the natives of the Highlands of Scotland, for instance, are short, broad, and hardy; those of the Lowlands are tall and shapely. The inhabitants of Greenland, who live upon dried fish and seals, are less than those of Gambia or Senegal, where Nature supplies them with vegetable and animal abundance.

The form of the face seems rather to be the result of custom. Nations who have long considered some artificial deformity as beautiful, who have industriously lessened the feet, or flattened the nose, by degrees, begin to receive the impression they are taught to assume; and Nature, in a course of ages, shapes itself to the constraint, and assumes hereditary deformity. We find nothing more common in births than for children to inherit sometimes even the accidental deformities of their parents. We have many instances of squinting in the father, which he received from fright, or habit, communicated to the offspring; and we have seen a child distinctly marked with a scar, similar to one the father had received in battle. In this manner accidental deformities may become natural ones; and by assiduity may be continued, and even increased, through successive generations. From this, therefore, may have arisen the small eyes and long ears of the Tartars, and Chinese nations. From hence originally may have come the flat noses of the blacks, and the flat heads of the American Indians.

In this slight survey, therefore, we may see that all the variations in the human figure, as far as they differ from our own, are produced either by the rigour of the climate, the bad quality, or the scantiness of the provisions, or by the savage customs of the country. They are actual marks of the degeneracy in the human form; and we may consider the European figure and colour as standards to which to refer all other varieties, and with which to compare them. In proportion as the Tartar or American approaches nearer to European beauty, we consider the race as less degenerated; in proportion as he differs more widely, he has made greater deviation from his original form.

That we have all sprung from one common parent, we are taught, both by reason and religion, to believe;

lieve; and we have good reason also to think that the Europeans resemble him more than any of the rest of his children. However, it must not be concealed that the olive coloured Asiatic, and even the jet black Negroe, claim this honour of hereditary resemblance; and assert that white men are mere deviations from original perfection. Odd as this opinion may seem, they have Linnæus, the celebrated naturalist, on their side; who supposes man a native of the tropical climates, and only a sojourner more to the north. But, not to enter into a controversy upon a matter of a very remote speculation, one argument alone will suffice to prove the contrary, and shew that the white man is the original source from whence the other varieties have sprung. We have frequently seen white children produced from black parents, but have never seen a black offspring the production of two whites. From hence we may conclude that whiteness is the colour to which mankind naturally tends; for, as in the tulip, the parent stock is known by all the artificial varieties breaking into it; so in man, that colour must be original which never alters, and to which all the rest are accidentally seen to change. We have seen in London, at different times, two white Negroes, the issue of black parents, that served to convince us of the truth of this theory. We had before been taught to believe that the whiteness of the Negroe skin was a disease, a kind of milky whiteness, that might be called rather a leprous crust than a natural complexion. We were taught to suppose that the numberless white Negroes, found in various parts of Africa, the white men that go by the name of Chacrelas, in the East-Indies, and the white Americans, near the Isthmus of Darien, in the West Indies, were all as so many diseased persons, and even more deformed than the blackest of the natives. But, upon examining that Negroe which was last shewn in London, the colour was found to be exactly like that of an European; the visage white and ruddy, and the lips of the proper redness. However, there were sufficient marks to convince us of its descent. The hair was white and woolly, and very unlike any thing ever seen before. The iris of the eye was yellow, inclining to red; the nose was flat, exactly resembling that of a Negro; and the lips thick, and prominent. No doubt, therefore, remained of the child's having been born of Negroe parents; and the person who shewed it had attestations to convince the most incredulous. From this then we see that the variations of the Negroe colour is into whiteness, whereas the white are never found to have a race of Negroe children. Upon the whole, all those changes which the African, the Asiatic, or the American undergo, are but accidental deformities, which a kinder climate, better nourishment, or more civilized manners, would, in a course of centuries, very probably remove.

CHAPTER XII.

OF MONSTERS.

HITHERTO we have only spoken of those varieties in the human species, that are common to whole nations; but there are varieties of another kind, which are only found in the individual; and, being more rarely seen, are, therefore, called monstrous. If we examine into the varieties of distorted nature, there is scarce a limb of the body, or a feature in the face, that has not suffered some reprobation, either from art or nature; being enlarged or diminished, lengthened or wrested, from its due proportion. Linnæus, after having given

No. 57.

a catalogue of monsters, particularly adds, the flat heads of Canada, the long heads of the Chinese, and the slender waists of the women of Europe, who, by strait lacing, take such pains to destroy their health, through a mistaken desire to improve their beauty. It belongs more to the physician than the naturalist to attend to these minute deformities; and, indeed, it is a melancholy contemplation to speculate upon a catalogue of calamities, inflicted by un pitying nature, or brought upon us by our own caprice. Some, however, are fond of such accounts; and there have been books filled with nothing else. It is sufficient here to observe, that every day's experience must have shewn us miserable instances of this kind, produced by nature, or affectation; calamities that no pity can soften, nor assiduity relieve.

Passing over, therefore, every other account, we shall only mention the famous instance, quoted by Father Malbranche; upon which he founds his beautiful theory of monstrous productions. A woman of Paris, the wife of a tradesman, went to see a criminal broke alive upon the wheel, at the place of public execution. She was at that time two months advanced in her pregnancy, and no way subject to any disorders to affect the child in her womb. She was, however, of a tender habit of body; and, though led by curiosity to this horrid spectacle, very easily moved to pity and compassion. She felt, therefore, all those strong emotions which so terrible a sight must naturally inspire; shuddered at every blow the criminal received, and almost swooned at his cries. Upon returning from this scene of blood, she continued for some days pensive, and her imagination still wrought upon the spectacle she had lately seen. After some time, however, she seemed perfectly recovered from her fright, and had almost forgotten her former uneasiness. When the time of her delivery approached, she seemed no ways mindful of her former terrors, nor were her pains in labour more than usual in such circumstances. But, what was the amazement of her friends, and assistants, when the child came into the world! It was found that every limb in its body was broken like those of the malefactor, and just in the same place. This poor infant that had suffered the pains of life, even before its coming into the world, did not die, but lived in an hospital, in Paris, for twenty years after; a wretched instance of the supposed powers of imagination in the mother, of altering and distorting the infant in the womb. The manner in which Malbranche reasons upon this fact, is as follows: The Creator has established such a sympathy between the several parts of nature, that we are led not only to imitate each other, but also to partake in the same affections and desires. The animal spirits are thus carried to the respective parts of the body, to perform the same actions which we see others perform, to receive in some measure their wounds, and take part in their sufferings. Experience tells us, that if we look attentively on any person severely beaten, or sorely wounded, the spirits immediately flow into those parts of the body which correspond to those we see in pain. The more delicate the constitution, the more it is thus affected; the spirits making a stronger impression on the fibres of a weakly habit than of a robust one. Strong vigorous men see an execution without much concern, while women of nicer texture are struck with horror and concern. This sensibility in them must, of consequence, be communicated to all parts of their body; and, as the fibres of the child, in the womb, are incomparably finer than those of the mother, the course of the animal spirits must, consequently, produce greater alterations. Hence, every stroke given to the criminal, forcibly struck the imagination of the

woman; and by a kind of counter stroke, the delicate tender frame of the child.

Such is the reasoning of an ingenious man, upon a fact the veracity of which many since have called in question. They have allowed, indeed, that such a child might have been produced; but have denied the cause of its deformity. How could the imagination of the mother, say they, produce such dreadful effects upon her child? She has no communication with the infant; she scarce touches it in any part; quite unaffected with her concerns, it sleeps in security, in a manner secluded by a fluid in which it swims, from her that bears it. With what a variety of deformities, say they, would all mankind be marked, if all the vain and capricious desires of the mother were thus readily written upon the body of child? Yet, notwithstanding this plausible way of reasoning, we cannot avoid giving some credit to the variety of instances we have either read, or seen, upon this subject. If it be a prejudice, it is as old as the days of Aristotle, and to this day as strongly believed, by the generality of mankind, as ever. It does not admit of a reason; and, indeed, we can give none even why the child should, in any respect, resemble the father, or the mother. The fact we generally find to be so. But why it should take the particular print of the father's features in the womb, is as hard to conceive, as why it should be affected by the mother's imagination. We all know what a strong effect the imagination has on those parts in particular, without being able to assign a cause how this effect is produced; and why may not the imagination produce the same effect in marking the child that it does in forming it? Those persons whose employment it is to rear up pigeons of different colours, can breed them, as their expression is, to a feather. In fact, by properly paring them, they can give what colour they will to any feather, in any part of the body. Were we to reason upon this fact, what could we say? Might it not be asserted, that the egg, being distinct from the body of the female, cannot be influenced by it? Might it not be plausibly said, that there is no similitude between any part of the egg and any particular feather, which we expect to propagate? and yet, for all this, the fact is known to be true, and what no speculation can invalidate. In the same manner, a thousand various instances assure us that the child, in the womb, is sometimes marked by the strong affections of the mother; how this is performed we know not; we only see the effect, without any connexion between it and the cause. The best physicians have allowed it; and have been satisfied to submit to the experience of a number of ages; but many disbelieve it, because they expect a reason for every effect. This, however, is very hard to be given, while it is very easy to appear wise by pretending incredulity.

Among the number of monsters, dwarfs and giants are usually reckon'd; though not, perhaps, with the strictest propriety, since they are no way different from the rest of mankind, except in stature. It is a dispute, however, about words; and, therefore, scarce worth contending about. But there is a dispute of a more curious nature, on this subject; namely, whether there are races of people thus very diminutive, or vastly large, or whether they be merely accidental varieties, that now and then are seen in the country, in a few persons, whose bodies some external cause has contributed to lessen or enlarge.

With regard to men of diminutive stature, all antiquity has been unanimous in asserting their national existence. Homer was the first who has given us an account of the pigmy nation, contending with the cranes; and what poetical licence might be supposed to exaggerate, Athenæus has attempted se-

riously to confirm by historical assertion. If we attend to these, we must believe that in the internal parts of Africa, there are whole nations of pigmy beings, not more than a foot in stature, who continually wage an unequal war with the birds and beasts that inhabit the plains in which they reside. Some of the ancients, however, and Strabo in particular, have supposed all these accounts to be fabulous; and have been more inclined to think this supposed nation of pigmies, nothing more than a species of apes, well known to be numerous in that part of the world. With this opinion the moderns have all concurred; and that diminutive race, which was described as human, has been long degraded into a class of animals that resemble us but very imperfectly.

The existence, therefore, of a pigmy race of mankind, being founded in error, or in fable, we can expect to find men of diminutive stature only by accident, among men of the ordinary size. Of these accidental dwarfs, every country, and almost every village, can produce numerous instances. There was a time, when these unfavoured children of Nature were the peculiar favourites of the great; and no prince, or nobleman, thought himself completely attended, unless he had a dwarf among the number of his domestics. These poor little men were kept to be laughed at; or to raise the barbarous pleasure of their masters, by their contrasted inferiority. Even in England, as late as the times of king James the First, the court was at one time furnished with a dwarf, a giant, and a jester: these the king often took a pleasure in opposing to each other, and often fomented quarrels among them, in order to be a concealed spectator of their animosity. It was a particular entertainment of the courtiers at that time, to see little Jeffery, for so the dwarf was called, ride round the lists, expecting his antagonist; and discovering, in his actions, all the marks of contemptible resolution.

It was in the same spirit, that Peter of Russia, in the year 1710, celebrated a marriage of dwarfs. This monarch, though raised by his native genius far above a barbarian, was, nevertheless, still many degrees removed from actual refinement. His pleasures, therefore, were of the vulgar kind; and this was among the number. Upon a certain day, which he had ordered to be proclaimed several months before, he invited the whole body of his courtiers, and all the foreign ambassadors, to be present at the marriage of a pigmy man and woman. The preparations for this wedding were not only very grand, but executed in a style of barbarous ridicule. He ordered, that all the dwarf men and women, within two hundred miles, should repair to the capital; and also insisted, that they should be present at the ceremony. For this purpose, he supplied them with proper vehicles; but so contrived it, that one horse was seen carrying in a dozen of them into the city at once, while the mob followed shouting, and laughing, from behind. Some of them were at first unwilling to obey an order, which they knew was calculated to turn them into ridicule, and did not come; but he soon obliged them to obey; and, as a punishment, enjoined, that they should wait upon the rest at dinner. The whole company of dwarfs amounted to seventy, beside the bride and bridegroom, who were richly adorned, and in the extremity of the fashion. For this little company in miniature, every thing was suitably provided; a low table, small plates, little glasses, and, in short, every thing was so fitted, as if all things had been dwindled to their own standard. It was his great pleasure to see their gravity and their pride; the contention of the women for places, and the men for superiority. This point he attempted to adjust, by ordering, that the most dimi-

nutive

native should take the lead; but this bred disputes, for none would then consent to sit foremost. All this, however, being at last settled, dancing followed the dinner, and the ball was opened with a minuet by the bridegroom, who measured exactly three feet two inches high. In the end, matters were so contrived, that this little company, who met together in gloomy pride, and unwilling to be pleased, being at last familiarized to laughter, joined in the diversion, and became, as the journalist has it, extremely sprightly and entertaining.

But whatever may be the entertainment such guests might afford, when united, a dwarf is seldom found capable of affording any when alone. They, in general, seem to have faculties very much resembling those of children, and their desires of the same kind; being diverted with the same sports, and best pleased with such companions. The little man, whose name was Coan, that died lately at Chelsea, was the most intelligent and sprightly we ever heard of. But this mirth, and seeming sagacity, were but assumed. He had, by long habit, been taught to look cheerful upon the approach of company; and his conversation was but the mere etiquette of a person that had been used to receive visitors. When driven out of his walk, nothing could be more stupid or ignorant, nothing more dejected or forlorn. But, we have a compleat history of a dwarf, very accurately related by Mr. Daubenton, in his part of the *Histoire Naturelle*; which we will here take leave to translate.

This dwarf, whose name was Baby, was well known, having spent the greatest part of his life at Lunenville, in the palace of Stanislaus, the titular king of Poland. He was born in the village of Plaisne, in France, in the year 1741. His father and mother were peasants, both of good constitutions, and inured to a life of husbandry and labour. Baby, when born, weighed but a pound and a quarter. We are not informed of the dimensions of his body at that time; but we may conjecture they were very small, as he was presented on a plate to be baptized, and for a long time lay in a slipper. His mouth, although proportioned to the rest of his body, was not, at that time, large enough to take in the nipple; and he was, therefore, obliged to be suckled by a she-goat that was in the house; and that served as a nurse, attending to his cries with a kind of maternal fondness. He began to articulate some words when eighteen months old; and at two years he was able to walk alone. He was then fitted with shoes that were about an inch and a half long. He was attacked with several acute disorders; but the small-pox was the only one which left any marks behind it. Until he was six years old, he eat no other food but pulse, potatoes, and bacon. His father and mother were, from their poverty, incapable of affording him any better nourishment; and his education was little better than his food, being bred up among the rustics of the place. At six years old he was about fifteen inches high; and his whole body weighed but thirteen pounds. Notwithstanding this, he was well proportioned, and handsome; his health was good, but his understanding scarce passed the bounds of instinct. It was at that time that the king of Poland, having heard of such a curiosity, had him conveyed to Lunenville, gave him the name of Baby, and kept him in his palace.

Baby, having thus quitted the hard condition of a peasant, to enjoy all the comforts and the conveniences of life, seemed to receive no alteration from his new way of living, either in mind or person. He preserved the goodness of his constitution till about the age of sixteen, but his body seemed to increase very slowly during the whole time; and his stupidity was such, that all instructions were lost in improving his understanding. He could never be

brought to have any sense of religion, nor even to shew the least signs of a reasoning faculty. They attempted to teach him dancing and music, but in vain; he never could make any thing of music; and as for dancing, although he beat time tolerably exact, yet he could never remember the figure, but while his dancing-master stood by to direct his motions. Notwithstanding, a mind thus destitute of understanding was not without its passions; anger and jealousy harrassed it at times; nor was he without desires of another nature.

At the age of sixteen, Baby was twenty-nine inches tall; at this he rested; but having thus arrived at his acme, the alterations of puberty, or rather, perhaps, of old age, came fast upon him. From being very beautiful, the poor little creature now became quite deformed; his strength quite forsook him; his back bone began to bend; his head hung forward; his legs grew weak; one of his shoulders turned awry; and his nose grew disproportionably large. With his strength, his natural spirits also forsook him; and, by the time he was twenty, he was grown feeble, decrepid, and marked with the strongest impression of old age. It had been before remarked by some, that he would die of old age before he arrived at thirty; and, in fact, by the time he was twenty-two, he could scarcely walk an hundred paces, being worn with the multiplicity of his years, and bent under the burthen of protracted life. In this year he died; a cold, attended with a slight fever, threw him into a kind of lethargy, which had a few momentary intervals; but he could scarce be brought to speak. However, it is asserted, that in the five last days of his life, he shewed a clearer understanding, than in his times of best health: but at length he died, after enduring great agonies, in the twenty-second year of his age.

Opposite to this accidental diminution of the human race, is that of its extraordinary magnitude. Concerning the reality of a nation of Giants, there have been many disputes among the learned. Some have affirmed the probability of such a race; and others, as warmly have denied the possibility of their existence. But it is not from any speculative reasonings, upon a subject of this kind, that information is to be obtained; it is not from the disputes of the scholar, but the labours of the enterprising, that we are to be instructed in this enquiry. Indeed, nothing can be more absurd, than what some learned men have advanced upon this subject. It is very unlikely, says Grew, that there should either be dwarfs or giants; or if such, they cannot be fitted for the usual enjoyment of life and reason. Had man been born a dwarf, he could not have been a reasonable creature; for to that end, he must have a jolt head, and then he would not have body and blood enough to supply his brain with spirits: or if he had a small head, proportionable to his body, there would not be brain enough for conducting life. But it is still worse with giants; and there could never have been a nation of such, for there would not be food enough found in any country to sustain them; or if there were beasts sufficient for this purpose, there would not be grass enough for their maintainance. But what is still more, add others, giants could never be able to support the weight of their own bodies; since a man of ten feet high, must be eight times as heavy as one of the ordinary stature; whereas, he has but twice the size of muscles to support such a burthen: and, consequently, would be overloaded with the weight of his own body. Such are the theories upon this subject; and they require no other answer, but that experience proves them both to be false: dwarfs are found capable of life and reason; and giants are seen to carry their own bodies. We have several accounts from mariners, that a nation of giants actually exists; and mere speculation

speculation should never induce us to doubt their veracity.

Ferdinand Magellan was the first who discovered this race of people along the coast, towards the extremity of South America. Magellan was a Portuguese of noble extraction, who having long behaved with great bravery under Albuquerque, the conqueror of India, he was treated with neglect by the court, upon his return. Applying, therefore, to the king of Spain, he was entrusted with the command of five ships, to subdue the Molucca islands; upon one of which he was slain. It was in his voyage thither, that he happened to winter in St. Julian's Bay, an American harbour, forty-nine degrees south of the line. In this desolate region, where nothing was seen but objects of terror, where neither trees nor verdure dress the face of the country, they remained for some months without seeing any human creature. They had judged the country to be utterly uninhabitable; when one day, they saw approaching, as if he had been dropt from the clouds, a man of enormous stature, dancing and singing, and putting dust upon his head, as they supposed, in token of peace. This overture for friendship was, by Magellan's command, quickly answered by the rest of his men; and the giant approaching, testified every mark of astonishment and surprize. He was so tall, that the Spaniards only reached his waist; his face was broad, his colour brown, and painted over with a variety of tints; each cheek had the resemblance of an heart drawn upon it; his hair was approaching to whiteness; he was cloathed in skins and armed with a bow. Being treated with kindness, and dismissed with some trifling presents, he soon returned, with many more of the same stature; two of whom the mariners decoyed on ship-board: nothing could be more gentle than they were in the beginning; they considered the fetters that were preparing for them, as ornaments, and played with them, like children with their toys; but when they found for what purpose they were intended, they instantly exerted their amazing strength, and broke them in pieces with a very easy effort. This account, with a variety of other circumstances, has been confirmed by succeeding travellers: Herrera, Sebald Wert, Oliver Van Noort, and James le Maire, all correspond in affirming the fact, although they differ in many particulars of their respective descriptions. The last voyager we have had, that has seen this enormous race, is Byron. We can no longer, therefore, refuse our assent to the existence of this gigantic race of mankind; in what manner they are propagated, or under what regulations they live, is a subject that remains for future investigation. It should appear, however, that they are a wandering nation, changing their abode with the course of the sun, and shifting their situation, for the convenience of food, climate, or pasture.

This race of giants are described as possessed of great strength; and, no doubt, they must be very different from those accidental giants that are to be seen in different parts of Europe. Stature with these, seems rather their infirmity than their pride; and adds to their burthen, without increasing their strength. The generality of these were ill-formed and unhealthful; weak in their persons, or incapable of exerting what strength they were possessed of. The same defects of understanding that attended those of suppressed stature, were found in those who were thus overgrown: they were heavy, phlegmatic, stupid, and inclining to sadness. The numbers, however, are but few; and it is thus kindly ordered by Providence, that as the middle state is the best fitted

for happiness, so the middle ranks of mankind are produced in the greatest variety.

However, mankind seems naturally to have a respect for men of extraordinary stature; and it has been a supposition of long standing, that our ancestors were much taller, as well as much more beautiful than we. This has been, indeed, a theme of poetical declamation from the beginning; and man was scarce formed, when he began to deplore an imaginary decay. Nothing is more natural than this progress of the mind, in looking up to antiquity with reverential wonder. Having been accustomed to compare the wisdom of our fathers, with our own in early imbecillity, the impression of their superiority remains when they no longer exist, and when we cease to be inferior. Thus the men of every age consider the past as wiser than the present; and the reverence seems to accumulate as our imaginations ascend. For this reason, we allow remote antiquity many advantages, without disputing their title: the inhabitants of uncivilized countries, represent them as taller and stronger; and the people of a more polished nation, as more healthy and more wise. Nevertheless, these attributes seem to be only the prejudices of ingenuous minds; a kind of gratitude, which we hope in turn to receive from posterity. The ordinary stature of men, Mr. Derham observes, is, in all probability, the same now as at the beginning. The oldest measure we have of the human figure, is in the monument of Cheops, in the first pyramid of Egypt. This must have subsisted many hundred years before the times of Homer, who is the first that deplores the decay. This monument, however, scarce exceeds the measure of our ordinary coffins: the cavity is no more than six feet long, two feet wide, and deep in about the same proportion. Several mummies also, of a very early age, are found to be only of the ordinary stature; and shew that, for these three thousand years at least, men have not suffered the least diminution. We have many corroborating proofs of this, in the ancient pieces of armour which are dug up in different parts of Europe. The brass helmet dug up at Medauro, fits one of our men, and yet is allowed to have been left there at the overthrow of Asdrubal. Some of our finest antique statues, which we learn from Pliny and others, to be exactly as big as the life, still continue to this day, remaining monuments of the superior excellence of their workmen indeed, but not of the superiority of their stature. We may conclude, therefore, that men have been, in all ages, pretty much of the same size they are at present; and that the only difference must have been accidental, or perhaps national.

As to the superior beauty of our ancestors, it is not easy to make the comparison; beauty seems a very uncertain charm; and frequently is less in the object, than in the eye of the beholder. Were a modern lady's face formed exactly like the Venus of Medicis, or the sleeping vestal, she would scarce be considered beautiful, except by the lovers of antiquity, whom, of all her admirers, perhaps, she would be least desirous of pleasing. It is true, that we have some disorders among us that disfigure the features, and from which the ancients were exempt; but it is equally true, that we want some which were common among them, and which were equally deforming. As for their intellectual powers, these also were probably the same as ours: we excel them in the sciences, which may be considered as an history of accumulated experience; and they excel us in the poetic arts, as they had the first risling of all the striking images of Nature.

C H A P. XIII.

Containing a particular Account of MUMMIES,
WAX - WORKS, &c.

MAN is not content with the usual term of life, but he is willing to lengthen out his existence by art; and although he cannot prevent death, he tries to obviate his dissolution. It is natural to attempt to preserve even the most trifling relicks of what has long given us pleasure; nor does the mind separate from the body, without a wish, that even the wretched heap of dust it leaves behind, may yet be remembered. The embalming, practised in various nations, probably had its rise in this fond desire: an urn filled with ashes, among the Romans, served as a pledge of continuing affection; and even the grassy graves in our own churchyards, are raised above the surface, with the desire that the body below should not be wholly forgotten. The soul, ardent after eternity for itself, is willing to procure, even for the body, a prolonged duration.

But of all nations, the Egyptians carried this art to the highest perfection: as it was a principle of their religion, to suppose the soul continued only coeval to the duration of the body, they tried every art to extend the life of the one, by preventing the dissolution of the other. In this practice they were exercised from the earliest ages; and the mummies they have embalmed in this manner, continue in great numbers to the present day. We are told, in Genesis, that Joseph seeing his father expire, gave orders to his physicians to embalm the body, which they executed in the compass of forty days, the usual time of embalming. Herodotus also, the most ancient of the profane historians, gives us a copious detail of this art, as it was practised, in his time, among the Egyptians. There are certain men among them, says he, who practice embalming as a trade; which they perform with all expedition possible. In the first place, they draw out the brain through the nostrils, with irons adapted to this purpose; and in proportion as they evacuate it in this manner, they fill up the cavity with aromatics; they next cut open the belly, near the sides, with a sharpened stone; and take out the entrails, which they cleanse, and wash in palm oil: having performed this operation, they roll them in aromatic powder, fill them with myrrh, cassia, and other perfumes, except incense: and replace them, sewing up the body again. After these precautions, they salt the body with nitre, and keep it in the salting-place for seventy days, it not being permitted to preserve it so any longer. When the seventy days are accomplished, and the body washed once more, they swathe it in bands made of linen, which have been dipt in a gum the Egyptians use instead of salt. When the friends have taken back the body, they make an hollow trough, something like the shape of a man, in which they place the body; and this they inclose in a box, preserving the whole as a most precious relick, placed against the wall. Such are the ceremonies used with regard to the rich; as for those who are contented with an humbler preparation, they treat them as follows: they fill a syringe with an odoriferous liquor extracted from the cedar tree, and, without making an incision, inject it up the body of the deceased, and then keep it in nitre, as long as in the former case. When the time is expired,

they evacuate the body of the cedar liquor which had been injected; and such is the effect of this operation, that the liquor dissolves the intestines, and brings them away: the nitre also serves to eat away the flesh; and leaves only the skin and the bones remaining. This done, the body is returned to the friends, and the embalmer takes no farther trouble about it. The third method of embalming those of the meanest condition, is merely by purging and cleansing the intestines by frequent injections, and preserving the body for a similar term in nitre, at the end of which it is restored to the relations.

Diodorus Siculus also, makes mention of the manner in which these embalmings are performed. According to him, there were several officers appointed for this purpose: the first of them, who was called the scribe, marked those parts of the body, on the left side, which were to be opened; the cutter made the incision; and one of those that were to salt it, drew out all the bowels, except the heart and the kidneys; another washed them in palm-wine, and odoriferous liquors; afterwards, they anointed for above thirty days, with cedar, gum, myrrh, cinnamon, and other perfumes. These aromatics preserved the body entire for a long time, and gave it a very agreeable odour. It was not in the least disfigured by this preparation; after which it was returned to the relations, who kept it in a coffin, placed upright against the wall.

Most of the modern writers who have treated on this subject, have merely repeated what has been said by Herodotus; and if they add any thing of their own, it is but merely from conjecture. Dumont observes, that it is very probable, that aloes, bitumen, and cinnamon, make a principal part of the composition which is used on this occasion: he adds, that after embalming, the body is put into a coffin, made of the sycamore-tree, which is almost incorruptible. Mr. Grew remarks, that in an Egyptian mummy, in the possession of the Royal Society, the preparation was so penetrating, as to enter into the very substance of the bones, and rendered them so black, that they seemed to have been burnt. From this he is induced to believe, that the Egyptians had a custom of embalming their dead, by boiling them in a kind of liquid preparation, until all the aqueous parts of the body were exhaled away; and until the oily or gummy matter had penetrated throughout. He proposes, in consequence of this, a method of macerating; and afterwards of boiling the dead body in oil of walnut.

We are of opinion, that there were several ways of preserving dead bodies from putrefaction; and that this would be no difficult matter, since different nations have all succeeded in the attempt. We have an example of this kind among the Guanches, the ancient inhabitants of the island of Teneriff. Those who survived the general destruction of this people, by the Spaniards, when they conquered this island, informed them, that the art of embalming was still preserved there; and that there was a tribe of priests among them, possessed of the secret, which they kept concealed as

a sacred mystery. As the greatest part of the nation was destroyed, the Spaniards could not arrive at a complete knowledge of this art; they only found out a few of the particulars. Having taken out the bowels, they washed the body several times in a lee, made of the dried bark of the pine-tree, warmed, during the summer, by the sun, or by a stove in the winter. They afterwards anointed it with butter, or the fat of bears, which they had previously boiled with odoriferous herbs, such as sage and lavender. After this unction, they suffered the body to dry; and then repeated the operation, as often as it was necessary, until the whole substance was impregnated with the preparation. When it was become very light, it was then a certain sign that it was fit, and properly prepared. They then rolled it up in the dried skins of goats; which, when they had a mind to save expence, they suffered to remain with the hair still growing upon them. Purchas assures us, that he has seen mummies of this kind in London; and mentions the name of a gentleman who had seen several of them in the island of Teneriff; which were supposed to have been two thousand years old; but without any certain proofs of such great antiquity. This people, who probably came first from the coasts of Africa, might have learned this art from the Egyptians, as there was a traffic carried on from thence into the most internal parts of Africa.

Father Acoſta, and Garcilaffo de la Vega, make no doubt but that the Peruvians understood the art of preserving their dead for a very long space of time. They assert their having seen the bodies of several Incas, that were perfectly preserved. They still preserved their hair, and their eye-brows; but they had eyes, made of gold, put in the places of those taken out. They were clothed in their usual habits, and seated in the manner of the Indians, their arms placed on their breasts. Garcilaffo touched one of their fingers, and found it apparently as hard as wood; and the whole body was not heavy enough to over-burthen a weak man, who should attempt to carry it away. Acoſta presumes, that these bodies were embalmed with a bitumen, of which the Indians knew the properties. Garcilaffo, however, is of a different opinion, as he saw nothing bituminous about them; but he confesses, that he did not examine them very particularly; and he regrets his not having enquired into the methods used for that purpose. He adds, that being a Peruvian, his countrymen would not have scrupled to inform him of the secret, if they really had it still among them.

Garcilaffo, thus being ignorant of the secret, makes use of some inductions, to throw light upon the subject; he asserts, that the air is so dry and so cold at Cusco, that flesh dries there like wood, without corrupting: and he is of opinion, that they dried the body in snow, before they applied the bitumen: he adds, that in the times of the Incas, they usually dried the flesh which was designed for the army; and that when they had lost their humidity, they might be kept without salt, or any other preparation.

It is said, that at Spitzbergen, which lies within the arctic circle, and, consequently, in the coldest climate, bodies never corrupt, nor suffer any apparent alteration, even though buried for thirty years: nothing corrupts or putrefies in that climate; the wood which has been employed in building those houses where the train-oil is separated, appears as fresh as the day they were first cut.

If excessive cold, therefore, be thus capable of preserving bodies from corruption, it is not less certain, that a great degree of dryness, produced by heat, produces the same effect. It is well

known, that the men and animals that are buried in the sands of Arabia, quickly dry up; and continue in preservation for several ages, as if they had actually been embalmed. It has often happened, that whole caravans have perished in crossing those deserts, either by the burning winds that infest them, or by the sands which are raised by the tempest, and overwhelm every creature in certain ruin. The bodies of those persons are preserved entire; and they are often found in this condition by some accidental passenger. Many authors, both ancient and modern, make mention of such mummies as these: and Shaw says, that he has been assured, that numbers of men, as well as other animals, have been thus preserved for times immemorial, in the burning sands of Saibah, which is a place, he supposes, situate between Rasein and Egypt.

The corruption of dead bodies being entirely caused by the fermentation of the humours, whatever is capable of hindering or retarding this fermentation, will contribute to their preservation. Both heat and cold, though so contrary in themselves, produce similar effects in this particular, by drying up the humours. The cold in condensing and thickening them, and the heat in evaporating them before they have time to act upon the solids. But it is necessary, that these extremes should be constant; for if they succeed each other so as that cold shall follow heat, or dryness humidity, it must then necessarily happen, that corruption must ensue. However, in temperate climates, there are natural causes capable of preserving dead bodies; among which we may reckon the qualities of the earth in which they are buried. If the earth be drying and astringent, it will imbibe the humidity of the body; and it may be probably for this reason that the bodies buried in the monastery of the Cordeliers, at Thoulouse, do not putrefy, but dry in such a manner that they may be lifted up by one arm.

The gums, resins, and bitumens, with which dead bodies are embalmed, keep off the impressions, which they would else receive from the alteration of the temperature of the air; and still more, if a body thus prepared be placed in a dry or burning sand, the most powerful means will be united for its preservation. We are not to be surprised, therefore, at what we are told by Chardin, of the country of Chorofan, in Persia. The bodies which have been previously embalmed, and buried in the sands of that country, as he assures us, are found to petrify, or, in other words, to become extremely hard; and are preserved for several ages. It is asserted that some of them have continued for a thousand years.

The Egyptians, as has been mentioned above, swathed the body with linen bands; and enclosed it in a coffin; however, it is probable that, with all these precautions, they would not have continued till now, if the tombs, or pits, in which they were placed, had not been dug in a dry chalky soil, which was not susceptible of humidity; and which was, besides, covered over with a dry sand of several feet thickness.

The sepulchres of the ancient Egyptians subsist to this day. Most travellers who have been in Egypt, have described those of ancient mummies, and have seen the mummies interred there. These catacombs are within two leagues of the ruins of this city, nine leagues from Grand Cairo, and about two miles from the village of Zaccara. They extend from thence to the pyramids of Pharaoh, which are about eight miles distant. These sepulchres lie in a field, covered with a fine running sand, of a yellowish colour. The country is dry and hilly; the entrance of the tomb is

choaked

choaked up with sand; there are many open, but several more that are still concealed. The inhabitants of the neighbouring village have no other commerce, or method of subsisting, but by seeking out mummies, and selling them to such strangers as happen to be at Grand Cairo. This commerce, some years ago, was not only a very common, but a very gainful one. A complete mummy was often sold for twenty pounds: but it must not be supposed that it was bought at such an high price from a mere passion for antiquity; there were much more powerful motives for this traffic. Mummy at that time made a considerable article in medicine; and a thousand imaginary virtues were ascribed to it, for the cure of most disorders, particularly of the paralytic kind. There was no shop, therefore, without mummy in it; and no physician thought he had properly treated his patient, without adding this to his prescription. Induced by the general repute, in which this supposed drug was at that time, several Jews, both of Italy and France, found out the art of imitating mummy so exactly, that they, for a long time, deceived all Europe. This they did by drying dead bodies in ovens, after having prepared them with myrrh, aloes, and bitumen. Still, however, the request for mummies continued, and a variety of cures were daily ascribed to them. At length, Paræus wrote a treatise on their total inefficacy in physic; and shewed their abuse in loading the stomach, to the exclusion of more efficacious medicines.

From that time, their reputation began to decline; the Jews discontinued their counterfeits, and the trade returned entire to the Egyptians, when it was no longer of value. The industry of seeking after mummies is now totally relaxed, their price merely arbitrary, and just what the curious are willing to give.

In seeking for mummies, they first clear away the sand, which they may do for weeks together, without finding what is wanted. Upon coming to a little square opening, of about eighteen feet in depth, they descend into it, by holes for the feet, placed at proper intervals; and there they are sure of finding what they seek for. These caves, or wells, as they call them, are hollowed out of a white freestone, which is found in all this country a few feet below the covering of sand.

When one gets to the bottom of these, which are sometimes forty feet below the surface, there are several square openings, on each side, into passages of ten or fifteen feet wide, and these lead to chambers of fifteen or twenty feet square. These are all hewn out of the rock; and in each of the catacombs are to be found several of these apartments, communicating with each other. They extend a great way under ground, so as to be under the city of Memphis, and in a manner to undermine its environs.

In some of the chambers, the walls are adorned with figures and hieroglyphics; in others, the mummies are found in tombs, round the apartment hollowed out in the rock. These tombs are upright, and cut into the shape of a man, with his arms stretched out. There are others found, and these in the greatest number, in wooden coffins, or in cloths covered with bitumen. These coffins, or wrappers, are covered all over with a variety of ornaments. There are some of them painted, and adorned with figures, such as that of death, and the leaden seals, on which several characters are engraven.

Some of these coffins are carved into the human shape; but the head alone is distinguishable; the rest of the body is all of a piece, and terminated

by a pedestal, while there are some with their arms hanging down; and it is by these marks that the bodies of persons of rank are distinguished from those of the meaner order. These are generally found lying on the floor, without any profusion of ornaments; and in some chambers the mummies are found indiscriminately piled upon each other, and buried in the sand.

Many mummies are found lying on their backs; their heads turned to the north, and the hands placed on the belly. The bands of linen, with which these are swathed, are found to be more than a thousand yards long; and, of consequence, the number of circumvolutions they make about the body must have been amazing. These were performed by beginning at the head, and ending at the feet; but they contrived it so as to avoid covering the face. However, when the face is entirely uncovered, it moulders into dust immediately upon the admission of the air. When, therefore, it is preserved entire, a slight covering of cloth is so disposed over it, that the shape of the eye, the nose, and the mouth, are seen under it. Some mummies have been found with a long beard, and hair that reached down to the mid-leg, nails of a surprising length, and some gilt, or at least painted of a gold colour. Some are found with bands upon the breast, covered with hieroglyphics, in gold, silver, or in green; and some with tutelary idols, and other figures of jasper, within their body. A piece of gold, also, has often been found under their tongues, of about two pistoles value; and, for this reason, the Arabians spoil all the mummies they meet with, in order to get at the gold.

But, although art, or accident, has thus been found to preserve dead bodies entire, it must by no means be supposed that it is capable of preserving the exact form and lineaments of the deceased person. Those bodies which are found dried away in the Deserts, or in some particular church-yards, are totally deformed, and scarce any lineaments remain of their external structure. Nor are the mummies preserved by embalming, in a better condition. The flesh is dried away, hardened, and hidden under a variety of bandages; the bowels, as we have seen, are totally removed; and from hence, in the most perfect of them, we see only a shapeless mass of skin discoloured; and even the features scarce distinguishable. The art is, therefore, an effort rather of preserving the substance than the likeness of the deceased; and has, consequently, not been brought to its highest pitch of perfection. It appears from a mummy, not long since dug up in France, that the art of embalming was more completely understood in the western world than even in Egypt. This mummy, which was dug up at Auvergne, was an amazing instance of their skill, and is one of the most curious relics in the art of preservation. As some peasants, in that part of the world, were digging in a field near Rion, within about twenty-six paces of the highway, between that and the river Artier, they discovered a tomb, about a foot and a half beneath the surface. It was composed only of two stones; one of which formed the body of the sepulchre, and the other the cover. This tomb was of free-stone; seven feet and a half long, three feet and a half broad, and about three feet high. It was of rude workmanship; the cover had been polished, but was without figure or inscription: within this tomb was placed a leaden coffin, four feet seven inches long, fourteen inches broad, and fifteen high. It was not made in the form of a coffin, but oblong, like a box, equally broad at both ends, and covered with a lid that fitted on like a snuff-box, without an hinge. This cover had two holes in it, each of about

about two inches long, and very narrow, filled with a substance resembling butter; but for what purpose intended remains unknown. Within this coffin was a mummy, in the highest and most perfect preservation. The internal sides of the coffin were filled with an aromatic substance, mingled with clay. Round the mummy was wrapped a coarse cloth, in form of a napkin, under this were two shirts, or shrouds, of the most exquisite texture; beneath these a bandage, which covered all parts of the body, like an infant in swaddling cloaths; still, under this general bandage there was another, which went particularly round the extremities, the hands and the legs. The head was covered with two caps; the feet and hands were without any particular bandages; and the whole body was covered with an aromatic substance, an inch thick. When these were removed, and the body exposed naked to view, nothing could be more astonishing than the preservation of the whole, and the exact resemblance it bore to a body that had been dead a day or two before. It appeared well proportioned, except that the head was rather large, and the feet small. The skin had all the pliancy and colour of a body lately dead; the visage, however, was of a brownish hue. The belly yielded to the touch; all the joints were flexible, except those of the legs and feet; the fingers stretched forth of themselves when bent inwards. The nails still continued entire; and all the marks of the joints, both in the fingers, the palms of the hands, and the soles of the feet, remained perfectly visible. The bones of the arms and legs were soft and pliant; but, on the contrary, those of the skull preserved their rigidity; the hair, which only covered the back of the head, was of a chestnut colour, and about two inches long. The pericranium at top was separated from the skull, by an incision, in order to open it for the introducing proper aromatics in the place of the brain, where they were found mixed with clay. The teeth, the tongue, and the ears, were all preserved in perfect form. The intestines were not taken out of the body, but remained pliant and entire, as in a fresh subject; and the breast was made to rise and fall like a pair of bellows. The embalming preparation had a very strong and pungent smell, which the body preserved for more than a month after it was exposed to the air. This odour was perceived wherever the mummy was laid; although

it remained there but a very short time, it was even pretended that the peasants of the neighbouring villages were incommoded by it. If one touched either the mummy, or any part of the preparation, the hands smelt of it several hours after, although washed with water, spirit of wine, or vinegar. This mummy, having remained exposed for some months to the curiosity of the public, began to suffer some mutilations. A part of the skin of the forehead was cut off; the teeth were drawn out, and some attempts were made to pull away the tongue. It was, therefore, put into a glass-case, and shortly after transmitted to the king of France's cabinet, at Paris.

There are many reasons to believe this to be the body of a person of the highest distinction; however, no marks remain to assure us either of the quality of the person, or the time of his decease. There only are to be seen some irregular figures on the coffin; one of which represents a kind of star. There were also some singular characters upon the bandages, which were totally defaced by those who had torn them away. However, it should seem that it had remained for several ages in this state, since the first years immediately succeeding the interment, are usually those in which the body is most liable to decay. It appears also to be a much more perfect method of embalming than that of the Egyptians; as in this the flesh continues with its natural elasticity and colour, the bowels remain entire, and the joints have almost the pliancy which they had when the person was alive. Upon the whole, it is probable that a much less tedious preparation than that used by the Egyptians would have sufficed to keep the body from putrefaction; and that an injection of petreoleum inwardly, and a layer of asphaltum without, would have sufficed to have made a mummy; and it is remarkable that Auvergne, where this was found, affords these two substances in sufficient plenty. This art, therefore, might be brought to greater perfection than it has arrived at hitherto, were the art worth preserving. But mankind have long since grown wiser in this respect, and think it unnecessary to keep by them a deformed carcass, which, instead of aiding their magnificence, must only serve to mortify their pride.

In our SKETCH of the UNIVERSE, in Page 477, the Printer having omitted to mention our Plate containing the twelve Signs of the Zodiac—we shall here insert the following Explanation:

THE ZODIACK is one of the greatest imaginary circles of the heavens, which passes obliquely between the two poles of the world; it is cut into two equal parts, by the equator, one of which comprehends the six northern signs towards the Arctick pole, and the other the six southern signs towards the Antarctick pole; it is furnished with twelve constellations represented upon globes, by the figure of twelve living creatures. The sun goes about this circle once every year, and the moon once a month, and in the middle of it is the Ecliptick line, from which the sun never departs; but the moon and planets wander up and down from the space of eight degrees, and sometimes more in both.

Figure 1. Shews ARIES, a constellation in the heavens represented by a ram, which is the first sign of the zodiack. The number of stars in this constellation, are 18 in Ptolemy's catalogue, 21 in Tycho's, and 65 in Mr. Flamsteed's.

Fig. 2. Is TAURUS, the bull, and is thus characterised, ♉ . The stars in the constellation Taurus, in Ptolemy's catalogue, are 44; in Tycho's catalogue, 41; in the Britannick catalogue, 135.

Fig. 3. Is GEMINI, *the Twins*, represented by two beautiful children, embracing and looking very affectionately in the face of each other; and is thus marked ♊ .

The poets say they represent Castor and Pollux, sons to Jupiter and Leda. The stars of Gemini in Ptolemy's catalogue contain 24; in Tycho's 29; in the Britannick catalogue 89.

Fig. 4. Is CANCER, represented on the globe in the form of a crab, and thus marked, ♋ . Ptolemy makes it contain only 13 stars; Tycho Brahe 15; Bayer and Hevelius 29; and Flamsteed no less than 71.

Fig. 5. Is LEO, containing, according to Ptolemy, 32 stars; according to Tycho, 37; and according to Flamsteed, 94.

The famous star of the first magnitude, called basilicus, regulus, cor leonis, or the lion's heart, is in this constellation.

Fig. 6. Is VIRGO, in which the sun enters in the middle of August. The stars in the constellation Virgo, in Ptolemy's catalogue, are 32; in Tycho's 39; in the Britannick, 89.

Fig. 7. Is LIBRA, or the balance, so called, because when the sun enters it, the days and nights are equal, as if weighed in a balance.

Fig. 8. Is SCORPIO, *Scorpion*, denoted by this character. ♌ . The stars in Scorpio, in Ptolemy's catalogue, are 20; in that of Tycho, 10; but in that of Mr. Flamsteed, 49.

Fig. 9. Is SAGITTARIUS, the archer, marked thus, ♍ . The stars in this constellation in Ptolemy's catalogue are 31, in Tycho's 16, and in Mr. Flamsteed's 52.

Fig. 10. Is CAPRICORNUS, or *Capricorn*, represented on the globe in the form of a goat, with a fish's tail. It is marked thus, ♎ . According to Ptolemy and Tycho, it contains 19 stars, according to Hevelius 29, and according to Flamsteed 51.

This constellation is very properly represented by No. 58.

the wild goat, whose nature being to seek its food from the bottom to the top of mountains, climbing from rock to rock, fitly emblemized the ascent of the sun, from the lowest point, in the beginning of this sign to its highest pitch or summit, in the summer solstice.

Fig. 11. Is AQUARIUS, a constellation, marked thus, ♏ . This constellation, consists of 45 stars in Ptolemy's catalogue, of 40 in Tycho's, and in Mr. Flamsteed's of 108.

Fig. 12. Is PISCES, marked thus, ♐ . The stars in Pisces, in Ptolemy's catalogue, are 38; in Tycho's, 33; and in the Britannick catalogue, 109.

In our NATURAL HISTORY of MAN have been also omitted, Explanations of several Plates belonging to this Work. We shall therefore give them as follow:

Explanation of the Plate representing the Skeleton of the Human Body.

a, The frontal bone. *b*, The coronal suture, *c*, The parietal bone. *d*, The occipital suture. *e*, The temporal bone. *f*, The mastoid apophysis. *g*, The zygomatic apophysis. *h*, The temporal apophysis. *i, i*, The bones of the cheek. *k*, The external part of the bone that lines the orbits of the eye. *l*, The os planum. *m*, The os unguis. *n*, The upper apophysis of the maxillary bone. *o*, The bone of the nose. *p*, The partition of the nose. *q, q*, The maxillary bone. *r, r*, The lower jaw. *s*, The orbit of the eye. *t*, The inferior part of the orbit. *u*, The fifth vertebræ of the neck. *x*, The sixth. *y*, The hole of their transverse apophysis. *z*, The chin. 1, 2, 3, The sternum. 4, The clavicles. 5, 6, 7, 8, 9, 10, 11, The true ribs. 12, 13, 14, The false ribs. 15, 16, 17, 18, The cartilages which unite the true ribs to the sternum. 19, The last vertebræ of the back. 20, 21, The five vertebræ of the loins. *θ, α*, Their transverse apophysis. 22, 22, The os sacrum. *τ, τ*, The orifice of the os sacrum. 23, The amoplata. 24, The humerus, or bone of the arm. 25, The radius. 26, The os cubitus. 27, The carpus. 28, The metacarpus. 29, The phalanges, or bones of the fingers. 30, The os ilium. 31, The os pubis. 32, The os ischium. These three last bones compose the ossa innominata. 33, The foramen ovale. 34, The os femoris. *α*, Its head. *β*, Its neck. *Δ*, The great trochanter. *ε*, the little trochanter. *η*, The internal condyle. *ζ*, The external condyle. 35, The rotula. 36, The tibia. *γ*, The external condyle. *δ*, The internal condyle. *μ*, The ligament of rotulo. *φ*, The malleolus internus. 37, The fibula. *ω*, The malleolus externus. 38, The tarsus. 39, The metatarsus. 40, The phalanges of the toes.

Explanation of the Plate representing a Front View of the Muscles.

1, 1, The muscoli frontales. 2, 2, The orbiculares palpebrarum. 3, The attollens auriculam. 4, The

4, The temporalis. 5, The maffeter. 6, Represents the muscle called by Lancisi constrictor, or depressor pinnæ narium. 7, The dilatator alæ nasi. 8, The zygomaticus. 9, The place of the elevato labiorum, or elevato labiorum communis, called by Lancisi gracilis. 10, The elevato labii superioris proprius. 11, 11, The constrictor or sphincter labiorum, or orbicularis labiorum; by some called osculatorius. 12, The buccinator. 13, 13, The muscoli mastoidæi. 14, 14, The sternohyoidei. 15, 15, Those parts of these muscles which arise from the clavicle. 16, 16, The coracohyoidei. 17, The scaleni. 18, Represents part of the cucullaris on the right side. 18, On the left side is the levator or elevato scapulæ, otherwise called musculus patientiæ. 19, 19, The place where the fibres of the pectoralis unite, in some measure, with those of the deltoïdes. 20, 20, The deltoïdes. 21, The place in the carpus, where the palmaris longus passes through a ring in the annular ligament. 22, A remarkable union of the tendons of the extensors of the three last fingers. 23, 23, The productions of the peritonæum, which, perforating the muscles of the abdomen at the rings descend to the scrotum. 24, 24, The place where the three tendons of the sartorius, gracilis, and feminovosus are inserted into the anterior and internal part of the tibia, just under the knee. 25, 25, The tendons of the extensors of the toes, which are secured by a ligament at the ankle, as appears on both sides. But on the right side internally another ligament is represented, which fixes the tendons of the extensor longus digitorum, the tibius posticus, and the flexor pollicis. 26, 26, The musculus pectoralis. 27, The triceps extensor cubiti on the right side. 28, and 30, The biceps on the left side, according to Lancisi's explication. 29, Part of the triceps extensor on the left side. 30, The biceps on the right side. 31, The brachius internus. 32, The anconæus. 33, The pronator rotundus. 34, 34, The supinator longus. 35, 35, The radius externus, according to Lancisi. 36, The extensor carpi ulnaris. 37, 37, The cubitanus interus, according to Lancisi. 38, The radius internus, according to Lancisi. 39, The palmaris, with its tendinous expansion. 40, 40, The tendons of the muscles of the thumb. 41, The tendon of the adductor pollicis. 42, The extensor magnus digitorum. 43, Ligamentum carpi. 44, 44, The tendons of the iliaci interni. 45, The pectinæus. 46, One of the heads of the triceps. 47, 47, The rectus femoris on each side. 48, 48, The vastus externus on each side. 49, The vastus internus on each side. 50, The gracilis. 51, The feminovosus. 52, The sartorius on each side. 53, A part of the origin of the vastus externus. 54, 54, The membranofus. 55, 55, The tibialis anticus. 56, The gemelli. 57, 57, The solæi. 58, The tendo Achillis. 59, According to Lancisi, is the extensor digitorum longus. 60, 60, The tendons of the extensors of the toes. 61, The tendons of the extensor longus, tibius, posticus, and flexor pollicis. A, A, Portions of the latissimus dorsi on each side. B, B, The indentations of the ferratus major anticus. C, C, The sternum.

Explanation of the Plate representing a Back View of the Muscles.

1, Two muscles upon the occiput called by Eustachius quadrati. 2, The musculus cucullaris. 3, The splenius. 4, The musculus mastoidæus. 5, The musculus patientiæ, or levator scapulæ proprius. 6, The rhomboides. 7, The articulation of the clavicle with the scapula on the right side. 8, The deltoïdes. 9, The teres minor. 10, The teres major. 11, 11, The latissimus dorsi on each

side. 12, The glutæus major. 13, The glutæus medius. 14, The musculus pyriformis. 15, The quadratus femoris. 16, The biceps femoris. 17, The semi-membranosus. 18, The membranofus, according to Lancisi. 19, 19, The vasti externi. 20, The gastrocnemii. 21, The solæus. 22, The plantaris.

Explanation of the Plate of Arteries.

Fig. 1. Will give a much better idea of the arteries of the human body, than is possible to be conveyed by words.

1. The aorta cut from its origin at the left ventricle of the heart. Fig. 3. of the same plate, represents part of the trunk of the aorta, turned inside out; *a, a*, the internal, or nervous coat; *b, b*, the muscular coat; *c*, the external, or vascular coat.

A. The three semi-lunar valves of the aorta, as they appear when they hinder the blood from coming back into the left ventricle of the heart, in its diastole.

2. 2. The trunk of the coronary arteries arising from the aorta.

3. Ligamentum arteriosum.

4. 4. The subclavian arteries.

5. 5. The two carotid arteries.

6. 6. The two vertebral arteries, which arise from the subclavica, and pass through all the transverse processes of the vertebræ of the neck.

7. 7. The arteries which convey blood to the lower part of the face, tongue, adjacent muscles and glands.

8. 8. The trunks of the temporal arteries, springing from the carotids, and giving branches to the parotid glands.

9. 9. Branches of the temporal arteries, conveying blood to the neighbouring muscles, the hairy scalp, and forehead.

10. 10. The trunks which send blood to the foramina narium, particularly to the glands of its mucous membranes.

11. 11. The occipital arteries, whose trunks pass close by the mamiform process.

12. 12. Muscles which carry blood to the fauces, gargareon, and muscles of those parts.

B. B. Small portions of the basis of the skull, perforated by the artery of the dura mater, part of which is represented as hanging to the arteries.

13. 13. The contortions of the carotid arteries before they pass the basis of the skull to the brain.

14. 14. These parts of the carotid arteries, where they pass by each side of the sella turcica, where several small branches arise from them, and help to compose the rete mirabile.

C. The glandula pituitaria, taken out of the sella turcica, lying between the two contorted trunks of the carotid arteries, marked 14. 14.

D. D. The arteriæ ophthalmicæ, which spring from the carotids before they enter the pia mater.

15. The contortions of the vertebral arteries, as they pass the transverse processes of the first vertebra of the neck, towards the os occipitis.

16. The two trunks of the vertebral arteries that lie on the medulla oblongata.

17. The communicant branches between the carotid and cervical artery.

18. 18. The rammifications of the arteries within the skull, the larger trunks of which lie between the lobes of the brain, and its fulci.

E. E. The arteries of the cerebellum.

19. 19. The arties of the larynx; thyroid glands and adjacent muscles and parts arising from the subclavian arteries.

20. 20. Others arising near the former, which convey blood to the muscles of the neck and scapula.

21. 21. The

MUSCLES .

ARTERIES.

Fig. 1.

Fig. 2.

Fig. 3.

BRAIN.

Fig. 1.

Fig. 2.

21. 21. The mammariæ, which arise from the subclavian arteries, and descend to the cartilages of the true ribs internally, on each side the os pectoris or sternum. Some branches of these pass through the pectoral as well as intercostal muscles, and give blood to the breast, where they meet some branches of the intercostal arteries.
22. 22. The arteries of the muscles of the os humeri, and some of those of the scapula.
23. 23. 24. 24. Those parts of the large trunks of the arteries of the arm, which are liable to be wounded in opening the vena basilica, or innermost of the three veins in the bending of the cubit.
25. 25. A communicant branch of an artery arising from the trunk of the artery of the arm, above its flexure at the cubit, which is inosculated with the arteries below the cubit.
26. 26. The external artery of the cubit, which makes the pulse near the carpus.
27. 27. Arteries of the hands and fingers.
28. 28. The descending trunk of the arteria magna.
29. The bronchial artery, springing from one of the intercostal arteries: it sometimes arises immediately from the descending trunk of the aorta; and at other times from the superior intercostal artery which springs from the subclavian.
30. A small artery, springing from the fore parts of the aorta descendens, and passing to the gula.
31. 31. The intercostal arteries on each side the arteria magna descendens.
32. The trunk of the arteria cæliaca, whence spring,
33. 33. The hepatick arteries, and
34. The arteria cystica, or the gall-bladder.
35. Arteria coronaria ventriculi inferior.
36. The pylorica.
37. The epiploica dextra, sinistra, and media, springing from the coronaria.
38. The ramifications of the coronary artery, which embrace the bottom of the stomach.
39. Coronaria ventriculi superior.
40. 40. The phrenick arteries, or the two arteries of the diaphragm; that on the left side arising from the trunk of the arteria magna; the right springing from the cæliaca.
41. The trunk of the splenick artery, arising from the cæliaca, contorted.
42. The two small arteries going to the upper part of the duodenum and pancreas; the rest of the arteries of the pancreas spring from the splenick artery in its passage to the spleen.
43. The trunk of the arteria mesenterica superior turned towards the right side.
44. The branches of the superior mesenterick artery, freed from the small guts. Here the various anastomoses the branches of this artery make in the mesentery, before they arrive at the intestines, may be observed.
45. The inferior mesenterick artery, arising from the arteria magna.
46. Remarkable anastomoses of the mesenterick artery with the superior.
47. 47. The branches of the inferior mesenterick artery, as they pass to the intestinum colon.
48. Those of the rectum.
49. The emulgent arteries of the kidneys.
50. The vertebral arteries of the loins.
51. 51. The spermatick arteries, which descend to the testes, and are so small as to escape being filled with wax.
52. Arteria sacra.
53. Arteriæ iliaci.
54. 54. Rami iliaci externi.
55. 55. Iliaci interni.
56. 56. The two umbilical arteries cut off; that

- on the right side is drawn as in the foetus, and the left expressed as in an adult.
57. 57. The epigastick arteries, which ascend under the right muscles of the abdomen, and are inosculated with the mammariæ.
58. 58. Branches of the external iliac arteries, passing between the two oblique muscles of the abdomen.
59. 59. Branches of the internal iliac arteries, which convey the blood to the extensores and obturatores muscles of the thighs.
60. The trunks of the arteries which pass to the penis.
61. 61. The arteries of the bladder.
62. 62. The internal arteries of the pudentum, which, with those here expressed with the penis, make the hypogastrick arteries in women.
63. The penis extended with wax, and dried.
64. The glans penis.
65. The upper part of the dorsum penis, cut from the body of the penis, and raised, to shew the corpora cavernosa penis.
66. Corpora cavernosa penis, freed from the ossa pubis, and tied after inflation.
67. The two arteries of the penis, as they appear injected with wax.
68. The capsula and septum of the corpora cavernosa penis.
69. The crural arteries.
70. 70. The arteries which pass to the muscles of the thighs and tibiæ.
71. That part of the crural artery that passes the ham.
72. The three large trunks of the arteries of the legs.
73. The arteries of the foot, with their communicating branch, from their superior to their inferior trunk, as well as their communications at the extremity of each toe, like those of the fingers.

Explanation of the Plate of the Brain.

Fig. 1. Is an interior view of the cerebrum and cerebellum.

A, The transverse septum or tent of the cerebellum. B, the longitudinal sinus of the dura mater, which is divided into two branches at its posterior extremity. C, the right sinus divided into two parts, one of which communicates with the right lateral sinus, and the other with the left. D, vestiges of the falx of the brain. E, E, the large veins of the septum A. F, the insertion of the veins of the cerebrum into the lateral sinus. G, the orifice of the posterior occipital sinus. H, H, the posterior occipital sinuses on the right and left. I, I, the falx of the cerebellum. K, K, the great transverse sinus. L, L, the jugular fossæ. M, M, the sinus petrosi inferior. N, N, the sinus petrosi superior. O, O, the veins of the cerebellum which open into the above sinuses. P, P, the inferior occipital sinuses. Q, Q, the canal by which they discharge themselves, and which joins the ninth pair. R, R, the anterior and superior occipital sinuses. S, S, the communication between the sinus cavernosus and circularis. T, the orifice of the sinus petrosus superior, by which it communicates with the sinus cavernosus. V, V, sinus cavernosi. X, X, the transverse sinus of the pituitary fossa. Y, Y, the circular sinus of Ridley. Z, Z, the insertion of the anterior veins of the cerebrum into the sinus cavernosi. a, a, the principal artery of the dura mater. b, b, the vein which accompanies it. c, the part of the cranium which it there enters by a particular foramen. d, d, the internal carotid arteries in the sinus cavernosus cut off at the place where they enter the cerebrum. e, e, the arterial branches sent to the sinus

of the nerve of the fifth pair. *f, f*, part of the internal carotid produced to the ophthalmick artery. *g, g*, the posterior apophyses clinoides. *h*, the apophysis, called crista galli. *i, i*, the frontal sinuses. *k, k*, branches of the fifth pair, distributed on the dura mater. *l*, the fourth branch of the fifth pair. *m*, the second branch. *n*, the first or ophthalmick branch. *o*, the third part. *q*, the partition which divides the fifth and sixth pair. *r*, the sixth pair. *s*, origin of the intercostal nerve. *t, t*, entrance of the seventh pair into the dura mater. *u, u*, first insertions of the eighth pair. *x, x*, second insertions of the eighth pair. *y, y*, the ninth pair. *z*, the foramen of the medulla spinalis.

In the right Eye, the superior Part of the Orbit taken off.

1, 1, The ophthalmick artery. 2, 2, its exterior branch, which accompanies the nerve of the same name. 3, 3, the interior branch distributed to the nostrils. 4, 4, the sclerotick branches, several of which are distributed to the uvea. 5, 5, vestiges of the levator muscles of the eye-lid and of the eye. 6, the extremity of the levator of the eye-lid. 7, the lacrymal gland. 8, the optick nerve. 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, the same as in the eye of the opposite side.

In the left Eye.

9, The annular cartilage. 10, the great oblique muscle. 11, the levator of the eye. 12, the abductor or internal muscle of the eye. 13, the abductor cut off. 14, the superior branch of the third pair, distributed to the eye and eyelid. 15, the other part of the trunk. 16, branch to the nerve to the obliquus inferior. 17, branch to the right inferior of the eye. 18, branch to the right internal. 19, branch to the ophthalmick ganglion. 20, superior branch of the first branch of the fifth pair. 21, the exterior rope of that branch. 22, interior rope. 23, exterior branch of the first branch of the fifth pair. 24, small branches extended to the face, through the foramina of the ossa malarum. 25, branches to the lacrymal gland. 26, inferior branches of the second branch of the fifth pair. 27, rope of that branch to the ganglion. 28, small filaments to the nostrils. 30, the ophthalmick ganglion. 31, the small ciliary nerves. 7, 8, the same as in the right eye.

Fig. 2. Exhibits the basis of the brain, with part of the medulla oblongata, the blood vessels being injected with wax.

A, A, the fore lobes of the brain.
B, B, the hinder lobes.
C, C, the cerebellum.
D, D, the lateral sinuses.
E, E, the vertebral arteries, as they pass between the first vertebra and the bone of the occiput.
F, the vertebral sinus.
G, G, G, G, G, the dura mater on the right side taken off from the spinal marrow, and remaining on the left.

1, 2, 3, 4, &c. the ten pair of nerves belonging to the brain, with seven of the spinal marrow.

a, the foramen that opens into the pituitary gland from the infundibulum.

b, b, the two white protuberances behind the infundibulum.

c, c, the two trunks of the carotid artery cut off where they began to run betwixt the fore and hinder lobes of the brain.

d, d, the two arteries joining the carotids, with the cervical artery called the communicant branches.

e, e, two large branches of the cervical artery, sometimes seeming as though they came from the communicant branch on each side, from the first of which the plexus choroides hath its original in chief, and from the last the plexus choroides of the fourth ventricle.

f, several little branches arising from the carotid artery.

g, the cervical artery composed of the two trunks of the vertebral artery within the cranium.

h, h, the two trunks of the vertebral artery.

i, i, i, the spinal artery.

k, a small branch of an artery running through the ninth pair.

l, l, the crura of the medulla oblongata.

m, m, the annular protuberance, or pons varolii.

n, that part of the caudex medullaris on the right side, called, by Willis and Vieussenius, corpora pyramidalia.

o, that part on the same side called corpus olivare.

p, the foremost branch of the carotid artery, dividing the fore lobes of the brain, consisting of two branches, one of them only appearing here.

q, q, little branches of arteries helping to make the plexus choroides in the fourth ventricle.

r, r, r, r, branches of arteries dispersed from the cervical artery upon and through the annular protuberance.

s, s, part of the second process or pedunculi of the cerebellum.

t, t, the spinal accessory nerve.

Illustration of the BOTANICAL PLATES.

IN our INTRODUCTION to the Natural History of VEGETABLES, page 296, we observed, that the immense labours, which some late botanists have undergone, to give a list of the names of plants, can contribute little to the discovery of their properties. We should be led to suppose, from the repeated endeavours to systematise this science, that the whole of the student's pursuit was directed to acquire the names of plants. More time has been consumed in making catalogues of this nature, than, if properly applied, would have been sufficient to have enabled the botanist to discover several new properties in the vegetable world, as yet unknown.

For these reasons, the botanical systems of flowers, plants, leaves, mosses, and cups of flowers, were, intentionally, omitted: however, in order to gratify the taste of curious speculators, and that of the learned, we shall here treat the above subjects agreeable to systematical arrangements; particularly those adopted by LYNNÆUS and TOURNEFORT; wherein the several Orders and Genera of flowers and plants will be considered; and for a particular account of the various characters, and Latin appellations, we refer our readers to the numerous plates, under the general head of Botany.

BOTANY.

THE term Botany, says a modern writer, has been understood as expressing the doctrine of plants at large, and in all its various lights; but tracing the origin and progress of the study, we see it at several periods under distinct appearances. These, however, are all reducible to those general heads, which we may distinguish by the terms philosophic, historical, and systematic Botany. Of these the first and noblest has been the least cultivated; it began, and in a manner ended, with Theophrastus; its object is the nature of vegetables as vegetables, independent of all other considerations; to this succeeded the historical branch, gathering the names and numbers of plants, their places of growth, their virtues, and other æconomic uses: this was the object of those, who studied herbs, from Theophrastus to the latter end of the sixteenth century, when Cæsalpinus gave origin to the systematic Botany: till this time plants were arranged, even those who wrote best on them, according to the old and irregular division, into trees, shrubs, and herbs; or according to their virtues, the letters of the alphabet, which began with their names, or by such vague and arbitrary methods. Their increased number now made it necessary they should be better arranged: and this great author has struck out that path, which has since been trod so happily; of examining their parts and deducing thence the characters of classes, arranging in each class all those, which had the peculiar mark which made its distinction. The origin of systematical distribution was the selecting some part of a plant, which was obvious and regular in itself, and establishing a character upon its description, to which all others that had the same mark were referred. Thus were formed the characters of classes first, and then the distinc-

tive mark of the genera. Between these there came naturally some lesser peculiarity, the subdivision of the classes by orders. The original invention was the choice of some one part of the character, and what part that should be was left to discretion. The great inventor chose the seeds, which he arranged according to the situation of the corculum, or heart of the seed, and to its place upon the plant; and upon this basis he founded the first arrangement of plants. Afterwards various parts of plants, and various collections of parts were adopted for the characters of classes. One hundred and three years after Cæsalpinus, Morrifon a Briton, entered successfully into the same path; Ray followed, Knoutius followed Ray, and Herman followed him. Riverius was cotemporary with Knoutius; these both wrote in the year 1690; and after four years more followed Tournefort, the greatest of them all. Thus closed upon the science the seventeenth century, in the last seventeen years of which the long neglected institution of Cæsalpinus was so well revived, that there appeared no less than six distinct systems of plants, and each of very considerable merit. The authors of the four first held the fruits and seed, according to the original practice of Cæsalpinus, to be the properest, at least the most essential parts, on which to found a system. Riverius struck out the design of fixing the characters in the flower, and Tournefort pursued this with the greatest attention, industry and truth. Boerhaave, who wrote in the beginning of the 18th century, continued the system in its original course, making the fruits and seeds of plants his great object in their arrangement. In 1711, Henschler of Wirtenberg appeared with credit, and led a long train; who less regarding the original object of distinction, followed Riverius and Tournefort in the choice of the flower. Seven years after, Ruppilus wrote, adopting the same part as the foundation of his system, and thus continued the established doctrine with Pontedera, Hebenstret, and Hudwig. In the mean time Magnal distinguished himself by a new system, formed upon the construction of the cup; and in the year 1735 Linnæus, too great for praise, published that system of Botany, which characterizes the classes according to the parts of generation or fructification, the filaments, and style; and takes into the general distinction all the flower.

FLOWERS.

THOUGH no part of plants is more different than their flowers; yet the definitions given by different authors of the word are extremely various, and are very necessary to be explained, in order to the understanding their works. Jungius defines it to be the most tender part of a plant, remarkable for its colour or form, or for both, and cohering with the fruit. Yet this author himself acknowledges his definition to be too confined, as he very well knew there were several plants, whose flowers were produced remote from the fruit.

Mr. Ray says, the flower coheres for the most part with the rudiments of the fruit, but such phraseology is by no means to be admitted into definitions

definitions. Tournefort defines it to be a part of a plant very often remarkable for its peculiar colours, for the most part adhering to the young fruit, to which it seems to afford the first nourishment, in order to explicate its most tender parts; but this is a more indeterminate definition than the former, from its loose mode of expression. Pontedera defines it to be a part of a plant, unlike the rest in form and nature. If the flower has a tube, it adheres to, or is fixed very near to the embryo, to the use of which it is subservient; but if the flower has no tube, then its base does not adhere to the embryo. This is scarce intelligible except to the expert botanist, and may be made to take in some parts of plants by no means to be understood by the name of flowers. Jussieu defines it to be composed of chives and a pistillum, and to be of use in the generation of the plant: but this is too imperfect, as there are many plants in which the pistillum is found at a great distance from the chives, and many flowers which have no pistillum, and many others which have no chives.

Valliant, however, has been happier in his definition; he says, that flowers are the organs which constitute the different sexes of plants, which are sometimes found naked and without any covering; and that the petals, which most of them have, are no way essential to their use, but serve and are intended merely as covers for them; but as these coats or coverings are the most conspicuous, and most beautiful part of the flower, these are to be called flowers, be they of whatever form or structure, or colour; and whether they contain only the organs of both sexes in each individual, or only of one, or even but of some part of one, provided that they are not of the same figure and colour with the leaves of the plant. The shortest and most express definition, however, seems to be Martyn's; which is, that flowers are the organs of generation of both sexes, adhering to a common placenta, together with their common covering, or of either sex separately with its proper coverings, if it have any. The structure of the different flowers are very various; but Dr. Grew has observed, that the far greater number of them have the impalement, the foliation, and the attire of chives, &c. Mr. Ray accounts that every perfect flower has the petals, stamina or chives, apices or summits, and the style or pistil, and such as want any of these parts he calls imperfect flowers. The greater number of plants have a flower-cup which is of a firmer structure than their leaves, and serves for their support. The parts of a flower are the ovary or pistil, the corolla or flower-petals, the stamina or chives, the impalement or calyx, and the perianthium, pericarpium, and fruit.

Explanation of the Terms used in BOTANY.

PISTIL, *Pistillum*, denotes the female organ of generation in flowers, and is defined, by Linnæus, as an entrail of the plant, designed for the reception of the farina, or male-dust, wherewith it becomes impregnated; it consists of three parts, viz. the germen, style, and stigma; the germen is the rudiment of the fruit, accompanying the flower, and is of various shapes, but always situated below the style, or stigma, and contains the embryo seeds; the style is the part that serves to elevate the stigma from the germen, and is also of different forms; the stigma, which is of various shapes likewise, is always placed on the top of the style, or, if that be wanting, on the top of the germen; this part is covered with a moisture, for the breaking of the farina into more minute parts.

COROLLA is the most conspicuous part of a flower. It expresses the coloured tender part,

which surrounds the organs of generation. The part it is composed of are called petals; if it consists only of one piece, it is called monopetalous: if of more, it is said to be dipetalous, tripetalous; and so on, as it consists of two, three, four, or more parts.

STAMINA, the male parts of a flower, or its male organs of generation. Linnæus defines the stamina the entrail of the plant, designed for the preparation of the pollen.

Each stamen consists of two parts. 1. The filament or thread, which serves to elevate the anthera or summit, and at the same time connects it with the flower. 2. The anthera, or summit itself, which contains within it the pollen, and when come to maturity, discharges the same.

The stamina being the male part of the flower, the construction and distribution of the sexual system, is principally founded upon, and regulated by them. Such flowers as want the stamina, are called female flowers: such as have the stamina, but want the pistillum, or female part, male flowers; such as have them both, hermaphrodite flowers; and such as have neither, neuter flowers.

Mr. Tournefort takes the use of the stamina to be, as it were, so many excretory canals for discharging the growing embryo of its redundant juices; and of these excrements of the fruit, he takes that farina, or dust, found in the apices, to be formed. But other writers, as Geoffroy, and Linnæus in particular, assign the stamina a nobler use: these authors, explaining the generation of plants in a manner analogous to that of animals, maintain the use of the stamina to be that of secreting, in their fine capillary canals, a juice, which being collected, hardened, and formed into a farina, or dust, in the tops of the apices, is thence, when the plant arrives at maturity, discharged by the bursting of the apices upon the top of the pistil, whence is a passage for it to descend into the uterus, where being received, it impregnates and fecundifies the plant.

CALYX, or Impalement, among botanists a general term, expressing the cup of flowers, or that part of a plant which surrounds, incloses, or supports the other parts of the flower. The cups of flowers are very various in their structure, and are distinguished by the names of perianthium, involucre, spathe and gluma. Botanists distinguish two sorts of Calices, one external, called the Calyx of the flower: by the ancients perianthium, as encompassing the flower and seed; the other internal, called the Calyx of the fruit: by the ancients pericarpium, as being the capsule which compasses the fruit, and is itself encompassed by the petals. The external Calyx may also be divided into two sorts, one which surrounds the flower, another which sustains it, different from the pedicle; as the latter spreads itself underneath the flower, to give room for the nutritious juice to raise more freely; the cavity of the pedicle enlarged, is reputed part of the Calyx both external and internal.

PERIANTHIUM, a flower-cup situated close to the fructification. It surrounds the lower part of the flower, and consists of several leaves, or of one leaf divided into several segments. If it includes the stamina and not the germen, it is the Perianthium of the flower; if the germen but not the stamina, the Perianthium of the fruit: but if it includes both, it is the Perianthium of the fructification.

PERICARPIUM, a covering or case for the seeds of plants; it is the germen of the pistil enlarged: there are no less than nine species of pericarpia. 1. A Capsule. 2. A Conceptaculum. 3. A Pod. 4. A Ligumen. 5. A Nut. 6. A Drupe. 7. An Apple. 8. A Berry. 9. A Strobilus.

ORDERS of FLOWERS.

Class I. Monandria. One Stamen on the Hermaphrodite Flower

Order 1. Monogynia

Canna, Indian Flowering Reed

Order 2. Digynia

Blitum, Virgate Strawberry Blite

Class II. Diandria Two Stamens in the Hermaphrodite Flower

Order 1. Monogynia

Monarda, Oswego Tea

Order 2. Digynia

Anthoxanthum, Vernal Grass

Order 3. Trigynia

Piper, Black Pepper

Class III. Triandria. Three Stamens in the Hermaphrodite Flower

Order 1. Monogynia

Crocus, Garden Crocus

Order 2. Digynia

Avena Fatua, Wild Oat

Order 3. Trigynia

Mollugo, (verticillate)

Class IV. Tetrandria. Four Stamens in the Flower with the Fruit

Order 1. Monogynia

Dipsacus, Laciniated Teasel

Order 2. Digynia

Hamamelis, witch Hazel

Order 3. Tetragynia

Potamogeton, Pond weed

Class V. Pentandria. Five Stamens in the Hermaphrodite Flower

Order 1. Monogynia

Nerium, Rose Bay

Order 2. Digynia

Anethum, Common Fennel

Order 3. Trigynia

Turnera

Order 4. Tetragynia

Parnassia, Grass of Parnassus

Order 5. Pentagynia

Crassula, Navelwort

Order 6. Polygynia

Myosurus, Mouse Tail

Class VI. Hexandria. Six Stamens in the Hermaphrodite Flower

Order 1. Monogynia

Amaryllis, Belladonna

Order 2. Digynia

Oryza, Rice

Order 3. Trigynia

Rumex, great curled Dock

Order 4. Tetragynia

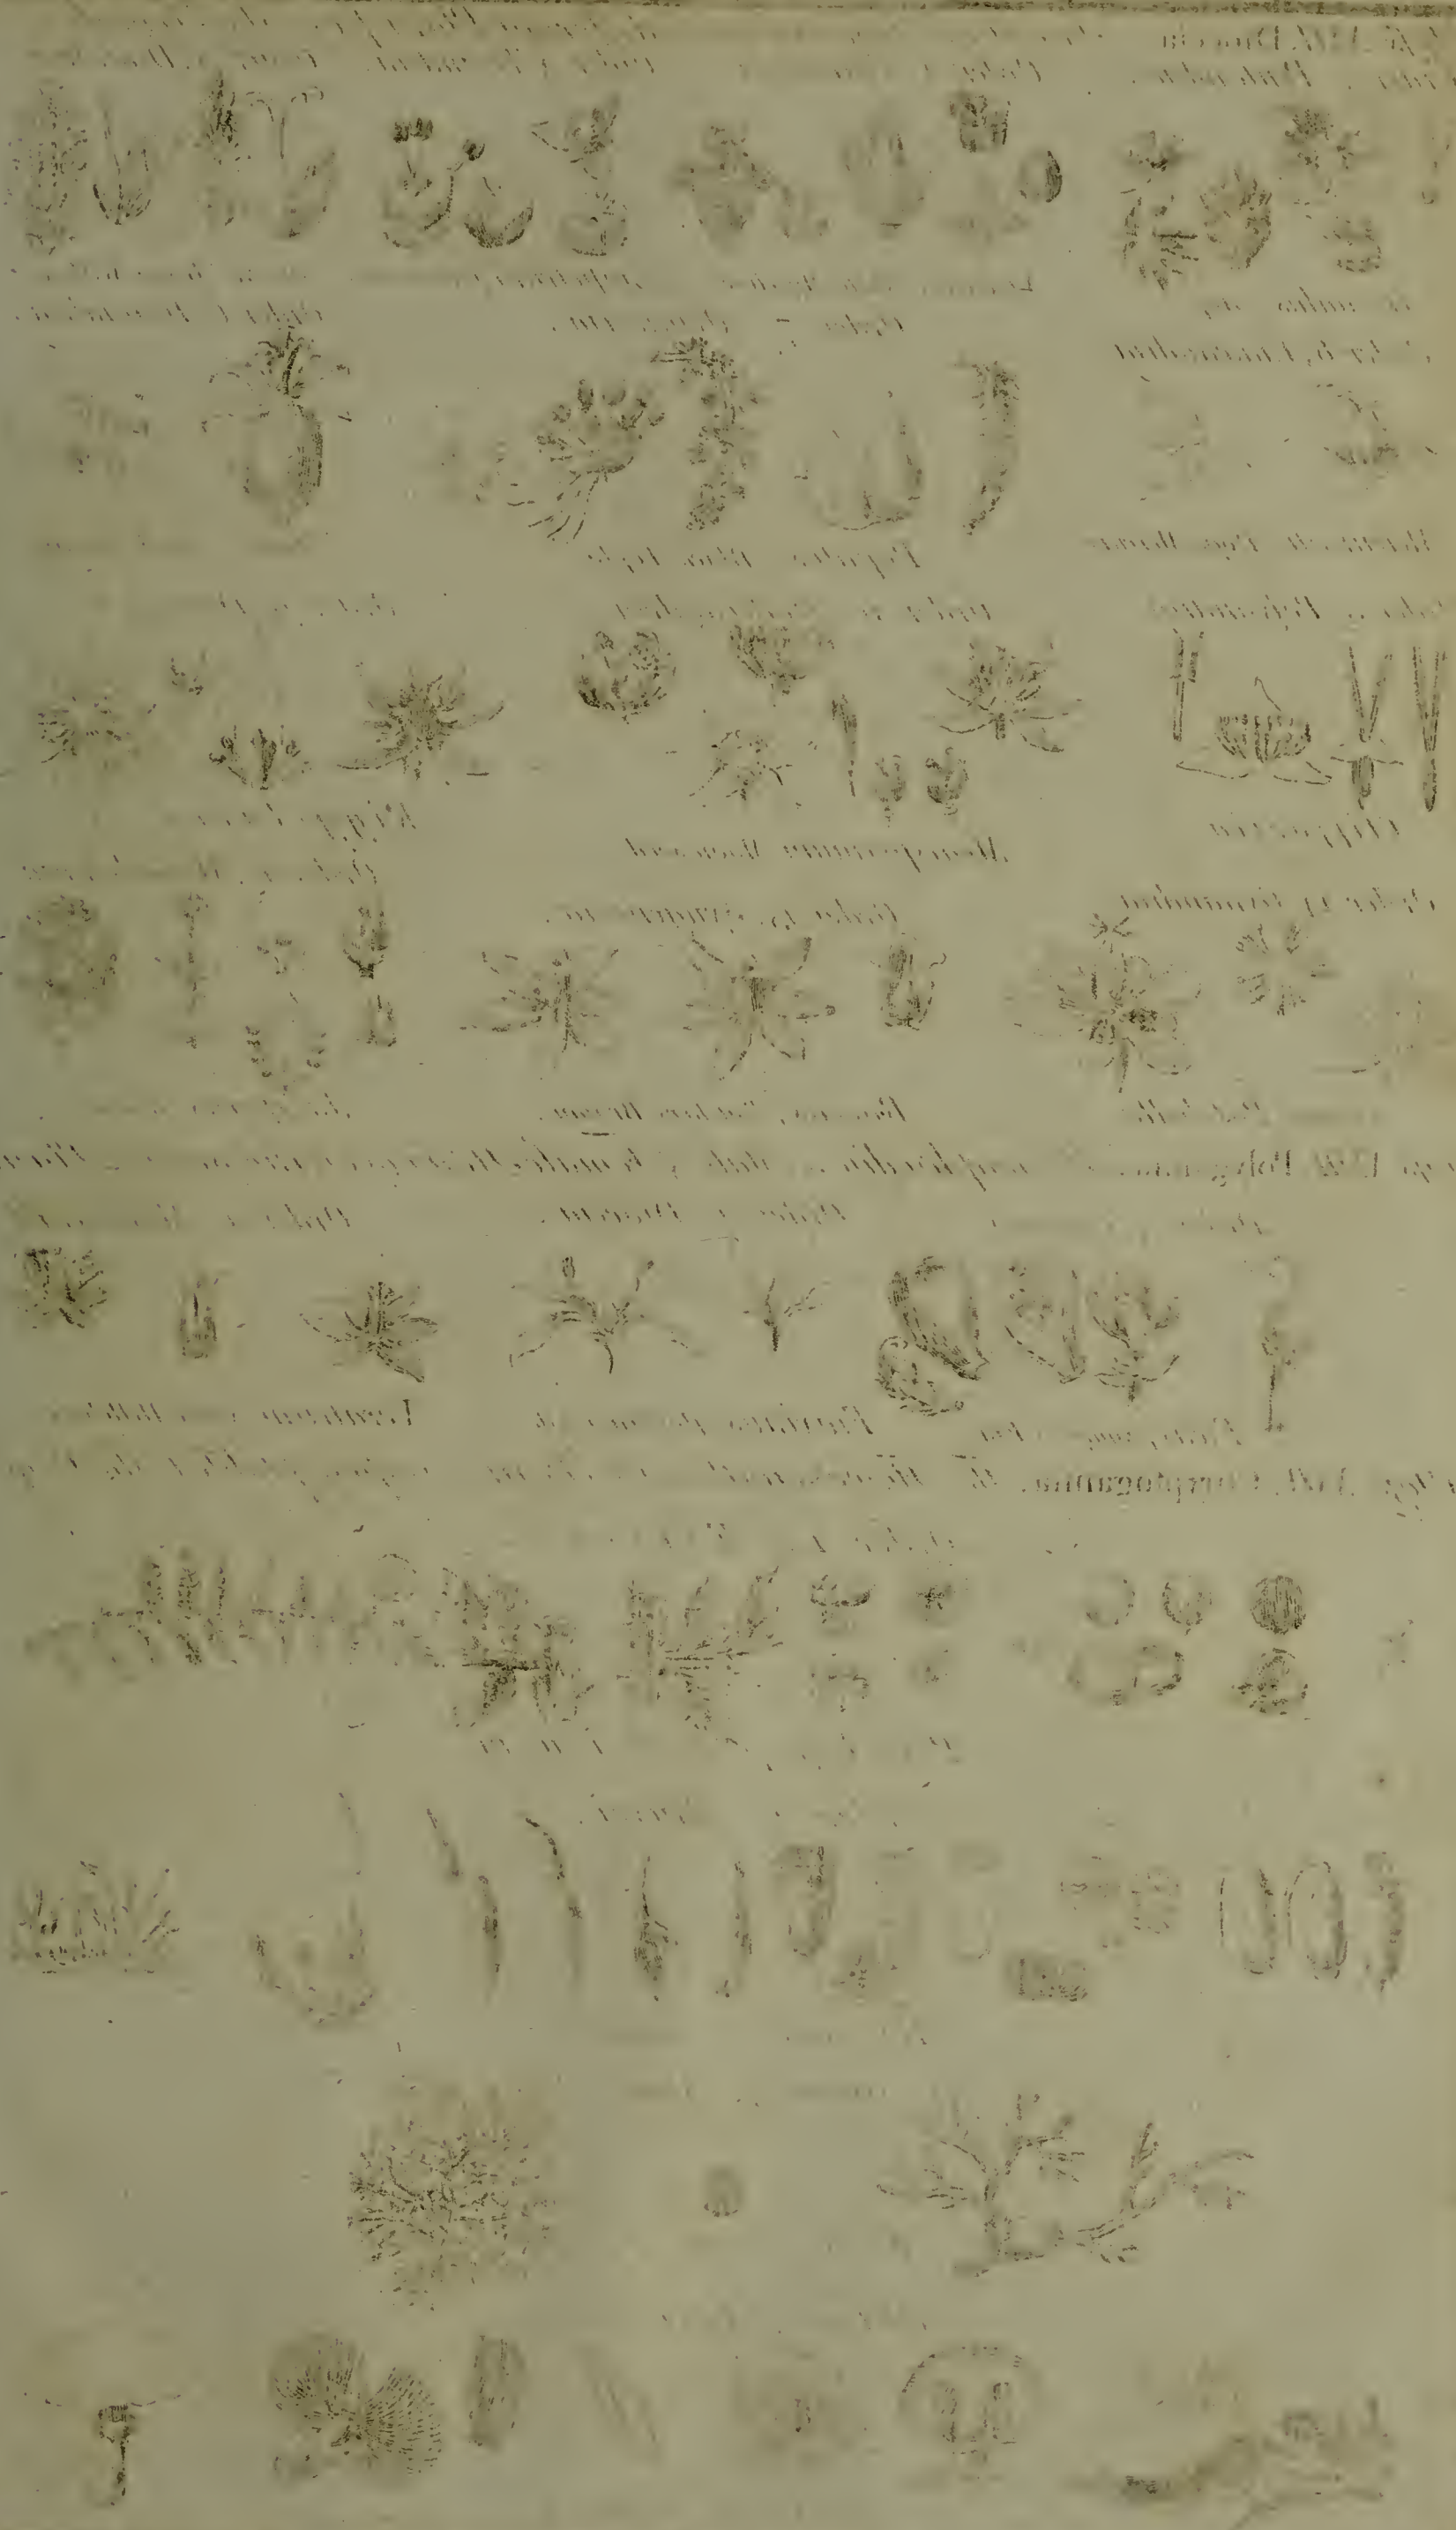

Petiveria

Order 5. Polygynia

Alisma, great water Plantain

Order 11. *Gynandria.*

Andrachne, Bastard Orpine.

THE LINNÆAN SYSTEM,

Containing the Various Orders or Classes of Flowers; such are,

I. THOSE that have one stamen on the hermaphrodite flower, as,

The Indian Flowering Reed, or Cane, of which there are three species. 1. Common broad-leaved Flowering Cane. 2. Indian Flowering Cane, with a pale red flower. 3. Indian Cane, with glaucous leaves, and a very large flower — The Virgate Strawberry Blite. 1. Blite with spikes, terminated with little heads, or the common Strawberry Blite, or Strawberry Spinach. 2. Blite with small heads growing scattered from the sides of the stalks.

II. Two stamens in the hermaphrodite flower, as,

Oswego Tea, having headed flowers; the stamina of which are almost in two bodies, and an acute angular stalk — Vernal Grass — Black Pepper.

III. Three stamens in the hermaphrodite flower, as,

The Garden Crocus. 1. That with a spathe of one valve near the root, with a very long tube to the flower, being the cultivated, or true Saffron — 2. The Crocus, with a two leaved spathe, and a short tube to the flower — The wild Oat — and the Molugo (verticillate.)

IV. Four stamens in the flower with the fruit, as,

Lacinated Teasel — Witch Hazel, a genus of plants, of which there is but one species — Pond Weed.

V. Five stamens in the hermaphrodite flower, as,

Rose Bay. 1. Oleander or Nerium, with linear, spear-shaped leaves, three at a joint. 2. Oleander, with spear-shaped, ovated leaves, and divaricated branches. 3. Oleander, with oval, accumulated foot stalks — Common Fennel, a biennial plant — Turnera. 1. With linear, spear-shaped, hairy leaves. 2. With oval, spear-shaped leaves, sawed, and rough — Grass of Parnassus. 1. Common Marsh-grass of Parnassus. 2. Grass of Parnassus, with double flowers — Navelwort. 1. Navelwort with roundish, plane, intire leaves. 2. Navelwort with semiglobular leaves. 3. Navelwort with oval crenated leaves, and a spiked stalk. 4. Navelwort with oblong pointed leaves ending with a spine; and a spiked stalk. 5. Navelwort with hooded leaves sharply indented, and growing alternate, and a branching stalk with erect flowers. 6. Navelwort with cut leaves, and four pointed flowers.

The first and second species are shrubby plants, and natives of the Cape of Good Hope. They flower in the months of July and August, but never ripen seeds in this country.

The third species is a biennial plant, and grows naturally in Crete and Siberia. The fourth is also a native of Siberia.

The fifth species grows upon old walls and other buildings in many parts of England and Portugal, and is seldom cultivated in gardens.

The sixth species is a native of Egypt. It is a shrubby plant, and requires a warm stove to preserve it through the winter in this country; nor should it be exposed abroad in summer, but kept in the stove, or placed in an airy glass case — Mouse-tail.

VI. Six stamens in the hermaphrodite flower, as,

Belladonna — Rice — Great-curved Dock — Petiveria — and Great Water Plantain.

VII. Seven stamens in the same flower, with the pistil, as,

Horse Chesnut — Lizard's Tail.

VIII. Eight stamens in the same flower with the pistil, as,

The Tree Primrose. 1. With oval spear-shaped, plain leaves. 2. With spear-shaped, waved leaves. 3. With spear-shaped leaves, and capsules which have acute angles. The first and third species are natives of Virginia, and the second of Buenos Ayres — Galenia. It grows naturally at the Cape of Good Hope, and in other parts of Africa — Buck-Wheat — Tuberos Moschatel.

IX. Nine Stamens in the hermaphrodite flower, as,

Cassita (Berry-bearing) — Palmated Rhubarb — Flowering Rush.

X. Ten stamens in the hermaphrodite flower, as,

Calmia, narrow leaved — Saxifraga — Greater Stilchwort — Wood Sorrel, of which there are thirteen species, but five of these only are cultivated in gardens; viz. 1. Wood Sorrel, with a foot-stalk supporting one flower, trifoliate leaves, and a bulbous root. 2. Wood Sorrel, with one flower on a foot-stalk, and stalks divided by pairs. 3. Wood Sorrel, with an umbelliferous stalk, and trifoliate leaves, divided into two parts. 4. Wood Sorrel, with a branching, diffused stalk, and umbellated foot-stalks. 5. Wood Sorrel, with a branching, upright stalk, and umbellated foot-stalks.

The first, second, and third species are natives of Africa. The fourth of Italy and Sicily; and the fifth of Virginia — American Nightshade: of which most botanists enumerate a vast number of species, but some writers have reduced them to the twenty-three following. 1. Night-shade, with a shrubby, unarmed stalk, oval, hairy, entire leaves, and compound umbels. 2. Night-shade, with a shrubby, unarmed stalk, oval, entire leaves, and thread-like foot-stalks to the flowers, proceeding from the sides of the branches. 3. Night-shade, with a shrubby, unarmed stalk, spear-shaped leaves, turning inward, and umbels sitting close to the stalks. 4. Night-shade, with a shrubby, unarmed stalk, leaves growing in pairs, one of which is bigger than the other, and cymose flowers. 5. Night-shade, with a shrubby, bended, and unarmed stalk, the upper leaves spear-shaped, and bunches of flowers at the top of the stalk, commonly called Bitter-sweet. 6. Night-shade, with a shrubby, bended, and unarmed stalk, oblong, sinuated leaves. at the sides of the stalk, and bunches of flowers at the top of the stalk. 7. Night-shade, with a shrubby, almost unarmed stalk, and wedge-shaped, sinuated leaves, turning backward. 8. Night-shade, with an herbaceous, unarmed stalk, and entire, winged leaves. 9. Night-shade, with an unarmed, herbaceous stalk, cut, winged leaves, and single bunches of flowers, or Pomum amoris. 10. Night-shade, with an herbaceous, unarmed stalk, cut, winged leaves, bunches of reflexed flowers divided into two parts, and hairy berries. 11. Night-shade, with an herbaceous, unarmed stalk, and heart-shaped leaves, turning inward. 12. Night-shade, with an unarmed, herbaceous stalk, oval, indented, angular leaves, and nodding umbels; or the common Night-shade of the shops, with a black fruit. 13. Night-shade, with an unarmed, herbaceous stalk, oval, hairy, intire leaves, and prickly cups; or the Melongena, Mad-apple, or Egg-plant. 14. Night-

Night-shade, with a prickly, herbaceous stalk, heart-shaped, sinuated leaves, and prickly cups. 15. Night-shade, with a prickly, herbaceous stalk, and heart-shaped leaves with five lobes, hairy, and prickly on both sides, commonly called Batchelor's Pear. 16. Night-shade, with a prickly, herbaceous stalk, winged leaves, sinuated, obtuse segments, and prickly cups. 17. Night-shade, with a prickly, shrubby stalk, angular, woolly, intire leaves, prickly on both sides, and unarmed cups. 18. Night-shade, with a prickly, shrubby stalk, spear-shaped, angular leaves, prickly on both sides, and loose bunches of flowers. 19. Night-shade, with recurved thorns on the stalks, and sinuated leaves, downy on their under-side, prickly on both sides, and the foot-stalks of the flowers prickly. 20. Night-shade, with a prickly, shrubby stalk, leaves turned inside, and prickly cups. 21. Night-shade, with a prickly, shrubby stalk, heart-shaped, hairy leaves, turned in at the brim, and unarmed cups. 22. Night-shade, with a prickly, shrubby stalk, and spear-shaped, angular, indented leaves. 23. Night-shade, with a prickly, shrubby stalk, smooth, obtuse, unarmed leaves, with three lobes.

These plants are natives of Europe, Asia, Africa, and America, but most of them grow naturally in America.

XI. Stamens with twelve, nineteen in the hermaphrodite flower, as,

Afarum, Afarabacca. 1. With kidney-shaped leaves, having two blunt points, or the common Afarabacca. 2. Afarum, with kidney-shaped leaves, ending in a point. 3. Afarum, with blunt, heart-shaped, smooth leaves, with foot stalks. 4. Afarum, with sessile imbricated leaves, and flowers cut into four parts, or the hypocist. These are perennial plants: the first grows in some parts of England, and other countries of Europe. The second is a native of Canada. The third grows naturally in Virginia, Maryland, and Carolina; and the fourth is a native of Spain and Portugal—Agrimonia—Euphorbia (Lathyrus)—Sempervivum, Houseleek: of which are seven species. 1. Houseleek with a smooth, tree-like, branching stalk, or Tree Houseleek. 2. Houseleek with stalks torn by the rudiments of the leaves, and blunt pointed leaves. 3. Houseleek with hairy edged leaves, and spreading off-sets; or the common large Houseleek. 4. Houseleek with hairy edged leaves, and globular off-sets. 5. Houseleek with threads from leaf to leaf, and globular off-sets. 6. Houseleek with entire leaves, and spreading off-sets. 7. Houseleek with leaves, whose borders are indented like a saw, and spreading off-sets.

The first species grows at the Cape of Good Hope, and in Portugal. The second is a native of the Canary Islands. The third is found growing on the tops of houses and walls in England. The fourth is a native of the northern parts of Europe. The fifth grows upon the Alps and Helvetian mountains. The sixth upon the latter: and the seventh is a native of the Cape of Good Hope.

XII. The stamens inserted in the inside of the calyx; and commonly twenty, or more, as,

Pumica, the Pomegranate. There is only one species of this genus with the following varieties. The wild, with single and double flowers. The small flowering with ditto. The Pomegranate with striped flowers; and the Sweet Pomegranate. The Tree is a native of Italy, Spain, and Africa—The Bean-tree — Quicken-tree — Codlin-apple — The Bramble.

XIII. The stamens from twenty to a hundred in the same pistil with the flower, as,

Sarracenia—The Piony—Wolfs-bane—Columbine. 1. With crooked nectaria, called Double Starry. 2. With straight nectaria, shorter than the petals, which are sharp-speared. 3. With straight nectaria, and stamina longer than the flower petals. The first species grows naturally in most countries of Europe. The second is a native of Switzerland, and the third of Virginia and Canada.—Water Aloe, of which there are fourteen species. 1. Aloe, with nodding flowers, growing upon foot-stalks, in form of a cylindrical corymbus, or the common Aloe. 2. Aloe, with nodding, branching, prismatic flowers, growing upon foot-stalks, and spreading equally at the brim, commonly called Partridge-breast Aloe. 3. Aloe, with flowers growing upon foot-stalks, and the foot-stalks oval, cylindrical, and crooked. 4. Aloe, with sessile, horizontal, funnel-shaped, equal flowers, turned back at the brim. 5. Aloe, with sessile, oval, crenated flowers, and the interior segments connivent. 6. Aloe, with sessile, triquetrous, two-lipped flowers, and the upper lip turned back, commonly called Cushion Aloe. 7. Aloe, with sessile, funnel-shaped, two lipped flowers, cut into five revolute segments, erect at the top. 8. Aloe, with sessile, two lipped flowers, the upper lip erect, and the under one spreading, commonly called Large Pearl-Aloe. 9. Aloe, with sessile, reflexed, imbricated, prismatic flowers. 10. The common Barbadoes Aloe. 11. The Socotrine Aloe. 12. The Cobweb Aloe. 13. The Guinea Aloe. 14. The Ceylon Aloe.

Of these species there are a vast variety, particularly of the first sort: they are all perennial plants, and natives of Africa, and the Indies—Crowfoot. In the garden's four kinds of the Ranunculus are particularly attended to, namely, the Double White—Proliferous Mountain—Golden Proliferous—and Oriental Meadow.

XIV. Four stamens; two of which are close together, and longer, as,
Melittis—Honey Flower.

XV. Six stamens, four long, the two opposite short, as,
Honesty—and the Stock July Flower.

XVI. The filaments of the stamens grown together into one body, as,

Hermannia—African Cranes-bill. Of this genus Linnæus distinguishes thirty-nine species; and Tournefort seventy-eight, too great a number to be inserted in this work.—Indian Vervain Mallow. 1. With angulated leaves. 2. With sinuated, hairy, many pointed leaves. 3. With spear-shaped, heart-shaped, undivided, sawed leaves, and a trailing stalk—Rose Mallow, a species of the Hollyhock. 1. With angular sinuated leaves. 2. With palmated leaves.

XVII. The filaments of the stamens grown together into two bodies, as,

Yellow Fumatory, of which there are eleven species. 1. Fumatory, with a naked stalk; or the Cucullaria. 2. Fumatory, with bilobated flowers behind, and a leafy stalk. 3. Fumatory, with a simple stalk, and bractæ as long as the flowers. 4. Fumatory, with narrow pods, growing in panicles, and an erect stalk, called Bastard Fumatory. 5. Fumatory, with narrow, four-cornered pods, and diffused stalks, with acute angles; or the Capnoides. 6. Fumatory, with three trifoliate leaves, and the small leaves heart-shaped. 7. Fumatory, with the seed-vessels growing in a racemus, containing a single seed, and a diffused stalk; or the common Fumatory. 8. Fumatory, with seed-vessels growing

growing in a spike, containing one seed, an upright stalk, and filiform, or thread-like leaves. 9. Fumatory, with seed-vessels growing in a racemus, containing a single seed, and climbing leaves, with short tendrils. 10. Fumatory, with narrow pods, and leaves with clasps. 11. Fumatory, with globular, inflated pods.

The first three species are perennial plants: the first grows naturally in North America, the second in Siberia, and the third in shady and woody places throughout Europe.

The other species of this genus are annual plants. The fourth sort grows naturally in North America, and is a proper plant to grow on the sides of grottos, or rock-work, where by its continuing green all the year, and its long continuance in flower, it has a good effect.

The fifth sort is a native of France, Italy, and Mauritania, and the sixth grows naturally in rocky places in Spain and Sicily; these plants are also proper for the joints of grottos, or any rock-work.

The seventh species is a native of Europe, and particularly of this country; the eighth sort is a native of France, Spain, and Italy.

The ninth species is a native of France and England; and the tenth is also a native of rocky places in England. The eleventh sort grows naturally at the Cape of Good Hope—Milkwort. Linnæus distinguishes no less than twenty-two species of this plant, but the three following only are to be met with in our English gardens. 1. Milkwort, with crested flowers, a moon-shaped keel, and a shrubby stalk, having oblong leaves, which end in obtuse petals. 2. With flowers growing thinly, and without beards; the point of the keel roundish, a shrubby stalk, and spear-shaped leaves. 3. With spiked flowers, without beards, an erect, single, herbaceous stalk, and broad spear-shaped leaves—Everlasting-pea.

XVIII. The filaments of the stamens grown together, into three or more bodies, as,

Theobroma—Orange. 1. The common Seville. 2. The China. 3. The Willow leaved, or Turkey. 4. The Pampelmoes, or Shaddock. 5. The Dwarf or Nutmeg.—St. John's-wort.

XIX. The stamens, and anthera's grown together in form of a cylinder. These have rarely filaments, as,

Dandelion — Xeranthemum — Sun-Flower, of which there are ten species. 1. Sun-flower, with all the leaves heart-shaped, veins uniting behind at the base, but towards the border naked; commonly called Annual Sun-flower. 2. Sun-flower, with the under leaves heart-shaped, veins uniting behind at their base, and the upper leaves oval; commonly called Perennial Sun-flower. 3. Sun-flower, with oval, heart-shaped leaves, with the nerves uniting in the leaf; commonly called Jerusalem Artichoke. 4. Sun-flower, with a stalk smooth on the under-side, heart-spear-shaped leaves, and ten petals in the rays. 5. Sun-flower, with a spindle-shaped root. 6. Sun-flower, with rough, spear-shaped leaves, and a slender stalk, smooth towards the bottom. 7. Sun-flower, with smooth, spear-shaped, sawed leaves. 8. Sun-flower, with narrow leaves. 9. Sun-flower, with oblong, opposite, oval, sessile leaves, three veins, and a dichotomous panicle. 10. Sun-flower, with oval, rough, crenated leaves, with three nerves, the scales of the cup erect, and as long as the disk of the flower.

All these species are natives of different parts of America. The second sort is most proper for large borders in great gardens: it begins flowering in July, and continues till October—The Marigold, of which there are seven species. 1. Marigold

with narrow, spear-shaped leaves, and prickly seeds, or the least Marigold. 2. Marigold, with boat-shaped, prickly seeds in the border, and those in the center bicorned. 3. Marigold, with spear-shaped, indented leaves, and slender foot-stalks. 4. Marigold, with sinuated, indented, spear-shaped leaves, and a naked stalk. 5. Marigold, with indented, spear-shaped leaves, and the upper part of the foot-stalk swelling. 6. Marigold, with narrow, entire leaves, and a naked stalk. 7. Marigold, with obverse, oval leaves, which are indented, and a perennial shrubby stalk.—Globe Thistle. 1. The Greater. 2. The Smaller. 3. With a large head. 4. With a small blue head.

The first species is a native of Italy and Spain; the second of France and Italy; the third of Spain; and the fourth of Greece—Cardinal Flower, a genus of plants, of which there are ten species. 1. Cardinal-Flower, with an erect stalk, spear-shaped, sawed leaves, and a spike of flowers, terminating the stalk, commonly called Scarlet Cardinal-Flower. 2. Cardinal-Flower, with an erect stalk, linear, spear-shaped, entire, acute-pointed leaves, and a spike of flowers terminating the stalk. 3. Cardinal-Flower, with an erect stalk, oval, spear-shaped, crenated leaves, and the sinuses of the implements reflexed, commonly called the Blue Cardinal-Flower. 4. Cardinal-Flower, with an erect stalk, heart-shaped leaves, which are somewhat indented, having foot-stalks, and the longest spike of flowers, which are placed thinly. 5. Cardinal-Flower, with an erect stalk, the lower leaves roundish and crenated; the upper spear-shaped, sawed, and a spike of flowers terminating the stalk. 6. Cardinal-Flower, with an erect stalk, oval leaves, which are somewhat sawed, longer than the foot-stalk, and swelling seed-vessels. 7. Cardinal-Flower, with oval, crenated leaves, which are downy, and flowers growing singly from the sides of the stalk. 8. Cardinal-Flower, with spear-shaped, indented leaves, very short foot-stalks to the flowers, which proceed from the sides of the stalks, and a very long tube to the petal. 9. Cardinal-Flower, with a spreading, branching stalk, spear-shaped leaves, which are somewhat indented, and very long foot-stalks to the flowers. 10. Cardinal-Flower, with trailing stalks, spear-shaped, sawed leaves, and foot-stalks proceeding from their sides.

The varieties are natives, or grow naturally in North America, at Campeachy, Virginia, Jamaica, Blois in France, and at the Cape of Good Hope. The third sort has a perennial fibrous root; the fourth is an annual; the sixth and seventh are biennial plants.

XX. The stamens inserted on the pistil; but not on the receptacle, such as,

Orchis — Sifyrinchium, Bermudiana — Passion-Flower. Of this genus of plants are no less than twenty four species mentioned by Linnæus; a particular description of all which would be needless, as they bear a great resemblance to each other; one, the most beautiful is the Laurel-leaved Passion-Flower, a native of South America.—Birthwort—and Cuckow Pint.

XXI. Male and female flowers on the same plant, such as,

Triple-headed Pond Weed—Tripsicum — Roman Nettle—Parthenium—Walnut—Scotch Fir—Malé Balsam Apple—Bastard Orpine, a native of France.

XXII. The male flowers on a different plant from the female, as,

The Hop — White Miffelto — Crow-berries — Brown Willow—Dogs Mercury—Black Poplar—Bryony

Bryony — Cliffortia — Moon-seed — Kiggelaria — Pulchella — Butcher's Broom — Juniper.

XXIII. Hermaphrodite, or male and female flowers on the same plant, such as,
The Common Fig — Flowering Ash — White Hellebore.

XXIV. Flowers within the fruit, or imperceptible to the eye, as,

Polypodium — Bryum (matted) Fucus — Agaric (field.)

Such is the Linnæan System of the different genera, and orders of flowers; to which we have added two plates, and half a one, under the title of leaves, wherein are distinguished by Linnæus, the cups and other parts of flowers, (as sexes, &c.) ranged under their different orders, as, Monogynia, Digynia, Monandria, Diandria, &c. &c. We proceed now to

TOURNEFORT'S SYSTEM of FLOWERS.

IN this the genera, or different kinds of plants are included in twenty-two classes; to which is prefixed general and classical characters of flowers. It is unnecessary to enter upon the particular plants, trees, shrubs, flowers, &c. enumerated under each class in this system, since most of them have been described either in the former one or in the Natural History of Vegetables, page 296; and to find the latter, the reader has only to consult the Index under the head of Botany. To these we have added a Plate of the Abutilon, with leaves resembling those of a red gooseberry-tree; having a flesh-coloured flower, and fruit of a pentagonal, or five cornered shape, and rough tasted; and the Hairy Abutilon of the shrub kind, with a roundish leaf; a large and spreading flower of a pale colour, and a single cup and calix. We have likewise given another plate of various objects in Natural History, as Feathers, Death Watch, Fibres, Plants, Water Spout, Seed, &c.

L E A V E S.

BOTANISTS consider the leaves with regard to their structure, surface, shape, consistence, edges, situation, and size: with regard to their structure, they are either single, as those of the apple, pear, and plumb-tree, or compound, as those of the strawberry, parsley, &c. a single leaf is one which is either immediately joined to the branch or connected with it by a foot-stalk; a leaf is said to be compound, when there are more than one upon a petiole or foot-stalk: with respect to their surface, they are either flat, as the origany, or in bunches, as the houseleek: with regard to their shape, they are either lanceolated, cordated, acuminate, hastated, &c. and are either thin and fine, as those of the hypericum; or thick and gross, as those of purslane; or fleshy, as those of several kinds of aloes; or woolly, as those of marsh-mallows: with regard to their edges, leaves are cut slightly, as in some species of geums, or deep, as in some of the centaury: with respect to their situation, they are either ranged alternately, as the alaternus; or opposite to each other, as the phillyrea, mint, baum, &c. with regard to their size, they are either very large, as those of the musa; or moderate, as those of the fig and vine; or small, as those of the elm or apple tree; or very small, as those of the heath, phylica, &c. See the Plate of Leaves.

Many sorts of plants, whose roots issue forth from the small end of the seed, put out two small leaves that are very unlike those which the plant

afterwards produceth; for as soon as the root has taken hold of the ground, between these false leaves (commonly called the seed-leaves) there comes forth a shoot which produces leaves like those of the mother plant; of this manner of growth there is an infinite number of plants.

Dr. Grew observes, that the fibres of leaves consist of two general kinds of vessels, viz. for sap and for air: and are ramified out of greater into less, as veins and arteries are in animals.

Mr. Frederick of Augsbourg, a celebrated gardener, took from the tree a leaf of the opuntia or Indian fig-tree; and setting it in the earth, it immediately took root, and produced blossoms and fruit.

The distinction of leaves, made by those who have written on botany, are the following:

A simple leaf is that which is not divided to the middle.

A compound leaf is divided into several parts, each resembling a simple leaf, as in liquorice, &c.

A digitated leaf is a compound leaf, divided into several parts, all of which meet together at the tail, as in the hemp, black hellebore, &c.

A trifoliated leaf is a digitated leaf, consisting of three fingers, as the trefoil; &c.

A quinquefoliated leaf is a digitated leaf, consisting of five fingers, as in the quinquefolium.

A pennated leaf is a compound leaf divided into several parts, each of which is called a lobe, placed along the middle rib, either alternately, or by pairs. When the middle rib is terminated by an odd lobe, it is said to be unequally pennated, as in the goats rue, &c. and equally pennated, when it is not terminated by an odd lobe, as in the cassia; when the lobes are all nearly of the same form and bigness, it is called an uniform pennated leaf, as in the liquorice; when they are not so, it is said to be difform, as in the agrimonia.

A winged leaf is, as it were, divided into several pennated leaves, as in the orobus, &c.

A ramose leaf is that which is still farther divided than the winged leaf, as in the osmund royal, female fern, &c.

An entire leaf or lobe is that which has no division on its edges, as in the apple-tree, &c.

A sinuated leaf is that which is cut about the edges into several long segments, as in common mallows.

A serrated leaf is that which is cut about the edges into several acute segments, resembling the teeth of a saw, as in the nettle, &c.

A crenated leaf is that which is cut about the edges into several obtuse segments, as in the betony, &c.

A lacinated or jagged leaf is that which is cut about the edges into several pretty deep portions, in an irregular manner, as in the horned poppy, &c.

If the surface of the leaves are altered, by reversing the branches of the trees on which they grow, the plants are stopped in their growth, until the foot-stalks are turned, and the leaves recover their former position. This shews how necessary it is to support all those weak shoots of plants, which are naturally disposed for upright growth, which either twine about the neighbouring trees for support, or that put out clasps, by which they take hold of whatever trees or plants grow near them, and are thereby supported; and, on the contrary, how absurd is that practice of tying up the shoots of those plants which are naturally disposed to trail upon the ground, for in both these cases nature is reversed, and consequently the growth of both sorts of plants is greatly retarded.

This is one of the great functions for which the leaves of trees and plants are designed; but, besides this,

BOTANY.

this, there are others of equal importance to the well-being of plants and fruits; the first is, that of the foot-stalks and leaves nourishing, and preparing the buds of the future shoots, which are always formed at the base of those foot-stalks, and during the continuance of the leaves in perfect health, these buds increase in their magnitude; and, in the deciduous trees, are brought to maturity before the foot-stalks separate from the buds in autumn; but if by accident the leaves are blighted, or if the entire surface of the leaves are cut off, and the foot-stalks are left remaining, the buds will decay for want of that proper nourishment which is conveyed to them from the leaves: so that whenever trees are divested of their leaves, or those leaves are cut, or otherwise impaired, though it may in either case happen when the buds may be nearly formed, yet if it is before the foot-stalks separate naturally from their branches, the future shoots will be weakened in proportion to the time when this is done; therefore from all the experiments which have been made in order to know how serviceable the leaves of trees and plants are to their well-being, it has been found, that when the plants have been divested of their leaves, or their leaves have been eaten or cut, during their growth, the plants have been remarkably weakened thereby. This should teach us not to pull or cut off the leaves of trees, or plants, on any account while they retain their verdure, and are in health; and this shews how absurd that common practice is, of feeding down wheat in the winter and spring with sheep; for by so doing, the stalks are rendered very weak, and the ears are in proportion shorter; nor are the grains of corn so plump and well nourished, as that which is not fed down upon the same ground: this is a fact which we can assert from many years experience. It is very evident, that grass which is often mowed, the blades will be rendered finer in proportion to the frequency of mowing it, yet the species of grass is the same with that on the richest pastures; so that although this may be a desirable thing for lawns, &c. in gardens, yet where regard is had to the produce, this should be avoided.

Another principal use of the leaves, is to throw off by transpiration what is unnecessary to the growth of the plants, answering to the discharge made by sweat in animal bodies; for as plants receive and transpire much more, in equal time, than large animals, so it appears how necessary the leaves are to preserve the plants, in perfect health; for it has been found by the most exact calculation, made from repeated experiments, that a plant of the sun-flower receives and perspires, in twenty-four hours, seventeen times more than a man.

M O S S E S.

THEIR genera, or different kinds, are so distinctly described in the three plates given of them; and these are so accurately and beautifully executed, as would render a scientific account of them here tedious and unnecessary. A mere inspection by any one acquainted with the subject of Botany, will be sufficiently informing, and entirely satisfactory.

Of F O S S I L S.

IN our Natural History of Waters, Earths, Minerals, &c. page 387, we have treated this subject in a copious and comprehensive manner; and our survey of nature, and her treasures has been such, that all, even the illiterate, may learn those truths, the know-

ledge whereof is a concern of the utmost importance: and the learned in scientific truths, may have their taste fully gratified, by consulting the plates we have given under the title of Fossils, Fossil-Shells, and Coralines. Here they will find them distinguished by their proper technical terms, and ranged, particularly Fossils, in systematic order, under ten classes. The first includes Native Fossils. 2. Selenitæ. 3. Chrystals. 4. Siderochitæ. 5. Pyritæ. 6. Extraneous Fossils. 7. Corals. 8. Fishes Teeth. 9. Fossil Shells. 10. Fossil bodies, once parts of animals.

M I C R O S C O P I C A L O B J E C T S.

OF these we have given three exceeding curious plates. The first contains Chrystallizations. —Marine Salts.—Essential Salts of Plants.—Silver dissolved in Aquafortis. In the second and third plates are distinguished, under two classes, Animal and Vegetable subjects. Among other curious objects in the first class, are, the circulation of the blood—a Flea—a Louse—Polipe—Darts of the Gnat, and a number of animalcules. The second class exhibits the Farinæ of plants, also seeds and sections of the same. Their names are well known, and most of them having been described in the body of this work, a further explanation would be superfluous.

S H E L L - F I S H and S H E L L S.

IN treating this subject, having been too concise and short, we must beg leave to introduce here the following addenda:

We observed, page 248, that Shell-Fish are usually divided by naturalists into crustaceous and testaceous animals. Crustaceous fish, such as the Crab and the Lobster, are furnished with a shell that is not of a stoney hardness; whereas testaceous fishes, like the Oyster and the Cockle, are furnished with a shell of a stoney nature, which is brittle and incapable of yielding.

Sea-Locust or Prawn, named in the plate of crustaceous animals, *Locusta Marina Indica*, has two large feelers placed before the eyes.

Elephant-Lobster. This is shaped pretty much like a common lobster, only the fore claws are longer, and the nippers, which are thinner and broader, open wider than in any of this kind.

Cray-Fish (the River) differs only from some Lobsters, in being less.

Shrimp. The common is the smallest of this kind. In the East-Indies is one that grows to be near a span in length, and has a shell like ours.

Crabs. Their varieties are numerous, as will appear from the plate, and the Natural History of them, page 249.

Of T U R B I N A T E D S H E L L - F I S H.

They are somewhat in the shape of a top, and are surrounded with spiral furrows, much like a screw, being wide at the mouth, and terminate by degrees in a point. Within they are all nearly alike with regard to their surface, which is exceeding smooth; of these kinds are—

The Nautilus, or Sailor; one of which is a small sort, and comes out of its shell; but the other keeps to its shell like a snail, or at least seldom comes out of it.

Pearl Shelled Nautilus; so called from having a shell exceeding bright on the inside.

Little Thick Nautilus, is of a roundish form, and rarely exceeds an inch and a half in diameter.

Thin

Thin Eared Nautilus has a very beautiful shell, which grows to ten inches in length, and is exceeding thin.

Paper Nautilus, so called from the thinness of its shell, is often met with twelve inches long, and is compressed on the sides.

Thin Nautilus without Ears, is smaller than the former kind, for it is but five inches long, and three or four deep.

Purpura is of the size of an egg, and sometimes bigger. There are several sorts of them, as—the yellow Long-snouted, with long crooked spines—The variegated Long-snouted, nearly of an oval shape—The Short-snouted, about two inches long, and its diameter, with the spines and thorns, is an inch and a half—and that with three rows of spines is about three inches long, including the spines, and as much in diameter.

Trumpet Shell, called Buccinum, from its imaginary likeness to a trumpet or horn.—One of the island of Goree, which is seldom above half an inch long, and its breadth is less by one half.—Another of Senegal: It is composed of ten turns or spires; which are all smooth, polished, and flattened, except the first; but they are not very distinct from each other.

The Hedge-Hog Murex is three inches and a half long, and about two and a half broad, where thickest.—One with a smooth clavicle, is two inches and a half long, and near two in diameter where broadest.

Ribbed Music Shell. Its body is short, and there are several low ribs at some distance from each other. It is a native of the East Indies.

Gold-mouthed Cochlia or Snail. This is round, and edged on the circumference with a narrow lip. It is common in America.

The Snail has numerous varieties, as the Hedge-Hog—The Smooth Ribband—The Watery—The Smooth Brown—The Three Ribbed—The Toothed—The Banded—The Prickly—The Clouded—The Conical Tuberculated—The French-Horn.

Others of different kinds of Shell-Fish are noticed by authors; the distinct names of them will be found in the plates; to enlarge upon which, by a particular description, would extend this work to a tiresome length, and very far beyond our prescribed limits.

OF TURBINATED SHELLS.

These are of a simple kind, consisting of one piece, and of a long slender make, always terminating in a very long fine point. The mouth is narrowest towards the base, and has a sort of an ear. They are of different shapes, and in general they are called Screw-Shells.

The Thick Turbo, or Screw-Shell, has an oval mouth, and consists of about fourteen turns, of which that next the mouth is the largest, from which they gradually diminish to the end which is pointed.

The Needle, or Slender Screw-Shell. This has roundish spires, and it becomes gradually smaller from the mouth to the other end, where it terminates in a point. It consists of sixteen spiral turns, which are all bellied, rising very high in the middle. It has only a notch, where the ear is placed, and the whole surface is perfectly smooth. The colour is white, variegated with yellow.

The Turbo, or Screw-Shell, with bellied spires and elevated ribs, is an inch and a half in length, and the largest turn a little more than the third of an inch in diameter. The colour is white, and the mouth round and pretty large, with a thick lip. It is common on the shores of Barbadoes.

The Conical Turbo, or Screw-Shell, with plain

streaked and numerous spires, is by some called the Telescope Shell.

The Slender Turbo, or Screw-Shell, with spiral lines on the turns, is four or five inches long, and scarce half an inch thick where thickest. The colour of the shell is yellow, unless it has lain long on the shore. It is found on the shores of the American islands, as well as in the East Indies.

The Turbo, or Screw-Shell, with distant and prominent spires, is about five inches long, and the diameter of the spire next the head, is about three quarters of an inch. The colour is whitish, with a tincture of yellow and red, and it is brought from the East and West Indies.

The Warty Turbo, or Screw-Shell, with a broad depressed mouth, called by some the Caterpillar-Shell, is about two inches and a half long, and near three quarters of an inch in diameter next the mouth. The shell in general is pale, variegated with a darker colour; but the protuberances are blueish. It is brought from China.

The Turbo, or Screw-Shell, with a long wide mouth, is three inches long, and of the thickness of a man's little finger. The colour is brownish, variegated with a deeper brown, and a reddish tawny. The surface is smooth, only there are a few tubercles on the second turn. It is brought from the East Indies.

The Oblong Mouthed Turbo, or Screw-Shell, with spires jagged at the edges, is about two inches long, and the third of an inch thick at the base. The colour is of a faint brown, a little variegated with tawny and reddish, and regular rows of little black dots. It is found in America, and some parts of Europe.

The Thick-Eared Turbo, or Screw-Shell, with turns deeply jagged at the edges, is three inches long, and in diameter, where thickest, an inch.

The Screw Shell of Senegal is like a cone rounded at the base, and grows gradually smaller to the top, where it terminates in a very fine point.

OF WREATHED SHELLS.

The Voluta are of one piece, and of a figure nearly conical, but short, the clavicle being commonly depressed; and the mouth long, perpendicular, and narrow.

The Jamar, is a Voluta of Senegal, very thick, and nearly of a conical shape. A membranous skin of a reddish colour surrounds the whole surface of the shell, and when this is taken off, it appears of a fine polish, and beautifully variegated with different colours. The ground is white, red, yellow, or brown, marbled with spots without any regularity, and sometimes encircled with pointed streaks. This shell is highly valued by the curious, who have given it different names, according to the varieties.

The Admiral Shell, or Voluta, with a broad yellow band, and a pointed line thereon, is an uncommon and very beautiful shell, bearing a great price. It is about two inches long, and near an inch in diameter towards the head, from whence, to the extremity of the mouth, it gradually decreases in size, so as to form a sort of a cone, with an obtuse point. The clavicle also diminishes in diameter, and terminates in a blunt point. The ground colour of the shell is of a beautiful yellow, but so variegated, that it does not take up above one third of the surface. There is a circle or ring of this colour at the head, of about the breadth of a straw, and below it there are three broad belts or rings finely variegated. The lowest of the three are broader than the others, and separated by five yellow lines. Under the belts the fine yellow again

The Yellow Zon'd Porcellane

The Exotic Heart Cockle

The Auriculated Paper Nautilus

makes its appearance in the form of a broad belt; and in the center there is a narrow pointed line of the same colours with the other variegations, which is the characteristick of this shell. From the verge of this, to the extremity of the shell, the yellow gold colour prevails again. It is brought from the East Indies.

The Vice-Admiral Shell is nearly as beautiful as the former, and is somewhat more than two inches in length, and about an inch in diameter at the head. The clavicle is a little longer than that of the Admiral, and has about ten turns; the ground is of a bright gold colour, with the same variegations as the former, only they have a greater mixture of white. There is a line of gold colour at the head, of the breadth of a straw, below which there is a circular line of the variegations, much of the same breadth. Under this there is a narrower line of yellow, and under that a very broad belt of the variegations. Below this there is another of yellow, as in the Admiral, but without the pointed line. Next to this there is another broad belt of the variegations, and then comes the point of the shell, which is yellow. The False Admiral is by some taken for the true one, but it is not near so valuable.

The Tiger Shell is scarce, and brought only from the East Indies. Its ground is of a dusky red, sprinkled all over with irregular spots a little whitish; some of these are oblong, others angular, and indented.

The Yellow Tiger Shell is beautifully variegated with white irregular spots of the size of a pea.

The White Voluta is of a faintish white variegated with dusky red spots, that are very large, and of irregular figures disposed without any order.

The Crown Imperial Shell is three inches long, and near an inch and a half in diameter at the top. The clavicle is so depressed, that in a front view of the shell it is not to be seen. The head is surrounded with a very beautiful row of tubercles pointed at the ends, and the ground colour is pale, with two broad beautiful belts running round it, the one near the head, and the other towards the other extremity. They are of a fine yellow, prettily variegated with black and white. It is brought from the East Indies, though few of them are quite perfect.

The Hebrew Letter Shell is smaller than the rest of this kind; for it is rarely above an inch and a quarter in length, and three quarters of an inch in diameter at the top. The body is in the shape of a cone, and the clavicle pretty long, with about five turns, but it is blunt at the extremity. The ground colour is of a pearly white, variegated with large irregular black marks, disposed in about four rows on the body, and there is a single row to each turn of the clavicle. Some have fancied they resemble Hebrew letters. It is brought both from the East and West Indies.

The Whitish Voluta, variegated with brown and purplish blue spots, is more than four inches long, and two in diameter at the head, from whence the body tapers very gradually, and is large and blunt at the end. The clavicle consists of seven or eight turns, and is blunt at the extremity; the ground of the shell is white, variegated with spots of different sizes running in circles round it; these circles are from twenty to thirty in number on the shell, some of which are brown, and others of a purplish blue. It is brought from the coast of Guinea.

The Half Crowned Voluta, with an undulated surface, is more like the Crown Imperial than any other shell of this kind. It is about two inches and a half in length, and near an inch and three quarters at the head. The edge of this is deeply

indented, so as to form a kind of crown. The colour is white, and the variegations of a faint brown. It is brought from the coast of Africa. To which may be added, the Slender Voluta.

The Butterfly Shell has three very beautiful belts round the body, and one narrower near the head, consisting of large spots of a deeper and paler brown, with some white: they resemble the spots, in the form of eyes, on the wings of some butterflies.

Of LIMPET S.

Limpets are simple shells of a conical, or gibbous shape, with a very wide opening at the bottom; of these are the—Streaked—Starry—Oval Smooth—The Great Oblong—and many other sorts, for which we refer our readers to the plates of Shell-Fish and Shells.

SEA-EAR-SHELLS.

The Haliotis or Ear-Shell is a simple one, of a depressed shape, with a large mouth, having somewhat of a spiral form at top: among this kind are reckoned the—Great Ear—The Long Ear—and the Streaked, or Wrinkled Ear-Shell.

DENTALIA, or TOOTH SHELLS.

Of these are distinguished the Streaked—The Ringed—The Dog-Tooth—Conical—Crooked Streaked, and Ringed; and the Great Sea-Pipe.

Of CYLINDRIC SHELLS.

The Brocade Shell is large and beautiful; the colour being as white as silver, variegated with a bright brown, in fine irregular lines, clouds, and spaces.

The Tulip Cylinder. The colour of this shell is white, variegated with clouds and spots of blue and brown. It is very scarce, and is brought from the East-Indies; but seldom in perfection.

The Porphyry Shell is about two inches and a half long, and an inch and quarter in diameter. The shape is nearly like that of a cylinder, with a short blunt clavicle. The colour is of a pale white, with a reddish cast, clouded with a deeper red approaching to purple, which takes up much the greater surface. This colour appears in most places in irregular longitudinal and dentated lines. It is brought from South America.

The Slender Whitish Cylinder Shell, variegated with brown, is three inches and a half long, and near an inch and quarter in diameter. It is shaped nearly like a cylinder, only it is somewhat smaller towards the point than elsewhere. The clavicle has four or five turns, and the body of the shell is cloven at the other extremity, by the continuation of the mouth. The colour is white, with a broad belt near each end, variegated in such a manner that some have imagined there are letters thereon: It is brought from the East Indies and South America.

The Slender ditto, variegated with brown and white, is three inches long, and about an inch and quarter in diameter. Its shape is nearly like that of a cylinder, only it is a very little smaller at both ends than in the middle. The clavicle is blunt, though it has four or five turns, and the whole shell is variegated with a bright white, and a pale tawny brown. They are disposed in denticulated lines, and the surface appears to be finely polished, it being very bright. It is brought from South America.

OF DOLIA, or PIPE SHELLS.

Pipe Shells are so called, from being imagined by some to be like the pipes or casks made to hold wine. However their shapes differ so much that it may be doubted whether this appellation is proper. In this class among others are placed the—Oval Pipe Shell—The Partridge Shell—The Harp Shell—And the Æthiopian Crown. The shape of the last is oblong, and somewhat oval, being smaller at each end than in the middle. The mouth is long and wide, and cleaves the extremity of the shell a little way. The clavicle is short and blunt at the end, and has four turns; that next the body, as well as the upper edge of the body, are deeply dentated, or as some say crowned, and the teeth are formed into regular even conical points. The surface is pretty smooth, only there are impressions of longitudinal lines; and the colour is of a pale brownish yellow. It is brought from Africa and the East Indies. There are some other sorts of this shell, which, for the sake of brevity, we shall omit.

OF PORCELAIN SHELLS.

The porcelain is a simple shell, consisting of one piece gibbous on the back; the mouth is long, narrow, and dentated on each side.

The White Porcelain Shell, yellow within and beaked at each end, is of an oblong shape and very gibbous. The length, including the beaks, is about three inches, and its diameter in the middle nearly two. It is white on the outside, and yellow within; and the mouth is large, having a sort of a snout or beak at each end. It is brought from Africa and the East Indies.

The Argus Shell is about three inches long, two in diameter, and somewhat less in height, though it is gibbous like the former. The mouth is wide, and the lips are continued at each extremity in the form of a broad short beak each way. The general colour is yellowish, only there are three brown bands of a considerable breadth running over it; the whole surface is adorned with a multitude of round spots like eyes, from whence it has its name. It is brought from Africa and the East Indies.

The Map Shell is about two inches and a half long, and nearly as much in diameter, with a gibbous back. At the head there is a short clavicle, placed a little above the extremity of the mouth, consisting of about four imperfect turns. To these may be added, the—Bluish Banded Porcelain—The Oval Porcelain—The White Porcelain—The Small Pox, and the Beetle.

OF BIVALVED SHELLS.

Of these there are six kinds, namely, Oysters, Bastard Cockles, Muscles, Heart Shells, among which Common Cockles are included, Scollops, and Razor Shells.

The Hammer Oyster has one of the most extraordinary shells in the world, it being in shape like a hammer, or rather like a pick-ax, with a very short handle and a long head. The body of the shell, which is taken for the handle, is about four inches long, and three quarters of an inch broad; but the head is five or six inches long, and except where it joins to the body, is little more than half an inch broad. It is of an irregular form, uneven at the edges, and terminates in a narrow blunt point at each end. The hinge or joint is at the lower end of the body; and the shells open all the way from each end to this part, and yet they shut very close. The edges of the body and head have often

great irregularities and protuberances on the surfaces, being deeply furrowed in all directions.

Under this class are included the Pearl Oyster—The Great Prickly—The Conical—The Hedge-Hog, and others; for an account of which see page 250 of the Natural History. Of Cockles are reckoned the Bastard—The Truncated Bastard—The Arabian Shell—The Venus, or Concha Veneris, and the—Oriental Concha Veneris.

OF MUSCLES.

These are composed of two valves or shells, of a longish shape, that shut all the way, and are both convex. Our sea and river Muscles are too well known to need any description.

The Carolina Muscle is four inches long, and an inch and a half broad.

The Ader is a very curious shell, of a fine sky-blue colour, with yellow rays one over another towards the bottom.

The Anpan has a bivalved shell, and is one of the largest that is met with at Senegal.

The Pinna Marina is of an olive brown colour on the outside; but within it is partly of a pearl colour, and partly reddish.

The Prickly Pinna is furnished with a sort of scales, many of which terminate in prickly points.

To which we may add Heart-shells and Cockles, as the—Thin White Heart—The deeply furrowed and Spinous Heart.

Scollop Shells, as the ribbed and variegated—The Red Ribbed and Furrowed—The Ducal Mantle—and the Irish Scollop.

Finger Shell Fish, as the Thick Red Finger—The crooked Finger—The slender, straight Brown and White—and the Violet Purple Finger Shell.

Acorn Shell Fish, as the Great Furrowed—The Bell fashioned—and the Greyish-white, Furrowed, Slender Acorn Shell.

Thumb-footed Shell Fish, as the Blueish Grey—The Reddish—and the White.

File Shell Fish, or the Pholades, as the longish White, Chequered and rough—The White and West Indian Pholas.

OF FRESH WATER SHELL FISH.

The Oval Limpet, with a crooked snout, is very thin, oval and depressed, except in the middle, where it rises into a beak. It is no bigger than a man's finger nail, and is found sticking to stones in the brooks of Northamptonshire.

The roundish Target Limpet is smaller than the former; and, instead of a beak, has a sort of button at the top. It is very thin and delicate, and has a pretty smooth surface, of an olive brown colour. It is found in some of the rivers of Leicestershire.

The Oval Limpet, with a hole at the top, is a quarter of an inch in diameter, and an eighth in height. The shell is very thin, rounded at both ends, and of a dusky brown colour. The hole is small and oblong, and seems to be formed of two round holes broken into each other. This is common near London.

The Spiral Snail Shell, with a clavicle a little elevated, and a round mouth, is three quarters of an inch in diameter, and the shell is firm, solid, and smooth at the surface. It consists of about four turns, and the clavicle at the center is raised above the rest of the surface. The colour is a greyish white, and the large turn has a streak of black running along it, but loses itself before it reaches the next turn. It is found in the lakes in the north of England.

St. Cuthbert's Horn Shell is of the spiral flatted kind, and about half an inch in diameter: It is firm and solid, and of a fine glossy brown, with a tincture of olive colour. It consists of two or three turns, and the clavicle is depressed in the center; the mouth is partly filled up with the next turn of the shell, and the lip is narrow, but thicker, and of a paler colour than the rest of the shell. It is common every where in England.

The taller Snail Shell, with a long clavicle, is one of the most beautiful of this kind, being about an inch high, and three quarters of an inch in diameter. The mouth is half round, and partly filled up by the succeeding turn of the shell: It is surrounded with a thin rim, of a palish yellow colour, and the clavicle has four turns, terminating in a point. The colour is of a dusky yellow, variegated with olive brown. It is sometimes met with in deep rapid rivers.

The variegated oval Snail Shell, with a blunt clavicle, is about three quarters of an inch high, and near half an inch in diameter. The body is large, but pointed at the extremity of the mouth. The clavicle has three turns, and the top is blunt. The colour is of a greyish white, variegated with belts of a deep brown. It is found in large rivers.

The large-mouthed brown Snail Shell, with a sharp clavicle, is about half an inch high, and the same in diameter. The body is oval, and the clavicle long and pointed at the top. The shell is of a dusky brown, and the mouth is remarkably large, and edged with a thin rim or lip. It is common in brooks.

The chequered fresh-water Nerite, or Snail Shell, is about half an inch in length, and nearly as much in diameter, being almost of an oval shape. The clavicle has but two turns, and the mouth is narrow, with a lip on each side. The surface has furrows lengthways, and others transverse. The colour is almost white, variegated with blackish clouds or spots. It is met with in the trout streams about Uxbridge and other places.

The red fresh-water Nerite, or Snail Shell, is about half an inch long, and above a third in diameter. The colour is of a pale red, but a little dusky, and the shell is more firm and thick than most others of this kind. The surface is pretty smooth, the mouth narrow, and the lips of a pale red. The clavicle is short, and has two turns near one edge, at the smaller end of the shell. It is found in plenty in the rivers of Northamptonshire.

The great conical Snail Shell, with a depressed mouth, is about a third of an inch high, and its diameter is near as much at the base, where it terminates in a blunt little button. The colour is of a pale grey, and the substance is very thin and tender. The mouth is partly filled up with the succeeding turn of the shell.

The long-mouthed Screw Shell. It consists of about thirteen turns, and has a long narrow mouth, edged with a furrowed lip.

The brown Pipe Shell, with a large mouth. Its surface is smooth, and very thin, and the colour is of a dusky brown, in others it is white, and in some yellow.

The large mouthed Ammons Horn Shell. The surface is undulated transversely, and the colour is of a pale grey.

Bastard Cockle. The white smooth depressed, and the gibbous whitish variegated.

The reddish round streaked Cockle is about an inch and a half in diameter, and as much from the joint to the opposite edge. They are lightly streaked with a pale brownish red colour on the outside, and are of a fine pearl colour within.

The blueish oval Bastard Cockle is about half an

inch long from the joint to the opposite edge, which is broad and rounded; but at the top it runs up smaller, terminating bluntly. It is finely streaked longways, and the colour is of a pale blueish grey.

The extremely thin greenish Muscle is near an inch from the joint to the opposite edge, the surface is lightly streaked, and the colour is of a pale fine green.

The whitish variegated streaked Muscle is an inch long, and half an inch broad. The colour is whitish variegated with brown, and the shells are both pretty hollow.

The narrow brown angular Muscle is near an inch long, but not half an inch broad, and the shells are both very deep. The substance is pretty thick and strong, and the colour is a pale brown, with a tincture of olive.

The blueish rounded Heart Shell, when viewed sideways, looks like a heart painted on cards, and is about an inch long, and as much broad; as also but very little less in thickness. The surface is elegantly, but not deeply furrowed, and the colour is a dusky blue.

The reddish streaked Heart Shell is about half an inch long, and nearly as much broad; both the shells are very deep, and of a pretty firm, solid substance, lightly streaked; but the intermediate surface is smooth and polished, and the colour is white with a tincture of red.

To the account already given in this Work of REPTILES, SERPENTS, and INSECTS, we must beg leave to make the following additions.

SACERTA, or LIZARD:

BESIDES the Watry, the Brown, the Green or Viridis, and the Tarantula, our most eminent Naturalists mention the—Cameleon—The Leo, or Lion Lizard—Squamosa, or Scaly—The Seps—and the Brazilian Lizard.

COLUBER or SNAKE.

The Conchris—of Esculapii—Cæcilia—Natrix, or ringed Snake—The Siren—Slow-worm, or Blind-worm—Hæmorrhous, or Blood Snake.

ARANEA, or SPIDER.

There are several kinds of this insect, differing slightly from each other in habits or conformation, but varying considerably in size, as may be seen in the plate, under the head of Insects without Wings.

SCORPIONS.

The Barbary Italian—and Black African, are remarkable for their malignity; but in Europe they are neither so large, nor so venomous.

C R A B S.

In the plate, under the title of Insects without Wings, are various and exact representations of the Great—Wart—Little Squall—Little Woolly—Frog—Long Clawed—Long-armed Dutch—and the Hermit Crab.

I N S E C T S.

1. Cicada, or Cricket Dragon Fly, &c.
2. Papilio, or Butterfly kind.
3. Aurelia, and Leaf Insects.
4. Tæniæ, Cafes, Worms and Flies.
5. Ephemeræ, Butterflies, Moths, and Bees. See the plates of winged insects.
6. Flies,

6. Flies, Beetles, Locusts, and Gnats.
7. Gall Insects and Water Worms.
8. Naked Insects, as the Amber—Snail—Medusa—Cuttle Fish, &c.
9. Tæniæ of the Oak—Of the Horn-bean—Of the Lilly—Of the Rose—Of the Elder—Of the Lime-tree—Of the Fig-tree, and Box, &c. &c. These are all accurately described in the plates, and may be known by mere inspection; but a particular description of each could scarcely be contained in a folio volume; and by the generality of Readers would be considered only as a disgusting prolixity.

B I R D S.

The S C O P S

IS an extremely elegant little species; it is of the bigness of a fieldfare, but has all the characters of the owl-kind in the strongest manner about it: the head is large, short, rounded, and very thickly covered with feathers; they are short, but very downy, and are of a dusky blackish-grey, or what we properly express by the term lead colour: the ears or horns, as they are called, are short, but very erect; they consist each only of a single feather, but that is very well plumed, and makes an extremely pretty appearance: the back and sides, and the covering feathers of the wings, are of a colour approaching to that of the head, but not exactly the same; they are paler, and are of a simple grey, without that admixture of the blue tinge, which gives the other what we call the lead colour. This, however, is not the sole simple colour, every feather has on it a number of elegant, round, white spots, and the whole back of the bird is by these variegated in an extremely beautiful manner: the larger feathers of the wings and tail are of the same grey with those of the back, only paler; and they are variegated with almost innumerable little white spots, disposed in several transverse series, and there is beside a long black line on each: the shoulders and upper part of the wings, in the male birds, have a beautiful cast of reddish-brown in the grey, which gives the white a yet greater advantage: on the belly the feathers are paler than any where else, and towards its lower part they are, indeed, whitish; but in these, as in all the others, the roots are black.

The eyes of this species are very large, and remarkably bright; their iris is of a flame colour: the beak is short, black, and crooked; the legs are not very robust, but they are feathered down to the toes, which makes them look thick; the plumage upon them is grey, with a tinge of reddish-brown: the toes are small and slender, they are of a greyish or lead colour; the feathering does not reach over

them, but they are squammose. It is frequent in Italy, but is not so common in any other part of Europe: it lives in woods, and sometimes about old buildings, and comes abroad only in the night, then making a loud hooting noise.

The H O O P O E or U P U P A

Is an extremely singular bird; its weight is about three ounces, but it is so thick covered with feathers, that it appears large, in proportion to that weight: the head is large, and is ornamented with an elegant crest: the eyes are small, but very bright and piercing: the beak is of a very singular figure; it is an inch and a half long, somewhat bent into the form of a bow, pointed at the end, very slender, and all over of a black colour: the nostrils are large and oval, and stand toward the base, and there runs on each side, all the way down, a longitudinal furrow: the tongue is short, and lies deep in the mouth; it is broad at the base, and pointed at the extremity, and is, upon the whole, of a figure approaching to triangular: the figure of the whole bird approaches to that of the plover.

The crest on the top of the head is extremely elegant; it is composed of a double series of feathers, two fingers breadth high, and continued from the base of the beak toward the extremity of the tail: the wings are moderately large, when expanded; they measure about sixteen inches from tip to tip, and, when closed, they reach nearly to the tip of the tail: the long feathers in each are eighteen; the ten first of these are black, with a white area on each; the succeeding ones have also a white area on them, and the tips and edges of some of the last are reddish.

The back is very elegantly variegated with black and white, in little alternate spaces on every feather: the legs are short, and not very robust; the toes are moderately long: the outer toe is connected to the middle one, some part of the way down, without the help of a membrane; the claws are moderately long and sharp.

This bird is a native of the northern parts of Europe, but is no where very plentiful. It had been long known in Germany and Sweden, before it was supposed to be a native of England, and several of our old writers declare it not to be such.

Q U A D R U P E D E.

Z E R D A.

THIS animal, according to M. Buffon, is found to the south of the Palus Tritonides, in Libia. It has something of the nature of the Hare, and something of the Squirrel. It lives on the palm-trees, and feeds on the fruits.

 Finder, or water-spaniel - - 62
 Fizzler, of the weasel kind - - 77
 Fiber, the beaver - - 81
 Fourmillier, or ant-eater. See Anteater.
 Fox, its Natural History - - 65
 — the greyhound, the mastiff, the cur, the brant, and the grey - - ib.

G.

Gazelle, or antelope, its Natural History - - 31
 Genet, of the weasel kind - - 77
 Gerbua, Egyptian or Pharaoh's rat, of the monkey kind - - 57
 Gibbon, or long-armed ape - - 52
 Goat, and its numerous varieties - - 29
 — of Natolia, long-eared Syrian, American, the blue, the Indian, or whidaw, &c. &c. 29
 Guanacoes, or camel sheep - - 60
 Gulo, or glutton. See Glutton.
 Guinea, or Angolan sheep - - 28
 — pig, or cavy - - 78
 Giraffe, or camelo pardalis. See Camelo Pardalis.
 Glutton, its description - - 73
 Greyhound, English, Spanish, Oriental and Irish 63

H.

Hare, its Natural History - - 79
 Harrier, species of the dog kind - - 62
 Hartshorn, its nature and uses - - 39
 Hedge-hog, its description - - 92
 — the tendrac, or Asiatic; the tanrec, and Gujana - - 93
 Hippelaphus, a kind of elk - - 45
 Hog kind of animals - - 46
 Hog, descriptive account of it - - ib.
 — the Guinea, the Chinese, the Peccary, or Mexican, the Ethiopian, babyrouessa or Indian, the cabiai or capibera - - 48
 Hog-Rabbit, or spotted cavy - - 79
 Hog-Cow, or beeve-hog - - 23
 Hound, of the dog kind - - 62
 — the gaze, and blood - - 63
 Horfe, its Natural History - - 8
 — the sea - - 49
 Hippopotame, or sea-horse - - ib.
 Hyæna, of the wolf kind - - 66

I.

Jackall, or lion's provider - - 66
 Jaguara, the panther - - 70
 Jerboa, or oriental mouse. See Mouse.
 Ibex, a kind of wild goat - - 30
 Ichneumon, or the rat of Pharaoh - - 76
 Indian-pig, or cavy - - 78
 Ifatis, of the dog or fox kind - - 66

K.

Kangaroo, see the plate

L.

Lacktach, or great Kamptschatkan seal Page 99
 Llamas, or camel sheep - - 60
 Laplanders, their manner of life - - 44
 Leopard, its Natural History - - 70
 Leymer, of the dog kind - - 63
 Lion, its Natural History - - 68
 Loris, or tail-less macauco - - 57
 Le Loir, or the fat squirrel - - 86
 Le Petit Gris, or the grey squirrel - - ib.
 Lynx, its Natural History - - 71

M.

Maimon, or pig-tailed baboon - - 53
 Macauco, its Natural History - - 56
 — the woolley, the black, the tail-less, the yellow, the flying - - 57
 Manati, of the seal kind - - 100
 Manis, the phatagin, or scaly lizard - - 95
 — the short-tail or pangolin - - ib.
 Mandrill, of the baboon kind - - 53
 Mantegar, or tyger. See Tyger.
 Many-horned sheep - - 28
 Mangabey, or white eye-lid monkey - - 55
 Marapute, or ferval, of the cat kind - - 72
 Marikin, or filky monkey - - 56
 Marmose, of the opposum kind - - 58
 Martin, its description - - 76
 Marmotte, its Natural History - - 83
 — the Maryland, Quebec, German, casan, Lapland, and earless - - 84
 — the minor, podolian, and Circassian 85
 Mexican ounce, or tyger-cat - - 71
 Mastiff dog described - - 63
 Mico, of the monkey kind - - 56
 Mole, its Natural History - - 91
 — the Siberian, radiated, brown, and red 92
 — methods used to take and destroy this animal - - ib.
 Mongooze, or woolley macauco - - 57
 Monkey, or ape kind of animals - - 51
 — its Natural History - - 53
 — the dog-faced, lion-tailed, hare-lipped, spotted, green, white eye-lid, talapoin, negroe, Chinese, varied, large of Cochinchina, tawny, winking, goat, and the four-fingered - - 55
 — the weeper, the orange, horned, Antigua, fox-tailed, great eared, marikina or filken, little lion or cagui, red-tailed, and the mico - - 56
 Morfe, or wolrus, of the seal kind - - 97
 — the Indian - - ib.
 Moose-deer - - 41
 Moufflon, a species of sheep - - 28
 Mouse, the common described - - 89
 — the long-tailed field, short-tailed field, harvest, oriental, gregarious, shrew, water-shrew, minute-shrew, murine-shrew, brasilian, and Mexican-shrew - - 90
 Moschifferum, or musk. See Musk.

N.

Nuna, or varied monkey described - - 55

Ocelot,

O.

Ocelot, or tyger-cat - 71

Onager, or wild afs - ib.

Oppoffum, and its varieties - 57

Otter, its Natural History - 78

— the leffer, fea - ib.

Ounce, a descriptive account of it - 71

Ourang-Outang, or wild man of the woods - 52

Ox, Natural Hiftory of this animal - 20

P.

Pacos, or camel sheep - 60

Pangolin, or fhort-tailed manis - 95

Panther, its Natural History - 70

Pica, or paca, the brasilian rabbit - 81

Pipiftrille, of the bat kind - 104

Pinche, the little lion monkey - 56

Pole-cat, its description - 75

Porcupine described - 82

— the long-tailed, Brasilian, Canada, and crested - 83

Potto, a fpecies of the floth - 94

Pointer, of the dog kind - 62

Phalanger, of the oppoffum kind - 58

Phatagin, or manis - 95

Puma, or red tyger - 71

Q.

Quickhatch, or the glutton - 73

R.

Rabbit, its Natural History - 80

— the Angora and Ruffian - ib.

— the Brasilian, baikal, and Cape - 81

Racoon, its Natural History - 73

Ram described - 25

Rat, the common or black - 87

— the Norway - 88

— the Water - 89

— methods used in destroying this pernicious animal - 88

— of Surinam, of the oppoffum kind - 58

— of Pharaoh, or the Ichneumon - 76

Rein-Deer, its Natural History - 42

— its formidable enemies - ib.

— particular ufes - 43

Rhinoceros, and the unicorn ditto, its description - 49

Renard Argente, or silver fox - 66

Roebuck, its description - 40

Roufette, or the great bat of Madagafcar - 103

Ruminating animals - 118

S.

Sai, or weeper monkey - 56

Sajou, of the monkey kind - ib.

Sable, an account of thefe animals and their furs - 76

Sheep, Natural History of its varieties - 25

— the weather and ewe - ib.

— the broad-tailed, many horned, Angolan, or Guinea, moufflon, and ftrepficheros - 28

Shammoy goat - 30

Sheep kind of animals, and the goat - 25

— how to be treated, and when to be fheered - 26

Samiri, or orange monkey - 56

Saki, or fox tailed ditto - ib.

Sapajou, or horned ditto - ib.

Sloth, its Natural History - 93

Spaniel, of the dog kind - 62

Squirrel, its Natural History - Page 85

— the Ceylon, Bombay, the grey, black, varied, Brasilian, ground, fat, garden - 86

— failing and flying - 87

Shunk, of the weafel kind - 77

Squafh, ditto - ib.

Stoat, or ermine - 75

Stag, or Hart, its Natural History - 36

— manner of hunting this animal, or the nature of the chace - 38

Stags of different countries described - 39

— their horns, to what ufes applied - ib.

Seal, and its varieties - 97

— the great, or fea calf, hooded, harp, little, and the urline, or fea bear - 99

Sea horfe, or fea lion - 100

Sea ape described - 101

Serotine of the bat kind - 104

Serval, a ferocious animal of the cat kind - 72

Simia Porcuria, a fpecies of the ape - 52

Siagufh, of the cat kind - 71

Sow described - 49

Suber, or bifon - 22

T.

Tajacu, the Mofchifferum. See Musk.

Talapoin, of the monkey kind - 55

Talgoi, the ant bear - 96

Tapiir, of the hog kind - 50

Tatoa, or Armidillo - 94

Tatu Apará ditto - 95

Tatuette ditto - ib.

Taupedoree, or the golden mole - 92

Terrier, of the hound kind - 63

Tucan, or Mexican fhrew moufe - 90

Turpier, of the oppoffum kind - 58

Tyger - 69

U.

Urfon, or Canada porcupine - 83

Unan, or floth - 93

V.

Vari, or black macauco - 57

Vacuna, or camel sheep - 60

W.

Walrus, or morfe, of the feal kind - 97

Wanderow, a fmall baboon - 53

Warine, of the monkey kind - 55

Weafel kind of animals - 74

Weafel, its description - ib.

— the Guinea - 76

— the ftiffing - 77

Weather sheep - 25

Wild man of the woods - 52

Wifent, or bifon - 22

Wiftiti, of the monkey kind - 56

Wolf, its Natural History - 64

Wolverene, or glutton - 73

Z.

Zebu, or Barbary cow - 23

Zebra of the Cape of Good Hope, a descriptive account of this animal - 23

Zorilla, of the weafel kind - 77

Zibet, or civet ditto - ib.

Zerda - 600

B I R D S.

BIRDS, A NEW and COMPLETE HISTORY of them - Page 110

A.

A UK, of the Penguin kind - 187
 Albatross, its Natural History - 185
 Anas Circa, or summer teal - 194
 Arracanga, or great macaw - 148
 Aracari, of the woodpecker kind. See Woodpecker:
 Asio, or lesser horn owl. See Owl.
 Atinga, of the starling kind. See Starling.
 Avosetta, or scooper - 181
 Aquila Pombina, or the leaden eagle - 115

B.

Barnacle, of the goose kind - 190
 Bee eater described - 197
 — of Bengal - ib.
 Beccafigo, or petty chaps - 165
 Black game - 134
 Blackbird, its Natural History - 156
 Black cap, of the swallow kind - 165
 Blue bird described - 156
 Brambling, its Natural History - 170
 Bittern, its description - 178
 — the North American, small and little - ib.
 Bird of Paradise, its Natural History - 143
 — the king, greater, and golden - ib.
 — the pied, and Ceylon - 144
 Birds of the hawk kind - 110
 — of the poultry ditto - 127
 — of the pie ditto - 137
 — of the sparrow ditto - 154
 — of the crane ditto - 174
 — of the water fowl ditto - 183
 — of the penguin ditto - 186
 Bunting described - 171
 Bustard (the little) described - 134
 Butcher bird (the greater) - 123
 — the lesser, and red backed - 124
 Buzzard (the common) described - 122
 — the honey, Turkey, and Moor - ib.

C.

Calao, or horned Indian raven - 139
 Chatterer described - 140
 Chaffinch - 170
 Canary bird, its Natural History - 162
 — directions for choosing a songster - ib.
 — ditto for breeding this kind of birds, - ib.
 Crane, its description - 174
 — the balearic - 175
 — the Numidian, or buffoon, hooping, jabiru, guacu, and the anhima - 176
 Cross bill described - 199
 Crow, its Natural History - 138
 — Royston - 139
 Cockatoo, its Natural History - 149
 Cocolzin, the Indian turtle - 153
 Cormorant described - 185
 Cole mouse, of the titmouse kind. See Titmouse.

Coot, its Natural History - Page 182
 — footed tringa - 194
 Cock, and its varieties - 128
 — the Bantam, the Hamburgh, and pea, of the wood, black, and the moor - 134
 Condor, or Condour, of South America, its description - 116
 Cuckoo, its Natural History - 144
 Curlew described - 181
 Caracias, or caracara. See Caracara.
 Caracara, of the hawk kind. See Hawk.
 Corvus Aquaticus, the sea crow. See Crow.
 Charadrius, the green plover. See Plover.

D.

Daker hen, of the quail kind. See Quail.
 Demoiselle, of the crane kind. See Crane.
 Diver, great northern - 187
 — grey speckled - ib.
 Didapper, of the diver kind. See Diver.
 Dobchick, or didapper. See Diver.
 Dodo, its description - 113
 Drake (the shell). See Duck.
 Duck, its Natural History - 190
 — tame, male or drake, mallard, eider, wild, sea, pond, and foreign - 191
 — decoy, velvet, tufted, scaup, pintail, grey headed, white bellied of Jamaica, and Barbary - 192
 — the Madagascar, and Bahama - 193
 Dunbird, or pochard, of the duck kind - ib.
 Dundiver, female of the goofander - ib.
 Dunlin, of the crane kind - 182

E.

Eagle (the golden) described - 113
 — bald, ring tail, sea, and the black - 115
 — crowned, common, white, rough footed; Jean le Blanc, Brazilian, Oroonoko, and of Pondicherry - 116
 Emigration of water fowl - 197
 — of British birds - 198
 Emu, its Natural History - 112

F.

Falcon, its Natural History - 119
 — the gyr, peregrine, facre, mountain, grey, and gentle - 120
 — white, Tunis, or Barbary, and the lanner - 121
 Falconry, or hawking, observations thereon - 119
 Fieldfare, its description - 156
 Finch, the green, described - 169
 — the gold, the chaf - 170
 Flamingo, its Natural History - 179
 Fly catcher (the) of the swallow kind - 165
 — the blue - ib.
 Fulmar, its description - 195

G.

Gadwall, of the duck kind - 194
 Game laws, remarks on them - 135
 Gannet

Gannet, its description	-	Page 186
Garganey, of the duck kind	-	194
Goatsucker, or swallow with an undivided tail	-	165
Godwit, its description	-	181
—— red, lesser, great American, and the white North American	-	ib.
Golden eye, of the duck kind	-	193
Goldfinch described	-	169
Goosander	-	193
Goose hawk	-	121
Goose, its Natural History	-	186
—— wild, tame, green	-	ib.
—— Spanish, and white footed	-	189
—— brent or brand, Canada, North American, Muscovy, blue winged, barnacle, mountain, and water	-	190
—— swan	-	188
Grebe, its description	-	183
—— white, dusky, and the little	-	ib.
Greenfinch	-	169
Greenshank, spotted and red	-	182
Grouse, its Natural History	-	134
Grosbeak (the)	-	199
Guillemot, of the penguin kind	-	187
Gull, its Natural History	-	186
Grus (the crane) described	-	176
Grus Balearica	-	175
Guinea hen. See Hen.		

H.

Hazel hen. See Hen.		
Halcyon, or king fisher	-	195
Heath cock, and black game	-	134
Hawk (the sparrow) &c.	-	123
Hedge-sparrow, its description	-	165
Hen, female of the cock	-	128
Hen harrier, the male buzzard	-	122
—— Guinea	-	133
Heron, its Natural History	-	177
—— the crested, egret, or great white, lesser white, little white, and yellow and green	-	178
Himantopus, of the plover kind. See Hen.		
Hobby, of the hawk kind	-	123
Hoopoe. See the Appendix	-	600
Humming-bird, and its varieties	-	173
—— larger, long tailed, black capped, lesser, little, black bill, green, and ash coloured	-	ib.

I.

Jacupema, or the pheasant	-	132
Jackdaw	-	139
Jay, its Natural History	-	140
—— the blue, and Bengal	-	ib.

K.

Kestrel, of the hawk kind	-	123
King fisher, its Natural History	-	195
—— American, little green and orange coloured	-	196
—— of Catesby, of the River Gambia, Smyrna, Bengal, Small of ditto, and querbatos	-	197
Kite, its description	-	121
Knot, of the crane kind	-	182

L.

Lagopus Greenland pigeon. See Pigeon.		
Elamysden, the merlin hawk	-	123
Lapwing, of the crane kind	-	182
Lark (the) and its varieties	-	160
—— sky, and wood	-	ib.
—— white, tit, crested, lesser crested, lesser field, red, black, grasshopper, willow, and petit, or, little	-	161

Linnet, its Natural History	-	Page 171
—— red-pole, or greater, and red-headed	-	ib.
—— lesser red-headed, and twite, or mountain	-	ib.
Loon (the greatest) of the diver kind. See Diver.		
Lory, of the parrot kind	-	148

M.

Maccaw, its Natural History	-	148
—— blue, yellow, great and Brasilian	-	ib.
Magpie described	-	139
Martin, its description	-	164
Mavis, or song thrush	-	157
Merganser, of the dobchick kind. See Dobchick.		
Merops, the bee-eater. See Bee-eater.		
Merlin, of the hawk kind	-	123
Merula, or red start	-	159
Migration of British birds	-	198
—— of water fowl	-	197
Mitu Porangu, of the pheasant kind. See Pheasant.		
Mock bird, the American	-	158
—— nightingale, or black cap swallow	-	165
Moor cock, its Natural History	-	134

N.

Nauseous bird, a name given by the Dutch to the dodo	-	113
Nazareth (bird of) or the dodo	-	ib.
Nightingale, its Natural History	-	158
Nuthatch described	-	198

O.

Oriolus, of the thrush kind. See Thrush.		
Osprey, its Natural History	-	110
Ostrich	-	115
Ouzel, its description	-	158
—— water, Indian, and the Brasilian	-	ib.
Owl, its Natural History	-	125
—— great, horned or eagle, lesser horned, white, brown, and the little	-	126
Ox-eye, or great titmouse	-	172

P.

Parrot, its Natural History	-	145
—— the white crested, and white headed	-	146
—— green, bluish green or black billed, red, blue, scarlet, oriental, ash coloured, red and white, blue faced green, green and red	-	147
—— hawk headed, and the diminutive green	-	ib.
—— dusky, and white breasted	-	148
—— Paragua, and tarabe	-	149
—— black capped lory, and long-tail scarlet lory	-	148
—— little, of Bontius	-	149
Paradisæa, or bird of paradise	-	143
Parroquet, or toe lory	-	149
—— red breasted, long tailed green, golden crowned, rose headed green, and the little red headed	-	ib.
—— little green and blue	-	150
Partridge, its Natural History	-	135
—— red, Hudson's Bay, mountain of Jamaica, of Hernandez, of Damascus, and the red of Aldrovandus	-	136
Passer Indicus, or Indian sparrow	-	169
Peacock, its Natural History	-	130
Pea-hen	-	ib.
Pettychaps described	-	165
Penguin	-	186
—— the Magellanic	-	ib.

F I S H E S,

NEW NATURAL HISTORY and DESCRIPTION of FISHES	Page	Page
	200	
A.		
A NCHOVY, its Natural History	243	
the golden	ib.	
Angel fish described	212	
Angler, his qualifications	287	
his rods, lines, and other sorts of tackle	ib.	
some particulars not generally known	295	
rules and cautions for a young angler	ib.	
Angling, directions for and containing the whole art of float and fly fishing, the best rules for the choice of tackle, with a description of natural and artificial baits	287

Baits (natural and artificial for angling)	289	
Barbel, its description	244	
instructions to angle for them	ib.	
Bass, its description	230	
Bib, or blind	223	
Blanny (the crested)	224	
the smooth, spotted, and viviparous	225	
Bleak, its Natural History	248	
manner of whipping for it	ib.	
Blind, or bib, described	223	
Bream, its Natural History	245	
method of angling for it	ib.	
(the sea)	228	
Bret, or turbot	227	
Bull-head, its description	225	
Burbot, or eel pout	224	
C.		
Cachalot, its Natural History	204	
the great headed, round headed, and high finned	205	
Carp, its description	243	
the pond and river	ib.	
methods of angling for them	ib.	
Charr, its Natural History	237	
the gelt, or barren	ib.	
Caviare, of the sturgeon kind	214	
Chub, its description	247	
how taken by dibbing	ib.	
Cockles described	252	
Cod fish, its Natural History	221	
manner of salting them	ib.	
principal fisheries	ib.	
Coal fish, described	223	
Cook (the)	229	
Cock paddle, or lump fish	216	
Conger eel, its description	219	
Crab fish, its Natural History	249	
the violet, and soldier	250	
the white, sea, square, South American, Indian, land, &c.	ib.	
Craw fish, described	249	
Crustaceous fish	248	
D.		
Dab, its Natural History	226	
Dab, the smeare	226	
Dace, or dare	247	
how to angle for them	247	
Doree, or gilt fish	225	
Dog fish, or canis charcarias	212	
Dolphin, its description	205	
Dragon fish described	220	
the small	ib.	
E.		
Eel, its Natural History	218	
the electrical, bed, silver, common, torporific, conger, sand	219	
launce	220	
pout, or burbot	224	
F.		
Father lasher, or sea scorpion	224	
Fire flare, or sting ray	211	
Fishes of the cetaceous kind	202	
of the cartilaginous ditto	207	
of the spinous ditto	216	
of the oyster ditto	252	
Flounder, its Natural History	226	
Flying fish	241	
Float and fly fishing, the art of	289	
Fly fishing	291	
Fork tails, of the salmon kind	232	
Fox (the sea)	213	
Frog fish, or fishing frog	212	
G.		
Gilt fish, or doree	225	
Gilt head, or gilt poll	228	
Gold fish described	248	
Grampus, its Natural History	205	
Grayling, or umbrae	237	
Grey, a species of salmon	234	
Grigs, or gluts (silver eels)	219	
Groundling, or tub fish	232	
Gudgeon, its description	245	
manner of angling for them	ib.	
Gudgeon (the sea)	225	
Guiniard described	238	
Gurach, or the old woman	229	
Gurnard, the grey	231	
the red	ib.	
Gymnotus (electric) of the torpedo kind	209	
H.		
Haddock, its Natural History	222	
Hake, its Natural History	223	
the lesser	224	
Herring, and its varieties	241	
the flat, meat, night, pluck, shotten, cop- shen, and the pickled herring	242	
fishery	241	
Huso germanorum, of the sturgeon kind	214	
Hollibut (the) described	226	
I.		
Jaculator, or launce fish	220	
Introduction to spinous fishes	216	
Isinglass, of the salmon kind	215	
Lamprey,		

Wraffe, or old wife - Page 228
 — the painted, black, striped, and variegated 229
 — the lesser green - ib.

N. B. Besides the above, there are several other fishes: but many of them being the same with those we have described, only under different

names, or imaginary ones, or minute distinctions of a particular species, we must refer our Reader to the plates, where they will see them accurately portrayed. To give a particular account of these might, perhaps, gratify the taste of over curious speculators, but it would be foreign to our design, and extend this Work far beyond its prescribed limits.

R E P T I L E S and I N S E C T S.

The NATURAL HISTORY of REPTILES and INSECTS - Page 254

A.

AMMODITES of Ceylon, an account of them - 265
 Amphibæna - 266
 Ant-lion described - 276
 Asp, its Natural History - 267
 Aurelia. See Silkworm:

Bee, its Natural History - 277
 — generation, polity, and labour of this insect 278
 — usual method of uniting swarms of bees - ib.
 — how to get their honey without destroying them - 279
 Blind worm described - 267
 Boiguacu, its Natural History - 266
 Bug described - 274
 Butterfly, its Natural History - 276

C.

Cameleon, its Natural History - 258
 Caterpillar described - 276
 Centipede, or gally-worm - 275
 Cobradi Capello, or hooded-serpent, described - 267
 Cobra de Veado, or boiguacu - 266
 Coral serpent - 267
 Coralines, and plants, at the bottom of the sea - 286
 Cricket, its Natural History - 276
 — mole ditto - ib.
 Crocodile, its Natural History - 258
 Cuckow-spit, of the worm kind - 283
 Cuttle fish, of ditto - ib.

D.

Double-headed serpent - 266
 Dragon-fly described - 275

E.

Earwig described - 276
 Ephemera - ib.

F.

Flea, its Natural History - 269
 — water ditto - 275
 Fly (the common) - 276
 — the Ichneumon - 280
 — the dragon - 275
 Frog, its Natural History - 254
 Froth insect - 276

G.

Gally-worm, or Centipede - 275
 No. 60.

Gerenda described - Page 265
 Giboya, the Brasilian serpent - ib.
 Gnat, its description - 280
 — different species of them - 281
 — its extraordinary propagation, and circumstances of life - ib.
 Grafshopper, its description - 276

H.

Hooded serpent described - 267
 Hornet, its Natural History - 280

I.

Jaculus, of the serpent kind - 267
 Ichneumon fly - 280
 Iguana, its Natural History - 262
 Insects, their Natural History, describing their different orders, and a suitable introduction - 267

L.

Leach, its Natural History - 275
 — the common, horse, snail, and broad-tailed - ib.
 Libella, or dragon fly - 275
 Lion (the ant) - 276
 Lizards, a general account of them - 257
 — the crocodile, iguana, and the viviparous - 258
 — the scaly, watry, green, and brown - 261
 — tarantala, taraquina, or Brasilian - 262
 Louse, its description - 269
 — wood ditto - 274

M.

Monoculus, or water flea - 275
 Moth, its description - 277

N.

Natter Jack described - 257

O.

Old Wife, its Natural History - 228
 Opah described - ib.
 Owl (the sea) - 216
 Oyster, and its various species - 252

P.

Pipal, or Surinam toad - 257
 Polypus, of the worm kind - 280
 — its different kinds - 284
 — properties of the polypi, and their surprising manner of propagation - 285

R.

Rattlesnake, its Natural History - 266
 Salamander,

S.

Salamander, its Natural History	Page 260
Scolopendra described	275
Scorpion, its Natural History	ib.
—— the water	276
Seps, of the serpent kind	267
Silk-worm, its Natural History	277
Snake, its description	267
Spider, its Natural History	268
Sponges and plants at the bottom of the sea	286
Star fish, &c. of the worm kind	283

T.

Tarantula, its description	268
Tipula, the water	276
—— the long-legged	280
Toad, its Natural History	255
—— Surinam	257

V.

Viper, its Natural History	263
—— antidotes against its bite	264

Viper, a particular remedy for ditto	Page 265
—— of Javan and Ceylon	ib.

W.

Wasp, its Natural History	279
Whip-snake described	267
Worms, their Natural History	281
—— sea and water	282
—— earth, small red headed, white water, &c.	ib.

Z.

Zoophites (the first class of worms)	281
--------------------------------------	-----

N. B. It is impossible to enumerate in the compass of this Index, calculated more to instruct and please the lovers of public utility, than the amateurs of useless curiosity, all the infinite orders and species of insects.—Of the Butterfly alone, Linnæus has reckoned above *Seven Hundred and Sixty*; and Mr. Ellis *Fifty* different kinds of Polypi: Therefore, to complete our Catalogue, under this head of Reptiles and Insects, we refer the more curious Readers to the Plates illustrating this Work.

B O T A N Y.

Containing the NATURAL HISTORY of VEGE-TABLES, as well foreign as indigenous: their roots, barks, woods, leaves, flowers, fruits, seeds; resins, gums, and concreted juices; with an account of their virtues, and medicinal uses: also the method of cultivating those planted in gardens; including likewise observations on hot-beds, and watering of plants 296
See also the Appendix for the Natural History of FLOWERS, according to the Linnæan system, &c. 591

A.

Absinthium vulgare, common wormwood	319
—— maritimum, sea ditto	ib.
—— Romanum, Roman ditto	ib.
Abutilon. See the Appendix, under the head of Botany.	
Acacia vera, true acacia	317
Acajous, or cajous, the cashew nut	310
Aconitum, monk's-hood	299
Acorus verus, sweet smelling flag	ib.
—— Indian	ib.
Acanthus, brank urfine	319
Acestofa, common sorrel	ib.
Adiantum verum, the true or French maiden-hair	ib.
Agallochum, aloes wood	305
Agaricus, agaric	318
Agnus castus, the chaste tree	320
Agrimonia, agrimony	ib.
Agrimony (hemp)	338
Alcea, vervein mallows	320
Alchimilia, ladies mantle	ib.
Allium, garlick	ib.
Alnus, the alder tree	ib.
Althæa, marsh mallows	ib.
Aloes, the succotrine, hepatic, and caballine	316
—— wood	305
Allspice, or pimenta	309
Amygdalus, the almond tree	321
—— amara, the bitter ditto	ib.
Amber (liquid)	312
Amomum verum, the true amomum	309
Ammoniacum, gum ammoniac	316

Anagallis mas, male pimpernel	321
Anethum, dill	ib.
Anemone (wood)	366
Anime, vel-animum	313
—— American gum anime	ib.
Angelica	299
Anisum vulgare, anise	321
—— Indicum stellatum	312
Anonis, five onnis, rest harrow	321
Apararine, goose-grass, or clivers	ib.
Apium montanum, or mountain parsley	356
Appium palustre, smallage	322
Apple tree	347
—— its varieties	348
Apricot tree, and its various kinds	322
Apple (the bitter)	308
Aquilegia, columbines	322
Arrach	323
Arbor Judæ, Judas's tree	373
Arbotanum, southernwood	318
Arbutus, the strawberry tree	382
Argentina, silver weed, or tansey	322
Aristolecha rotunda, round birthwort, and various other kinds	300
Armeniaca malus, the apricot-tree	322
Artemisia, mugwort	ib.
Artimoak	ib.
Arun, cuckow pint, or white robin	ib.
—— the many leaved, or dragons	336
Asa foetida, a kind of gum resin	ib.
Asrabacca	323
Aarum	ib.
Aselepias, swallow wort	ib.
Asparagus, called sparrow-grass	ib.
Atriplex foetida, arrach	ib.
Auricula Judæ, Jews-ear	318
Aurantia malus, the orange tree, and its numerous varieties	323

B.

Balm	351
—— of Gilead	312
Balanus myrepica	310
Balsamine, five noli metangere	355
Balsamum	

Balsamum Peruvianum, balsam of Peru, and other varieties	Page 312	Carrot (the candy)	Page 336
Barberry tree	324	Carlina, or chamælion albus	300
Bardana, bardock	ib.	Casumunar, or Indian root	ib.
Barks, their Natural History	304	Cassia lignea, woody cassia	304
Bdellium, a gum resin	316	— caryophyllata, the bark of a tree, called clove berry tree	ib.
Bay tree	345	Cascarilla, the grey Peruvian bark	305
Balaustia, balaustines	348	Carica, dried figs	308
Beans, Windsor and other sorts	338	Cassia fistularis, the pudding pipe tree	ib.
— buck	350	Cardemomum, cardemum	309
Beccabunga, brook lime	324	— the middle sized, of Matthiolus, and the greater of Bontius	ib.
Bella donna, deadly nightshade	ib.	Caryophilli, aromatic cloves	310
Bellis major, the greater, or ox-eye daisy	ib.	Caranna	314
— minor, the common daisy, with its varieties	ib.	Castanea, the chefnut	330
Behen, red and white	300	Catechu, Japan earth	317
Benzonium, Benjamin	313	Cauliflower	326
Berula, water parsnip	324	Centaurium majus, the greater centaury	330
Beta, beet	325	— the lesser	ib.
— white, red, and turnep rooted	ib.	Cepa, the onion	ib.
Betonica, betony	ib.	Carthamus, bastard saffron	311
Betony (water)	373	Chamæcy parissus, lavender cotton	318
Bilberry, or wertle	380	Chamædris, ground oak	331
Bindweed (greater)	374	Chamælion albus of the shops	300
— small ditto	375	Chamæmelum, camomile	331
Birthwort, and its varieties	300	Chamæpitys, ground pine	ib.
Bird's foot	357	— moschata, musk ditto	ib.
Bistorta, snake weed	325	Cherry-tree, and its different kinds	330
Blackberry	369	Cherry, the winter	320
Bluebottle	335	Chaste tree	ib.
Bonus Henricus, the English herb mercury	325	Chefnut tree	330
Boletus Cervinum, deer's balls	318	Cheiri, the wall flower	33
Borrago, burrage	325	Chelidonium, celandine	it
Box tree, and its varieties	327	— minus, pile wort	ib.
Brassica, cabbages, and their varieties	325	Cheese rennet	34
— cauli flora, the cauliflower	326	Christ's thorn	35
— fimbriata, broccoli	ib.	China tree	300
Broom	340	— the American	ib.
— butcher's	370	Chocolate nut	310
Broccoli	326	Ciboule, or cepula	ib.
Brooklime	324	Cicily (sweet)	353
Bryonia alba, white bryony	326	Cichorium, wild succory	332
Bramble (common)	369	Cicuta, hemlock	ib.
Buckthorn (purging)	367	Cinnamomum, cinnamon, the second bark of a tree called canella zeylanica	304
Bugula, bugle or confound	327	Cinara hortensis, the artichoak	332
Buglossum, garden bugloss	ib.	Citreum, the citron tree	333
Burdock	324	Cliyers	321
Burnet, or pimpernel parsley	360	Cloves	310
Burfa pastora, shepherd's pouch	326	Cocao, or coco	ib.
Butter bur	359	Cochlearia hortensis, scurvy grass	333
Butter wort	ib.	Coffee	311
Butua, or pareira brava	300	Colchicum, meadow saffron	334
Buxus, the box tree	327	Columbines	322
		Colocynthis, coloquintida, or bitter apple	308
		Confound-(middle)	327
Cabbages, and their varieties	325	Consolida major, the greater comfrey	334
Calamus Aromaticus, sweet smelling flag	299	Corn fallad, or lamb's lettuce	379
Calambac, aloes wood	305	Cork tree	375
Caltha vulgaris, marigold	328	Coriandrum, coriander	334
Calamintha, calamint	327	Contrayerva	300
Calendula, the marigold	328	Cortex winteranus verus, true winter's bark	304
Camella alba, winter's bark, or wild cinnamon	304	Cortex Peruvianus, Peruvian or Jesuit's bark	ib.
Camel's hay	306	Cortex Elutheriæ, by some called the grey Peruvian bark	305
Camomile	331	Costos (the sweet)	300
Camphora, camphire	313	Cotonea malus, the quince tree	334
Cannabis fativa, manured hemp	328	Crassus, the cherry tree	380
Caper, its several sorts	ib.	Cranes (bloody)	340
Caprifolium, woodbind	ib.	Cræffes (garden and water)	353
Capficum, Guiney pepper	360	— common	374
Capparis, the caper bush	328	— sciatica	342
Camphorata, stinking ground pink	ib.	Clara	ib.
Cardica, mother wort	329	Cromwell	346
Carduus Benedictus, the blessed thistle	ib.	Crow-foot (bulbous)	360
Caryophilus, clove July flowers, or carnations	ib.	—	366
Carnations	ib.	Cubebæ of the shops	309
Caruus, carraway, and its various sorts	ib.		
Cardones, the spiny artichoak	332		

Cuckow pint	Page 322
Cucumis sativis vulgaris, the cucumber	334
—— the wild, &c.	ib.
Cupressus, the cypress tree	335
Cucurbita, the gourd	ib.
Currants, their various kinds	368
—— use in medicine	ib.
Curcuma, fermeric	300
Cyperus longa, long cyperus	ib.
—— round ditto	301
Cyprinum, Rhodium weed	305
Crocus saffron	307
Cyanus, the blue bottle	335
Cyclamen, sow bread	ib.

D.

Dactyle, dates	307
Daisy (the greater) or ox eye	324
—— the common	ib.
Daucus creticus, the candy carrot	336
Dandelion	ib.
Dens leonis ditto	ib.
Deers balls	318
Dictamnus creticus, dittany of Crete	301
—— the leaf ditto	306
Digitalis, fox glove	336
Dittander (common broad)	345
Dittany of Crete	301
—— white, a sort of flaxinella	ib.
Dock (great water)	344
Dill (the)	320
Dragon's blood	314
Draganthum, gum dragacanth	315
Dracontium	336
Dracunculus, and its varieties	ib.
Doronicum Romanum, Roman wolf's bane	301
Drop wort	338

E.

Ebulus, dwarf elder	336
Elemi (gum)	314
—— American	ib.
Elecampane	337
Elder tree	371
—— dwarf	336
—— marsh	356
Elm tree, and its varieties	381
Endivia, endive, and its three sorts	337
Enula campana, elecampane	ib.
Eruca, rocket	ib.
Erysimum, hedge mustard	ib.
Esula minor, the lesser spurge	338
Eupatorium cannabinum, hemp agrimony	ib.
Euphrasia, eye bright	ib.
Euphorbium	316
Eye bright	338

F.

Faba major hortensis, Windsor beans	338
Fennel flower (Roman)	355
Feverfew	350
Figs (dried)	308
Filipendula, drop wort	338
Flag, sweet smelling	299
—— stinking	380
Flax (common)	346
Florentine orris, or the common	302
Flower de luce	ib.
Flowers, their Natural History	306
—— for their orders and genera, according to the Linnæan system, see the Appendix	Page 591
Feniculum vulgare, common fennel	338
—— dulce, sweet ditto	ib.

Fænum Græcum, fænugreek	Page 339
Fox gloves	336
Fragaria, the strawberry plant	339
Fruits, their Natural History	307
Fungus sambucinus, Jews ear	318
—— laricis, ditto	ib.
—— campestris esculentus vulgarissimus, the common esculent mushroom	339

G.

Galega, goat's rue	340
Galeopsis, dead nettle	ib.
—— angustifolia foetida	ib.
Galanga minor, the lesser galangal	301
Galbanum	316
Gallium luteum, ladies bed straw, or cheese rennet	340
Garlick	320
Gelder rose	356
Gentiana, gentian	301
Genista, broom	340
Geranium sanguineum, bloody cranes	ib.
Germander, or ground oak	331
Ginger	303
Glycyrriza, liquorice	301
Gold of pleasure	353
Gonzing	302
Guaicum, or wood guaiac	305
Goose grass	321
Gooseberry (common, and other sorts)	340
Grounel (common)	373
Grossularia, the gooseberry	340
Gums, their Natural History	315
Gum resins	316
Gummi arabicum, gum arabic	315
—— fenica, gum feneca	ib.
Gum anime	313
—— elemi	314
—— sandrich	ib.
—— tragacantha	315
—— ammoniac	316
Gumboge	317
Gutta galbanum	316

H.

Hawthorn, or white thorn	352
Hellebore (white)	379
Helleborus albus et niger, white and black hellebore	301
Helianthemum tuberosum, five indicum tuberosum	341
Henbane, black and white	342
Hedera terrestris, ground ivy	341
—— arborica, common	ib.
Hemlock	332
Hemp (manured)	328
Herniaria glabra, rupture wort	341
—— herfuta, hairy ditto	ib.
Hoar hound	350
—— base ditto	375
Honeysuckle	328
Hermodactylus, hermodactyl	301
Hop plant	347
Horminum, clary	342
House leek	371
Hot-beds, observations on them	380
Hyoscyamus niger vulgaris, black hanbane	342
—— albus, white ditto	ib.
Hypericum, St. John's wort	ib.
Hyssopus, hyssop	ib.

I.

Jalapa, jalap	301
Jasminum, the jessamine	342

Iberis sciatica, cresses	Page 342	Mistletoe	Page 380
Jesuits, or Peruvian bark	304	Money wort	355
Jew's ear	329	Moufe ear (common)	360
Imperatoria, master wort	301	Mother wort	329
Indian leaf	306	Mosses their Natural History	595
Indibus, endive	336	Mullein (white and female)	380
Ipecacuanha, the Peruvian and Brasilian	301	Mushroom (the common esculent)	339
Iris florentina, orris	302	Mug wort	322
Juglans, the walnut	243	Mustard (hedge) and its varieties	337, 373
Juniperis, the juniper	ib.	Myagrum, gold of pleasure	353
Juices extracted from plants	316	Myrris, sweet cicily	ib.
Ivy, common and ground	340	Myrtus minor vulgaris, box leaved myrtle	ib.
July flowers; carnations	329	Myrobolans, and its varieties	308
	K.	Myrrha, myrrh	316
Kidney-bean plant	360		N.
	L.	Nacotiana major latifolia, tobacco, its kinds	354
Lactuca fativa non capitata, common lettuce	343	Narcissa lucocum, the snow drop	353
Ladies bed straw	340	Nardus celtica, celtic nard	302
—— mantle	320	Nasturtium aquaticum, water cresses	353
—— finger, or kidney vetch	383	Navel wort	382
Lapathum rotundifolium, bastard monk's rhubarb	344	Nepeta, nep, or cat mint	354
Lavandula angustifolia, narrow leaved lavender	345	Nepthritic wood	305
—— latifolia, greater or broad ditto	344	Nettle (common and other kinds)	382
Laurus vulgaris, the bay tree	345	Nigella Romana, Roman fennel flower	355
Laurel (Alexandrian)	360	Nettle (deadly)	340
Laureola mas, spurge laurel	345	Nectarine tree, its varieties	349
Laudanum, vel labdamen	314	Ninzin	302
Leaves, their Natural History	306, 594	Nightshade (deadly) and its varieties	324
Leek (common)	360	Nose-bleed, or yarrow	353
Lemon tree	333	Nummularia, money wort	355
Lepidium latifolium, common broad dittander	345	Nutmeg	301
Levisticum, lovage	ib.	Nux Moschata, or myresteca, the nutmeg	ib.
Ligustrum, privet	ib.	Nux vomica, the vomit nut	311
Lignum aloes, aloes wood	305	Nymphoea alba, et lutea major, the white water and great yellow water lilly	355
Logwood	ib.		O.
Liquorice	301	Oak, (ground, fern, and tree)	331, 360, 366
Lillium albinum, white lily	346, 350	Occidental Anacardium, cashew nut	310
Lime, or lindel-tree	377	Olea major, the olive tree	355
Linum vulgare, common flax	346	Olibanum	314
Linnæan system of flowers	591	Onion, and its various sorts	330
Liquidum amberum, liquid amber	312	Onobrichis, sain-foin, and its different kinds	356
Lovage	345	Opium	317
Lung wort	360	Opopanax	316
Luzula, wood forrel	346	Opopobalsamum, balm of Gilead	312
Lupinus flora albo, white lupine	347	Orach (stinking)	323
Lupulus, the hop plant	ib.	Orange tree and peel	323, 324
	M.	Orchis, five sambucus aquatica	356
Mace	311	Orielle d'homme, or man's ear	323
Madder (Dyers)	369	Organum vulgare, wild marjorum	357
Maiden-hair (the true or French)	319	Oriza, rice	ib.
Malabrathrum, the Indian leaf	306	Ornithopodium majus; greater bird's foot	ib.
Mallows (vervein)	320		P.
Malus Medica, the citron tree	333	Paliurus, Christ's thorn	357
—— limonia et fativa, lemon and apple trees	ib.	Palieteria, pellitory of the wall	358
—— granata five punica, the pomegranate	348	Pareira brava, or Brasilian plant	300
Malva vulgaris, mallows	347	Parfnip (water)	324
Manna calabria, &c.	315	—— common and wild	358
Mandrakes	350	Parsley (pimpernel and milky)	360, 376
Marum verum, five cortufe	ib.	Papave Cornutum, yellow horned poppy	358
Marrubium, hoarhound	ib.	Pastinaca, the garden	ib.
Mandragora mas, seu candida	349	Pasque flower	364
Marygold (garden)	328	Pea, and its various sorts	361
Master wort	301	Pears, their different kinds	364, 376
Mastich, and its different sorts	350	Peach tree, and its numerous varieties	349
Matricaria, feverfew	ib.	Pellitory of Spain	302
Mechoacanna, mechoacan	302	Penny royal	363
Melilotus, melilot	351	Pæonia mas, male peony	357
Melissa, balm	ib.	Peripolca, Virginian silk	359
Melo vulgaris (common musk)	ib.	Perlicaria mitis, dead arse smart	ib.
Melon, and its various kinds	ib.	Pepper wort	345
Mentha vulgaris, mint and its different kinds	352	Petasites, butter bur	359
Mercurialis, male and female mercury	ib.	Petroselinum, parsley	ib.
Meum athamanticum, spignel	302	Phillyrea, mock privet	360
Mercury, the English	325	Phitollaca, American nightshade	ib.
Majorana, marjorum	347	Pile wort	332
Millium, miller	353	Pilocella, common mouse ear	360
Millefolium vulgare, yarrow	ib.		
No. 60.		7 Q	Pimpinella,

Pimpinella, pimperel or burnet	-	Page 360	Santalum rubens, red Sanders	-	Page 305
Pimenta, Jamaica pepper, or allspice	-	309	Santonium semen, worm-feed	-	312
Pinci Nuclei, pine apple nuts	-	311	Santolina, lavender cotton	-	318
Pine (ground)	-	332	Sanicula, fanicle	-	371
Pipe tree (the pudding)	-	308	Sarfaparilla	-	303
Piper, pepper, black, white, &c.	-	309, 360	Sarcocolla	-	316
Pimpernel (male)	-	201	Saffrafas	-	306
Pink (stinking ground)	-	328	Saturia, favory	-	372
Pinguicula, butter wort	-	360	Saxafraga, saxifrage	-	ib.
Pistacia, pistachio nuts	-	311	Scallion (the)	-	330
Pisum, the pea plant	-	361	Scammonium, scammony	-	317
Pistilochia, slender birth wort	-	300	Schoenanthus, camel's hay	-	306
Plants, herbs, shrubs, and trees, their Natural History	-	318, 589	Scapularia aquatica, water-betony	-	373
Plantago, the plantain	-	361	Scorfonera, viper's grafs	-	372
Plumb, and its numerous kinds	-	363	Sebestein	-	307
Polygomatum, Solomon's seal	-	361	Sedum majus vulgare, common house leek	-	373
Polypodium, polypody	-	ib.	Seeds, their Natural History	-	307
Populus, the poplar tree, and its varieties	-	362	Seneca of the polyala virginia	-	303
Porrum commune capitatum, the common leek	-	ib.	Senna, or fena	-	306
Portulaca, purslane	-	ib.	Septfoil, or tormentile	-	378
Pomegranate, and its rind	-	348	Serpentaria Virginia, Virginian snakeroot	-	303
Primula veris, the primrose	-	362	Sea moss	-	306
Prunus, the plumb tree	-	ib.	Scurvy grafs	-	333
Pulegium, penny-royal	-	363	Sainfoin, or cocks	-	356
Pulmonaria, lungwort, or sage of Jerufalem	-	364	Silver weed	-	322
Pulfatilla, pasque flower	-	ib.	Sium, water parsnip	-	324
Purslane	-	362	Sifarum germanorum, or skirret	-	374
Pyrethrum, pellitory of Spain	-	302	Sorrel (common)	-	319
Pyrola, winter green	-	364	Smallage	-	322
Q.			Snake weed	-	325
Quince tree, and its several kinds	-	334	Sorrel wood	-	346
Quercus vulgaris, the common oak	-	366	Solomon's seal	-	361
Quinque folium, cinque foil	-	ib.	Soldanella, Scots scurvy grafs	-	375
R.			Sonchus asper, prickly sow bread	-	335
Race mosa, black bryony	-	227	Sow thistle	-	375
Radishes, garden and horse	-	367, 314	Southernwood	-	318
Ranunculus bulbosus, bulbous crow foot	-	366	Speedwell (common male)	-	380
Raisins, their various sorts	-	307	Spignel	-	302
Rapa, the turnip	-	366	Spikenard (Indian)	-	ib.
Raphanus, garden radish	-	367	Spunk	-	318
Raspberry bush	-	370	Sparrow grafs, asparagus	-	323
Rattle snake	-	303	Spurge, the lesser	-	338, 377
Refeda vulgaris, common rocket	-	367	Spinage, and its various sorts	-	344
Refina Hederæ, gum of the ivy tree	-	314	Spina alba, hawthorn	-	352
Resins (liquid, &c.) their Natural History	-	312	Squill, common, red and white	-	372
Rest harrow	-	321	Statice, thrift, or sea pink	-	375
Rhabarbarum verum, true rhubarb	-	302	Stoechas arabica, French lavender	-	370
Rhapontic, rhubarb of discorides, English rhubarb	-	303	Storax, liquid, &c.	-	312, 314
Rhodium wood	-	305	Strawberry tree	-	380
Rhubarb, monks and bastard	-	344	Suber, the cork tree	-	375
Rice, monk's	-	357	Succus, aloes	-	316
Rhamnus Catharticus, purging buckthorn	-	367	Succory (wild)	-	332
Rhus folio ulmi, common sumach	-	368	Sumach (common, &c.)	-	368
Ribes vulgares, the common red currant bush	-	ib.	Sun dew	-	369
Robin white	-	322	Shepherd's pouch	-	327
Rocket (common bastard and water)	-	337, 374	Swallow wort	-	323
Rosa, the rose, and its numerous varieties	-	368	T.		
Ros folis, sun dew	-	369	Tacamahaca, tacamahac	-	315
Rosmarinus, rosemary, and its different sorts	-	ib.	Tamarindi, tamarinds	-	308
Roots, their Natural History	-	299	Tame poison	-	323
Rubia tinctorum fativa, dyer's madder	-	369	Tamariscus, tamarisk tree, and its varieties	-	375
Rubus vulgaris fructu nigro, common bramble	-	ib.	Tartarus (tartar)	-	317
Ruta fylvestris major, greater wild rue	-	370, 376	Tanfey (wild)	-	322, 376
Rue (goats)	-	339	Tea, or thea, its various sorts	-	306
Rupture wort, smooth and hairy	-	341	Terebinthina, turpentine, and its varieties	-	313
S.			Thyme (mother of)	-	373
Sabine (sabina mas,) common, &c.	-	370	Time, the true of the antients	-	377
Saccharum, sugar	-	317	Thistle, the blessed	-	329
Saffron	-	307, 311, 334	Thrift, or sea pink	-	375
Sagapenum	-	316	Tilia, the lime, or linden tree	-	377
Sage, and its different kinds	-	363, 371	Tinctorius flos, dyer's weed	-	ib.
Salicaria, willow herb	-	371	Tithimalis, spurge	-	378
Salix, the willow tree	-	ib.	Thaseolus, kidney bean	-	359
Salvia major, greater sage	-	ib.	Tobacco, and its numerous sorts	-	354
Sambucus (common eder)	-	356, 371	Tormentila filivstris, wild tormentile	-	378
Sandaracha, gum sandarach	-	314	Touchwood, or spunk	-	318
Sanguis draconis, dragon's blood	-	ib.	Trifolium (trefoil)	-	ib.
			Throat wort	-	383

Tournefort's system of flowers	- Page 594	Vitis, the vine tree	- Page 381
Tubera fungi, cervina, &c.	- 318	Viper's grafs	- 372
Tulipa, the tulip	- 379	Vomit nut	- 311
Turmeric	- 300	Vulneraria rufica, kidney-vetch	- 383
Turpethium, turbeth	- 303	W.	
Turnips, their various uses	- 367	Wallflower (the)	- 332
Turpentine, its different sorts	- 313	Walnut tree, and its varieties	- 343
Tussilago, colt's foot	- 379	Wall pepper, or stone cramp	- 373
U. V.		Watering of plants, observations thereon	- 380
Ulmaria, meadow sweet	- 381	Weed, dyers or yellow	- 377
Ulmus, the elm tree	- ib.	Woods, their Natural History	- 305
Umbilicus veneris, navel wort	- 382	Woodbind	- 328
Urtica, the common nettle	- ib.	Worm feed	- 312
Uvularia major, throat wort	- ib.	Wormwood (common)	- 319
Uvæ passæ, raisins	- 307	Willow tree	- 364, 371
Valeriana, valerian	- 379	Wolf's bane (Roman)	- 299, 301
Valerianella, corn fallad, or lamb's lettuce	- ib.	Wortle, or bilberry	- 380
Vegetables (foreign) their Natural History	- 299	Wort (St. John's)	- 341
Veratrum, white hellebore	- 379	X.	
Verbascum, white mullein	- 380	Xyris, five iris foetida, stinking gladden or flag	- 383
Veronica mas, male speedwell	- ib.	Y.	
Vetch	- 383	Yarrow, or nose bleed	- 253
Viola, violet, and its varieties	- 380	Z.	
Vine, and its grapes, and wild	- 326, 381	Zedoary	- 303
Vincetorixicum, tame poison	- 323	Zerumbeth	- ib.
Viscum, misletoe	- 380	Zingiber, ginger	- ib.

WATERS, EARTHS, FOSSILS, and MINERALS.

The Natural History of WATERS, EARTHS, FOSSILS, and MINERALS, with a copious Introduction	- 387	Chrystals, their varieties	- Page 412 to 415
A.		Cinnabar	- 423
A BESTOS, and its various sorts	- 410	Clays, their different kinds	- 401
Acton, its mineral waters	- 394	Codfall, its mineral waters	- 398
Agate, its difference from jasper	- 431	Cobalt	- 420
Alabaster-stone	- 436, 442	Coal pit, and its mines	- 211
Alford, its mineral waters	- 397	Colurian, its mineral waters	- 391
Allum	- 418	Conchites, or petrified shells	- 469
Ambergrease and amber	- 420	Cornelian, or fardius	- 431
Amethyst, a transparent gem	- 429	Cornu Ammonis, or Ammon's horn	- 470
Amianthus, and other sorts of foffile substances	- 410	Copper, the vitrious ore, &c.	- 426
Antimony	- 421	D.	
Anthropocardites	- 472	Diamond, a transparent gem	- 427
Apyri (talcs)	- 407	Diorchites (petrifactions)	- 472
Armenian stone (the)	- 434	Dog and duck, its mineral waters	- 399
Arsenick	- 420	Dulwich, its mineral ditto	- 393
Asteria, a kind of opal	- 431	E.	
Asteriæ, or star-stones	- 473	Earths, their various sorts, as cimolian, &c.	- 401
Astroites (petrifactions)	- ib.	Eagle stone (the)	- 435
Auriculares ditto	- 472	Emerald, a transparent gem	- 430
B.		Enhydrus, a stone of the eagle sort	- 436
Bath waters, an account of them	- 390, 397	Emery, or smiris	- ib.
Belemites (petrifactions)	- 471	Enorchus, a kind of eagle stone	- 435
Berill, a bluish green gem	- 430	Entrochi (petrifactions)	- 472
Bitumen, or pitch	- 420	Euny-well, in Cornwall	- 391
Bismuth	- 422	F.	
Barnet East (its mineral waters)	- 393	Foffile substances that are not elastic, &c.	- 410
Boles, their various kinds	- 406	Fire stone	- 464
Borax	- 419	Foffile salt	- 417
Brimstone, or sulphur	- ib.	Fungites (petrifactions)	- 471
Brontia (petrifactions)	- 471	G.	
Bristol, its mineral waters	- 397	Garnets, or carbuncles	- 429
Buxton well	- 392	Geodes, a kind of eagle stone	- 435
C.		Gems of all kinds described	- 427
Carlton, its mineral waters	- 393	Gold, and gold mines	- ib.
Carbuncle (the)	- 428	Granite, red, and pale whitish	- 443
Cats eye, a particular gem	- 430	Grits, and their varieties	- 461
Cerufs, or white lead	- 424	Gypsums, a particular kind of foffils	- 410
Chalcedony, a gem	- 431	H.	
Cheltenham, its mineral waters	- 398	Hampfstead, its mineral waters	- 399
Chippenham, its mineral ditto	- 399	Harrowgate, its ditto ditto	- 392
Chryfolite, a gem, the topaz of the ancients	- 430	Hartlepool, its ditto ditto	- ib.
		Hæmatites, or blood stone	- 425, 436
		Hyacynth, a gem	- 429
		Iron	-

I.					
Jasper, and its varieties	-	-	Page 433	Petroleum	- - - Page 420
Iron, and its mines	-	-	425	Pit coals, and their mines	- - - 421
Isinglass, and its varieties	-	-	407	Pitch, or bitumen	- - - 420
				Porphyry, and its varieties	- - - 443
K.				Prassius, or prassite, a gem	- - - 430
King's-futton, its waters	-	-	395	Pumice stone	- - - 436
Knareborough, its dropping well	-	-	400	Pyriiformes (petrifications)	- - - 471
				Pyrites, flat, round, &c.	- - - 464
L.					Q.
Lachnis, and its varieties	-	-	409	Quicksilver, or mercury	- - - 423
Llandrided, its mineral waters	-	-	396		R.
Lapis lazuli, an opaque stone of a sapphire colour	-	-	434	Rock stones, their various sorts	- - - 436
Lapis Judaicus, or Jew's stone	-	-	474	Realgar, or zarnick	- - - 419
Lead, and its mines	-	-	424	Rotten stone, a sort of Tripoli	- - - 407
Lemington, its mineral waters	-	-	399	Ruby, a transparent gem	- - - 428
Loams found in beds, as the brownish white, &c.	-	-	403		S.
Loadstone, or magnet	-	-	436	Salts, their several kinds	- - - 417
Litharge	-	-	424	Sal ammoniac	- - - 419
Lythopites of Linnæus	-	-	479	Sapphire, a hard gem	- - - 429
				Sardonix, a semi-transparent stone	- - - 431
M.				Sardius, or cornelian	- - - ib.
Magnet, or loadstone	-	-	436	Sands, fine shining white, &c.	- - - 455
Marchasites, silver, gold-coloured, &c.	-	-	464	Sand stones described	- - - 436
Mardepore, of the coral kind	-	-	475	Scarborough, its mineral waters	- - - 400
Marble stone, its various kinds	-	-	440	Selenites described	- - - 411
Marles, their varieties, as samian, &c.	-	-	403	Silver, and the vitrean silver ore	- - - 426
Mercury, or quicksilver	-	-	423	Shadwell, its mineral waters	- - - 394
Metals, and semi-metals	-	-	421	Slates, and their varieties	- - - 439
Mica aurea, gold-coloured talc	-	-	408	Smiris, or emery	- - - 436
Mineral waters, the different kinds, &c.	-	-	387	Slate stone (the)	- - - 438
Mundick	-	-	425	Spars of various figures and shapes	- - - 415
Muscovy, or isinglass	-	-	407	Star stone, or astroites	- - - 434
				Stones (of the more ignoble kind)	- - - 435
N.				—— (common, circumscribed, &c.)	- - - 443
Naptha	-	-	420	Sulphurs	- - - 419
Nephritic stone (the white)	-	-	433	Sydenham Wells, its waters	- - - 393
Nevil Holt, its mineral waters	-	-	394		T.
New Malton, its ditto ditto	-	-	400	Talc, Venetian, shining black, &c.	- - - 408
New Tunbridge Wells, ditto ditto	-	-	395	Teeth, and other monstrous productions	- - - 472
Nitre	-	-	418	Tilbury waters	- - - 392
Northall, its mineral waters	-	-	393	Tin, and its mines	- - - 424
				Toad stone (the)	- - - 435
O.				Trochites (petrifications)	- - - 472
Ochres, their different kinds	-	-	404	Tripolies, yellow, reddish, white, &c.	- - - 407
Ombria (petrifications)	-	-	471	Tuberoides (petrifications)	- - - 471
Onyx stone, its different kinds	-	-	431	Tunbridge Wells, its waters	- - - 393
Opal, a beautiful gem	-	-	429	Turquoise, or Turkey stone	- - - 434
Orpiment, red, or zarnick	-	-	419		V.
Orfton, its mineral waters	-	-	395	Vitriol	- - - 418
Orites (petrifications)	-	-	472		W.
Orphomorthites (petrified stones)	-	-	471	Waters (mineral). See Mineral Waters.	
				Westwood, its mineral waters	- - - 392
P.					
Pancras, its mineral waters	-	-	394		
Pebble chrystal stones	-	-	450		
Pebble stones (the common, &c.)	-	-	452		
Petrified bodies, and the causes of petrifications	-	-	466		

THEORY of the EARTH in general.

THEORY of the EARTH in general	-	476	Earthquakes, to what causes ascribed	-	493
A.			Elden Hole, in Derbyshire	-	486
AIR, its mechanical properties, &c.	-	525	Evaporation, its nature and effects	-	537
Air-pump, its mechanism and use	-	526		F.	
Alps and Andes, a description of those mountains	-	500	Fossil shells, and other extraneous fossils	-	482
Atmosphere, its nature, causes, and effects	-	527		G.	
Aurora Borealis	-	539	Globe, an astronomical and geographical survey of it	-	477
B.			Gulph of Pluto, Ælian's description of it	-	482
Barometer, its mechanism and use	-	526		H.	
C.			Halos, or luminous circles round the moon	-	539
Chasms in the earth, &c.	-	485	Hurricanes, and rainy seasons	-	535
Cataracts, or falls of water	-	512	Hydrostatics, and other discoveries relative to water	-	
Caverns (subterraneous)	-	487		I.	
Currents in rivers	-	509	Ice, its formation, &c.	-	516
—— in the sea	-	516	Illusions of the meteor kind	-	540
E.			Inundations, and their effects	-	511, 521
Earth, a survey of its surface, &c.	-	478 to 520	Islands (new) the appearance of some	-	496
					Lakes

L.	
Lakes (salt and fresh water) -	Page 514
Luminous appearances -	516
Lunar rainbow -	539
M.	
Meteors, their Natural History -	536
—— a remarkable beautiful one -	539
Mines, an account of them -	488
Monsoons described -	533
Mountains, their formation and uses -	498
O.	
Ocean, its saltness, &c. -	513
P.	
Pen-park-hole, in Gloucestershire -	487
Pike of Teneriffe, an account of it -	501
Plague, its rise, progress, and history -	530
R.	
Rivers, their origin, &c. -	507
—— the largest in Europe, Asia, Africa, and America -	510
—— the length, breadth, and depth of ditto -	511
S.	
Sand-storms, or tempests -	535
Sea, the formation of new lands by it -	521

Sea shores -	Page 520
—— its dreadful inundations -	521
Solar rainbow -	539
Suns (mock) -	ib.
Storms, instances of remarkable ones -	537
T.	
Tides, and motion of the sea -	516
—— the greatest where found -	518
Tracts of land, the appearance of some -	496
Typhons, or land spouts -	541
V.	
Vapours, an account of them -	489
Volcanoes, their Natural History -	490
Universe, a general sketch thereof -	476
W.	
Water, its nature, properties, &c. -	503
—— manner in which it forms clouds -	536
Water-spout, account of this phenomenon -	540
Whirlpools -	519
Wind-gun, its construction and use -	526
Winds, regular and irregular -	531
—— variable and trade -	532
Z.	
Zodiack, an explanation of its twelve signs -	585

The NATURAL HISTORY of M A N.

The NATURAL HISTORY of MAN, with a copious introductory discourse - Page 543

A.	
A BSTINENCE, the benefits arising from it -	559
Age (old) and the causes of decay -	569
Americans described -	575
Arabians -	ib.
Arteries, the plate of them explained -	586
Asiatics (southern) described -	574
B.	
Beauty, ideas of it in different countries -	550
Blood; proved to circulate through the bones -	569
Brain, the plate of it explained -	587
C.	
Caffres, of the Cape of Good Hope -	574
Chinese, their Natural History -	573
Complexion, its varieties -	575
D.	
Deformity, to what causes owing -	577
Deafness, its causes -	566
Death, and the causes of decay -	571
Distance, our ideas of it how attained -	563
Dreams, the theories of them -	560
Dwarf, a complete history of one -	579
E.	
Ear, its construction and use -	566
Europeans, their Natural History -	575
Education of children -	548
Embalming, how performed -	581
Eunuchs, an account of them -	549
Eyes, their formation, use, &c. -	561
—— how objects are seen by them -	562
F.	
Feeling, the most useful of all the senses -	568
Funerals (hasty) cautions against them -	572
G.	
Greenlanders, their Natural History -	573
Growth of the human body -	547
Giants, their Natural History -	580
H.	
Hearing, remarks on that sense -	564
Human strength and agility -	555
Human race, its varieties -	572
Hunger, its nature, &c. -	557

I.	
Infancy of man -	Page 546
Japanese, their Natural History -	574
Indians, or Southern Asiatics -	ib.
L.	
Longevity, remarkable instances thereof -	570
Laplanders (Danish and Swedish) -	572
M.	
Man, his internal properties, &c. -	544
Mankind, their varieties and differences -	572
Manhood described -	550
Materiality and immateriality -	544
Monsters of the human species -	577
Mummies, a particular account of them -	581
Muscles, a front and back view of them -	586
Music, and musical sounds -	565
N.	
Negroes of Africa, their Natural History -	574
Near-sighted persons; how such see objects -	563
P.	
Passions, how expressed -	551
Portuguese, resemble the negroes -	575
Puberty, or youth -	544
S.	
Seeing, nature and effects of that sense -	561
Sensuality, its refinements -	550
Sensations (internal) not in matter -	545
Seraglio, an account of it -	549
Sight, a boy restored thereto -	563
Senses, one corrected by another -	ib.
Sleep -	557, 560
Smelling, its nature, properties, and use -	567
Soul of man, its nature, &c. -	544
Sounds, how produced -	564
Stature of men, its varieties in different countries -	576
Strength and agility in man -	555
Structure of man -	546
T.	
Tasting, the nature of that sense -	567
Tartars, their natural history -	573
Tone, a collection of successive sounds -	564
V.	
Vision, its errors how corrected -	561
W.	
Women, of their symmetry -	550

F I N I S.

DIRECTIONS to the BOOK-BINDER,

Respecting the elegant COPPER-PLATES, &c. belonging to MILLAR's New and Complete NATURAL HISTORY.

In the First place, the BINDER is desired, for the Credit of this Work, as well as of himself, not to bind up any of the Sheets while they are in the least damp.

Secondly, Take Care that the Whole is folded as even as possible.

Thirdly, Plough off but little of the Margin.

Fourthly, Beat the Work before the Plates are placed, that the Letter-Prefs may not set off on and spoil them.

Lastly, Attend carefully to the placing of the Cuts, according to the following Directions:

No.		No.	Page.
1	THE Frontispiece. To face the Title Page.	26	Naked Insects; the Amber Snail, Star-Fish, Cuttle-Fish, &c. - 283
2	Quadrupeds; the Elk, Fourmillier, &c. 41	27	Plants; Abutilon, &c. - 594
	Birds; the Flamingo, Soland Goose, &c. 179		Fishes; the Sea Eagle, Dog-Fish, &c. 212
	Fishes; the Lupus Marinus, &c. - 220	28	Serpents, Lizards, and Tortoises; the Amphibœna, &c. - 266
3	Birds; the Eagle, Guinea Hen, &c. - 113	29	Testaceous Animals; Echinodermata or Sea Urchins, &c. - 253
	Shells; Pattellæ, or Limpets, &c. - 597		Botany; Linnæan System, Orders of Flowers, Class VII. to XII. - 591
4	Quadrupeds; the Cat a Mountain, Rhinoceros, &c. - 72	30	Fossils; Class VI. VII. and VIII. of Extraneous Fossils, - 409
	Corallines; Articulated; Keratophyta, &c. 595	31	Birds; the Rose coloured Ouzel, &c. 158
5	Quadrupeds; the Dromedary, Elephant, &c. 59	32	Corallines; Vesciculated, &c. - 286
6	Natural History of Men; the Hottentot, American, &c. - 572	33	Shell-Fish; the Ribbed Musick Shell, &c. 596
	Fishes; the Needle Fish, Carp, &c. - 243	34	Botany; Tournefort's System, General Characters of Flowers, Petalodes flos, &c. 594
7	Winged Insects, Flies, Beetles, &c. 276	35	Shells; the Murex, &c. - 596
	Botany; Tournefort's Plants, Class XIV. to XXII. - 594	36	Botany; Linnæan System, the Monogynia, &c. 591
8	Birds; the Humming Bird, Jay, &c. 173	37	Fishes; the Great Square Fish, Charr, &c. 237
	Botany; Linnæan System, Monandria, &c. 591	38	Botany; Linnæan System, Orders of Flowers, Class XIII. to XVIII. 591
9	Birds; the Grey Owl, Afo, &c. - 126	39	Fishes; the Peseë Pectine, Turbot, Hake, &c. 227
	Fossils; Shells, Class IX. and X. - 483	40	Botany; Genera of Mosses, Fontinallis, &c. 595
10	Quadrupeds; the Manis called the Scaly Lizard, &c. - 95	41	Natural History of Man; the Passions, De-fire, &c. - 557
	Various Objects in Natural History; the Death Watch, Water Spout, &c. 540	42	Botany; Genera of Mosses, Lycopodioides, &c. - 595
11	Birds; the great Didapper, Dobchick, &c. 187	43	Fishes; Pogge, Porcupine, &c. - 225
	Botany; Linnæan System, orders of Flowers, Class I. to VI. - 591	44	Botany; Tournefort's System, Genera of Plants, Class VI. to XIII. - 594
12	Insects without Wings; Worms, Spiders, &c. 281	45	Botany; Linnæan System, Orders of Flowers, Class XIX. to XXI. - 591
	Microscopical Objects, Class I. Polipe, &c. 595		Quadrupeds; the Zebra, American Buffalo, &c. - 23
13	Birds; the Black Stork, &c. - 176	46	The Human Muscles; - 586
	Shells; Conchæ Cordiformes, or Heart Shells, 598	47	Quadrupeds; the Broad Tailed Sheep, &c. 28
14	Birds; the Spoon Bill, Vulture, &c. 178	48	Botany; Leaves, Orbiculated, &c. 594
	Botany; Leaves Duplicato pinnated, &c. 594	49	Serpents; Americana, or Brazilian Lizard, &c. 262
15	Shell-Fish; the Long Ear Shell, &c. 597	50	Insects; Tæniæ of the Oak, &c. 599
	Botany; Linnæan System, Orders of Flowers, Class XXII. to XXIV. - 591		The Human Muscles, - 585
16	Birds; the Carrion Crow, &c. - 138	51	Brain, - 587
	Microscopical Objects; Crystallizations, 595	52	The Pearl Fishery, - 252
17	Fishes; Gymnotus, Electricus, &c. 209	53	Zodiac, the Aries, &c. - 585
	Microscopical Objects, Class II. Vegetable Subjects, Farinæ of Plants, 595	54	Insects; Dragon Fly, Lanthorn Fly, &c. 275
18	Birds; the Oxeye, Creeper, &c. - 172	55	Whale Fishery in Greenland, 204
	Shell-Fish; the Conic Prickly Oyster, &c. 252		The Human Arteries, - 586
19	Fishes; the Gattorugine; Sword-Fish, &c. 220	56	The Human Skeleton - 585
	Botany; Genera of Mosses, - 595	57	Birds; Toucan, Spoon-Bill, Soco, &c. 141
20	Quadrupeds; the Jaquara, &c. - 70	58	Quadrupeds; Nyl-ghacé, Ocelot, &c. 71

The *Publisher* returns his most respectful Acknowledgements to the numerous *Subscribers* for their great Encouragement and Recommendations of THIS WORK, and humbly solicits a Continuance of their Favours with Respect to some of his other *New Publications* (a List of which may be seen in his *Catalogue*, or on some of the Wrappers of this Publication, &c.) assuring them, that nothing shall be wanting to render those Periodical Works in which he shall be engaged, deserving the Public Patronage. Notwithstanding printed Notices given for the Purpose, several Weeks ago, and other necessary Steps taken for collecting the Whole, yet we have not been able to procure near half the Names of our *Subscribers*. Those *Subscribers* whose Names are not in the List, will therefore excuse the Omission; and such as find any Error in Spelling, will please to observe, that the Fault is not chargeable on the *Publisher*, as he has ordered the Names, Places, of Abode, &c. to be literally transcribed from the Notes, as delivered in by the various *Bookseller, Stationers, Newsmen, &c. &c.*
