Henderson, Texas, town, county-seat of Rusk County; on a branch of the International & G. N. railroad; about 122 miles southeast of Dallas and 165 miles north by east from Houston. It is situated in an agricultural section, and the chief industries are connected with agricultural products. Its chief industrial establishments are a foundry, a pottery, and cotton-gins. The trade is in manufactured articles, live-stock, cotton, and vegetables. It is the seat of a normal college.

Hen'dersonville, N. C., town, county-seat of Henderson County; on the Southern Railway; about 21 miles south of Asheville and 100 miles west of Charlotte. It is situated in a mountainous portion of the State, but in the valleys are fertile farm lands. The chief industrial establishments are a furniture factory, a tannery, a canning factory, and a lumber yard. Apples and vegetables are among the agricultural products shipped to other markets. Hendersonville has a large number of summer guests owing to the healthfulness of the climate and the beauty of the scenery. Pop. (1900) 1,917.

Hen'dricks, Thomas Andrews, American politician, 21st Vice-President of the United States: b. near Zanesville, O., 7 Sept. 1819: d. Indianapolis, Ind., 25 Nov. 1885. He was graduated at South Hanover College, Indiana, in 1841: studied law and was admitted to the Indiana bar in 1843. In 1845 he was elected to the legislature, and in 1850 and 1852 to Congress. In 1860 he was the Democratic candidate for governor of Indiana, but was defeated. He was a United States senator 1863–9: and at the Democratic National Convention of 1868 received 132 votes for the Presidential nomination. In the same year he was again defeated for the governorship of Indiana, but in 1872 was elected. In the Democratic National Convention of 1876 he was nominated for the Vice-Presidency, but the ticket, headed by Tilden, was defeated. Hendricks was again nominated for the Vice-Presidency in 1884, however, on the ticket with Cleveland, and on this occasion was elected.

Hen'drix, Eugene Russell, American Methodist bishop: b. Fayette, Mo., 17 May 1847. He was graduated from Wesleyan University, Middletown, Conn., 1867: and the Union Theological Seminary 1869. Appointed bishop of the Methodist Episcopal Church South, in 1886, he has since made official visits to China, Japan, Korea, Mexico, and Brazil. He is the possessor of John Wesley's manuscript 'Journal' written in America 1736–7. He has written 'Around the World' (1878): 'Skilled Labor for the Master' (1900).

Hengist, hĕng'gist, Saxon founder of the kingdom of Kent in Great Britain: d. about 488. He and his brother Horsa were renowned among the Saxons for their bodily strength and the antiquity of their family, which derived its origin in a direct line from Odin. In 449 the Britons sued for aid from the Saxons against the inroads of the Scots and Picts. Under command of Hengist and Horsa the Saxons landed at the mouth of the Thames, attacked the enemies of the Britons, and defeated them near Stamford in 450 A.D. As soon as they had received reinforcements from home they sought occasion for a quarrel, and uniting with the Scots and Picts they attacked the Britons, who were forced to flee or submit to the Saxons. Some fled to Armorica (Haute-Bretagne), to which they gave their name. Hengist, who had lost his brother in the battle near Eglesford (now Aylesford) in 455 A.D., founded the kingdom of Kent. He established his residence in Canterbury. By some of our writers Hengist and Horsa are regarded as mythical personages.

Hening's Statutes, the first complete collection of the laws of any American State, including those of its colonial times, those repealed and those dropped in revision. These were the 'Statutes at Large of Virginia, 1619–1792,' in 13 volumes, published at Richmond 1809–23, by William Waller Hening, clerk of the court of chancery; Jefferson is said to have suggested the publication. It is highly valued as a historical source.

Hen'ley, William Ernest, English poet, critic, and journalist: b. Gloucester 23 Aug. 1849: d. Woking 12 July 1903. He entered on a journalistic career in London, and in 1877 became first editor of the magazine 'London.' He was then editor successively of the 'Magazine of Art' (1882–6), of the 'Scots'— later the 'National Observer'—(1888–93), and of the 'New Review' (1893–8). His first publication, 'In Hospital: Rhymes and Rhythms' (1888), was inspired by his own experiences as a patient in Edinburgh Infirmary. Its contents were subsequently included in 'A Book of Verses' (1888). A second volume of poems, 'The Song of the Sword,' appeared in 1892 (2d ed. as 'London Voluntaries' 1893). Both of these books were incorporated in the collection of his 'Poems' (1898). Later poetical works were: 'For England's Sake' (1900): and 'Hawthorn and Lavender, and Other Verses' (1901). Henley collaborated with Stevenson four plays, 'Deacon Brodie,' 'Beau Austin,' and 'Admiral Guinea' and 'Macaire.' He also edited, either alone or in cooperation with others, the following anthologies and collections: 'Lyra Heroica' (1891), an anthology of English patriotic verse; 'A London Garland: from Five Centuries of English Verse' (1895): 'Book of English Prose' (1896): 'English Lyrics, 1340–1809' (1897): 'The Works of Lord Byron' (1897): 'The Poetry of Wilfrid Blunt' (1896): and 'London Types' (1898), and was editor of a series of 'Tudor Translations.' The 'Centenary Burns' (1896–7) is an important work edited by him with the cooperation of T. F. Henderson. The fourth volume contains an elaborate estimate by Henley of Burns as poet and man, published separately in 1898. His critical work appears at its best in 'Views and Reviews: Literature' (1890), and 'Views and Reviews: Painting and Sculpture' (1901). Both as poet and critic he was prejudiced and aggressive, but keen, vigorous, and often distinguished in style. A paper on Stevenson contributed to the 'Pall Mall' in 1901 aroused much unfavorable comment by its arraignment of Balfour's 'Life.'

Henley-on-Thames, England, a market-town and municipal borough of Oxfordshire, on the Thames, 35 miles by rail west of London. The town is especially famous for its annual regatta in July, a notable event in the British sporting world. The university boat races are held on the river here, and Americans frequently take part in the various open events. Pop. (1901) 5,984.

Henlopen. See CAPE HENLOPEN.

Henna, a shrub (*Lawsonia inermis*) resembling the privet, but of the order LYTHRACEÆ. It grows in moist situations throughout the north of Africa, Arabia, Persia, and the East Indies, and has acquired celebrity from being used by the inhabitants of those countries to dye the nails of their fingers and the manes, hoofs, etc., of their horses. For this purpose the leaves are dried, powdered, and made into a paste with hot water, which imparts a yellow color, requiring renewal every three or four weeks. It is cultivated extensively in Egypt, and the powdered leaves form a large article of export to Persia and Turkey. Henna is supposed to be the *kopher* of the Hebrew, translated *camphire* in the Song of Solomon.

Hennepin, Louis, loo-ē ĕn-păṅ or hĕn'ĕ-pĭn, French Franciscan missionary and explorer in North America: b. Ath, Belgium, about 1640; d. Utrecht, Holland, about 1706. He entered a convent, and being sent by his superiors to Calais and Dunkirk, the stories he heard from the sailors inspired him with a desire to visit distant countries. At length he embarked for Canada, and arrived at Quebec in 1675. In 1676 he went to the Indian mission at Fort Frontenac, whence he visited the Five Nations and the Dutch settlement at Albany. In 1678 he was attached to La Salle's expedition, and, in company with the Chevalier de Tonty and the Sieur de la Motte, was ordered to sail from Fort Frontenac to Niagara, and there construct a vessel for navigating the Lakes above the falls. This accomplished, La Salle joined the party, and on 7 Aug. 1679 the adventurers began their voyage on Lake Erie. They passed through Lakes Erie, Huron, and Michigan, to the mouth of the St. Joseph's River, ascended this in canoes to the portage, carried their frail barks several miles by land to the Kankakee, and floated down this stream and the Iroquois to the Illinois, on the banks of which they built Fort Crèvecœur near the present site of Peoria. After a delay of two months at this place, La Salle returned to Fort Frontenac for supplies, charging Father Hennepin with a voyage of discovery to the sources of the Mississippi, which had never been explored above the mouth of the Wisconsin. Accompanied by Picard du Gay and Michel Ako, he set out in a canoe 29 Feb. 1680, followed the Illinois to its mouth, and ascended the Mississippi to the Falls of St. Anthony, which he was the first European to see, and which he named in honor of his patron saint. This was on 30 April. Arriving at the mouth of the St. Francis River, in what is now the State of Minnesota, he traveled by land about 180 miles along its banks, naming it in honor of the founder of his order, and visited the Sioux Indians, whom he mentions by the names Issati and Nadouessioux. He stayed with them three months, being, according to his own account, held in captivity, and then, meeting a party of Frenchmen who had come into the country by way of Lake Superior, returned with them to Canada, descending the Mississippi to the Wisconsin, and passing up that river and down the Fox, and so through Green Bay to Lake Michigan. From Quebec he sailed for France, where he published in 1683 his 'Description de la Louisiane Nouvellement Découverte au Sud-Ouest de la Nouvelle-France, etc.,' containing the fullest published account of La Salle's first expedition, a history of his second voyage, and of Hennepin's own explorations, with a description of the upper Mississippi. Notwithstanding the writer's vanity and fondness for exaggeration, the work is valuable. He put off his clerical dress in Holland about 1697, but to the end of his life seems to have written himself: "Recollect missionary and apostolic notary." In 1697, 10 years after La Salle's death, Hennepin published his extraordinary 'Nouvelle Découverte d'un Très-Grand Pays Situé dans l'Amérique entre le Nouveau Mexique et la Mer Glaciale, etc.,' reprinted the next year under the title 'Nouveau Voyage dans un Pays Plus Grand que l'Europe, etc.' In this work, which embodies his 'Description de la Louisiane,' written anew and enlarged, he claims to have descended to the mouth of the Mississippi, and to have been the first European who floated on that river. He gives a description of the scenery, Indian tribes, and distances along the route, with a minuteness which easily gained him credit for veracity, and explained his long silence on this important point by saying that he feared the enmity of La Salle, who had ordered him to follow a different course, and who prided himself upon his own claims as the first who descended the Mississippi to the Gulf of Mexico. Notwithstanding the utter impossibility of reconciling the dates given in Hennepin's narrative, the story obtained general credence until its falseness was exposed by Jared Sparks. (See 'Life of La Salle' by Sparks in the 'Library of American Biography.') Consult: Saint-Genois, 'Les Voyageurs Belges du XIII. au XIX. Siècle' (1867); Van Hulet, 'Notice sur le Père Louis Hennepin' (1845); Shea, 'Discovery of the Mississippi' (1852); Parkman, 'La Salle and the Discovery of the Great West'; Winsor, 'Narrative and Critical History of America,' Vol. IV. (1884).

Hen'nessey, William J., Anglo-American artist: b. Thomastown, County Kilkenny, Ireland, 1839. He was brought to New York when 10 years of age, and became a student of the Academy of Design in 1856. He paints in oil and water colors, with a preference for landscape, and draws in black and white as an illustrator. In 1863 he was elected a National Academician, and since 1870 has lived in London, England.

Hennessy, John, American Roman Catholic bishop: b. Ireland 20 Aug. 1825; d. Dubuque, Iowa, 4 March 1900. He came to the United States in 1847, and pursued his theological studies in Carondelet Seminary, near St. Louis. After serving several years as a missionary in Missouri he became professor in Carondelet Seminary in 1854, and its president in 1857. He was afterward pastor in St. Joseph, Mo.; became bishop of Dubuque in 1866, and archbishop in 1893.

Hennessy, John Joseph, American Roman Catholic bishop: b. County Cork, Ireland, 19 July 1847. He came to America in early life and was graduated at the Christian Brothers' College, St. Louis, Mo., in 1862. He was ordained priest in 1869; founded the Railroad Men's Benevolent Union 1871; established the Ursuline convent, Arcadia, Mo., 1877; and edited 'The Youth's Magazine,' St. Louis, 1880–6. He was consecrated bishop of Wichita, Kan., in November 1888.

Hen'niker, Hon. Mrs. **Arthur,** English novelist. She is a daughter of Richard Monckton Milnes (q.v.), 1st Baron Houghton, and was married to Hon. Arthur Henniker in 1882. Her books, which have had an American as well as English circulation, include: 'Sir George' (1891); 'Foiled' (1893); 'Outlines' (1894); 'In Scarlet and Gray' (1896); 'Sowing the Sand' (1898); etc.

Hen'ningsen, Charles Frederick, American military officer: b. in England, of Swedish parents, 1815; d. Washington, D. C., 14 June 1877. He joined the Carlists in Spain in 1834, and later was a follower of Kossuth in the Hungarian Revolution. He went to Nicaragua in 1856, where he distinguished himself in the defense of Granada, and in the victory at Queresma. During the Civil War he served in the Confederate army, becoming a brigadier-general. He directed the construction of the first Minie rifles manufactured in the United States. His publications include 'Eastern Europe'; 'Past and Future of Hungary'; 'Sixty Years Hence'; 'Personal Recollections of Nicaragua'; 'The White Slave'; etc.

Henri, Robert, American painter; b. Philadelphia, Pa., 1865. He began his art studies in his native city and became an instructor in the Philadelphia School of Design. He has exhibited in Paris, and his picture 'Snow' was purchased by the French government and hangs in the Luxembourg. While in Paris he gathered round him a group of pupils in his studio, and as a landscape painter did much to impress younger men with his breadth and vigor of style. While he is a landscape painter of notable attainment, his portraits also are admirable for the power of individualization and the directness which characterizes them.

Henriet'ta, Duchess of Orleans: b. Exeter 16 June 1644; d. St. Cloud, France, 30 June 1670. She was the daughter of King Charles I. Her mother fled with her to France where she was educated a Roman Catholic. Her marriage with the brother of Louis XIV., Philip of France, Duke of Orleans, was celebrated in March, 1661. Louis XIV. was desirous of detaching her brother, Charles II., from the triple alliance with Holland and Sweden, in order to accomplish his plan of obtaining possession of a part of Holland. She went, therefore, in 1670, with the court to Flanders, and, under pretense of visiting her brother, passed over to Dover, where Charles was awaiting her arrival, and there succeeded in obtaining his signature to the secret treaty of Dover. Shortly after her return she died so suddenly as to excite the suspicion of her being poisoned. Bossuet pronounced her funeral oration.

Henrietta Maria, queen of Charles I. of England: b. Paris 25 Nov. 1609; d. Colombes, near Paris, 31 Aug. 1669. She was the youngest child of Henry IV. of France. Her marriage ceremony was celebrated by proxy at Paris in 1625. On Henrietta's first arrival in England she enjoyed great popularity with her husband's subjects, but her attachment to the Roman Catholic faith, combined with her hauteur and despotic ideas as to divine right, soon dissipated these favorable prepossessions. Much of Charles' subsequent arbitrary and injudicious procedure, may be traced indirectly to the influence of his queen. On the breaking out of the civil war Henrietta proceeded to Holland, where she procured money and troops for the assistance of her husband, and afterward joined him at Oxford. She again returned to the Continent, and took up her abode in France.

Henriet'ta, Texas, town, county-seat of Clay County; on the Little Wichita River, and on the Missouri, K. & T., and the Fort Worth & D. R.R.'s; about 90 miles northwest of Fort Worth and 128 miles northwest of Dallas. It is situated in an agricultural and stock-raising region, and the building-stone quarries in the county add to the industrial wealth of the town. The chief manufactures are flour and lumber. The town has cotton-gins, grain elevators, lumber-yards, and stock-yards. The trade is chiefly in live stock, grain, flour, lumber, cotton, and building-stone. Pop. (1900) 1,614.

Hen'rotin, Ellen M., American social reformer; b. Portland, Maine, July 1847. She was educated in Europe and in 1869 was married to Charles Henrotin, Belgian consul at Chicago. In 1893 she was vice-president of the Congress Auxiliary of the World's Columbian Exposition; the same year she was decorated by the Sultan of Turkey with the order of Chafkat and made an Officier de l'Academie by the French Republic, 1899. She was president from 1894 to 1898 of the General Federation of Women's Clubs.

Henry I., king of England, surnamed Beauclerc, youngest son of William the Conqueror: b. Selby, Yorkshire, 1068; d. Rouen, France, 1 Dec. 1135. He was hunting with William Rufus in the New Forest when that prince received his mortal wound in 1100, and instantly going to London, caused himself to be proclaimed king, to the prejudice of his elder brother Robert, then absent in the Crusade. To reconcile the people to his usurpation Henry issued a charter containing concessions to public liberty, and also performed another popular act, by recalling Anselm, archbishop of Canterbury. In November 1100 he married Matilda, daughter of Malcolm III., king of Scotland. This union strengthened his party, when his brother landed an army in 1101, with a view of asserting his claim to the crown. Actual hostilities were prevented by Anselm, who induced Robert to accept a pension; and it was agreed that in the event of the death of either of the brothers without issue, the other should succeed to his dominions. He subsequently invaded Normandy, and in 1106 took Robert prisoner, and reduced the whole duchy. His usurpation of Normandy involved him in continual war, but although William, son of Robert, escaped out of custody, and was assisted by the king of France, Henry maintained possession of the duchy. His only son William was drowned in 1120 in returning from Normandy, and Henry was never seen to smile afterward. He married his only daughter, Matilda, to the Emperor Henry V., and when she became a widow married her a second time to Geoffrey Plantagenet, son of the Count of Anjou. Henry was succeeded by Stephen.

Henry II., king of England, the first of the line of the Plantagenets, b. Normandy 1133; d. Castle of Chinon, near Saumur, France, 6 July 1189. He was the son of Geoffrey, count of Anjou, and the empress Matilda, daughter of Henry I. He was invested with the duchy of Normandy, by the consent of his mother, in 1150. The next year he succeeded his father in the possession of Anjou and Maine, and by a marriage with Eleanor of Guienne, just divorced from Louis VII., king of France, annexed that province with Poitou to his other dominions. He succeeded Stephen as king of England in 1154. Although involved with his brother Geoffrey, who attempted to seize Anjou and Maine, and in a temporary dispute with France, he reigned prosperously till the memorable contest with Thomas Becket. Anxious to dominate the clergy, Henry in 1164 summoned a general council of nobility and prelates at Clarendon, which assembly passed the famous constitutions named from that place, the effect of which was to render the church and ecclesiastical dignitaries subject to the temporal authority. (See CLARENDON, CONSTITUTIONS OF.) After the murder of Becket Henry receded from his position and restored the Church to its rights. Before this matter was terminated, Henry, in 1171, undertook an expedition into Ireland, and having left Earl Richard in the post of seneschal of Ireland he returned to England — proceedings so important to the future destinies of both countries having occupied only a few months. Being an indulgent father Henry had assigned to each of his four sons a provision out of his extensive territories. The eldest son, Henry, was not only declared heir to England, Normandy, Anjou, Maine, and Touraine, but actually crowned in his father's lifetime. On paying a visit to the court of his father-in-law, Louis VII. of France, the prince was induced by the French monarch to demand of his father the immediate resignation either of the kingdom of England or of the dukedom of Normandy. This request being refused he withdrew from his father's court, and was openly supported in his claim by Louis. Henry's various gallantries, exemplified in the popular and not altogether unfounded legend of fair Rosamond, or Rosamond Clifford, also embroiled him with his queen, Eleanor, who incited her other sons, Richard and Geoffrey, to make similar claims. A general invasion of Henry's dominions was in this way concerted, and began in 1173 by an attack on the frontiers of Normandy, but the king presently subdued his opponents and entered into an accommodation with his sons on less favorable terms than they had previously rejected. Henry now employed himself in regulations and improvements which equally manifest his capacity and love of justice. He partitioned England into four judiciary districts, appointed itinerant justices to make regular excursions through them, revived trial by jury, discouraged that by combat, and demolished all the newly erected castles as shelters of violence and anarchy. The turbulence of his sons still disquieted him; but Henry, the eldest, was cut off by fever in 1183, and three years after the death of the equally restless Geoffrey occurred. Philip Augustus, then king of France, however, continued to foment the differences between Henry and his sons, and Richard was again prompted to rebel. A war followed, the event of which was so unfavorable to Henry, that he was at length obliged to agree that Richard should receive an oath of fealty from all his subjects. He also stipulated to pay a sum of money to the French king, and to grant a pardon to all Richard's adherents. The mortification of Henry at these humiliating terms was aggravated to despair when he saw the name of his favorite son John at the head of the list of delinquents whom he was required to pardon. Henry II. ranks among the greatest kings of England. His wisdom and love of justice were acknowledged by foreign potentates, who made him arbiter of their differences, and regarded him as the first prince of the age. Consult: Stubbs, 'The Early Plantagenets' (1876); Mrs. J. R. Green, 'Henry II.' (1888); Norgate, 'England Under the Angevin Kings' (1887).

Henry III., king of England: b. Winchester 1 Oct. 1207; d. Westminster 16 Nov. 1272. He was the son of John, whom he succeeded in 1216. As Henry approached to manhood he displayed a character wholly unfit for his station. One of his first false steps was to discard his most faithful and able minister Hubert de Burgh. In 1236 Henry married Eleanor of Provence, which increased the dislike which his subjects already felt toward him; for she brought a train of foreigners to the court, and encouraged her husband in extravagant courses which forced him to all kinds of oppressive exactions to raise money. He received frequent grants of money from Parliament, but always on condition of confirming the Great Charter, which had been extorted from King John. Henry at length raised the national discontent to such a pitch that the nobles rose in rebellion under Simon de Montfort, the earl of Leicester, the husband of the king's sister; and in 1258, obliged the king to sign a body of resolutions, which threw all the legislative and executive power into the hands of an aristocracy of twenty-four barons, assisted by a lower house, consisting of four knights chosen from each county. By the aid of his son Edward, Henry was gradually restored to authority; on which Leicester, calling in Llewellyn, prince of Wales, involved the kingdom in a civil war. The power of the barons was by this means partially restored; but both parties agreed to abide by the award of Louis IX., king of France. This being favorable to the king, Leicester and the barons refused to submit to it, and a battle was fought near Lewes, in which Henry was taken prisoner, and the person of Prince Edward also ultimately secured. A convention provided for the future settlement of the kingdom; but in the meantime Leicester ruled without control. To him, however, was owing the first example of a genuine House of Commons in England; for in a Parliament summoned by him in 1265, deputies from boroughs were sent, as well as knights of shires. Prince Edward at length escaped, and, assembling an army, defeated Leicester's son. The decisive battle of Evesham (1265) quickly followed, in which Leicester himself was slain. Replaced upon the throne Henry remained as insignificant as ever. He died in the 64th year of his age, and the 56th of his reign, the longest in English history, except those of George III. and Victoria. He was succeeded by his son, Edward I.

Henry IV., king of England, first king of the house of Lancaster: b. Bolingbroke 3 April 1367; d. 19 March 1413. He was the eldest son of John of Gaunt, duke of Lancaster; fourth son of Edward III. by the heiress of Edmund, earl of Lancaster, second son of Henry III. In the reign of Richard II. he was made Earl of Derby and Duke of Hereford, and while bearing the latter title appeared in the Parliament of 1398, and preferred an accusation of treason against Mowbray, duke of Norfolk. The latter denied the charge, and offered to prove his innocence by single combat, which challenge being accepted, the king appointed the lists at Coventry; but on the appearance of the two champions at the appointed time and place, Richard would not suffer them to proceed. Both were banished the kingdom, Norfolk for life, and Hereford for 10 years, shortened by favor to four, with the further privilege of immediately entering upon any inheritance which might accrue to him. On the death of John of Gaunt in 1399 he succeeded to the dukedom of Lancaster, and laid claim, according to agreement, to the great estates attached to it; but Richard retained possession of the estates. The duke, therefore disregarding the unfinished term of his exile, landed with a small retinue at Ravenspur in Yorkshire, where he was quickly joined by the Earls of Northumberland and Westmoreland, and soon found himself at the head of 60,000 men. Richard falling into the hands of his enemies, was brought to London by the duke, who now began openly to aim at the crown. A resignation was first obtained from Richard, who was then solemnly deposed in Parliament; and Henry unanimously declared lawful king under the title of Henry IV. The death of Richard soon removed a dangerous rival; yet a short time only elapsed before the nobles rebelled against the king of their own creation. The first plot, in 1400, was discovered in time to prevent its success, but an insurrection in Wales, under Owen Glendower, proved more formidable. That chieftain having captured Mortimer, earl of March, who was descended from Lionel, duke of Clarence, the second son of Edward III., and therefore the lineal heir to the crown, Henry would not suffer his relation, the Earl of Northumberland, to treat for his ransom. He thus offended that powerful nobleman, who, with his son, the famous Hotspur, soon after joined Glendower. The king met the insurgents at Shrewsbury, and a furious battle ensued, 21 July 1403, which ended in the death of Percy, and the defeat of his party. A new insurrection, headed by the Earl of Nottingham and Scrope or Scroop, the archbishop of York, broke out in 1405, which was suppressed by the king's third son, Prince John. The archbishop afforded the first example in this kingdom of a capital punishment inflicted upon a prelate. The rest of this king's reign was comparatively untroubled. Henry was succeeded by his son of the same name.

Henry V., king of England: b. Monmouth 19 Aug. 1387; d. Vincennes, France, 31 Aug. 1422. He succeeded his father, Henry IV., in 1413. His dissipated youth, and fondness for joviality and low company, gave his father much uneasiness; but circumstances occurred, even in the midst of his wildness, which showed that better principles were latent in his mind. His conduct when he ascended the throne justified the best expectations. The circumstances of France, torn asunder by the opposing factions of the dukes of Orleans and Burgundy, afforded a tempting opportunity to an ambitious neighbor, and Henry was easily induced to revive the claims of his predecessors upon that country. He accordingly assembled a great fleet and army and landed near Harfleur, 14 Aug. 1415. He took that town after a siege which so much reduced his army that he was advised to return to England by sea. But Henry determined to march on Calais, and on his way was met on the plain of Agincourt by a French army ten times as numerous as his own. A battle took place there on 25 October, in which the French host was totally defeated, with a comparatively trifling loss on the side of the English. In 1417, the liberal grants of the Commons enabled Henry once more to invade France with 25,000 men. By the famous Treaty of Troyes (21 May 1420), Henry engaged to marry the Princess Catharine, and to leave Charles in possession of the crown, on condition that it should go to Henry and his heirs at his decease, and be inseparably united to the crown of England. Henry, after espousing Catharine, took possession of Paris, and then went over to England to raise recruits for his army. All his great projects seemed about to be realized, when he was attacked by a disease which carried him off at the age of 34, and in the 10th year of his reign. He was succeeded by his son Henry VI. Henry V., as the gallant, youthful, and successful conqueror of France, is a favorite name in English history; but he was inferior in wisdom and solid policy to many of his ancestors.

Henry VI., king of England: b. Windsor 6 Dec. 1421; d. London 21 May 1471. He was crowned at Westminster in November 1429, and at Paris in December 1430. As he was not nine months old at the death of his father Henry V., John, duke of Bedford, a brother of the late king, was appointed Regent of France; and Humphrey, duke of Gloucester, another brother of the same, Protector of the realm of England, with a council at his side appointed by Parliament. A few weeks after Henry's succession, Charles VI. of France died, when, according to the provisions of the Treaty of Troyes, Henry was proclaimed King of France. But the French did not quietly submit, and a war began at first favorable to the English, but in the end, after they had been roused to more effectual efforts by the heroism of Joan of Arc (q.v.) (1428–30), resulted in the almost total loss to the English of their possessions in France. In 1453 nothing remained to them in that country but Calais. In April 1445, Henry married Margaret of Anjou, daughter of René of Provence. Two years later the Earl of Suffolk acquired the chief power in the kingdom, and was created first marquis and then duke. His government was very unpopular, which caused the people to look to the claim of Richard, duke of York. The insurrection of Cade followed, and the Duke of York was by Parliament declared Protector of the kingdom. The York and Lancaster parties were now in such a state that the sword only could decide between them; and that course of civil contention commenced, the first bloodshed in which occurred at St. Albans in May 1455, and as far as the reign of Henry was concerned, the last in the battle of Tewkesbury in 1471. When the latter took place the king was a prisoner in the Tower, where he soon after died, but whether by a natural or violent death is uncertain. Henry was gentle, pious, and well-intentioned, but weak. Eton College reveres Henry as its founder, as does likewise King's College, Cambridge.

Henry VII., king of England, first sovereign of the house of Tudor: b. Wales 28 Jan. 1457; d. Richmond, Surrey, 22 April 1509. He was the son of Edmund, earl of Richmond, son of Owen Tudor and Catharine of France, widow of Henry V. His mother, Margaret, was the only child of John, duke of Somerset, grandson of John of Gaunt. After the battle of Tewkesbury he was carried by his uncle, the Earl of Pembroke, to Brittany, to seek refuge in that court from the jealousy of the victorious house of York. On the usurpation of Richard the young Earl of Richmond was naturally turned to as the representative of the house of Lancaster. In 1485 Richmond landed at Milford Haven, where he was immediately joined by some leaders of rank, but had only 6,000 men when Richard met him at Bosworth, with an army twice as numerous in appearance; but the defection of Lord Stanley with his forces, who joined Richmond during the battle, obtained for the latter a complete victory. Henry was proclaimed king on the field of battle, and his right was subsequently recognized by Parliament. In 1486 he married Elizabeth, daughter of Edward IV., and heiress of the house of York, and thus united the claims of the rival houses of York and Lancaster. The reign of Henry VII. was troubled by repeated insurrections. The project of France for annexing the province of Brittany, by marriage with the heiress, induced Henry to declare war, but his measures were so tardy and parsimonious that the annexation was effected. He then raised large sums on the plea of the necessity for hostilities; and landing a numerous army at Calais in 1492, almost immediately accepted a large compensation for peace. The Duchess-dowager of Burgundy, governess of the Low Countries, now advocated the cause of Perkin Warbeck, a youth who gave himself out to be Richard Plantagenet, the younger of the two sons of Edward IV., supposed to have been murdered in the Tower of London, and the justice of his claim has been maintained even by some historians of a recent date. The duchess professed to be satisfied with the proofs of his identity, and acknowledged him as her nephew. He was so far successful as to secure a large following, with which he marched to Taunton; but there his heart failed him, and he fled. Captured by Henry he confessed himself an impostor, and was sent to the Tower, where he became acquainted with the Earl of Warwick, and persuaded him to accompany him in an attempt to escape. They were both retaken, and Warwick was recommitted to the Tower and Perkin Warbeck hanged at Tyburn (1499). Soon after, the king ordered the Earl of Warwick also to be executed. After a long negotiation he brought about a match between the Infanta Catharine, daughter of Ferdinand of Aragon and of Isabella of Castile, and his eldest son Arthur; and on the death of the latter, in order to retain the dowry of this princess, caused his remaining son Henry to marry the widow by Papal dispensation, an event which, in the sequel, led to a separation from the See of Rome. He married his eldest daughter to James IV., king of Scotland, from which union there ultimately resulted the union of the two crowns. His reign was, upon the whole, beneficial to his country. Being conducted upon pacific principles it put a period to many disorders, and gave an opportunity to the nation to flourish by its internal resources. His policy of depressing the feudal nobility, which proportionably exalted the middle ranks, was highly salutary; and it was especially advanced by the statute which allowed the breaking of entails and the alienation of landed estates.

Henry VIII., king of England: b. Greenwich 28 June 1491; d. Westminster 28 Jan. 1547. He succeeded his father, Henry VII., in 1509. His disposition for show and magnificence soon squandered the hoards of his predecessor. James IV., king of Scotland, having made an incursion with a numerous body of troops into England, was completely defeated and slain at the battle of Flodden Field. Henry, however, granted peace to the Queen of Scotland, his sister, and established an influence which rendered his kingdom long secure on that side. The aggrandizement of Cardinal Wolsey now began to give a leading feature to the conduct of Henry, that prelate being appointed chancellor in 1515. His favor was now sought by Maximilian I., emperor of Germany, who hoped to secure the support of England against France, and as Wolsey was at first neglected by the French king the German emperor gained his point; but when Maximilian was succeeded by Charles V., hereditary king of Spain as well as emperor of Germany, Francis found it expedient to gain Wolsey, and for that purpose entered into an amicable correspondence with them. In order to cement this new friendship the two monarchs had an interview near Calais, the magnificence of which gave the place of meeting the denomination of the Field of the Cloth of Gold (1520). Notwithstanding these indications, a prospect of the papacy being artfully held out to the cardinal by the young emperor Charles, his interest at length gained a preponderance in the English councils. The principles of the Reformation were now making rapid strides, and Henry himself wrote a Latin book against the tenets of Luther, which he presented to Pope Leo X., who favored him in return with the title of defender of the faith. After being married to Catharine for about 18 years, Henry began to feel some scruples as to the validity of the marriage, on the ground that she had previously been his brother's wife, and his scruples were no doubt increased by the fact of his having conceived a passion for Anne Boleyn, one of the queen's maids of honor. He accordingly applied in 1527 to Pope Clement VII. for a divorce, and the Pope appointed cardinals Wolsey and Campeggio to try the case. Wolsey had at first been favorable to the project of a divorce, but when he perceived the desire of Henry to marry Anne Boleyn, fearing that this marriage would result in winning over Henry to the side of the reformers, since Anne Boleyn's friends belonged to that party, he did all in his power to prolong the inquiry, until the commission was at last withdrawn, and it was decided by the Pope that the case should be tried at Rome. This procrastination on Wolsey's part led to his own ruin. Henry, disgusted at these delays, eagerly caught at the advice of Thomas Cranmer (q.v.), afterwards archbishop of Canterbury, to refer the case to the universities, from whom he got the decision desired. In May 1533 his marriage with Catharine was declared null, and as he had by that time privately married Anne Boleyn, this second marriage was a few days later declared lawful. As these decisions were not recognized by the Pope, an act of Parliament was obtained in the following year (1534), setting aside the authority of the chief pontiff in England, which was followed by another in 1535 declaring Henry the supreme head of the church. Thus was effected the great revolution by which, in ecclesiastical annals, this reign is so much distinguished. The birth of a daughter by the new queen produced a bill for regulating the succession, which settled it on the issue of this marriage, and declared the king's daughter by Catharine illegitimate. But although Henry discarded the authority of the Roman Catholic Church, he adhered to its theological tenets. While he executed Bishop Fisher and Sir Thomas More (who had been appointed chancellor after the fall of Wolsey) for refusing the oath of supremacy, he displayed an aversion to the principles of the reformers, and brought many of them to the stake. Finding that the monks and friars in England were the most direct advocates of the papal authority, he suppressed the monasteries by act of Parliament. The fall of Anne Boleyn was, however, unfavorable for a time to the reformers. Henry then married Jane Seymour, and the birth of Prince Edward in 1537 fulfilled his wish for a male heir, although his joy was abated by the death of the queen. Henry now resolved to marry again, and Thomas Cromwell, a Protestant, who had succeeded More as first minister, recommended Anne of Cleves. The marriage took place in January 1540, and Henry created Cromwell Earl of Essex: but his dislike to his new wife hastened the fall of that minister, who was condemned and executed upon a charge of treason. At the same time Henry procured from the convocation and Parliament a divorce from Anne of Cleves. He then married Catharine Howard, niece to the Duke of Norfolk, but Henry now found that his new queen, of whom he was very fond, had proved false, and on further inquiry her conduct before marriage was discovered to have been loose and criminal. She was therefore accused and brought to the block in 1542. In 1543 he married his sixth wife, Catharine Parr, widow of Lord Latimer, a lady of merit, secretly inclined to the Reformation.

Henry was succeeded by his son, Edward VI. The complete union of Wales with England, and the conversion of Ireland into a kingdom, date from the reign of Henry VIII. Consult: Histories of England by Lingard (1854–5); Froude (1870); and Green (1879 and 1884); also Brewer, 'History of the Reign of Henry VIII. to the Death of Wolsey' (1884); Dixon, 'History of the Church of England from the Abolition of the Roman Jurisdiction' (1884–91); Froude, 'The Divorce of Catharine of Aragon' (1891).

Henry I., king of France: b. 1005; d. Vitri, 4 Aug. 1060. He was the third son of Robert II. He succeeded to power in 1031. His reign was a continuous series of difficulties with the nobility and with the growing power of the clergy. His younger brother, Robert, led a revolt against him, but this he suppressed with the aid of Duke Robert of Normandy.

Henry II., king of France: b. St. Germain-en-Laye 31 March 1519; d. 10 July 1559. He succeeded his father, Francis I., 31 March 1547. He severely persecuted the Huguenots, and was involved in wars with the Emperor Charles V. and Philip II. of Spain. The Constable de Montmorency was defeated at St. Quentin (10 Aug. 1557); the Marshal de Thermes at Gravelines (13 June 1558), and the peace of Cateau-Cambrésis (3 April 1559) lost to France most of the advantages previously gained. Henry was a monarch of slight capability, despite his regal bearing.

Henry III., king of France: b. Fontainebleau 19 Sept. 1551; d. by assassination St. Cloud 2 Aug. 1589. He was the third son of Henry II. He fought, as Duke of Anjou, against the Huguenots, was elected king of Poland in 1573 and crowned 15 Feb. 1574, but in June 1574 left Poland and succeeded his brother, Charles IX., as king of France. The Peace of Beaulieu (1576), confirmed by the Edict of Poitiers (1577), granted to the Huguenots so many privileges that the Holy League was formed, seeking openly Catholic supremacy and secretly the elevation of Henry of Guise to the French throne. When all privileges granted to Huguenots were repealed by the Edict of Nemours (1585) war broke out. Henry of Navarre was victor at Coutras, while Henry of Guise drove the king from Paris. The king then caused the murder of Guise and Guise's brother, the Cardinal of Lorraine, in consequence of which the doctors of the Sorbonne absolved the people from obedience to him. He then joined cause with Henry of Navarre, with whom he marched against Paris; but in camp at St. Cloud was stabbed by Jacques Clément, a fanatical Dominican, 1 Aug. 1589. Henry III. was the last of the branch of Orléans-Angoulême of the stock of the Valois.

Henry IV., known as Henry of Navarre, king of France: b. Pau 13 Dec. 1553; d. 14 May 1610. He was a son of Anthony of Bourbon, Duke of Vendôme, and of Jeanne d'Albret, daughter of Henry, king of Navarre, and herself afterward queen of Navarre. Educated by his mother in the Calvinistic faith, he early joined, at her wish, the Protestant army of France, and served under Admiral Coligny. In 1572 he married Margaret of Valois, sister of Charles IX., and after the massacre of St. Bartholomew, which took place during the festivities in connection with this marriage, adopted the Roman Catholic creed. For the next four years he was compelled to reside in Paris, but 3 Feb. 1576 succeeded in making his escape, and after retracting, at Tours, the abjuration of Calvinism which he had made at Paris, put himself at the head of the Huguenots, and took a leading part in all the subsequent religious wars. He occupied a still more important position, when, in 1584, the death of the Duc d'Anjou, brother of the king (Henry III.), made him presumptive heir to the crown, as descended from Robert, Count of Clermont, the sixth son of Louis IX. Rejected by the Roman Catholic party and the League as a heretic, Henry found himself obliged to resort to arms to assert his claims. On 20 Oct. 1587 with an inferior force, he defeated the army of the League at Coutras. In 1589 he became king through the assassination of Henry III. (q.v.), but found innumerable difficulties in establishing his claims. His Protestant religion was brought forward by all the competitors to prejudice the Catholics against him. At the head of the opposite party stood the Duke de Mayenne. Philip II. of Spain also claimed the French throne, and sent aid to the League. Henry IV. defeated his enemies in the celebrated engagement of Ivry (14 March 1590). In consequence of this victory Paris was besieged, and Henry IV. was upon the point of compelling the citizens to surrender by famine, when the Spanish general, Alexander, Duke of Parma, by a skilful maneuver, obliged him to raise the siege. Convinced that he should never enjoy quiet possession of the French throne without professing the Catholic faith, Henry at length yielded to the wishes of his friends, was instructed in the doctrines of the Roman Church, and professed the Catholic faith, 23 July 1593, in the church of St. Denys. He was anointed king at Chartres in 1594; and entered the capital amid the acclamations of the people. He quickly brought France entirely into subjection, and concluded the war against Spain in 1598, by the Peace of Vervins, to the advantage of France. The same year was signalized by the granting of the Edict of Nantes, which secured to the Protestants entire religious liberty, and freed them from all political disabilities. Henry made use of the tranquillity which followed to restore the internal prosperity of his kingdom, and particularly the wasted finances. In this design he was so successful, with the aid of his prime minister Sully, that the national debt of 350,000,000 livres was diminished by 125,000,000, and 41,000,000 livres were laid up in the treasury. As Henry was riding through the streets of Paris he was stabbed by the fanatic Ravaillac. The great benefits which Henry IV. bestowed upon France entitle him to the designation which he himself assumed at an assembly of the Notables at Rouen in 1596, the Regenerator of France. His benevolent mind, his paternal love to his subjects, his great achievements, his heart, always open to truth, though it exposed his own faults, have preserved his memory in the hearts of the nation. To the end of his life he had to contend against the governors of provinces, Protestant as well as Catholic, who had rendered themselves almost independent under the last kings of the house of Valois. Many of the acts of his internal government show that, while he aimed at restoring the prosperity of the nation by encouraging agriculture, commerce, and manufacturing industries, he was determined by all means in his power to strengthen the authority of the crown. In his foreign policy Henry IV. revived the projects of Francis I. and Henry II. against the house of Austria, and re-established the influence of France in the Catholic states of Italy. He supported Holland in its revolt against Spain; allayed the bitterness of feeling between the Lutherans and the Calvinists, and induced them to form the Evangelical Union. Consult: Lacombe, 'Henri IV. et sa Politique' (1878); and Willert, 'Henry of Navarre and the Huguenots in France' (1893).

Henry V. (of France). See Chambord, Compte de.

Henry I., emperor of Germany: b. about 876; d. Memleben 2 July 936. He was the son of Otho I., the Illustrious, duke of Saxony, who had refused the regal dignity offered him in 912. Henry, on the death of his father, became duke of Saxony and Thuringia. He was chosen king of the Germans by the Franks and Saxons, April 919, at Fritzlar. The surname der Finkler or der Vogler (the Fowler), sometimes applied to him, did not arise until the 12th century, and is based upon the unauthentic legend that the princes who notified him of election found him at fowling. He subdued Duke Giselbert of Lorraine, and in 924 concluded with the Hungarians a nine-years' treaty of peace, with the condition that he should pay a yearly tribute. This tribute he finally refused (933), whereupon the Hungarians invaded his realm with two large armies which he defeated, the one near Göttingen, the other at Riade (Riethenburg). In 934 he waged a victorious contest against the Danes. He thoroughly reorganized the German defensive military system, built fortified cities, and fortified others. Though he did not technically possess the title of emperor, he was the real founder of the mediæval German empire, and is recognized as a wise ruler and skilful military leader.

Henry II., the Lame, emperor of Germany: b. 6 May 973; d. Grona, near Göttingen 13 July 1024. He was the last of the Saxon line, a son of Henry the Quarreler of Bavaria, and great-grandson of the Emperor Henry I. He inherited Bavaria on the death of his father in 995. On the death of Otho III. in the beginning of 1002 he laid claim to the kingdom, and was crowned at Mainz 7 June. He was for a time busily occupied in wars with Duke Boleslav II. of Bohemia, the Margrave Henry of Schweinfurt, and the Margrave Ernest of Austria. In 1004 and 1013 he was obliged to make expeditions to Italy, where Arduin of Ivrea was twice chosen king. Having thoroughly defeated his opponent, he was invested with the imperial insignia at Rome by Pope Benedict VIII. 14 Feb. 1014. His somewhat protracted struggle with Boleslav of Poland ended without any considerable success. At the call of the Pope he fought against the Greeks in lower Italy. For his zeal in the interests of the Church he was canonized by Eugenius III. in 1146.

Henry III., variously surnamed the Old, the Black, and the Pious, emperor of Germany: b. Osterbeck, Netherlands, 28 Oct. 1017; d. Botfeld 5 Oct. 1056. He was the second of the house of the Salian Franks, son of the Emperor Conrad II., whom he succeeded in the imperial dignity 1039. He had already been chosen king in 1026. He weakened the power of the nobles by keeping the great fiefs when they became vacant for himself or members of his family, or by bestowing them upon less powerful nobles than had previously possessed them. He also extended the power of the empire by forcing the duke of Bohemia in 1042, and the king of Hungary in 1044, and again in 1047, to accept their dominions as imperial fiefs. His influence was paramount in Italy, especially in the south, where the Normans in Apulia and Calabria paid homage to him as their feudal chief. On the occasion of his first visit to Italy (1046) he put an end to the contention between Benedict IX., Sylvester III., and Gregory VI. for the papacy, causing them all to be deposed, and Suitger, bishop of Bamberg, to be elected in their stead with the title of Clement II. His efforts were now directed toward rooting out the evils which were rife among the clergy, but not less toward securing the permanence of the influence of the empire over the See of Rome. Henry III. was not only a powerful ruler, but also a patron of arts and sciences. He founded numerous schools in connection with the monasteries, and built the cathedrals of Worms, Mainz, and Spires.

Henry IV., emperor of Germany: b. 11 Nov. 1050; d. Liège 7 Aug. 1106. He was the son of Henry III. He was crowned at Aix-la-Chapelle in 1054. His reign was from the first disturbed by contests with his vassals. The Saxons joined with the inhabitants of Thuringia, drove Henry from Saxony (1073), and destroyed many of the castles which he had built to overawe the inhabitants. But some churches having been destroyed by the populace, Henry accused the Saxons to the pope of sacrilege, and thus gave him an opportunity to interfere as umpire. The Saxons offered to make every satisfaction; but Henry suddenly invaded their territory with a powerful army, and attacked them 9 June 1075, at Hohenburg, on the Unstrut, where they suffered a total defeat. He imprisoned nobles and ecclesiastics, and aroused the attention of the papacy. Gregory VII. (Hildebrand), who had been elevated to the papal chair some years before, without the consent of the imperial court, eagerly seized this opportunity to challenge Henry's usurpation of the power of investing bishops with the spiritual insignia of office, and in December 1075 presented to the king a list of charges, and demanded proofs of obedience to the Church. Henry then instigated the bishops, assembled by his order at Worms, to renounce their obedience to the pope (24 Jan. 1076). Gregory, however, pronounced the sentence of excommunication against him (22 Feb.), and absolved his subjects from their allegiance, and Henry soon found himself deserted. In this state of affairs he was obliged to go to Italy and make his submission to the pope. He found Gregory at Canossa, not far from Reggio, a strong castle belonging to Matilda, countess of Tuscany, whither he had retired for security. Three days successively, in the depth of winter, Henry appeared in a penitential dress, in the court of the castle, before the intercession of Matilda obtained for him an audience of the pope (28 Jan. 1077), when he was, after all, released from the sentence of excommunication only upon submitting to the most humiliating conditions. Some of the Italian princes, who had long been dissatisfied with Gregory, and were desirous of deposing him, gathered round Henry, who was not disposed to fulfil the hard conditions imposed upon him, and offered him their assistance. The German princes, however, at the instigation of the pope, assembled at Forchheim in 1077, and elected Rudolf, Duke of Swabia, king. Henry hastened back to Germany and overcame his rival, who lost his life in battle at Merseburg, in 1080. Gregory again excommunicated Henry; but at the councils of Brixen and Mainz in 1080, he was declared deposed by the German bishops as a heretic and a sorcerer, and Guibert, archbishop of Ravenna, set up in his place, with the title of Clement III. In 1081 Henry marched into Italy to take vengeance on Gregory, and appeared at Easter before Rome. He was not able in that year, however, to pursue the siege of the city, which did not fall into his hands till 1084. He was forced by a conspiracy of the majority of the nobles, led by his son, Henry V., to abdicate at Ingelheim 31 Dec. 1105.

Henry V., emperor of Germany: b. 11 Aug 1081; d Utrecht 23 May 1125. He was the son and successor of Henry IV. He was crowned emperor in 1111. His reign was continually disturbed by troubles with the papacy. He was excommunicated no less than four times, and finally in the concordat of Worms (23 Sept. 1122) conceded the advantage to the pope. He also carried on wars with Flanders, Hungary, and Poland, and with various German nobles. He was the last of the Salic or Frankish family of emperors, which was succeeded by the Swabian house.

Henry VI., the Cruel, emperor of Germany; b. 1165; d. Messina 28 Sept. 1197. He was the son of Frederick I. (Barbarossa), was crowned king in 1169, and succeeded his father as emperor in 1190. He was involved in wars in Italy to assure his possessions there. It was during his reign that Richard Cœur de Lion, returning from Palestine, was imprisoned by Leopold of Austria and surrendered to the emperor, who exacted a heavy ransom.

Henry VII., of Luxemburg, emperor of Germany: b. 1269; d. Buonconvento, Italy, 24 Aug. 1313. He was son of the Count of Luxemburg, and was chosen king of the Romans 27 Nov. 1308, and crowned at Aix-la-Chapelle 6 Jan. 1309. In 1311 he received the iron crown of the Lombards, and 29 June 1312 was crowned emperor at the Lateran. His march into Italy at the head of a Ghibelline army (October 1310) was hailed by Dante, who did homage at some time and place unknown. His sudden death immediately after reception of the Eucharist led to the unfounded rumor that he had been poisoned.

Henry, prince of Portugal, surnamed the Navigator: b. 4 March 1394; d. 13 Nov. 1460. He was a grandson of old John of Gaunt; nephew of Henry IV. of England; and great-grandson of Edward III. His father, King João or John, who formed a close English connection by marrying Philippa of Lancaster, was the first king of the house of Avitz, under which Portugal, for two hundred years, rose to its highest prosperity and power. The career of Portugal in exploration and discovery, due to the genius and devotion of Prince Henry, his biographer characterizes as "a phenomenon without example in the world's history, resulting from the thought and perseverance of one man." Prince Henry had become one of the first soldiers of his age when, in 1420, he refused offers of military command, and undertook to direct, at Sagres (the extreme point of land of Europe looking southwest into the Atlantic Sea of Darkness), plans of exploration of the unknown seas of the world lying to the west and south. His idea was to overcome the difficulties of the worst part of that immense world of storms, that lying west of Africa, and thereby get round Africa to the south and sail to India, and China, and the isles beyond India. Every year he sent out two or three caravels; but his great thought and indomitable perseverance had yielded only "twelve years of costly failure and disheartening ridicule," when, in 1434, the first great success was achieved by Gil Eannes, that of sailing beyond Cape Bojador. Prince Henry made his seat at Sagres, one of the most desolate spots in the world, a school of navigation, a resort for explorers and navigators. His contemporary Azurara says of him: "Stout of heart and keen of intellect, he was extraordinarily ambitious of achieving great deeds. His self-discipline was unsurpassed; all his days were spent in hard work, and often he passed the night without sleep; so that by dint of unflagging industry he conquered what seemed to be impossibilities to other men. His household formed a training-school for the young nobility of the country." Consult: Major, 'Life of Prince Henry the Navigator' (1868).

Henry, prince of Prussia, German naval officer: b. Berlin 14 Aug. 1862. He is a brother of Emperor William, and married Princess Irene, daughter of the late Grand Duke Ludwig IV. of Hesse, in 1888. He succeeded Vice-Admiral von Diederichs in command of the German fleet in Chinese waters, in March 1899. In January 1902, Emperor William requested that the president's daughter, Alice, should christen the royal yacht then building in the United States. After receiving the consent of President Roosevelt, the Emperor informed the President that he had ordered his yacht, the "Hohenzollern," to be present at the ceremony, and had appointed his brother, Admiral Prince Henry of Prussia, to represent him on the occasion. The Prince arrived in New York city on 23 February and left on 12 March, after receiving many national, municipal, and social honors.

Henry, surnamed THE LION, duke of Saxony and Bavaria: b. Ravensburg 1129; d. Brunswick 6 Aug. 1195. He was the son of Henry the Proud, and the head of the Guelphs. He greatly enlarged his domains, and so increased in power as finally to become a dangerous rival of the Emperor Frederick I., Barbarossa. His refusal to support Frederick was among the chief causes of the latter's defeat at Legnano (29 May 1176). He was summoned to appear at three diets, and, having failed to attend was placed under the imperial ban (1180). Later he was allowed to retain Lüneburg and Brunswick upon condition of going for three years into exile. He was finally reconciled with Henry VI.

Henry, Alexander, American traveler: b. New Brunswick, N. J., 1739; d. 1824. He joined the Canadian expedition under Amherst against the French (1760) and when peace followed he went to Michilimackinac and engaged in the fur trade. After the massacre of the English by the Indians in that place he being one of the few survivors, remained a captive among the Ojibways at Sault Ste. Marie for 12 months, when he escaped and resumed the fur trade. In the pursuit of this business he traveled between Montreal and the Rocky Mountains. He also interested himself in the copper mines on Lake Superior and for many years made an effort to establish a company for their exploitation.

Henry, Edward Lamson, American painter: b. Charleston, N. C., 12 Jan. 1841. He began his artistic studies at the Philadelphia Academy and in 1860 went to Paris where he studied for three years under Saisse and Courbet. In 1869 he was elected a member of the National Academy. He has frequently revisited Europe for the purpose of sketching the scenery, although his specialty is domestic genre, and history. In the Corcoran Gallery at Washington is one of his most characteristic pictures, which shows his careful grouping of figures, his attention to detail as well as the stiffness of his drawing and his deficiency in the sense of color which recalls Wilkie, whose swing and movement he lacks, though he exhibits some of the humor of the Scottish master. The picture referred to is a crowded canvas of fifty figures with the title 'Initial Excursion of the First Railway Ever Constructed in New York State.' Among his historical pictures the best are 'Battle of Germantown,' owned by William Astor, 'Declaration of Independence,' owned by J. W. Drexel, and 'Reception to Lafayette.'

Henry, Guy Vernon, American soldier: b. Fort Smith, Indian Territory, 1839; d. Ponce, Porto Rico, 1899. He was graduated at West Point 1861, and went to the front in the Civil War, taking part in four years of the hardest fighting, from Bull Run to Cold Harbor. At 23 he was commissioned colonel of the 40th Massachusetts volunteers. After the Civil War he was transferred to the 3d Cavalry, and in 1874 was in Arizona. He continued his Indian campaign, though severely wounded on one occasion, and compelled to be invalided. He served through the outbreak of the Sioux in 1890, and was also on service at Porto Rico during the Spanish-American War, where he died of typhoid fever.

Henry, Joseph, American physicist: b. Albany, N. Y., 17 Dec. 1797; d. Washington, D. C., 13 May 1878. He was educated at the Albany Academy, after graduation undertook the study of chemistry, anatomy and physiology with a view to adopting the medical profession. During the years 1824–5, he contributed occasional scientific papers to the Albany Institute, his especial subjects being chemistry and mechanics, and was appointed assistant engineer on the survey instituted for a road between Lake Erie and the Hudson. In the spring of 1826 he was elected teacher of mathematics and natural philosophy in the Albany Academy and in the latter part of 1827 read a very important paper before the Albany Institute, 'On Some Modifications of the Electro-Magnetic Apparatus.' He made his first public demonstration of his magnetic discoveries in exhibiting before the Institute small electro-magnets wound with silk-covered wire. These magnets had a greatly multiplied lifting power over any that had yet been known. In this lay the essential point of his first discovery, for he was undoubtedly the earliest physicist to adopt insulated or silk-covered wire for the magnetic coil, and to employ spool winding for the limb of the magnet. He demonstrated also for the first time, by a very intelligent experiment, the difference of action in a quantity magnet excited by a quantity battery of a single pair, and an intensity magnet with a long fine wire coil excited by an intensity battery of many elements, having their resistances suitably proportioned. The first of these two forms was not capable of being employed for telegraphic purposes, while the intensity magnets with their attachments could be so applied. The quantity magnets which he exhibited caused a good deal of excitement in the scientific world. Their attractive power was at that time quite unprecedented. One of them had sufficient power to raise as much as 3,500 pounds.

Henry was the first to show that iron could be magnetized at a distance, and to invent a suitable combination of magnet and battery for the production of this result. In 1831 he made this experimental demonstration. He suspended a mile of insulated copper wire round a chamber in the Academy, and so placed a bell at one extremity of it that it was struck by the polarized armature of an intensity battery connected with the other extremity. This was the earliest example of the magnetic telegraph, for the galvanometer or needle had been the principle on which all preceding experiments had been conducted. It was not long after that he invented a machine, and finally constructed it, which is recognized as the first electro-magnetic engine with automatic pole-changer. In 1832 after repeated experiments he discovered how to give greater intensity to a magnetic discharge by the induction of a current on itself in a long spiral or helical wire. These progressive steps in magnetic science gained for him an extended reputation, and soon after the publication of the last experiment in Silliman's 'American Journal of Science' Henry was elected professor of natural philosophy in Princeton College. The discovery of the spiral or helical conductor suggested to him further experiments, and his extended researches and their results were announced by him in a paper published 1834, under the title 'On the Influence of a Spiral Conductor in Increasing the Intensity of Electricity from a Galvanic Arrangement of a Single Pair.' He supplemented these discoveries by many others, and by his experiments produced electrical combinations which were undoubtedly precursors of later relay and receiving magnets, while his demonstration of the conditions and range of induction from electrical currents, and the successive orders of induction in the passage of frictional electricity, as well as his discovery of the oscillatory nature of electricity, paved the way for that great scientific and practical resolution which was to consummate by the genius of Morse and his confrères.

In 1846 Henry was called to a new sphere of activity, in which he exhibited his usual zeal and enthusiasm. The Smithsonian Institution had just come into existence, and during the formative period of the great museum, he was appointed to be its secretary. The office did not so far engross his attention as to make him neglectful of practical work in science. He found time to investigate the acoustics of public buildings, meteorological changes of the atmosphere and methods for telegraphic transmission of meteorological observation from all points of the continent. From 1868 up to his death he was president of the National Academy of Sciences, and of the Philosophical Society of Washington from 1871, when it was first organized.

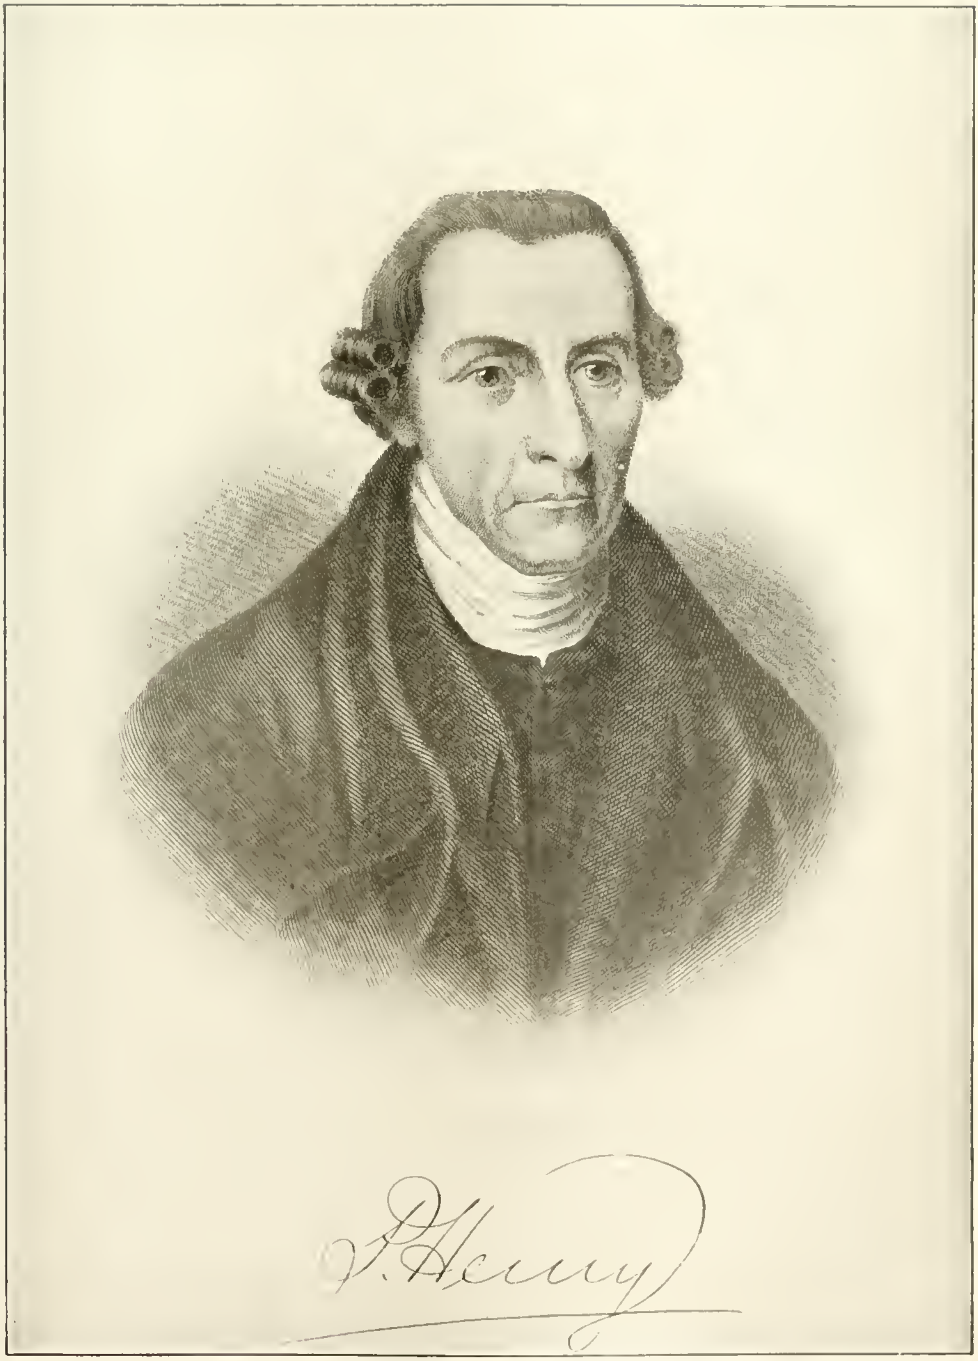
Henry, Matthew, English Nonconformist clergyman: b. Broadoak, Flintshire, Wales, 18 Oct. 1662; d. Nantwich, Cheshire, 22 June 1714. In 1686, having qualified himself for the ministry, he began to preach; and in the succeeding year he was settled as pastor to a congregation at Chester, and continued to discharge the duties of his office for 25 years, when he removed to Hackney, London, where his clerical labors were still more extended. Besides his greatest work, 'Expositions on the Bible' (1710), he was the author of 'A Discourse on Schism'; 'A Scripture Catechism'; 'Family Hymns'; etc.

Henry, Patrick, American orator and statesman: b. 29 May 1736, in Hanover County, Va., within a few miles of the birthplace of Henry Clay; d. 6 June 1799, in Charlotte County, Va. His father, John Henry, was a well-educated Scotchman, presiding judge of the Hanover court. He was a cousin of William Robertson, author of the 'History of the Emperor Charles the Fifth.' Another relative of his was Henry Brougham, the radical Scotch writer, who became lord chancellor of England. Of Patrick Henry's mother, "a portly, handsome dame," a pleasing portrait is left us by William Byrd, of Westover, the genial litterateur of colonial Virginia.

Poor as were the schools in his neighborhood, Patrick seems to have profited little by them. From his uncle, the rector of the parish, he gained a rudimentary knowledge of the classics and mathematics. He was a frolicsome and vagrant youth, fond of hunting and frontier life in general. At 18 years of age, and without money or employment, he married Sarah Shelton, a poor girl of the neighborhood. He kept a store and failed; he tried farming, and failed; then he returned to the store, only to fail again. He now turned to law, and spent a few weeks in reading upon that subject. Having received his license, he began to practise in his native county, while he assisted in the tavern kept by his father-in-law.

In 1763 Henry singled himself out as a born orator by his impassioned plea in "The Parsons' Cause." The king had annulled a statute of the Virginia burgesses, which compelled the clergy to accept the depreciated currency of the colony in payment of their annual salaries, in lieu of 16,000 pounds of tobacco as theretofore, a product which was then selling at a high price. Henry startled the court and the countryside by asserting "that a king, by annuling or disallowing acts of so salutary a nature, from being the father of his people, degenerates into a tyrant and forfeits all right to his subjects' obedience." Henry's utterance on this occasion was in keeping with the bold address, two years previous, of James Otis, who declared that the tyranny lurking in general search warrants had "cost one king of England his head and another his throne."

Henry became a member of the House of Burgesses in May 1765, just at the time of the arrival of the Stamp Act. Unabashed by his rustic appearance and inexperience in legislative matters, he brought forward a series of resolutions to the effect "that the general assembly of this colony have the only sole and exclusive right and power to lay taxes." In the bloody debate which followed he was "opposed by Randolph, Bland, Pendleton, Nicholas, Wythe, and all the old members, whose influence in the House till then had been unbroken," so we learn from Jefferson, then a college student, who was present at the session of the burgesses. In pleading the injustice of the Stamp Act, Henry used the famous words: "Caesar had his Brutus; Charles the First, his Cromwell; and George the Third ['Treason!' shouted the Speaker. 'Treason,' 'treason,' echoed others. After a moment's pause, the orator completed the interrupted sentence in a manner that showed no less defiance than adroitness] and George the Third may profit by their example. If this be treason, make the most of it." As the royal governor of Massachusetts wrote the ministry: "The Virginia resolves proved an alarm bell to the disaffected." By his intrepidity, his oratory, and his intuition, at once patriotic and prophetic, Patrick Henry became henceforth the protag-



P. Henry

onist of the colonial cause, sharing with Otis, Gadsden, and Samuel Adams the high honor of launching the American Revolution.

Henry represented Virginia in the first colonial congress, which met at Philadelphia 5 Sept. 1774, when he gave final expression to the feeling of nationality: "The distinctions between Virginians, Pennsylvanians, New Yorkers, and New Englanders are no more. I am not a Virginian, but an American." With this speech compare Christopher Gadsden's remark nine years before at the Stamp Act congress in New York: "There ought to be no New England men, no New Yorkers, known on the continent, but all of us Americans."

On 23 March 1775, Henry, as a member of the second Virginia convention, which met in St. John's Church, Richmond, moved that the colony be armed, and again electrified the patriots with his eloquence in support of this radical measure. "Gentlemen," said he, "may cry peace, peace — but there is no peace. The war is actually begun! The next gale that sweeps from the North will bring to our ears the clash of resounding arms! Our brethren are already in the field! . . . Is life so dear, or peace so sweet, as to be purchased at the price of chains and slavery? Forbid it, Almighty God! I know not what course others may take; but as for me, give me liberty, or give me death." Col. Edward Carrington, listening at a window in the east end of the church, was so transported by the eloquence of Henry, that he exclaimed, "Let me be buried at this spot," a wish that was respected at his death in 1810. Such was the universal testimony of those present as to the overmastering effect of Henry's speech at that crisis.

On 5 Aug. 1775, Henry was made commander-in-chief of the Virginia troops. In May of that year he had made a dash against Lord Dunmore, on account of the governor's secret seizure of some powder belonging to the colony. Deeming himself slighted by the Committee of Public Safety, which acted during the interim as the executive of Virginia, Henry, with some heat, threw up his military commission, 28 Feb. 1776.

Fortunate was it for the colonial cause that Henry was again at liberty to exert his forensic powers in the councils of the State. Representing Hanover County in the convention which met at Williamsburg 6 May 1776, he contributed greatly to the constructive work of that celebrated body, notably the motion for a declaration of American independence and the framing of a constitution for Virginia. Among the convention papers in the State Library at Richmond were found three endorsed by the clerk, "Rough Resolutions. Independence." William Wirt Henry, after minute comparison of the handwriting of these, concluded that the first was penned by Patrick Henry; the second by Meriwether Smith; and the third by Edmund Pendleton; and that the resolution actually introduced by Nelson was the one written by Henry. On the other hand, Edmund Randolph, who was a member of the convention, says that the resolution declaring for independence "was drawn by Pendleton, was offered in convention by Nelson, and was advocated on the floor by Henry."

On 29 June 1776, the natal day of the commonwealth of Virginia, Patrick Henry was elected governor, took the oath of office 5 July, and served for three annual terms in succession. As governor he commissioned, on 2 Jan. 1778, Col. George Rogers Clark to enlist seven companies of men for the expedition against the British garrisons in the Northwest Territory. After leaving the executive office, Henry settled in Henry County, on an estate of about 10,000 acres, called Leatherwood, where he lived until he became governor for the fourth time, on 30 Nov. 1784. In the Virginia convention of 1788, which was called to ratify the Constitution of the United States, Henry led the opposition on the ground that such a federal government encroached too far upon the rights of the several States. While the arguments of Madison and the influence of Washington happily prevailed on that critical occasion, Henry was a chief agent in securing the amendments which constitute a bill of rights in the national instrument. His objection to the Constitution was stated concisely in his first speech before the convention: "That this is a consolidated government is demonstrably clear; and the danger of such a government is, to my mind, very striking. . . . Who authorized them (the framers) to speak the language of *we the people*, instead of *we the States?* States are the characteristics and the soul of a confederation. If the States be not the agents of this compact, it must be one great, consolidated, national government of the people of all the States." Such was his clear discernment of the real nature of the government established by the Constitution of the United States.

S. C. Mitchell,
Professor of History, Richmond College, Richmond, Va.

Henry, William Arnon, American educator: b. Norwalk, Ohio, 16 June, 1850. He obtained his early education in the Holbrook Normal School at Lebanon, Ohio; studied at Ohio Wesleyan University from 1867–9, and at Cornell University from 1876–80, receiving the degree of B. S. Agr. He was appointed professor of botany and agriculture in the University of Wisconsin in 1881, professor of agriculture in 1883, director of the agricultural experiment station in 1887, and since 1891 has been dean of College of Agriculture in that university. He has had charge, from the beginning, of the agricultural college and experimental station of the University of Wisconsin, which now has buildings valued at $300,000 and 450 pupils. He has written: 'Rush's Special Report on Diseases of Cattle and Cattle Feeding' (Part II. 1892); 'Handbook on Northern Wisconsin' (1895); 'Feeds and Feeding' (1898), etc.

Henry, William Wirt, American historian and lawyer: b. Red Hill, Va., 14 Feb. 1831; d. 5 Dec. 1900. He was educated at the University of Virginia, and took up the practice of law, later being elected to the legislature for four terms. He preferred, however, historical research to his law practice, and spent much of his time in that pursuit. He was president of the American Historical Association and of the Virginia Historical Society. He is chiefly noted for his 'Life, Correspondence, and Speeches of Patrick Henry' (3 vols. 1890–1).

Henry College, a coeducational institution, founded in 1892, in Campbell, Texas. At the close of 1902 there were connected with the school 10 professors and instructors, with 150 students in attendance. The estimated value of the grounds and buildings is $125,000.

Henry Documents, 26 letters of 1809 between John Henry and several British officials — Sir James H. Craig, governor of British North America, his secretary Ryland, and the English foreign secretary Lord Liverpool, with related papers. Tempted by the hostility of the New England Federalists to the Embargo (q.v.), and the threats of secession by the extremists, Craig sent the adventurer Henry in January 1809 to sound the people as to reunion with Great Britain. Henry remained till June, and sent back the most extravagant reports of the secession feeling, but the British ministry not paying him as he thought fitting, he sold the copies of the letters and other documents to the United States government in February 1812 for $50,000. Madison used them to hurry forward the War of 1812, by sending them to Congress on March 9 with a special message, in which he accused Great Britain of attempting to dismember the Union by intrigue and annex the North to itself. So far as the New Englanders were concerned, however, the papers contained nothing incriminatory of secession movements.

Henry Phipps Institute, The, for the study, treatment, and prevention of tuberculosis, was founded at Philadelphia, 1 Feb. 1903 by Henry Phipps. The incorporators were Henry Phipps, George E. Gordon, Lawrence F. Flick, Miss Amy Phipps, and S. P. Harbison. The scientific work of the Institute is in the hands of a medical staff, consisting of a medical director, an assistant medical director, clinicians, bacteriologists, and pathologists. In the Institute's organization there are a number of paid fellowships open to any member of the staff and a number of honorary fellowships open to any person throughout the world who has done distinguished work in the cause of the study, treatment, or prevention of tuberculosis. The eleemosynary work of the Institute contemplated is the care of the consumptive poor in their homes, the care and treatment of consumptives in hospital beds, and the care and treatment of consumptives in a sanatorium. Consumptives in their homes are to be cared for and treated through a dispensary. The patients come to the dispensary where they are prescribed for and given medicines and supplies for the prevention of tuberculosis. They are instructed in preventive measures, and during the intervals between their visits to the dispensary are supervised in the carrying out of these instructions by a visitor from the dispensary. The consumptive who is entirely destitute and who cannot be cared for in his home even with such assistance as can be given is brought into the hospital and treated as a ward of the Institute. The scientific work of the Institute contemplated is education in preventive measures, study of the disease, dissemination of knowledge about the disease among physicians, stimulation of effort on the part of scientific men throughout the world, and encouragement of workers in the cause. This work is to be pursued through lecture courses, laboratory and clinical experiments, distribution of literature, organization of the workers in the cause of prevention of tuberculosis, and public receptions to persons who have done distinguished work. The Institute will seek to aid all workers in the crusade against tuberculosis. It will act as a bureau of information and with this end in view will index literature on the subject of tuberculosis and collect objects of various kinds which have a bearing upon the prevention or treatment of the disease. The Institute has inaugurated an international course of lectures by the foremost workers in the crusade against tuberculosis. One lecture a month is given during the fall and winter months. The Institute will publish annually a report of its work which will be distributed gratuitously to the libraries of the world.

Lawrence F. Flick,
Of the Henry Phipps Institute.

Henschel, Georg, gā-ōrg' hĕn'shĕl, German composer and concert singer: b. Breslau, 18 Feb. 1850. He began his musical education under the pianist Moscheles, the contrapuntist Richter, and the vocal teacher Gosse in the Conservatory at Leipsic. In 1870 he sang with great success at the Beethoven celebration at Weimar, and toward the end of the same year went to Berlin to complete his studies in musical science and vocalization. He met with a brilliant reception in his professional tour through Cologne, Düsseldorf, and the lower Rhine provinces, and his fame spread over all Germany, Austria, Holland, and Russia (1874–7). He was received with immense applause in London, and crossing the Atlantic was appointed musical director in Boston (1883–5); when he returned to London and became teacher of singing in the Royal College of Music. He wrote among his numerous compositions many songs and duets, such as 'Wanderlieder'; 'Duette in Kanonform,' 'Serbisches Liederspiel'; etc. He married in 1881 Lilian Jane Bailey (d. 1901) a well known American singer.

Hens'ley, Sophia Almon, American lecturer and author: b. Nova Scotia 31 May 1866. She studied in England and Paris, and moved to New York in 1889. She has been interested in the study of social problems and actively identified with the work of the "Mother's Congress." She has served as president of the Society for the Study of Life in New York city and as vice-president of the New York City Mothers' Club, and lectures frequently. She is author of 'Woman's Love-Letters' and 'Souls.'

Hen'son, Herbert Hensley, English Anglican clergyman: b. London 8 Nov. 1863. He was graduated at Oxford and elected fellow of All Souls College in that university 1884. He was head of the Oxford House at Bethnal Green, 1887–8, and since 1900 has been canon of Westminster Abbey and rector of St. Margaret's. He has attracted wide attention as a fresh and powerful preacher by his utterances on national topics of social and political interest, and among his published works may be noted: 'Light and Leaven' (1897); 'Cross Bench Views of Current Church Questions' (1902).

Henson, Josiah, American negro slave and clergyman: b. Port Tobacco, Md., 1787; d. 1883. His early life was one of great hardship, but he finally escaped to Canada (1828), where he became a Methodist clergyman with a charge at Dresden, Bothwell County, Ontario. He also lectured in the United States. Upon the story of his slave career was based the character of Uncle Tom in Harriet Beecher Stowe's 'Uncle Tom's Cabin' (1852).

Henty, George Alfred, English writer of novels and stories for boys: b. Trumpington, Cambridgeshire, 8 Dec. 1832; d. Weymouth, Dorsetshire, 16 Nov. 1902. He was educated at Westminster and Cambridge; he went to the Crimea during the war with Russia, and served there in the purveyor's department of the army. Soon afterward he went to Italy to organize the hospitals of the Italian legion. As special correspondent of the *Standard* newspaper he went through the Austro-Italian, Franco-German, Turco-Servian, Abyssinian, and Ashanti campaigns, besides accompanying Garibaldi in the Tyrol. He described two of these campaigns in the works 'The March to Magdala' (1868) and 'The March to Coomassie' (1874). He wrote eight novels, among which are: 'A Woman of the Commune' (1895); 'The Queen's Cup' (1897); and 'Colonel Thorndyke's Secret' (1898); but he is much more widely known as the author of a large number of stimulating stories of adventure for boys, many of them based on famous historical events. Among these are: 'The Young Franc-Tireurs' (1871), a story of the Franco-German war; 'The Young Buglers,' a tale of the Peninsular War (1879); 'In Times of Peril,' a tale of India (1881); 'Under Drake's Flag' (1882); 'The Lion of the North' (1885), a story of Gustavus Adolphus; 'With Lee in Virginia' (1889); 'By Pike and Dyke' (1889), a story of the Dutch War of Independence; 'In the Irish Brigade' (1900); and 'Out with Garibaldi' (1900).

Hepat'ica, a genus of plants, the liverworts, of the crowfoot order (*Ranunculaceæ*), closely related to *Anemone*. The best-known species is *H. hepatica*, found wild throughout North America as well as Europe in woods, and widely cultivated for its attractive and fragrant star-like blue, white, or purple-red flowers, which open in early spring. It is, indeed, the earliest of American spring flowers. Sometimes even under the snow its buds, well wrapped up in a warm down, lie upon the broad, furry liver-shaped leaves, awaiting the first warmth to induce them to open. In the southern Alleghanies its leaves are dried and steeped into a medicinal tea. A more southern species is *H. acuta*.

Hepburn vs. Griswold, 1869: the great case in which the Supreme Court of the United States decided that the government had no power to make its own notes legal tender; reversed through a change in the constitution of the court in Knox *v.* Lee and Juilliard *v.* Greenman. Mrs. Hepburn of Kentucky had given Henry Griswold a note for 11,250 "dollars," payable 20 Feb. 1862; it was not paid when due, and five days subsequently the government passed the act authorizing $150,000,000 in notes (see GREENBACKS), receivable for public and private debts. In 1864 Griswold brought suit in the chancery court of Louisville for principal and interest; $12,270 in greenbacks was tendered in settlement, but refused, on the claim that the act did not extend to debts contracted before its passage. The court decided for Mrs. Hepburn. Griswold carried the case to the Kentucky court of appeals, which reversed the decision; Mrs. Hepburn carried it to the Supreme Court, which on account of the far-reaching importance of the case, and at the request of the attorney-general, laid it over till 1868, when it was reargued, and finally decided in the December term 1869. Chief Justice Chase, for five justices against three, decided that the act extended to all debts, contracted as well before as after its passage, and that the question therefore must be whether the government had the power to make anything but coin a legal tender; that it could not do so, under the Constitution, because at the time of its adoption no money but gold and silver was recognized; that as paper money never rose above coin and almost always fell below it, each particle of depreciation was so much abstracted from the value understood by the parties to the contract, and was therefore an unlawful deprivation of private property; that the power of Congress to use "necessary means" to carry out its power of making war did not convey this right, because this was no more a special means of carrying out war powers than any other powers, and would enable it to issue bills of credit and make them legal tender just as much in the post-office business or the patent business as the war. The minority admitted that it was so impairing the obligation of contracts, but asserted that Congress was given the power to do so; and this is now law. See LEGAL-TENDER CASES.

Hephæstus, hē-fĕs'tus, a god of the ancient Greeks, identified by the Romans with their Vulcanus. He presided over fire, and was the patron of all artists who worked in iron and metals. He was the son of Zeus (Jupiter) and Hera (Juno). Homer says that his mother was so disgusted with the deformities of her son, that she threw him into the sea as soon as born, where he remained for nine years. He afterward returned, but for taking the part of his mother on one occasion against Zeus was thrown down by the latter a second time. He was a whole day in passing from heaven to earth, and fell in the island of Lemnos. He broke his leg by the fall, and ever after remained lame of one foot. He fixed his residence in Lemnos, where he built himself a palace, and raised forges to work metals. The Cyclopes of Sicily were his ministers and attendants; and with him they fabricated not only the thunderbolts of Zeus, but also arms for the gods and the most celebrated heroes. His forges were supposed to be under Mount Ætna, in the island of Sicily, as well as in every part of the earth where there were volcanoes. Aphrodite (Venus) was the wife of Hephæstus. Her infidelity is well known. Her amours with Ares (Mars) were discovered by Phœbus, and exposed to the gods by her own husband. He appears on some monuments with a long beard, disheveled hair, half naked, and a small round cap on his head, while he holds a hammer and pincers in his hand.

Hep'tarchy, seven Anglo-Saxon kingdoms into which England was at one time or other supposed to be divided, although the kingdoms were founded at different times, and at no one time were they all independent monarchies together. In 827 King Egbert of Wessex united them into one kingdom, and claimed the title King of England. See ENGLAND.

Hep'tasophs, Improved Order of, a benefit society, organized in 1878 as an independent branch of the Order of Heptasophs (q.v.). At the time of secession the Heptasophs had not adopted the benefit system. The constitution and ceremonies are identical with those of the parent order. At the close of 1902 it had 722 conclaves, a membership of 52,825, and since its organization had disbursed in benefits nearly seven million dollars.

Heptasophs, Order of, a benevolent society in the United States founded in New Orleans 1852 by Alexander Leonard Saunders, and other Freemasons, originally called "The Seven Wise Men." The ritual of its ceremonial is elaborate: the membership of each chapter is seven, or a multiple of that number. In 1872 the adoption of a death benefit system was agitated, and the discussion led to the secession in 1878 of the Zeta Conclave of Baltimore, which organized the Improved Order of Heptasophs (q.v.). In 1880 the Order of Heptasophs adopted the benefit system. Members must be white males and profess a belief in the Supreme Being. Their number in 18 States amounts to about 4,000.

Hep'worth, George Hughes, American clergyman, journalist, and author: b. Boston 4 Feb. 1833; d. 7 June 1902. He was brought up a Unitarian, and after leaving the Harvard Divinity School held Unitarian pastorates at Nantucket, Boston, and New York. He advocated preaching in theatres and conducted theatre meetings in various cities, but being not wholly at ease in the Unitarian denomination, entered the Congregationalist ministry in 1872. He subsequently quitted the ministry and became attached to the editorial staff of the New York *Herald*. He published: 'The Whip, Hoe, and Sword' (1864); 'The Criminal, the Crime, the Penalty' (1865); 'Starboard and Port' (1876), record of a yacht cruise; a book entitled '! ! !'; 'Rocks and Shoals'; 'Brown Studies'; 'Hiram Golf's Religion'; 'They Met in Heaven'; 'Through Armenia on Horseback' (1899). Consult S. H. Ward, 'George H. Hepworth: the Story of his Life' (1903).

Hera, hē'rā or -rē, a mythological goddess of the Greek pantheon, identified by the Romans with their Juno, the sister and wife of Zeus (Jupiter), and daughter of Kronos (Saturn) and Rhea (Cybele). The poets represent Zeus as a faithless husband, and Hera as a violent, jealous and vindictive wife. She was worshipped in all Greece, but her principal seats were at Argos and at Samos. The companions of Hera were the Graces and Hours. Iris, a personification of the rainbow, which seems to stretch from heaven to earth, was her messenger. Her usual attribute is a royal diadem. The temples built in her honor were called Heræa. The principal one was at Argos, which city was considered to be especially under her protection. She is represented by Homer as taking the part of the Greeks in the Trojan war, being actuated by revenge for the slight passed on her by the Trojan Paris, who gave the golden apple inscribed "To the Fairest" not to her, but to Aphrodite.

Her'acles. See HERCULES.

Heracli'tus, Greek philosopher: b. Ephesus, who flourished about 513 B.C. He traveled in different countries, particularly in Africa. On his return to Ephesus he was offered the chief magistracy, but refused it. He left a work on nature, in which he treats also of religion and politics. Some fragments only of this work remain. He is considered as belonging generally to the Ionic school of philosophers, though he differed from it in important particulars. He considered fire as the first principle of all things, describing it as an ethereal substance, "self-kindled and self-extinguished," from which the world is evolved (not made) by a natural operation. It is also a rational principle, and the source of the human soul. Phenomena exist in a constant state of flux, always tending to assume new forms, and finally returning again to their source.

Heraclius, hĕr-a-klī'ŭs, Roman emperor of the East, from 610 to 641: b. Cappadocia about 575 A.D. He was the son of Heraclius, exarch of Africa, who had gained great renown by his victories over the Persians, the elder Heraclius of the East was applied to by a powerful body of insurgents to claim the throne for himself. This he declined, but sent his son Heraclius to do so. Heraclius the younger therefore ascended the throne, and though he undoubtedly possessed considerable talents, the Roman Empire in the East was tottering to its fall, and nothing he was able to do could save it. Before his death Mohammed had carried his victorious arms on every side, and Syria, Palestine, Mesopotamia, and Egypt had fallen under the dominion of the caliphs. He was permitted, however, to die in peace, and to transmit the succession to his son, who mounted the throne under the title of Constantine III.

Heraldry is the whole group of ceremonial duties discharged by the heralds of a court, an army, a great noble, or the like, with the assistance of their pursuivants, and under the direction of the Earl Marshal, King-at-Arms, the College of Arms, or other chief of the confraternity. These duties are generally divisible into heraldry proper, or the business of regulating ceremonial occasions such as coronations, marriages among princes, proclamations of important events, and the like; and armory, or the art or quasi-science of armorial bearings. In the first of these divisions but little remains of any interest at the present day, for only in Great Britain is the herald of any consequence. There, however, he still has some direction, as at the eventful proclamation of 1 Jan. 1877, when the Queen of Great Britain assumed the title of Empress of India. In the second branch of the subject, the order and marshaling of arms, the Germans are perhaps at the head of modern writers, though the English and Scottish treatises on the subject are more numerous and more widely used. The Germans' thoroughness of investigation has marked their treatment of this subject, which is eminently a branch of mediæval and subsequent history serving to elucidate genealogical research.

Modern heraldry is no older than the tournaments of the Middle Ages. No linking evidences of the science occur during the Dark Ages, although badges and emblems are found on shields and helmets discovered in the ruins of antiquity, while in Biblical times the men of Israel were directed to pitch their tents, every man by his own camp and standard with the ensigns of his father's house. Greek and Roman writers describe devices on shields and helmets; the golden eagle on the shields of the kings of Media; the standards and brilliantly colored shields borne by the ancient Germans in battle. The office of herald is as ancient as that of priesthood. Spartans, Greeks, and Romans had heralds, the Roman officers being divided into three classes: *caduccatores*, heralds of peace; *fetiales*, heralds of war and peace; and *præcones*, judicial criers or messengers. The *caduceator* on a mission carried a wand of laurel or olive (*caduceus*, q.v.), as a symbol of his office and for his security. The *fetiales* are thought to have had a college of 20 members founded by Numa, who formulated the procedure and ceremonies connected with the declaration of war and the making of treaties. The *præcones* were employed to proclaim matters of public interest to the people at religious ceremonies, in the *comitia*, at public sales, judicial trials, in the senate, on the publication of laws which they read, at funerals, at games, in the army when a general wished to address his men, at executions, and at all public meetings. The heralds of the Middle Ages had duties which in part resembled those of the heralds of antiquity. Thus, they carried messages of peace and of defiance, and yet even in the earlier years of feudality their office was an inferior one, they being replaced by ambassadors, diplomats almost in the modern sense, statesmen in whose suite the heralds and pursuivants went to the foreign court. So it was that the chief duty of the herald came to be the care of armories.

The first known tomb or monument with escutcheons in the period of modern history is stated to be the eleventh century tomb in the Church of St. Emmeran at Ratisbon. where are the bearings of Varmond, a count of Vasserburg; but this may be a later addition. Another very old specimen and certainly genuine is the shield at Le Mans of Geoffrey Plantagenet, who died in 1150. The use of coats of arms seems to have first become general in the 12th century. Rolls of arms in England are extant in the reigns of Henry III., Edward I., and Edward II. Surcoats displayed armorial bearings in the reign of Henry III. The Roll of Caerlaverock, a poem in Norman-French, contains the names and armorial bearings of the knights and barons who attended Edward I. at the siege of the Castle of Cærlaverock, Dumfriesshire in 1300, and exhibits heraldry already in a developed form. On coins also, no armorial ensigns are found till the 13th century; but then both coins and the seals of nobles and monasteries display them; the use of arms on the Great Seal of England was introduced by Richard I.

The study of armory became essential when at mediæval tournaments aged knights were appointed, whose duties were to act as arbiters, and to pass judgment on coats of arms and the right of knighthood. Whenever a new knight appeared at a tournament, the herald had to *blasen* — that is to blow — the trumpet, and proclaim and explain the bearing of his shield or coat of arms. Hence to blason (*blasen*) came to mean, to describe and explain a display of bearings. The heralds were also the chroniclers of the times and were present on all occasions of public ceremony. In France the first herald — *roi-d'armes* — was crowned and consecrated with religious ceremonies, and was called *Montjoie*, from the war-cry of the French royal armies. The heralds were united in associations, and their duties formed a branch of science which was communicated only to the members. If any person pretended to the character of a herald, who on examination was found not to belong to the corporation, he was driven away with insults and frequently with violence. The heralds in modern courts are masters of ceremonies. In England there are now three kings at arms; the highest is the Garter king at arms; the second, known as *Clarencieux*, is for the southern counties; the third, styled *Norroy*, for the northern provinces. These three kings at arms with six subordinate heralds and four pursuivants form under the presidency of the Earl Marshal, always the Duke of Norfolk, the herald's college or herald's office, established in 1340. The use of arms by private persons in the British Isles was forbidden by proclamation in the reign of Henry V. All persons who had not borne arms at Agincourt were prohibited from assuming them unless by hereditary descent, or with the sanction of the constituted authorities. Periodical circuits called visitations were held afterwards by the provincial heralds to take cognizance of the arms, pedigrees, and marriage of such as were entitled to the use of armorial bearings. These visitations continued till about the end of the 17th century; their records, many of which are preserved in the British Museum and elsewhere, contain much genealogical information and are still consulted for evidence of the hereditary right to bear arms.

The practice of *blazoning the arms* is frequently referred to in the poetry of the Troubadours of the 12th and 13th centuries. Those knights who asserted a right to appear at tournaments did so by the blazoning of their arms, and from the Germans this custom was transmitted to the French, for tournaments were held in Germany before they became general in France. The French, however, carried to far greater perfection the tournament, and the blazon of heraldry connected with it, as they did the whole system of chivalry; the French language prevailing at the court of England after the Norman Conquest, pure French expressions came to be preserved in British heraldry. German heraldry, on the contrary, contains almost pure German expressions.

The whole display of any person's arms is called an achievement, also spelled atchievement. Only the escutcheon, however, is of vital importance. This is the broad surface upon which the bearings are charged. It is always assumed to be a shield in the case of a man not an ecclesiastic; but churchmen's arms are charged upon an oval or other architectural form, a sort of cartouche, and women's bearings are charged upon a lozenge set vertically. The arms of husband and wife, however, may be charged on a shield divided vertically in the middle, and are then said to be dimidiated or impaled; thus we might say that such an escutcheon bears the arms of Smith impaling the arms of Jones — Smith and Jones standing for the two spouses. It is rare to charge the wife's arms unless she was an heiress, that is to say, the owner of real estate in her own right. These rules, however, are those of Great Britain; they differ widely in other countries.

A single escutcheon may be complete with one simple division. Thus, a horizontal line divides the chief or top of the field at one third of its height from the remainder of the field. If that chief is, say, of gold, while the rest of the field is blue, that by itself makes a very respectable and honorable heraldic statement. The chief is one of the honorable ordinaries, and others are almost as simple. They are the pale, the vertical stripe in the middle of the shield and one third of its width; the fess, a horizontal stripe; the bend, which goes diagonally from the left hand upper corner to the right hand lower part, stopping against the rounded border of the shield; the bend sinister, which is a bend turned the other way (but see below, dexter and sinister); the chevron, which is a pair of stripes meeting in the middle, forming a figure like the letter A without the cross-bar; the cross, the two arms of which are usually of one quarter the width of the escutcheon; and the saltire, which is a diagonal cross. A shield upon which there is any one of these honorable ordinaries and nothing else, is most respectable. In general the simpler shields are the older; thus the old family Erskine, with a black pale on a silver field, or the family of Beauchamp with a gold fess on a red field, occupy the most enviable position in having such a plain escutcheon. There are ordinaries of the second rank, such as the quarter or canton, the orle, and besides these there are very many bearings in common use, especially those which are diminutives of the honorable ordinaries. Thus, the pallett is a smaller pale, and the shield of Aragon has four red palletts side by side on a gold ground. These again may be used to charge upon the greater ordinaries. Thus, the escutcheon of Loreyn bears a blue bend sinister on a gold field and the bend itself is charged with three golden six-pointed stars. That also is a simple and presumably ancient armory.

In describing the escutcheon the side on the left of the spectator is called the dexter and that on his right is called the sinister side; that is because the shield, when carried on the arm with the man-at-arms behind it would be to him so disposed. The escutcheon is supposed to be divided into a certain number of imaginary points or divisions for the fixing and placing of the bearings when they are described in words. When there are nine points, the three at the top following each other from the dexter to the sinister side are dexter chief, middle chief and sinister chief, and a similar nomenclature is used throughout. A modern and fuller arrangement is to give eleven points, the honor point interposed between the top horizontal row and the middle one; and the nombril point spaced between the middle row and the lowermost one. A small bearing as a mullet (a five-pointed star) may be located as being in the dexter chief or the like.

The main business of armory is to present simple patches of bright colors which can be recognized at a great distance. The tinctures used in Great Britain are nine — two metals, *or* and *argent* (gold and silver); five colors, *gules* (red); *azure* (blue), *sable* (black), *vert* (green), *purpure* (purple); though this last is very rare and green is not very common. There are also two furs, which are represented by curious conventional patterns supposed to represent the patchwork of small skins sewed together which make a garment or the lining of a garment. These furs are ermine and vair, but each has many curious variations known by different names. Thus "ermine" shows black tails on a white field, or in modern times a flower-like pattern suggested by the real ermine; but erminois has the same pattern in black on a gold field.

Dimidiation and impaling, mentioned above, are varieties of the great general subject of marshalling. The more elaborate form of marshalling is to divide an escutcheon into quarters. Thus, the son of a married pair who have borne their arms impaled, may divide the escutcheon into four quarters and will put his father's arms on the first and fourth quarters (dexter chief and sinister base) and those of his mother on the second and third quarters. This quartering may be quartered again, and so on indefinitely. Thus, the escutcheon of the Prince of Wales during the reign of Queen Victoria (of him who is now King Edward VII.) is too elaborate to describe fully here. This is because his bearings as Duke of Rothsay, Lord of the Isles, Duke of Cornwall, Baron Renfrew, and the like are all charged together, so that the number of small subdivisions is remarkable. Now, there are different ways of charging these. Those which his escutcheon must bear are the royal arms of England differenced (see differencing above) with the label of the heir apparent, which is a label of three points *argent*, and this escutcheon will bear in the middle a small shield with the arms of Saxony. Even in this the inescutcheon is out of place when we are considering his arms as heir to the crown. It is held by many that the Prince of Wales should display two shields; the first as simple as possible, with only the quarters for England, Scotland, and Ireland; while the second should display all his primary and secondary arms, including those of his wife, who, in the case assumed above, was the Princess Alexandra of Denmark. Again, a system is adopted by which a large shield bears those royal arms upon it, an inescutcheon with the secondary arms of Cornwall, Rothsay, Chester, Dublin, Lordship of the Isles, Carrick, Renfrew, Wales as a principality, and over all a small escutcheon of pretense charged with the arms of Saxony for Saxe-Coburg-Gotha. But even these do not include the arms of the Princess, his wife, which should rightly occupy the sinister side of the shield, while all the achievement described above should be charged upon the dexter side. It is evident, then, that a person whose family has formed many dignified alliances may have an indefinitely great number of quarterings. But let us take the escutcheon of a king of the House of Hanover, as George IV., and we shall find that the four quarters of the shield are filled in this way: the first quarter (dexter chief) in *gules*, bearing three lions *passant gardant*, and the fourth quarter (sinister base) exactly the same. These two quarters are England. The second quarter (sinister chief) is Scotland, a field *or* with a lion *rampant gules*, framed in a *bordure fleur-de-lisée*, also gules. The third quarter (dexter base) is Ireland, the Irish harp *or* on a ground *azure*. Upon this shield is set an inescutcheon, divided in a curious way into three parts, for Hanover, and having above it a royal crown. Upon this inescutcheon is still a second inescutcheon, very small, simply *gules* with a bearing *or*, which is supposed to stand for the imperial crown of Charlemagne, this in commemoration of the electoral dignity of the sovereign of Hanover, who was called the elector until after the Napoleonic wars. It is a rule never to place metal upon metal or color upon color. Thus, if your shield is argent, any bearing put upon it must be in one of the colors — never in *or*. But there is one curious exception: that of the Latin Kingdom of Jerusalem (which lasted only from 1099 to 1187, but which is perpetuated by the addition of its bearings to many private shields) was *argent*, a cross potent between four crosses *or*. This means a large gold cross, at the end of each arm of which is a cross head like the handle of a crutch; and in the little corners left by the cross, four small Greek crosses: all these in gold on a silver ground.

No two persons should bear the same arms at the same time, therefore a distinction is made between the escutcheons of younger children. Even the heir may distinguish his bearings from his father's by a special mark, apart from the quartering described above. The term marks of cadency is used for these distinctions. Many different plans have been followed, and one which has been much accepted is the label. This is a band with pendant strips hanging from it, usually three; and this is laid right upon the escutcheon near its head, and crosses it, partly concealing all the bearings. This label will be plain for the oldest son, differenced by a bearing like a crescent, *or*, a mullet for the second son, another bearing for the third son, and so on.

The practical functions of the herald developed into blazoning, historifying, passing judgment on, and marshalling coats of arms. Blazoning is the methodical description of a bearing. In the first place the shield is described according to its tinctures, figures and partitions. The inferior parts of an escutcheon are then blazoned — the helm with its insignia which are trumpet, wings and plumes, men and animals, or their members; then the wreath and its tinctures; after which the coronet, cap, etc.; finally the supporters, the mantle, the device and other secondary addenda. To historify in heraldry is to explain the history of a coat of arms, its origin, and the changes it has undergone. If the herald is to explain a bearing historically, he must show that this figure is the proper emblem of the family or country. He derives, for instance, from historical sources the proof that the double-headed eagle of the German king was first introduced in the beginning of the 14th century under Albert I., and that previously from the time of Otho II. the royal eagle had but one head; and he records the privilege given to wear that eagle on a private escutcheon. So he shows that the three leopards (lions passant gardant) in the English arms were first derived in 1127 under Henry I. from the Norman house. The marshalling of arms is especially important in the preparation of new escutcheons. In this matter, the herald either follows the orders of the sovereign, or he invents the idea, and makes the plan of the escutcheon according to his own judgment, or he composes a new escutcheon from several coats of arms.

When color is not used, a system of conventional expression is substituted; thus, *argent* is plain white, *or* is white with black dots, *azure* by horizontal black lines on white, *gules* by vertical black lines, *sable* by crossing black lines horizontal and vertical, *vert* by lines from the dexter chief to the sinister base, *purpure* by lines from the sinister chief to the dexter base. The furs have peculiar patterns and surfaces of their own.

The crest is the highest part of an achievement of arms and is set above the escutcheon. It is called crest from the Latin word *crista*, which signifies a comb or tuft, such as many birds have upon their heads. Crests were anciently marks of honor, because they were worn only by heroes of valor and high rank that they might be the better distinguished in an engagement, and thereby rally their men if dispersed; or else they were of the nature of badges worn by all the followers of a chieftain and serving to identify them. They are at present considered as mere ornaments; and they may be assumed without authority; obviously they should not be used by women. Supporters are figures placed on each side of the shield and perhaps originated from the custom of pages in fantastic dresses guarding the achievements of arms of their masters while the latter were taking part in the exercises of the tournament. The scroll is an ornament usually placed below the shield and supporters, containing a motto or short sentence alluding to the crest, or to the bearing or to the bearer's name. The motto had its origin in the war cries of knights, though in some instances mottoes were borne differing from the war cry of the wearer. The badge is not subject to heraldic rule, though it may be a part of the heraldic achievement, used separately. The porcupine was the badge of Louis XII. of France, and the salamander was chosen by Francis I. when he came to the throne, but neither of these was included in the escutcheon or worn as a crest. The reader may consult Palliser, 'Historical Devices, Badges and War Cries' (London 1870). The most recent large and important book on heraldry in English is 'The Art of Heraldry,' by Arthur Charles Fox-Davies, which is based upon the Heraldischer Atlas of H. G. Ströhl. An excellent book for persons who are making a serious study of the matter is Berry's 'Encyclopædia Heraldica,' in three volumes, n. d. (about 1820). The treatise on Heraldry by Woodward and Burnett, two volumes, 1892, is a very full and up-to-date manual. Smaller books are numerous. To name English ones alone Cussan's 'Handbook of Heraldry,' Planche's 'The Pursuivant at Arms,' Worthy's 'Practical Heraldry,' and especially Charles Boutell's two books, 'English Heraldry,' second edition, 1871, and the very remarkable essay, 'Heraldry, Historical and Popular,' third edition, 1864, now scarce, but nevertheless the most suggestive book that can be found.

Revised by RUSSELL STURGIS.

Herat, hĕr-ăt'. Afghanistan, a city in the northwest near the Heri-Rud River, about 370 miles west of Cabul. It is enclosed by a broad deep moat and an earthen mound surmounted by a lofty wall of unburned brick, and defended by a strong citadel. The caravansaries, public baths, and mosques are numerous. The trade, almost entirely in the hands of Hindus, is greatly favored by the situation of the town on the great thoroughfare from India westward. Herat was long the capital of the empire founded by Tamerlane, and was once much larger and more splendid than now. Its possession has been repeatedly contested among the peoples of central Asia, and, being regarded as a key to Afghanistan on the side next Persia and Russia it is of great importance politically. Its capture by Persia in 1856 led to a short war between Britain and Persia. Pop. about 45,000.

Herault de Sechelles, sā'shĕl, **Marie Jean,** French revolutionist: b. Paris 1760; d. there 1794. He became imbued with the teachings of Diderot, but, after his election to the Legislative Assembly in 1791, being rather a philosopher than a revolutionist, he at first paid little attention to the radical element there. He soon, however, joined the extreme left, and later on supported Danton in the revolution of August and September 1792. He was a deputy from the department of Seine-et-Oise to the Convention of 1792 and voted for the king's death. He became a member of the Committee of Public Safety, and as such gained the enmity of Robespierre, who claiming that he had betrayed certain secrets to the army of the Rhine, caused him to be arrested and executed. His best writings were published under the title 'Voyage à Montbard' (last ed. 1890).

Herb Paris, a poisonous plant of the lily family (*Paris quadrifolia*), resembling and related to white hellebore (q.v.), the toxic principle of which is a specific alkaloid called paradin.

Herbarium, a collection of dried plants, leaves, and fruit or seeds, arranged for preservation between sheets of bibulous paper; it is sometimes called *hortus siccus,* "dry garden," and is an indispensable adjunct to the apparatus of the systematic botanist, and microscopist. The most famous public herbariums are those of Kew, London; those of the British Museum and the London Linnæan Society. Those in Paris, Leyden, Berlin, and Vienna are also very full and complete.

In the United States there are three herbaria both copious and of the first order, namely, the Gray Herbarium of Harvard University, the Herbarium of the New York Botanical Garden, and the United States National Herbarium at Washington. The first named contains a vast majority of the older types of American plants, and the last contains the material brought together by the government collectors and many of the most important collections of the early Government surveys. There are also important collections at the Missouri Botanical Garden (Saint Louis) and the Field Columbian Museum (Chicago).

Herbart, Johann Friedrich, German philosopher: b. Oldenburg, 4 May 1776; d. Gottingen, 11 Aug. 1841. His career is evidence of the fact that at least some men may live peaceful lives in stormy times. A student at Jena under Fichte, a tutor in Switzerland, a docent at Göttingen in the theory of education, and after that a professor to the end at Göttingen, at Königsberg, and finally at Göttingen again,—that is the story of his life. But if he took no part in the revolutionary tumults that afflicted his country, he at least became a leader in her intellectual contests. His metaphysics stands at the opposite pole from that of Hegel. His psychology laid the foundations for modern psychophysics and experimental psychology, while his pedagogics is still the source of much of our best educational theory and practice.

Metaphysics.—The turning point between Herbart and Hegel lies in the use to be made of the principle of contradiction. Herbart took the orthodox stand that what contradicts itself cannot be truly real or actual, whereas Hegel boldly incorporated the principle of contradiction as a stage in what might be called his dialectic of evolution, which follows the formula, thesis, antithesis, synthesis. The antithesis is the contradiction of the thesis, but only that the two may come together again in a higher synthesis. A familiar illustration is the relation of (1) being, (2) non-being and (3) becoming, in which the second is thought as the contradiction of the first, while the third is conceived as a higher synthesis of the first two, since becoming has elements both of being and of non-being. Herbart, however, rejects such reasoning as insufficient, and demands that philosophy shall accept the validity of the principle of contradiction, and honestly endeavor to remove the contradictions inherent in our everyday thought of the world. Such contradictions are encountered when we consider a thing and its attributes or the ego, which is both subject and object, or when we trace experience back to matter, in which the notions discrete and continuous are seen to be at variance. The effort to remove the contradictions leads Herbart back to a pre-Kantian method of speculation, for he holds himself ready to accept any sort of a presupposition, rational, or irrational, which promises to resolve the difficulty, even though the principle of explanation should forever resist demonstration as to its reality. In other words, we may assume anything to be true which clears up our thinking. But this is the method of Leibnitz, of Spinoza, and of many others antecedent to the time of Kant (q.v.). The fundamental form in which contradiction appears is that the simple is conceived as manifold. For example, the thing we call water is at the same time thought of as heavy, fluid, colorless, having the quality of quenching both fire and thirst, and as being capable of transformation from a liquid to a solid or to a vapor. The way to overcome this contradiction is to assume a plurality of simple beings, and to explain the manifold as appearances arising from their relations. These simple beings that underlie the phenomenal world are atoms, or monads, or as Herbart prefers to call them, *Reals.* They are conceived to be in mechanical interaction, and to give rise to the manifold we have in experience. Like the atoms of Democritus they are simple and alike in quality, but unlike the monads of Leibnitz they are not points of self-active force, containing an inherent principle of development. Why and how the *Reals* act and interact Herbart does not explain, not even how they get and exercise their one function of *self-preservation.* The inability to explain these things which we most want to know is the penalty attached to this type of metaphysics. Yet it would be unfair to assume that no good results can come from even such pre-suppositions. *The Reals* are not spatial in the ordinary meaning of that term, for space and time as we know them are themselves phenomenal products, but they may be conceived to be in what Herbart calls *intelligible* space, in which the *Reals* exist in a state of partial or total interpenetration. Here they reciprocally "disturb" one another, a "self-preservation" resulting, which is a "state" of the *Real.* When the *Real* which is "disturbed" happens to be a soul, the disturbance, or the state of self-preservation, becomes an *idea,* which is the primary form of mental life. Psychology is, therefore, the science of these self-preservations of the soul-monad, which is like all *Reals* unknowable, but as Herbart thinks a necessary presupposition of our experience. Psychical life is the reciprocal tension of ideas. Consciousness depends upon the degree of this tension. The lowest degree of strength which an idea can have and still be actual marks the threshold of consciousness. If reduced below this degree it remains as "*impulse,*" and may rise again when freed from "*arrest.*" The soul monad has its seat in the brain and is in intimate interaction with a multitude of other *Reals.* Outwardly originating stimuli are conveyed to the brain by the nerves and reach the soul through the medium of the other *Reals* present. Since the idea is the primary form of mental life, feeling and volition must be explained through an examination of the inhibitory relations of the ideas. Pleasure arises when there is a furthering of mental movement, and pain when there is an arrest. Volition arises from desire, a state of feeling, which has a natural impulse to find satisfaction through action. Since mechanical action and reaction of the *Reals* is the source of ideas, it seems a natural conclusion that there may be a statics and mechanics of mental states. This led to Herbart's attempt to work out the calculus of ideas, thus opening the road for the modern quantitative study of mental phenomena, as seen in psychophysics and experimental psychology. Herbart claims to have founded psychology anew upon metaphysics, mathematics, and experience. The third of these bases is treated under the term *apperception,* which has important results for education.

Apperception.—Leibnitz, who introduced this term, employed it in a double sense. Its first meaning is the original power of the mind to unify experiences originating in sensation; this is the sense in which Kant uses the term. The second meaning is the mental assimilation that takes place when we use knowledge already acquired to interpret new knowledge. It is natural that Herbart should emphasize the latter process, for though he could hardly deny the validity of the first form of apperception, yet so slight is the original equipment of the mind —merely the power of preserving itself against the encroachments of other *Reals*—that all the significance of its activity must be found in acquiring experience. This, it may be remarked, is the process most important to teachers, for they can help to supply and order experience, whereas they have no control whatever over the original constitution of the mind. Herbart sees in each new sensation a stimulus to ideas already possessed, an attractive force for the similar, a repelling one for the dissimilar. The new idea therefore at first holds the centre of consciousness, gathering about itself similar ideas, and repelling hostile ones already in consciousness or newly attracted to it by contrast. But this very domination of the new idea is in most cases the cause of its reduction to a subordinate place, for by bringing to consciousness a body of more deeply rooted related ideas, it enables the old to control the new by placing the new in its true relation to older and better ordered experience. In other words, the new is apperceived by the old. Herbart's theory, thus briefly stated, has been extended and freed from contradictions, by subsequent writers, notably Lazarus, Steinthal and Wundt (qq.v.).

Ethics.—All knowledge, feeling, desire, and will, being explained by the various relations into which ideas may come, there is no room in Herbart's system for transcendental will, hence no ethical imperatives antecedent to those developed by experience. Ethics consequently becomes a branch of æsthetics, and ethical judgment is founded upon pleasurable or painful feelings as the case may be. The mind spontaneously approves some will relations and as spontaneously disapproves others. These basal relations refer to five fundamental aspects of conduct, two relating to the self as such, and the remaining three to the relations of the self to others. The first two are *Inner Freedom* (the feeling that arises from good conscience) and *Efficiency of Will* (the pleasure that is aroused by efficient action). The three other ideas are first *Good Will* (subjective attitude toward others), the second *Justice* (the legal basis of rights), and the third *Equity* (the demand that requital shall be adequate to deed).

Education.—Upon the basis of his psychology and ethics as above explained, Herbart built his educational structure. Since there is no source of character but experience, it is to experience, i.e., to organized knowledge or groups of ideas, that we must look for the development of character, which thus has its roots, not in a single department of knowledge as, e.g., that grounded in sacred writings, but in the whole content of the mind. A man must be ethical all over, not in spots only. For this reason the Herbartians speak fondly and proudly of *educative instruction,* meaning thereby such instruction as shall render all ideas contributory to moral character. But since feeling is the bridge between cognition and volition, this bridge the teacher must induce the pupil to cross if his conduct is to be adequate to his knowledge. This leads to the

Doctrine of Interest.—By means of direct interest incited in the pupil for the subject-matter itself, not amusement connected with the subject-matter, as some have erroneously thought, the pupil's permanent attitude of mind toward the circle of thought itself and consequently toward the aspects of life involved will be established. This interest falls naturally into two groups, first that pertaining to knowledge itself, and second that pertaining to intercourse with others. The first group embraces empirical, speculative (causal), and æsthetic interests; the second sympathetic, social, and religious interests. This doctrine of interest, so important in modern educational thought, has been brought into harmony with our more spiritualistic systems of philosophy and psychology by Professor John Dewey ('Interest as Related to Will'). The next important topic arises when we ask how the teacher is to lead the pupil to build his circles of thought adequately, and then to have the right mental attitude toward them. This leads to the subject of

Method.—It is a common experience that faulty methods may easily lead to inadequacy of insight; they may still more easily lead to the wrong attitude of mind, as when the student hates a subject and everything connected with it. The first point to consider is *Attention*, which is either spontaneous or forced. With the young where forced attention is painful, it is better to induce spontaneous attention, for here the ideas rise freely, producing liveliness and pleasure. Apperception has two marked stages, that of *absorption*, in which the mind gives itself up to new impressions; and that of *reflection*, in which the newly acquired elements of knowledge find their appropriate place in the systems of the old. To bring about this twofold process of absorption and reflection most effectively and most agreeably to the mind, we must observe at least four prominent stages of method. The first of these is *clearness*, by which is meant the adequate apprehension of the single object or element as such. The second is *association*, which consists in the progress from one absorption to another related one. The third is *system*, or the step in which each part of that which is learned finds its proper place in relation to other parts. Steps two and three may be said to embrace the process of generalization. The fourth stage is what Herbart calls *method*, by which he understands the well-ordered activity of the pupil in the solution of problems and tasks.

Making due allowance for those parts of Herbart's system that are now of historical interest only, it may be seen that many of its elements are still of importance to the world, for they involve the most potent of modern educational processes and aims.

Herbart's chief philosophical works are 'Lehrbuch zur Einleitung in die Philosophie' (1813); 'Lehrbuch zur Psychologie' (1816); 'Psychologie als Wissenschaft, neu gegründet auf Erfahrung, Metaphysik und Mathematic (1824-25); 'Allgemeine Metaphysik nebst den Anfangen der philosophischen Naturlehre (1828-29); 'Kurze Encyclopädie der Philosophie, aus practischen Gesichtspunkten entworfen' (1831). The complete works of Herbart have been edited in 12 volumes by G. Hartenstein (Leipzi 1850-52). Herbart's aducational works, including the 'Allgemeine Pädagogik' and the 'Umriss Pädagogischer Vorlesungen,' were edited by Dr. Otto Willmann in two volumes (Leipzig 1880). The Psychology is translated and to be found in the International Series (Appletons), while the 'Allgemeine Padagogik' and the 'Umriss' are also found in English, the former under the title of the 'Science of Education,' and the latter under that of 'Outlines of Educational Doctrine.' The Herbartian School has produced a literature in metaphysics, psychology and education too voluminous for mention here.

Charles De Garmo.
Professor of the Science and Art of Education, Cornell University; Author of 'Herbart and the Herbartians.'

Herbelot, Barthelemy, d', bär-tāl-mē dĕr-blō, French Orientalist: b. Paris 4 Dec. 1625; d. there 8 Dec. 1695. Having gone through a course of study in the university of his native city, he applied himself particularly to the eastern languages, with a view to the elucidation of the Hebrew Scriptures. He visited Italy, and while there commenced his great work, the 'Oriental Library.' Recalled to Paris by Colbert, a pension was given him, that he might be at liberty to proceed with his undertaking. It was his first design to have published his collection in Arabic, and types were cast for the purpose of printing it. But the death of Colbert having interrupted this plan, he recomposed the work in the French language, as likely to prove more generally useful. He was appointed to the royal professorship of Syriac in 1692. His book was published in 1697, under the title of 'La Bibliothèque Orientale.' The best edition of the 'Oriental Library' is that of The Hague (1777), with the supplements of Galland and Visdelou.

Herbert, Edward, Lord Herbert of Cherbury, English philosopher: b. Eyton-on-Severn, near Wroxeter, 1583; d. London 20 Aug. 1648. He was a famous soldier and diplomatist in his day, but at the present is remembered as an author and philosopher. At Paris, in 1624, he printed his famous book, 'De Veritate prout Distinguitur a Revelatione, a Verisimili, a Possibili et a Falso,' the object of which was to assert the sufficiency, universality, and perfection of natural religion, and thereby prove the uselessness of revelation. In 1624 he returned from France, and was created an Irish peer; and in 1629 became an English baron with the title of Lord Herbert of Cherbury. In the civil war he at first tried as far as possible to play a neutral part, but afterwards sided with the Parliamentary party chiefly with a view, it appears, to save his property. The character of Lord Herbert is strongly marked in his memoirs, which show him to be vain, punctilious, and fanciful, but open, generous, brave, and disinterested. The 'De Veritate' was followed by works entitled 'De Causis Errorum' (1645);

and 'De Religione Gentilium' (1663; Eng. trans. 1709). In 1649 was published his 'Life and Reign of Henry VIII.' The English style of Lord Herbert is strong, manly, and free from the quaint pedantry of his age. He was one of the first to attempt a systematic proof of the sufficiency of natural religion. "Herbert's religious doctrine," says Sidney Lee, "starts with the assumption that religion, which is common to the human race, consists merely of the five innate ideas or axioms that there is a God, that He ought to be worshipped, that virtue and piety are essential to worship, that man ought to repent of his sins, and that there are rewards and punishments in a future life. He regards Christianity as on the whole the best religion, because its dogmas are least inconsistent with his five primary articles." His autobiography remained in manuscript till 1764, when it was published by Horace Walpole. There is a recent critical edition by Sidney Lee (1886).

Herbert, Lady Elizabeth, English writer, mother of Sir Michael Herbert, British ambassador at Washington 1902-3. She is well known as an authoress, and has written books of travel in Spain, Algeria, and many other countries, as well as novels and biographies. Among these may be noted: 'Rambles Round the World'; 'Wayside Tales'; 'Cradle-Lands'; 'Impressions of Spain'; 'Algeria, or Search After Sunshine'; 'Love and Sacrifice'; 'Thekla'; 'Edith'; 'Wives and Mothers in the Olden Times'; 'First Martyrs of the Holy Childhood in China'; 'Children of Nazareth'; 'Lives' of Monsignor Dupanloup, Garcia Moreno, Alexis Clerc, General de Stonis, the Archbishop of Braga, Geronimo, Père Eymard, Ven. Clement Hofbauer, Saint John Baptist de Rossi, Saint Cajetan, Mother Teresa Dubouché, Père Peract, etc.

Herbert, George, the best known of English religious poets: b. at the Castle of Montgomery, Wales, 3 April 1593; d. Bemerton, March 1633. His father, Richard Herbert, came of an illustrious Welsh family; his mother, Margaret Newport, also of excellent family, is more remembered for her own noble character. She was of the best type of Renaissance woman, cultured, highminded—the companion and friend of intellectual men. Between her and her poet son was rare sympathy; she guided his life in all things and early destined him to the saintly career in which he came slowly to find his happiness. Upon her husband's death in 1597, the care of her ten children fell to her. The oldest son, Edward, Baron Herbert of Cherbury, himself a poet and the author of the famous autobiography (printed by Horace Walpole in 1764), went to Oxford in 1595; there his mother followed him with her other children, to watch over his career. Here George Herbert was brought up until 1605, when he entered Westminster School. From the first he distinguished himself, partly by his learning, partly by his daring, which showed itself in his attack in Latin epigrams upon Andrew Melville, the noted Presbyterian. In 1609 he was elected scholar of Trinity College, Cambridge, where three years later he took his degree. In 1614 he became a Fellow of Trinity, and won his Master's Degree in 1616. In 1610 he was elected Public Orator, an office he filled until 1627.

Until this election Herbert had looked toward a worldly career. Pride of family and ambition were strong in him; the influence of his relatives and friends at court was great; he knew his own powers. But all that the court favor bestowed upon him was the lay rectorship of Whitford (1623), a sinecure post which Sir Philip Sidney had held; and shortly afterward the death of his most powerful friends darkened the promise of worldly advancement, and aided his mother's effort to turn him to the Church. In July 1626, while yet a layman, he became prebendary of Layton Ecclesia, in the diocese of Lincoln. With the help of his mother and others, he restored the ruined church building—an act more expressive perhaps of the beauty-loving courtier than of the future parish priest.

His mother had married Sir John Danvers in 1609. Her death in 1627 called forth Dr. Donne's famous funeral sermon and her son's 'Parentalia.' This sorrow marks the beginning of George Herbert's nobler life. Shattered in health, and threatened with consumption, he resigned his oratorship and spent the next three years in London and Essex and Wiltshire, communing with himself and with his friends.

In 1629 he married Jane Danvers, a relative of his father-in-law's, and the next year he was presented to the living of Bemerton, with which his name is remembered. The short remainder of his life was remarkably active. In these years he wrote most of his poems and the best of them, and also the charming "Character of the Country Parson." It has been thought that his extraordinary zeal hastened his end. He died of consumption in 1633; the date of his burial was March 3. Later in the same year his famous book of poems, 'The Temple,' was published in Cambridge.

Herbert's life must have seemed to him an elaborate and delayed preparation for the last saintly years at Bemerton—one long turning from high hopes of a career and broad experience of the best of worldly society, to the humble life of the spirit. The wasting of his physical frame paralleled this increasing otherworldliness. Yet in his final achievement his early life counts for more than at first might be guessed; he could turn from such a past less completely than he thought. He owed it to this broad experience of the world at its best that his nature remained normal. His extreme saintliness took no strange outward form, as did the piety of his friend Nicholas Ferrar, nor did it mar his writing with eccentricities of fervor or mysticism: his genius is entirely sane. In no English poet, religious or secular, do the small common-places of life count for more. In such poems as 'The Elixir,' with its famous praise of "Drudgery Divine," he insists on that kind of aspiration which scorns no humble or routine task; and his longest poem, 'The Church Porch'—a series of wise maxims for the familiar discipline of the soul—sums up the moral and religious traditions of the English race, though in his individual way. His genius is for common sense ennobled by lofty faith and passionate devotion. It is this normal quality in him, this quickness to find inspiration along the highway, rather than his frequent reference to ecclesiastical customs and offices, that makes him, as Coleridge said, the representative poet of the English Church.

Herberts' wide fame rests on the substance of his work, rather than on the skill of its expression. But technically in his own field he is an accomplished artist. In a certain striving to crowd too much thought into words or to secure a striking phrase, he must be classed with Donne and the other "fantastic poets," but in him this quality is rarely pressed beyond a charming quaintness. He has the artist's sense of word-values; his verbal felicity, as in the oft-quoted "Sweet day, so cool, so calm, so bright," could hardly be excelled, and in many of his poems the fine openings and cadences recall the best manner of the Cavalier Poets (q.v.), among whom Herbert would naturally have found his place, had he not devoted his genius to sacred poetry. Good illustrations of such qualities, besides the titles already mentioned, are the song "I got me flowers to straw Thy way," the lovely poem with the fantastic title 'The Pulley,' and the more passionate 'When blessed Mary wiped her Saviour's Feet.' In all these verses Herbert's individuality is strong—the quiet depth of his religious nature, and his indescribable sweetness of temper, the fruit of the winning over of his worldly ambition to saintly ideals.

Bibliography. — The best editions are: George Herbert Palmer; Grosart, in the Fuller's Worthies Library and in the Aldine edition; the Pickering edition, with the Life by Isaak Walton. For criticism, consult: 'Introductions' to the above, especially to Palmer's edition; also, for a charming study, consult the essay on Lady Danvers in Louise Imogen Guiney, 'A Little English Gallery.'

John Erskine,
Associate Professor of English in Amherst College.

Herbert, Henry William, "Frank Forester," American author: b. London, England, 7 April, 1807; d. New York 17 May 1858. He was graduated from Caius College, Cambridge, in 1828; removed to the United States in 1831; and until 1839 was instructor in the Greek and Latin languages in a private school of New York. In 1833 he established and until 1836 was editor of the 'American Monthly Magazine,' during a portion of that time with Charles Fenno Hoffman (q.v.) as associate. From 1834 he became largely known as the first important American writer on sports and out-of-door subjects. He wrote also on French and English history, and made excellent translations from Dumas and Sue. His volumes include: 'Cromwell' (1837); 'Marmaduke Wyvil' (1843); 'The Cavaliers of England' (1852); 'The Chevaliers of France' (1853); 'The Puritans of New England' (1853); 'Field-Sports of the United States and the British Provinces' (1848); 'Sporting Scenes and Characters' (1857); 'Horses and Horsemanship of the United States and British Provinces' (1859).

Herbert, Hilary Abner, American lawyer and politician: b. Laurensville, S. C., 12 March 1834. He was educated at the universities of Alabama and Virginia, studied law and was admitted to the bar. He began practice at Greenville, Ala., but served in the Confederate army as captain and colonel of the 8th Alabama regiment; being disabled at the battle of the Wilderness (1864), he retired from the army, and continued the practice of his profession, first at Greenville, then at Montgomery (1872). He was elected to Congress in 1877, and seven times re-elected; in three Congresses he was chairman of the committee on naval affairs. In March 1895, he was appointed secretary of the navy by President Cleveland, an office which he held till 1897.

Herbert, John Rogers, English historical and portrait painter: b. Maldon, Essex, 23 Jan. 1810; d. London, 17 March 1890. He studied at the Royal Academy, where he exhibited as early as 1830; later went abroad and in 1840 became a Roman Catholic, after which the subjects of his paintings were chiefly religious. In 1841 he was elected one of the masters of the government school of design at Somerset House, and in 1846 became a member of the Academy. His principal works are the frescoes in the peer's robing-room in the House of Lords; 'The Appointed Hour' (1834); 'King Lear Disinheriting Cordelia'; 'Sir Thomas More and his Daughter' in the Vernon collection at the National Gallery; and 'Saint Gregory Teaching His Chant.'

Herbert, Sir Michael Henry, English diplomatist: b. England 25 June 1857; d. Davos-Platz, Switzerland, 30 Sept. 1903. He went to Paris as attaché in 1879; was *charge d'affaires* at Washington (1888-9); secretary to the British legation at Washington (1892-3); at The Hague (1893-4); and at Constantinople (1894-7). On 4 June 1902 he was appointed British ambassador to the United States at Washington, in succession to the late Lord Pauncefote, and the following year was compelled by ill health to return to Europe.

Herbert, Victor, American musical director and composer: b. Dublin, Ireland, 1 Feb. 1859. After studying music from his childhood in Germany, he was appointed principal 'cello player in the court orchestra, Stuttgart, from which time he appeared in concerts throughout Europe. In 1886 he took the position of solo 'cellist in the Metropolitan orchestra, New York, and has since been connected as soloist and conductor with the principal orchestras of the United States. Since 1894 he has been bandmaster of the 22d regiment band, New York, was conductor of the Pittsburg, Pa., orchestra from 1898 to 1904, and since 1904 has conducted Victor Herbert's New York Orchestra. As a composer he has written: 'The Captive,' an oratorio; and the comic operas, 'Prince Ananias'; 'The Wizard of the Nile'; 'The Serenade'; 'Cyrano de Bergerac'; 'The Ameer'; 'The Viceroy'; 'The Idol's Eye'; 'The Fortune Teller'; 'The Singing Girl'; 'Babette'; 'Babes in Toyland'; 'It Happened in Nordland'; etc.

Herbiv'ora, a group of mammals characterized by their herbaceous diet; the grazers or ruminants. The term is no longer in use.

Herbs, Culinary, fragrant or aromatic plants used to add flavor to food, especially stews, soups, dressings and salads. They usually owe these qualities to essential oils, which, being readily soluble or easily volatilized by heat, quickly permeate the mass of food in which they are mixed. The seed of some, as caraway, anise (qq.v.) and dill, is employed; the foliage of others, as parsley, sage, thyme, is more frequently used. The former plants are cut and placed loosely upon sheets as soon as the seed reaches maturity; allowed to dry a few days; lightly thrashed and the seed cleaned; still further dried and stored in air-tight packages. The latter are gathered just before the first blossoms would open, because they are then richest in flavor. With parsley the leaves are gathered as soon as mature, several cuttings being made in a season. They are then dried upon trays at a temperature below 120 degrees and in freely circulating air until crisp, when they are rubbed to powder and stored as above. Paper or pasteboard packages are bad, because they allow the flavors to escape. Both seeds and leaves may be used in decoction, being covered with vinegar or alcohol in stoppered bottles. Fresh herbs, which are always preferable to dried or decocted, are especially useful in salads; dried and decocted in dressings, stews, etc., and at seasons when fresh ones cannot be obtained. In the United States the species most in demand are parsley, sage, thyme, savory, marjoram, spearmint, dill, fennel, tarragon, balm and basil (qq.v.) in nearly the order named. Parsley is beyond question the most popular because of its double use as a garnish and flavoring plant but sage is perhaps more frequently used in the latter capacity. It is most esteemed with pork, goose, duck, and similar rich meats. Spearmint is used mainly with roast lamb; tarragon with boiled fish; dill with pickles; and the other kinds mentioned with mild meats, such as turkey, chicken, veal, venison, etc. The kind, quantity and mixture used with each sort of food depends upon personal preference.

In general, herbs are of simplest cultivation. They usually prefer rather light, moderately rich, well drained soil, and sunny exposures. Since the seeds of many are small or slow to germinate they are frequently started in a greenhouse, hotbed or window, and transplanted to the garden when they are large enough and when conditions are favorable. Clean cultivation and the removal of weeds is essential. The perennial kinds, such as sage, are often propagated by stem cuttings, divisions or layers; tarragon always thus because it does not produce seed; spearmint usually by cuttings of the rootstock. The great majority are grown as annuals, being replaced each spring with fresh plants. Commercially they follow such crops as early cabbage, peas, etc., thus permitting a double use of the same soil annually. They are easily grown for winter use in the borders of benches in the greenhouse or in boxes placed in sunny windows.

Herculaneum, hĕr-kū-lā'nē-ŭm, or **Herculanum**, Italy, an ancient buried city, about five miles southeast of Naples. Strabo says it was first occupied by Oscans, afterward by Tyrrhenians and Pelasgians, and then by the Samnites. It took part in the social war against the Romans. In the time of Sulla it was a *municipium* and a fortified town. It was situated between Neapolis and Pompeii, on elevated ground between two rivers, and its port was one of the best on the coast. It suffered in 63 A.D. in the same earthquake that nearly destroyed Pompeii. In the greater irruption of 79 A.D. it was buried under a volcanic tuff formed of sand and ashes, partly consolidated by the agency of water. The site of Herculaneum, though well described, had been long sought in vain, when in 1713 three female statues (now in the Dresden Museum) were found in digging a well at Portici, a village situated on the ancient site. After this discovery further excavation was prohibited by the government, until in 1738 the well was dug deeper, and the theatre of Herculaneum was discovered. In 1750 a long, narrow passage, sloping down into the theatre, was opened, and is still the only way by which travelers descend to examine this structure. The excavations were continued more or less industriously for 50 years; but comparatively little progress was made, as the work was difficult and also dangerous to the houses in the populous villages of Resina and Portici, situated above. As soon as one part was excavated and explored it was filled up with the rubbish from a new digging. The theatre is the only building to be seen underground, and it is encumbered with the supports built to sustain the rock above it. It is a noble edifice, massively built of solid stone, and seated 8,000 persons. Bronze statues of Drusus and Antonia and of the Muses were found in various parts of the building. In a square on the south of the theatre a temple was found which was connected with another temple, to the east of it, by a wide street lined with porticoes. One of these temples, dedicated to the mother of the gods, had been restored by Vespasian after the earthquake of 63 A.D. On the north of the theatre was a basilica 228 feet long and 132 broad, surrounded by a portico of 42 columns, and adorned with paintings. Many beautiful paintings and works of art were removed from these buildings to the museum at Naples. A sumptuous private villa was disinterred, containing a number of statues, and in one of the rooms a quantity of papyrus manuscripts. Some of the statues are excellent as works of art, such as those of Agrippina, Aristides, the Sleeping Faun, and the Mercury. Other precious relics discovered here, and now in the museum, are busts of Plato, Demosthenes, Scipio Africanus, Augustus, Seneca, etc., beautiful mosaics, and articles of furniture. New excavations were carried out in 1828–37, and since 1868. The chief discoveries made were those of the forum, a small and elegant temple, a basilica, a dilapidated building supposed to have been an inn, dwelling-houses, tombs, etc. One of the houses discovered at Herculaneum contained a quantity of provisions, dates, chestnuts, large walnuts, dried figs, almonds, prunes, corn, oil, pease, lentils, pies, and hams, none of which had been disturbed for 18 centuries, for the doors remained fastened, in the same state as they were at the period of the catastrophe which buried the town. The internal arrangement of the house, and the manner in which it was ornamented, proved that it had belonged to a rich family, admirers of the arts; for it contained many pictures, vases, articles in glass, bronze, and terra-cotta. Few skeletons comparatively have been found either in Pompeii or Herculaneum, so that it is probable most of the inhabitants saved themselves by flight. At the door of a villa in Herculaneum were found two, one of which held a key in one hand, and in the other a bag with coins and cameos. Near them were silver and bronze vessels.

Among the most interesting objects discovered here are the papyri above mentioned, over 1,750 of which are now in the Naples Museum. The rolls are of cylindrical form, and much charred. Hardly a third of them have been unrolled. The process presents great difficulties, from the tendency of the MSS. to crumble. One of the works is a treatise by Epicurus on Nature; there are some writings of Philodemus, a Syrian philosopher; but on the whole they are of little value. There have been published 11 volumes of the 'Volumina Herculanensia,' containing engraved transcripts of the unrolled papyri (folio, Naples, 1793–1855), and since 1861 several volumes of a continuation of the same.

Her'cules, hėr'kū-lēz, called by the Greeks Herakles, and also Alcides, al-sī'dēz, after his grandfather, Alcæus: a mythological hero of Greece, typified by poets, sculptors, and artists of later ages, as a model of human perfection, physical and mental. According to the traditions of the heroic age, he united the finest qualities of mind and heart, as understood at that period, with the highest development of bodily vigor, and under a ceaseless succession of labors and sacrifices, strove perpetually after divine excellence. His indomitable perseverance was crowned with victories which showed the triumph of the divine part of man's nature over the earthly, while his death secured him immortality, a seat among the gods, and the homage of divine honors.

The legends relate that he was the son of Zeus or Jupiter, king of the gods, and of Alcmena the Theban, daughter of Alcæus, son of Perseus. Knowing that the child born on a certain day would rule over the descendants of Perseus, Hera or Juno, wife of Jupiter, consumed with jealousy, contrived to prolong the travail of Alcmena, and hasten that of the wife of Sthenelus, another son of Perseus, who gave birth to Eurystheus, subsequently chief of the Persidæ. Hercules was brought up at Tirynthus, or according to Diodorus, at Thebes. Jupiter sought to protect his favorite son in every manner, and to make him worthy of immortality. On one occasion, while Juno was asleep, he laid the infant on her breast, that he might feed on the milk of the goddess. She awoke, and cast the hated babe from her, and the drops that then fell from her are said to have formed the Milky Way. Under the care of Amphitryon, Alcmena's husband, Hercules received the best instruction in all arts. Castor, the son of Tyndarus, taught him how to fight: Eurytus, archery; Autolycus, driving; Eumolpus, singing; Linus, to play the lyre; and under the centaur Chiron, he perfected his training, and became the most valiant and accomplished hero of the age.

In his eighteenth year he slew a huge lion in the neighborhood of Mount Cithæron which had preyed on the flocks of Amphitryon and of the king of Thespis. The king, desirous that his 50 daughters might have children by such a hero, entertained him at his court for 50 days, and Hercules became the father of their sons, the Thespiadæ. Hercules next freed his native city from the annual tribute of a hundred oxen, paid to Erginus, king of the Orchomenians. Creon, king of Thebes, rewarded Hercules by giving him his daughter Megara in marriage, and intrusting him with the government of his kingdom. Subjected to the power of Eurystheus owing to priority of birth, the latter acquainted with Hercules' successes and rising power, ordered him to appear at Mycenæ, and perform the labors which he was empowered to impose upon him. Hercules refused, and Juno to punish him, afflicted him with melancholic madness, during which he killed his own children by Megara, supposing them to be the offspring of Eurystheus. When he recovered he was so horrified by the misfortunes which had proceeded from his disobedience and insanity, that he consulted the oracle at Delphi; he was told that he must be subservient to the will of Eurystheus and perform ten labors imposed by the king, after which he would attain immortality. Hercules thereupon went to Mycenæ, where Eurystheus, apprehensive of so powerful an enemy, commanded Hercules to achieve a number of enterprises, the most difficult and arduous ever known. The favors of the gods, however, had completely equipped him for their performance; from Minerva he had received a coat of arms and helmet, a sword from Mercury, a horse from Neptune, a shield from Jupiter, a bow and arrows from Apollo, and from Vulcan a golden cuirass and brazen buskin with a celebrated brass club.

The first labor was to destroy the lion which infested the forests of Nemea and Cleonæ near Mycenæ, and was invulnerable to mortal arrows. Hercules attacked him with his club, chased him to his den, and after a sharp and fierce struggle choked him to death. He carried the dead beast on his shoulders to Mycenæ, and ever after clothed himself with the skin. The second labor was to destroy the Lernæan hydra, which he accomplished with the assistance of his friend Iolaus, who burnt with a hot iron the root of each head as Hercules crushed it to pieces with his club. The third labor was to catch the hind of Diana, famous for its swiftness, golden horns, and brazen feet. The fourth labor was to bring alive to Eurystheus a wild boar which ravaged the neighborhood of Erymanthus. In this expedition he destroyed the Centaurs, and caught the boar by closely pursuing it in the deep snow. In his fifth labor Hercules was commanded to clean the stables of Augeas, where 3,000 oxen had been kept for many years; this he accomplished in one day by turning the rivers Alpheus and Peneus through the stables, receiving as payment a tenth of the cattle, and concealing the fact that he had been commanded to perform the service. The sixth labor was to destroy the carnivorous birds, with brazen wings, beaks, and claws, which ravaged the country near Lake Stymphalis in Arcadia. In his seventh labor he brought alive into Peloponneseus the wild bull, a gift of Poseidon to Minos, king of Crete, which had laid waste the island. In his eighth labor he was commissioned to capture the mares of Diomedes, which fed upon human flesh. He killed Diomedes, and gave him to be eaten by his mares, which he brought to

Eurystheus. For his ninth labor he was commanded to obtain the girdle of the queen of the Amazons. In his tenth labor, he killed the monster Geryon, king of Gades, and brought to Argos his numerous flocks, which fed upon human flesh. Adjudging the second and fifth labors as unlawfully performed, Eurystheus imposed two others. These were: the eleventh, to obtain the golden apples from the garden of the Hesperides; and the twelfth, to bring from hell the three-headed dog Cerberus. Pluto promised him Cerberus on condition that he should use no weapons but force. Eurystheus, pale with fright when Hercules brought the monster to him, ordered its immediate removal. This ended what are generally known as the Twelve Labors of Hercules, and relieved the hero from bondage.

Besides these, Hercules achieved other labors equally great and celebrated, such as his war with Jupiter against the giants, his expedition with the Argonauts to Colchis, the pillage of Troy, the liberation of Prometheus and Theseus, etc. During three years' slavery, imposed by the Delphian oracle for plundering the temple to avenge supposed neglect, Hercules' mistress, Omphale, queen of Lydia, married him. Hercules afterwards married Dejanira, daughter of Œneus, king of Ætolia, and when Iole, daughter of the king of Œchalia, a princess formerly refused to Hercules, became his captive, Dejanira sent Hercules the tunic given her by the dying centaur Nessus, as having the power to recall a husband from unlawful love. The tunic had been infected by the poisoned arrow shot by Hercules at the centaur, when he offered violence to Dejanira, after carrying her across the river Evenus. When Hercules put the tunic on, the poison penetrated his system and he suffered untold torments; in remorse Dejanira killed herself. In his agony Hercules had himself conveyed to Mount Œta and laid on a funeral pyre which at his commands was set on fire. In the midst of a dark cloud, accompanied by lightning and thunder, his immortal spirit was transported to Heaven, where he took his place among the gods, became reconciled to Juno and married her daughter Hebe.

While the myth of Hercules is of Greek origin, counterparts of the legend appear among many nations. Some scholars regard Hercules as a solar hero, and the twelve labors to represent the 12 zodiacal signs. Artists represent him under a variety of forms, as a child, a youth, and man, in his numerous adventures and exploits. The principal ancient statue is the Farnese Hercules at Naples, by the Athenian Glycon. In the Vatican, the Torso di Michelangelo, so called because that artist studied it during several years, is a remarkable fragment of an ancient statue of Hercules.

Hercules, in astronomy, one of Ptolemy's northern constellations. It is within this constellation that the point toward which the sun, with its accompanying system of planets, is traveling at present is situated. The constellation contains the finest globular cluster of stars in the northern heavens, and the bright double and variable star Ras Algethi.

Hercules-beetle, a very large South American lamellicorn beetle (*Dynastes hercules*). An enormous horn projects from the prothorax of the male, and a smaller one from the head; they act together like a pair of forceps. The length of the male is about six inches, but the female is smaller and lacks the horns. Numerous related species are known, of which *D. tityrus,* found in the southern United States, is 2½ inches long.

Hercules' Club, a North American shrub or tree growing to height of 12 feet and sometimes to 40 feet. See Aralia.

Hercules, Pillars of, name of the Straits of Gibraltar among the ancients. Hercules is said to have erected a pillar on each side of the strait between Europe and Africa, upon the mountains Calpe and Abyla, as the limits of his wanderings toward the west. The earliest Greek writer by whom the Pillars of Hercules are mentioned is Pindar. On the other hand the Phœnicians called the strait the Pillars of Melkant (q.v.), whom the Greeks knew as Melicertes.

Herder, Johann Gottfried von, yō hän gŏt'frēd fōn hĕr'dĕr, German critic and poet: b. Mohrungen, Prussia, 25 Aug. 1744; d. Weimar 18 Dec. 1803. He was the son of a poor schoolmaster, but friends procured him an appointment in Frederick's College, where he was at first tutor, and at a later period instructor. During this period he became known to Kant, who permitted him to hear all his lectures gratis. His unrelaxing zeal and diligence enabled him to become acquainted with science, theology, philosophy, philology, natural and civil history, and politics. In 1764 he was appointed an assistant teacher at the cathedral school of Riga, with which office that of a preacher was connected. In 1769 he went to Paris; he became traveling tutor to the Prince of Holstein-Oldenburg, but in Strasburg he was prevented from proceeding by a disease of the eyes; and here he became acquainted with Goethe, on whom he had a very decided influence. Herder had already published his 'Fragments on the More Modern German Literature,' his 'Critical Woods' (Kritische Wälder), etc., which had gained him a considerable reputation, though he had not published anything of importance in theology; yet, while in Strasburg, he was invited to become court preacher, superintendent, and consistorial counsellor at Bückeburg, whither he proceeded in 1771. He soon made himself known as a distinguished theologian, and in 1776 received an invitation to become court preacher, general superintendent, and consistorial counsellor at Weimar. This appointment was through the influence of Goethe. In 1801 he was made president of the high consistory, a place never before given to a person not a nobleman and was subsequently made a noble by the Elector of Bavaria. As a theologian Herder contributed to a better understanding of the historical and antiquarian part of the Old Testament. His 'Geist der hebräischen Poesie' is highly valued. He did much for the better appreciation of the classical authors, and his philosophical views of human character are full of instruction. His greatest work is his 'Ideen zur Philosophie der Geschichte der Menschheit' (1785 *et seq.*). In poetry Herder effected more by his various accomplishments, his vast knowledge, and fine taste, than by creative power; yet he has produced some charming songs; and his 'Cid,' a collection of Spanish romances into a kind of epic, is one of the most popular poems of Germany.

Heredia, José Maria, Spanish-American poet: b. Santiago de Cuba 31 Dec. 1803; d. Toluca, Mexico, 7 May 1839. He was graduated from the law department of the University of Havana in 1819; for taking part in the attempted revolution of 1823 was banished from Cuba, lived for two years in the United States, and in 1825 removed to Mexico, where he held various civil, judicial, and journalistic positions. His poetic works have been to some extent rendered into other languages. The 'Ode to Niagara' is well known. Heredia has been considered by many the greatest of Spanish-American poets. One of the best editions is that of Ponce de Leon, 'Obras Poeticas de Don José Maria de Heredia' (1875).

Heredity, the transmission of parental characteristics to the offspring. The child possesses the mean between the character of each parent, that is, the father and mother share equally in transmitting their peculiarities. Yet it should be borne in mind that no two individuals are exactly alike, and besides the resemblances to the parents, every child differs in certain respects from the parent. We speak of the force of heredity, and this, whatever be its nature, is very wonderful. Thus the Egyptian of to-day inherits the features and mental characteristics of his ancestors who lived 10,000 years ago. One cause of this is the fact that the physical features and climate of Egypt have remained unchanged for that period. Did heredity act rigidly we should have no modification of type from one geological age to another. The inheritance of one set of characters may, owing probably to profound changes in the environment, lapse, and the original peculiarities be replaced by others. Thus civilized man has thrown off certain habits and tendencies of his savage ancestors, and acquired new and higher culture — modes of action and feeling. Heredity has its limits, and in certain highly specialized types of animals has lapsed or ceased to act as at first. Hurst remarks: "Heredity is merely a likeness of effects due to the likeness of the causes producing them."

There are four types or forms of inheritance: (1) Continuous or normal inheritance, that is, where the children resemble the father and mother. (2) Interrupted inheritance, where the offspring resemble the grandparents. (3) Collateral inheritance, where the offspring inherit the qualities of their uncle or aunt. (4) Atavism or reversion, which is inheritance from a remote ancestor. Thus when individuals of two domesticated races are crossed, the offspring may resemble neither parent, but are like the supposed ancestral or wild species. This is called "throwing back" by breeders. Galton speaks of alternative heredity, and illustrates it by the color of the human eye. "If one parent," he says, "has a light eye-color and the other a dark eye-color, some of the children will, as a rule, be light and the rest dark, they will seldom be medium eye-colored, like the children of medium eye-colored parents." What is called particulate inheritance is common in the color of the hair of horses, dogs, mice, and other mammals, and in the hairs on the leaves of certain plants.

Galton's Law.— We do not know why certain characters are transmitted and others are not, and we cannot foretell, says Bateson, which individual parent will transmit characters to the offspring, and which will not, yet this problem may at some time become solved. From his studies on human stature, and on the transmission of colors in Bassett hounds, Galton has shown that the expectation of inheritance is such that a simple arithmetical rule is approximately followed. He deduced the rule that of the whole heritage of the offspring the two parents together on an average contribute one half, the four grandparents one quarter, the eight great-grandparents one eighth, and so on, the remainder being contributed by the more remote ancestors.

This rule does not in many cases apply, and Galton points out that it takes no account of individual prepotencies. Moreover, says Bateson, there are numerous cases in which on crossing two varieties the character of one variety almost always appears in each member of the first cross-bred generation. For example, the offspring of the polled Angus cow and the shorthorn bull is almost always polled or with very small loose "scurs." Seedlings raised by crossing *Atropa belladonna* with the yellow-fruited variety have without exception the blackish-purple fruits of the type. These are now recognized as instances of Mendel's principle of dominance.

Mendel's Law.— As far back as 1865 an Austrian monk, Mendel, made prolonged experiments in crossing varieties of the pea (*Pisum sativum*). His paper was overlooked until attention to his remarkable results was called by De Vries in 1900: he and also Correns and Tschermak at the same time independently rediscovered Mendel's law. Mendel selected seven pairs of characters, such as the shape of the ripe seed, of the cotyledons, of the seed-pod, color of the seed-skin, length of stem, etc. Large numbers of crosses were made between peas differing in respect of one of each of these pairs of characters. It was found, says Bateson, that in each case the offspring of the cross exhibited the character of one of the parents in almost undiminished intensity, and intermediates which could not be at once referred to one or other of the parental forms were not found. "In the case of each pair of characters there is thus one which in the first cross prevails to the exclusion of the other." This prevailing character Mendel called the dominant character, and to the other he gave the name of recessive character.

This law of dominance has been found by Bateson and by Castle to apply to animals as well as plants, and thus is a most important biological law. Thus when mating occurs between two organisms, whether vegetable or animal, differing in some character, the offspring frequently all exhibit the character of one parent only, in which case that character is said to be "dominant." For example, on crossing white mice with gray mice, Castle found that the offspring are gray, that color-character being dominant. The character which is not seen in the immediate offspring is called recessive, for though unseen it is still present in the young, white in the experiment being the recessive color.

The law of dominance has its exceptions: the hybrid often possesses a character of its own, instead of the pure character of one parent, as is true in cases of complete dominance. The hybrid form often resembles a supposed ancestral condition, when it is usually regarded as a reversion. Examples are the gray hybrid mice, which are indistinguishable in appearance from the house mouse; also slate-colored pigeons resulting from crossing white with buff pigeons.

One result of Mendel's discovery is the purity of the germ-cells. As stated by Castle: "The hybrid, whatever its own character, produces ripe germ-cells which bear only the pure character of one parent or the other." To breeders Mendel's law is of great importance because, as remarked by Castle, it reduces to an exact science the art of breeding in the case most carefully studied by him, that of entire dominance. "No animal or plant is 'pure' simply because it is descended from a long line of ancestors possessing a desired combination of characters, but any animal is pure if it produces gametes (germ-cells) of only one sort, even though its grandparents may among themselves have possessed opposite characters."

The bearings of Mendel's discovery, confirmed by De Vries' experiments, on the origin of species is of great interest and moment. The problem is whether aberrations, sports, or discontinuous variations may not sometimes result in the formation of new species and types, or whether species are all the result of slow, continuous variations. As stated by Castle, "A sport having once arisen affecting some one character of a species, may by crossing with the parent form be the cause of no end of disintegration on the part of any or all of the characters of the species, and the disintegrated characters may, indeed must, form a great variety of new combinations of characters, some of which will prove stable and self-perpetuating.

Mendel's discoveries also explain the principle that new types of organisms are extremely variable, whereas old types are subject to little variation. A new type which has arisen as a sport will cross with the parent form. The offspring, says Castle, will then inherit some dominant character, others latent, and this will result in polymorphism of the race. Thus the suggestion of Galton that species may arise from sports is confirmed, while added cases are afforded by the recent remarkable experiments of De Vries, resulting in the origination of seven new species of primrose by sudden variations, or what he calls "mutations."

Homochronous Heredity.— This is a form of heredity called by Darwin "inheritance at corresponding periods of life." It is exemplified in animals with a metamorphosis, whose larvæ lead a different life and differ greatly in structure and form from the parent. Thus the butterfly inherits in its infancy the caterpillar stage, then the pupa, finally the features of the imago; one character or set of characters appear by heredity, are cast aside, and new features arise, those of the pupa stage, and so on. Each butterfly, beetle, or bee, as well as the fluke-worms, tapeworms, etc., inherit at different periods of their lives stages which have become fixed by homochronous heredity.

The Physical Basis of Heredity.— A number of biologists from Spencer to Jaeger and Weismann have supposed that heredity is due to the transmission from parent to offspring of particles developed in the reproductive cells of the parent, whence arose the theory now generally held that the nucleus of the spermatozoon and of the egg is the bearer of heredity. Even in the protozoa, if one be divided into nucleate and enucleate halves, the portion without a nucleus degenerates, while the part containing the nucleus lives and regenerates the lost parts. The nucleus contains a portion which stains readily with reagents, and is called the "chromatin," which consists of particles called "chromosomes." Now the nucleus of the egg and that of the spermatozoon contain the same number and quantity of chromosomes, to what are called the cleavage-spindles, hence the chromatin, that is, the chromosomes, are regarded as the bearers of heredity, some of these passing down from one generation to another.

Consult: Weismann, 'The Germ-Plasm' (New York 1893); Bateson, 'Mendel's Principles of Heredity' (Cambridge, England, 1902); Castle, 'Mendel's Law of Heredity' (Cambridge, Mass., 1903); with the earlier works of Darwin, Brooks, Galton, Hertwig, and others.

Alpheus S. Packard,
Late Professor of Zoology, Brown University.

Hereford, hĕr'ē-fōrd, England, a city and parliamentary borough, capital of Herefordshire on the Wye, 120 miles northwest of London. The chief building is the cathedral, built in 1012–56, rebuilt in 1072, and restored in 1863. It is of early Norman architecture, 335 feet long and 174 feet wide, contains many fine monuments, some as ancient as the cathedral, and its accessory features include a lady chapel, charterhouse, cloisters, an episcopal palace and a library containing valuable MSS., Wyclif's Bible, and a 13th century map of the world. A musical festival of the united choirs of Gloucester, Worcester, and Hereford is given in the cathedral triennially. The see dates from 673; the city was incorporated in the reign of King John. Pop. (1901) 21,382.

Her'esy (Gr. *hæresis*) primitively means a choice or election, and in its application to religious belief is used to designate as well the act of choosing for one's self, and maintaining opinions contrary to the authorized teaching, as also the heterodox opinions thus adopted. In the Acts of the Apostles the word seems to be used of a sect or party, apart from the consideration of its character, whether good or bad; but in the Epistles and in the early Christian writers it is almost invariably used in a bad sense, which is the sense uniformly accepted in all subsequent theological literature.

Even in the apostolic times heresies had arisen in the Church, and before the Council of Nice the catalogue of sects had already swelled to considerable dimensions.

From the very date of the establishment of Christianity in the Roman empire heresy appears to have been regarded as a crime cognizable by the civil law; and Constantine enacted several severe laws for its repression, which were continued and extended by his successors, and were collected into a single title, 'De Hæreticis,' in the Justinian code. The penalties of heresy ordained by these enactments are very severe, extending to corporal punishment, and even to death; and they all proceed on the distinct assumption that a crime against religion is a crime against the state. These enactments of the Roman law were embodied in the various codes of the European kingdoms; in English law heresy consisted in holding opinions contrary to the faith of Holy Church. By common law the offender was to be tried in the provincial synod by the archbishop and his council, and, after conviction, was to be given up to the king to be dealt with at his pleasure. But the statute 2 Hen. IV. chap. 15 (*De hæretico comburendo*) empowered the diocesan to take cognizance of heresy, and, on conviction, to hand over the criminal directly, and without waiting for the king's writ, to the sheriff or other competent officer. This statute continued practically in force, with certain modifications, till the 29 Charles II. chap. 9, since which time heresy is left entirely to the control of ecclesiastical legislation.

The doctrines considered heretical by the Christian Church may be found in the 'Dictionnaire des Heresies,' by the Abbé Pluquet, with the history, progress, nature, and also the refutations of their errors.

Her'etic, in ecclesiastical terminology, one who embraces a heresy. It is evident that the word heretic can have only the relative meaning of heterodox. The early Christian Church always made a distinction between heretics who obstinately persisted in their heresy, and heretics merely through error, or who had been born in heresy. The fathers of the Church declare themselves ignorant of the final condition of the latter. Again, peaceable heretics are distinguished from those whose doctrines produce public confusion and disorder. However, the general view is that all heresies lead, sooner or later, to disturbances and bloodshed.

Hereward, hĕr'ĕ-ward, a Saxon yeoman who flourished about 1070. He was practically the last to withstand the Normans, holding the Isle of Ely against William the Conqueror 1070–1. After William had succeeded in reaching the refuge of the Saxon patriots, Hereward, scorning to yield, fled to the fastness of the swampy fens to the northward. He was commonly styled HEREWARD the WAKE, and his character and adventures form the theme of Charles Kingsley's popular historical romance, 'Hereward.'

Her'ford, Oliver, American humorous author and illustrator: b. England. He is at present on the staff of the 'Criterion.' Among his works are: 'Artful Antics'; 'The Bashful Earthquake and Other Fables and Verses' (1898); 'Alphabet of Celebrities' (1899); 'A Child's Primer of Natural History' (1899); 'Wagner for Infants' (1899); 'Overheard in a Garden' (1900).

Hering, Ewald, German psychologist: b. Altgersdorf, Saxony, 5 Aug. 1834. He studied medicine, and settled at Leipsic as physician in 1860; in 1862 he was lecturer in physiology at the Leipsic University, and in 1865 was professor of physiology and medico-physics in a medical school at Vienna, and in 1870 held the same chair at Prague. Hering is best known for his work in the field of psychophysics, especially for his investigations of visual space perception and for the color theory which he originated. This theory is opposed to the empiristic theory of Helmholtz and is most generally accepted by psychologists at the present time. His writings include: 'Die Lehre vom Binocularen Sehen' (1860); 'Zur Lehre vom Lichtsinne' (1872–4); 'Der Raumsinn und die Bewegung des Auges'; 'Das Gedächtniss als eine allgemeine Funktion der organisierten Materie' (1870).

Her'ing, Rudolph, American hydraulic and sanitary engineer: b. Philadelphia, Pa., 26 Feb. 1847. He was graduated at the Dresden (Germany) Polytechnic School, 1867, and became assistant engineer of Prospect Park, Brooklyn, N. Y., the following year. He was assistant engineer of Fairmount Park, at Philadelphia, 1869–71, and astronomer at Yellowstone National Park in 1872. After serving as assistant city engineer 1873–80 he opened an office for private practice in engineering and has furnished designs for sewerage and water supply for numerous towns and cities in the United States, Canada and South America. He is member of many professional societies both in Europe and America, and has written many published reports on sewerage and water supply of cities.

Heriot, hĕr'ĭ-ŏt, **George**, Scottish philanthropist: b. Edinburgh 1563; d. London 12 Feb. 1624. His father was a goldsmith in Edinburgh, and the son followed his father's profession, and was admitted a member of the Incorporation of Goldsmiths in May 1588. In 1597 he was appointed goldsmith to the queen by a charter from James VI., and on the accession of the latter to the English crown followed the court to England. From the period of Heriot's settlement in London little is known of his history. He died on 12 Feb. 1624, and was buried at St. Martin's-in-the-Fields. By his will he left nearly the whole of his fortune toward the founding and erecting of a school for poor boys in Edinburgh, styled in the bequest a "hospital." The foundation of the present structure, known as Heriot's Hospital, was laid in July 1628; and the expense of the erection exceeded £30,000 sterling. From the rise in value of property the yearly revenue of the hospital has very greatly increased; and the governors were empowered in the reign of William IV. to establish elementary schools within the city for the gratuitous education of poor children, 16 day schools being ultimately established, besides evening schools. In 1885, however, an entirely new scheme was introduced and a great part of the funds are now devoted to the support of Heriot's Hospital School and the Heriot-Watt College. The former is a day school for boys of 10 and upward, and the Heriot-Watt College is a college giving a thorough technical, commercial, and literary education chiefly by evening classes, though there are also day classes. The annual revenue is now about $150,000.

Her'kimer, Nicholas, American military officer: b. about 1715; d. Danube, N. Y., 17 Aug. 1777. He became a lieutenant of militia, served in the French and Indian war, and defended Fort Herkimer in 1758. Promoted brigadier-general of militia in 1776, he directed operations against Sir John Johnson, and when Fort Stanwix was threatened by a combined force of Indians, Tories, and regulars, advanced to its relief. He was ambushed by Col. Saint Leger at Oriskany, and one of the most closely-fought battles of the Revolutionary War followed.

Herkimer having lost a third of his force, was unable to continue, and Saint Leger's army was rendered thoroughly ineffective. Herkimer himself was wounded, and died as the result of an unskilful operation. The town and county of Herkimer, N. Y., were named in his honor.

Herkimer, N. Y., village, county-seat of Herkimer County; on the Mohawk River, the Erie Canal, and on the New York C. & H. R. railroad; about 25 miles east of Utica and 68 miles northwest of Albany. The chief manufactures are flour, furniture, mattresses, knit goods, beds, paper, creamery products, and cigars. The city owns and operates the electric plant and the waterworks. It is the seat of Folts Mission Institute. Pop. (1900) 5,555.

Her'komer, Hubert, English painter: b. Waal, Bavaria, 26 May 1849. His father, a wood carver, went to America in 1851, but returned to Europe and settled in Southampton in 1857. Hubert studied at the School of Art in that city, where he assisted in founding a life school for drawing. In 1867 he exhibited in the Dudley Gallery. From this time he gradually gained recognition as a painter in water colors, and in 1871 was elected a member of the Institute of Water Color Painters. His first picture exhibited at the Royal Academy, 'After the Toil of the Day' (1873), a German subject, attracted attention; and two years later he gained a great reputation by his famous picture representing 'The Last Master — Sunday at the Royal Hospital, Chelsea,' to which a grand medal of honor was awarded at Paris in 1878. Later pictures are: 'Eventide: a Scene in Westminster Union' (1878), "a worthy companion of the other realistic yet more heroic study of old age, which the artist made in his Chelsea Pensioners"; 'Missing: a Scene at the Portsmouth Dockyard Gates' (1881), "a masterpiece in its way"; 'On Strike' (1891), his diploma work; 'Back to Life: a District Nurse Taking out a Child for the First Walk after a Long Illness' (1896); and 'The Guards' Cheer' (1898), representing a scene in the Diamond Jubilee procession. Among many portraits painted by him the best known are those of Wagner, Ruskin, and Tennyson. His best water-color pictures are: 'Im Walde'; 'The Woodcutter's Rest'; 'The Poacher's Fate'; and 'At the Well.' Mr. Herkomer was elected associate of the Royal Academy in 1879, and full member in 1890, and from 1885 till 1895 held the Slade professorship of fine art at Oxford in succession to Mr. Ruskin. He holds a life professorship at Munich, superintends an art school founded by himself at Bushey in Hertfordshire, and for the theatre connected with it has written several plays. Herkomer also occupies a high place as an etcher and mezzotint engraver. He has published: 'Lectures on Etching and Mezzotint Engraving' (1892). See Courtney, 'Life' (1892).

Hermandad, ĕr-män-däťh', a confederation of the cities of Aragon, formed to defend themselves against the usurpations and the rapacity of the feudal nobility. This object was most clearly apparent in the brotherhood (Hermandad) formed about the middle of the 13th century in Aragon, and that formed about 1282 in Castile. In 1295, 35 cities of Castile and Leon formed a joint confederacy for the same object. These fraternities were the model of the later Hermandad of the municipal communities, which was formed in Castile under the reign of Ferdinand and Isabella. It was established in 1486 with the approbation of the king. The city authorities raised a military force, and appointed judges in different parts of the kingdom. Neither rank nor station protected the offender against the tranquillity of the country, nor could he find safety even in the churches. The Santa Hermandad (holy brotherhood) which readers of Don Quixote will be acquainted with, had, like the earlier institution, of which it was a continuation, the object of securing internal safety, and seizing disturbers of the peace and highway robbers, but did not act except in case of offenses actually committed. It consisted of a company of armed police officers, who were distributed in the different provinces of the kingdom of Castile, and whose duty it was to provide for the security of the roads outside of the cities. One of their strictest regulations was not to use their power within the cities. They were subject to the Council of Castile. The principal divisions of the company had stations at Toledo, at Ciudad Rodrigo, and at Talavera.

Hermann, hėr'man, **Alexander**, American conjurer: b. Paris, France, 10 Feb. 1844; d. near Great Valley, N. Y., 17 Dec. 1896. From his brother Carl, Alexander took his earliest lessons in sleight-of-hand and the brothers then traveled in Europe and became widely known as skilled conjurers. Coming to the United States in 1867 they met with great success. The elder presently returned to Europe, but Alexander became a citizen of the United States, made a tour of the world and had few equals in his profession.

Hermann (hĕr'män) **und Dorothea**, dŏr-ō-tā'ä, a pastoral poem by Goethe, published in 1797. It contains about 2,000 hexameter lines. The scene is the broad Rhine plain, and the time the poet's own. The standard English translation is that by Miss Ellen Frothingham (1870).

Hermann, Mo., a town in Roark Township, the capital of Gasconade County, on the south bank of the Missouri River, here crossed by a bridge, 81 miles west of St. Louis, and on the Missouri Pacific railroad. It is in a grape-vine-growing region and manufactures wine, beer, flour, tools and cigars. Pop. (1900) 1,575.

Hermannstadt, or **Nagy-Szeben**, Austria, the capital of a county in Transylvania. See SZEBEN, NAGY.

Hermaph'roditism, the occurence of both kinds of sexual glands in one and the same animal. The differentiation of the sexes begins with the polyps, when for the first time in the animal kingdom we meet with individuals which are male and female. The lower plants and in the animal kingdom the sponges and Hydra (q.v.) are monœcious, that is, sexual cells occur in the same individual. In the more highly specialized animals, the sexual glands exist in different individuals, and the form is said to be bisexual, or diœcious, as opposed to hermaphroditic forms.

True or Natural Hermaphroditism.— This is found in many flowering plants, in sponges, most cœlenterates, many worms, including the earthworm, many mollusks, and in most barnacles, and this appears to be in relation with their more or less fixed mode of life. As a rule testes and ovaries occur in the same animal, but situated in different regions of the body, while in land snails there is a hermaphroditic gland which produces spermatozoa and eggs in the same follicle. Certain animals, or frogs, which are bisexual as adults, pass through an embryonic hermaphroditism. Normal hermaphroditism is very rare in insects and vertebrates: in the latter only two cases are known, that is, a sea-perch (*Serranus scriba*) and the hagfish (*Myxine*).

Abnormal Hermaphroditism.— What in man is called hermaphroditism is a misnomer, as it arises from malformation of the external reproductive organs. In insects occurs lateral hermaphroditism in which one half of the moth or butterfly, for example, is male and the other female. In some of these cases dissection has shown that only male or female sexual glands alone occur in an undeveloped condition. This is called *gynandromorphism*. Abnormal hermaphroditism sometimes occurs in fishes and batrachians where an ovary is found on one side and a testis on the other. It is curious that in a threadworm (*Angiostomum*) and in certain isopod crustacea (*Cymothoidæ*) the reproductive glands are first male, the same gland afterward producing eggs.

Hermes, Georg, gā-ōrg' hĕr'mĕs, German theologian: b. Dreyerwalde, Westphalia, 22 April 1775; d. Bonn 26 May 1831. He studied theology at the University of Münster, became a teacher in the gymnasium of that city, and in 1807 professor of dogmatic theology in the university. When the Prussian government established the University of Bonn, Hermes was appointed to the chair of Catholic theology (1819). Here he began to distinguish himself by his attempts to found a speculative, philosophic, and dogmatic school in the church itself, delivering a series of lectures which caused great sensation by aiming at an alliance between Protestants and Catholics. This attempt to base the positive theology of the church (a doctrine known as Hermesianism) drew around him great numbers of followers. Many of these in time filled chairs of theology and set forth their views in conjunction with their master in a magazine, the 'Zeitschrift für Philosophie und katholische Theologie,' published at Cologne from 1832. The method which Hermes advocated insisted that the truth of revelation and of the Catholic Church should first be tested by reason, and that revelation should then be followed. He did not go so far as to declare that all the dogmas in themselves could be proved *a priori*, but endeavored to found the right of the church to teach them on the ground of reason. Hermesianism was in fact an ingenious effort to base the doctrines of the church on Kant's system of philosophy. It aroused powerful opposition, being condemned as heretical by a papal letter of 26 Sept. 1835. Hermes' scholars stoutly defended their orthodoxy, many of them repeatedly appealing to the pope, but without success.

Hermes, hĕr'mēz (called by the Romans *Mercurius*, and identified with their own god of that name), in Greek mythology the son of Zeus and Maia. According to legend his birthplace was in the mountains of Cyllene, Arcadia. Four hours after his birth he invented the lyre, which he made by killing a tortoise, and stringing the shell with three or seven strings. He then sang to it the loves of Zeus and his mother Maia. Having concealed the lyre in his cradle, he was seized with hunger, went in the dark evening to Pieria, and stole 50 oxen from the sacred herd of Apollo which he drove backward and forward to confound their tracks; then walking backward himself, he drove them backward also; and after having killed two of them near the river Alpheus roasted and sacrificed a part to the gods. He concealed the remainder in a cavern. He also carefully destroyed all traces of them. The next morning Apollo missed his oxen, and went in search of them, but he could discover no traces of them until an old man of Pylos told him that he had seen a boy driving a herd of oxen in a very strange manner. Apollo now discovered that Hermes was the thief. He hastened to Maia, and accused the infant, who pretended to be asleep, and, not terrified by the threat of the god that he would hurl him into Tartarus, steadily maintained his innocence. Apollo, not deceived by the crafty child, carried his complaint to Zeus. Hermes lied even to him. But Zeus perceived him to be the offender; but was not angry with him, and smiling at his cunning, ordered him to show the place where the oxen were concealed. To secure him Apollo bound his hands, but his chains fell off, and the cattle appeared bound together by twos. Hermes then began to play upon his newly-invented lyre, at which Apollo begged the instrument of the inventor, learned of him how to play on it, and gave him a whip to drive the herd, thenceforth belonging to both in common.

They then concluded a contract with each other: Hermes promised never to steal Apollo's lyre or bow; the latter gave him the *caduceus*. The ancients represent Hermes as the herald and messenger of the gods. He conducts the souls of the departed to the lower world, and is therefore the herald of Pluto, and the executor of his commands. His magic wand had the power to close the eyes of mortals, to cause dreams, and wake the slumbering. The qualities requisite for a herald he possessed in the highest perfection, and bestowed them on others — grace, dignity, and insinuating manners. He was also the symbol of prudence, cunning, and fraud, and even of perjury, and was the god of theft and robbery. In the wars of the giants he wore the helmet of Pluto, which rendered him invisible, and slew Hippolytus. When Typhon compelled the gods to fly before him and conceal themselves in Egypt, he metamorphosed himself into an ibis. He is also mentioned by Homer as the patron of eloquence, and still more particularly by Hesiod. Of his inventions Homer makes no mention. Later writers ascribe to him the invention of dice, music, geometry, the interpretation of dreams, measures and weights, the arts of the palæstra, letters, etc. He was also regarded as the patron of public treaties, as the guardian of roads, and as the protector of travelers. He was represented in art as a boy in the prime of youth, sometimes with the caduceus, and sometimes with a winged cap, standing, sitting, or walking. The artists of later times placed him among the youthful and beardless gods. The most prominent traits of his character are vigor and dexterity. In the representation of Hermes of a later date the relations of corporeal beauty and mental dexterity are wonderfully preserved. Artists made the cock his symbol, on account of its vigilance or love of fighting (in allusion to gymnastics); the tortoise, on account of his invention of the lyre; the purse, because he was the god of traffic; a ram and a goblet, because he was the director of religious ceremonies and sacrifices; the trunk of a palm-tree, upon which his statues lean, because he was the inventor of arithmetic and writing (upon palm-leaves); the *harpe* or sickle-shaped knife, because he was the slayer of Argus.

Hermes Trismegistus, trĭs-mē-jĭs'tŭs, the Greek title of the Egyptian moon god, Thoth, one of the most interesting figures in Egyptian mythology. He is represented as Ibis or with the ibis head, and is fully illustrated in the monuments and papyrus rolls from time to time brought to light. He is the god of time and of its divisions; he is the measurer and the god of measurements. He is the conductor of the dead. He is also the god of human intelligence, to whom are attributed all the productions of human art. All the literature of Egypt is attributed to him—all the writings that relate to the different sciences, mathematics, astronomy, medicine, music. These were called by the Greeks the Hermetic Books. Thoth is also credited with the invention of alchemy and magic. The Hermetic art is used to mean alchemy. The secrets of this art were handed on from teacher to pupil orally and in secret and this transmission was termed the Hermetic chain. For these reasons the Greeks identified him with their Hermes, and besides called him Trismegistus, "thrice great." By later writers, Euhemerists, Neoplatonists (q.v.), and Christians, Thoth was considered a great Egyptian king, a teacher of mankind, who had left books of magic and mystery behind him. Numerous books of such a sort once existed in Egypt. Clement of Alexandria knew of 42, and so-called Hermetic fragments are still extant, in the works of Stobæus, Cyrillus, Suidas and Lactantius. The Hermetic books as we know them belong probably to no earlier date than the 3d or 4th century of our era, and are in Greek and Latin.

Her'mit (Gr. *eremitēs*), a solitary ascetic, who, with a view to more complete freedom from the cares, temptations, and business of the world, took up his abode in a natural cavern or a rudely formed hut in a desert, forest, mountain, or other solitary place. Hermits began to appear in the Christian church in the 3d century. The advocates of asceticism (q.v.) were the first to set the example of retiring from cities to rural districts and villages. But the hermits sought to withdraw altogether from mankind, that they might give themselves up to holy contemplation. The earliest hermit is said to have been Paul of the Thebaid (Egypt), who during the Decian persecution fled to the desert (250); there he lived for the rest of his life, dying, 113 years old, about 342. The fame of his sanctity quickly incited others to imitate his mode of life. The most famous amongst these successors was St. Anthony (q.v.). At the time of his death (365) hermit cells existed in considerable numbers in the deserts of Egypt, Syria, and Palestine. The fame of their sanctity drew many to visit these hermits partly out of curiosity, to get religious advice from them, partly also in the belief that diseases were cured by their blessing. Sometimes they returned for a short time to the midst of their fellow-men to deliver warnings, instruction, or encouragement, and were received as if they had been inspired prophets or angels from heaven. But the number of hermits gradually diminished as the cenobite life of convents grew into fashion. Indeed the institution at no time secured the same footing in the Western Church that it did in the Eastern; and perhaps the reason may in part be found in the difference of climate, which renders a manner of life impossible in most parts of Europe that could be pursued for many years in Egypt or Syria. Partial revivals of the practice continued to be made, however, during some centuries, St. Cuthbert (q.v.) being a case in point. See MONACHISM, and Charles Kingsley's 'Hermits' (1869).

Hermit-crabs, crabs that shelter themselves in spiral sea-shells, for the protection of the soft-skinned and unsymmetrical abdomen. They are members of the *Macrura* (see DECAPODA), and have very large and generally unequal claws, one being used to close the entrance of the shell into which the hermit can wholly retract himself. The abdominal appendages are practically aborted, with the exception of those at the tip of the tail, which hold firmly to the spire of the inhabited shell. The hermit-crabs belong to three families, namely: *Paguridæ*, or common marine hermit-crabs; *Parapaguridæ*, or deep-sea hermit-crabs; and *Cenobitidæ*, or terrestrial hermit-crabs. Two species are numerous on the American Atlantic coast running actively about in rock pools and shallows. The little hermit-crab (*Eupagurus longicarpus*) generally inhabits the shells of dog-whelks (*Ilyanassa*), while the larger species (*E. pollicaris*) occupies those of *Lunatia* or sometimes of the winkles and conchs. As they grow they must move to larger and larger shells, and the search for new tenements and dangerous change of abodes in the presence of enemies makes the life of one of these animals more than ordinarily exciting. The habits of these and other hermit-crabs are of great interest, generally, and especially on account of the various hydroids, anemones and mollusca which associate with them as commensals. The palm or robber-crab (q.v.) of the East Indies, and the land-crabs of the West Indies, are good examples of terrestrial hermit-crabs. Consult J. R. Henderson, 'Challenger Report on Anomura'; Verrill, 'Invertebrates of Vineyard Sound' (1875); Arnold, 'Sea Beach at Ebb tide' (1901). See COMMENSALISM, CRAB, CRUSTACEA.

Hermit Thrush. See THRUSH.

Her'mitage, The, Andrew Jackson's home at Nashville, Tenn., from about 1804, when he removed there from Hunter's Hill. In 1819 the house was built in which he lived till his death in 1845. The Hermitage is now the property of the State of Tennessee.

Hermite, Charles, shärl ăr-mēt, French mathematician: b. Dieuze, Meurthe, German Lorraine, 24 Dec. 1822; d. Paris 14 Jan. 1901. He entered the Ecole Polytechnique in 1842, but left it to devote his attention wholly to mathematics. From 1876 to his death he held the chair of higher algebra in the University of

Paris. His principal claim to be considered a great and original mathematician rests on his investigations in the line of functions, and his first important work on this theory won for him election to the Academy of Sciences. He proceeded to make discoveries in the theory of algebraic forms and in the theory of numbers. He finally settled the question of the solubility of the quintic equation, and really led the way to Lindemann's further investigations. For a list of his writings see 'Catalogue of Scientific Papers of the Royal Society of London,' Vols. III. and VII.

Hermosillo, här-mō-sēl'yō, Mexico, capital of the state of Sonora, on the river Sonora, about 60 miles from the Gulf of California, and 78 by rail north from the port of Guaymas, with which it has a large traffic, being the principal entrepôt for the trade with the interior. Large quantities of fruit are grown in the vicinity, especially grapes, from which much brandy is made. Pop. (1903) 17,800.

Hern'don, William Henry, American lawyer: b. Greensburg, Ky., 28 Dec. 1818; d. near Springfield, Ill., 18 March 1891. He studied at Illinois College, was admitted to the bar in 1844, and in the same year formed a law partnership with Abraham Lincoln, which continued formally till the latter's death. He was mayor of Springfield, Ill., in 1855. With J. W. Weik, he wrote the well-known 'Herndon's Lincoln: The True Story of a Great Life' (in a new ed. 1891), which is particularly valuable for the study of Lincoln's personality and the details of his early career.

Herne, James A. (James Aherne), American actor and playwright: b. Troy, N. Y., 1 Feb. 1840; d. New York 2 June 1901. He first appeared in a traveling company, and later in various roles and organizations throughout the United States. Later he was actor-manager at San Francisco, and in 1878 presented his first play, 'Hearts of Oak,' which won immediate success. 'Drifting Apart' (1885), 'The Minute-Men' (1886) and 'Margaret Fleming' (1890) were less favorably received, although the last was highly ranked by the critics. In 1883-4 Herne wrote his most successful work, 'Shore Acres,' which was first performed as 'The Hawthornes' at Chicago in 1892, and in 1892-3 in Boston under its present title. He himself appeared as 'Uncle Nat' Berry. 'Shore Acres' was followed by 'The Rev. Griffith Davenport' (1899), a dramatization of Helen Gardner's 'An Unofficial Patriot,' and 'Sag Harbor' (1900). As both actor and dramatist Herne was a skilful delineator of types of everyday life.

Her'nia (Latin, a rupture, a burst, a descent), a swelling formed by the displacement of a soft part, which protrudes by a natural or accidental opening from the cavity in which it is contained. The three great cavities of the body are subject to these displacements. The brain, the heart, the lungs, and most of the abdominal viscera may become totally or partially displaced, and thus give rise to the formation of hernial swellings. Displacements of the brain and of the organs of the chest are, however, extremely rare, and are in general the result or symptom of some accident or disease. Many parts of the abdominal wall may become the seat of hernias, but they most commonly appear in the front lower regions, which, being destitute in great measure of muscular fibres, and being the site of many of the openings leading from the abdomen to the limbs, offer less resistance to the displacement of the viscera. Hernias are most common in the groin, at the navel, more rarely in the vagina, at the interior and upper part of the thigh, and at its lower and posterior part. They have received different names from their positions. All the abdominal viscera, with the exception of the duodenum, the pancreas, and the kidneys, may form a hernia, but they are not all displaced with the same facility. The omentum and intestinal canal escape easily; the stomach, liver, and spleen rarely form hernias. Most of the viscera, when displaced, push the peritoneum forward before them; this membrane thus forms a covering to the hernia, which is called the hernial sac. If the hernia, with its sac, can be entirely replaced, it is said to be reducible; if, from its size or other cause, it cannot be restored to its former place, it is irreducible.

Among the predisposing causes of hernia may be ranked any circumstance which diminishes the resistance of the abdominal walls, whether natural or accidental; such as muscular weakening of those walls by a forced distention, as in pregnancy, by accidents, by lifting heavy weights, or by excessive standing. Any prolongation of the viscera which tends to bring them in contact with points at which they may protrude, and articles of dress which push the organs toward the weaker parts of the abdominal wall (as corsets), may also produce hernia. The efficient causes of hernia are all circumstances which may break the equilibrium existing between the abdominal walls and the viscera, which react and mutually press upon each other. The simultaneous contraction of the abdominal muscles and of the diaphragm, which takes place on every violent effort, is one of the chief of these cases. Hence sneezing, coughing, leaping, playing on wind-instruments, etc., may be the direct cause of a hernia.

The symptoms of a hernia are the existence of a tumor or swelling at any point of the abdomen, but more particularly in the region of the groin. A reducible hernia is not a very troublesome disease, but may become so by acquiring an increase of size, and by strangulation. A hernia is said to be strangulated when it is not only irreducible, but also subjected to a continual constriction; this constriction may be produced by different causes, but it is generally a constriction at the opening through which the hernia protrudes. As soon as a patient perceives that he is affected with a hernia he should have recourse to medical advice, for the disease is then in its most favorable state for treatment. The hernia is immediately reduced, and must then be subjected to a constant compression. This is done by means of a truss (q.v.). An irreducible hernia must be supported with great care. All violent exercises and excess in diet must be avoided. Strangulated hernia, presenting greater danger, requires more prompt relief. The object of treatment is to relieve the constriction. If the reduction cannot be effected by other means, an operation will be necessary. This consists in dividing the parts which produce the constriction. The longer this operation is delayed, the more dangerous it will become. After the parts are healed, the opening must be subject to compression, as in the case of a simple hernia. Radical operation for hernia is the most advisable form of treatment. It is safe in the hands of a competent surgeon.

Hero, a priestess of Aphrodite at Sestos. The loves of Hero and Leander, a youth of Abydos, on the other side of the Hellespont, are related in a poem by Musæus. No difficulties could discourage Leander. He swam every night across the Hellespont, guided by a torch which shone across the strait from the tower of Hero, and even continued his visits during the winter. On one occasion, however, the guiding light was extinguished, and his strength failed him, and the waves carried his body to the foot of the tower, where Hero anxiously awaited him. Overcome with anguish at the sight, she threw herself from the tower and perished.

Hero of Alexandria (Gr. *Herōn*), Greek mathematician and natural philosopher; fl. perhaps in the 1st century A. D. He seems to have invented a number of machines, among which are "Hero's fountain," and a steam-engine on a principle similar to that of Barker's mill (q.v.). He also made some contributions to pure mathematics. Hultsch edited the remaining fragments of his geometrical works in 1864, and Schmidt began in 1899 an edition of his complete extant writings. See HERO'S FOUNTAIN.

Herod, called THE GREAT, king of the Jews: b. about 62 B.C.; d. 4 B.C. He reigned from 37 B.C. until his death. He was the second son of Antipater the Idumean, who, being made procurator of Judea by Julius Cæsar, appointed him to the government of Galilee. He at first embraced the party of Brutus and Cassius, but after their death reconciled himself to Antony, by whose interest he was first named tetrarch, and afterward king of Judea. After the battle of Actium Augustus confirmed him in his kingdom. As a politician and commander, his abilities were conspicuous. He rebuilt the temple at Jerusalem with great magnificence, and erected a stately theatre and amphitheatre in that city, in which he celebrated games in honor of Augustus, to the great displeasure of the more zealous of the Jews. He also rebuilt Samaria, which he called Sebaste, and adorned it with very sumptuous edifices. He likewise, for his security, constructed many strong fortresses throughout Judea, the principal of which he termed Cæsarea, after the emperor. On his palace, near the temple of Jerusalem, he lavished the most costly materials, and his residence of Herodium, at some distance from the capital, by the beauty of its situation, drew around it the population of a great city. Such, indeed, was his magnificence, that Augustus said his soul was too great for his kingdom. Herod was the first who shook the foundation of the Jewish government, by dissolving the national council, and appointing the high-priests, and removing them at pleasure, without regard to the laws of succession. His policy, ability, and influence with Augustus, however, gave a great temporary splendor to the Jewish nation.

Herod Agrip'pa I., king of Judea: d. Cæsarea 44 A.D. He reigned from 37 A.D. until his death. He was son of Aristobulus. At Rome with Drusus, son of Tiberius, on whose death he left Rome for Idumæa; but returned some years after. On the accession of Caligula 37 A.D. he was honored with the title of king, and received the tetrarchies of Philip and Lysanias, and later that of Antipas. Upon the accession of Claudius his rule was extended to include all the dominions of Herod the Great. It was this Herod who, to please the Jews, caused St. James to be put to death, and St. Peter to be imprisoned. His power and opulence acquired him a great reputation, and he really did much for the benefit of the Jews. His death is described in Acts xii. 20–3.

Herod Agrippa II., king of Judea: d. 100 A.D. He reigned from 53 A.D. until his death. He was son of Herod Agrippa I. He resided much at Jerusalem, and here, together with his sister, Berenice, heard the defense of Paul, addressed to the Roman governor Festus (Acts xxv. 13–xxvi. 32). A great builder, he improved his capital city of Cæsarea Philippi; renamed by him Neronias. It was in his reign that the Temple was completed. Being driven from Jerusalem in the revolt which proved so fatal to the Jews, he joined Cestius, the Roman commander, and, when Vespasian was sent into the province, met him with a considerable reinforcement. During the siege of Jerusalem he was very serviceable to Titus.

Herod An'tipas, tetrarch of Galilee. He reigned from 4 B.C. to 37 A.D. He was son of Herod the Great. This was the Herod who put to death St. John the Baptist (Mark vi. 14–29), in compliment to his wife Herodias, and it is he who is the familiar 'Herod' of the New Testament narrative. Accused of having been concerned in the conspiracy of Sejanus, and of being in secret league with the king of Parthia, he was stripped of his dominions, and sent (39 A.D.) with his wife into exile at Lugunum (Lyons), or, as some say, to Spain, where he died.

Herodes, Atticus. See ATTICUS HERODES.

Hero'dias, a granddaughter of Herod the Great and Mariamne, daughter of Aristobulus and sister of Herod Agrippa I. She was first married to her half-uncle Herod Philip, whom she abandoned to connect herself with his half-brother Herod Antipas. It was by her artifice that Antipas was persuaded to order the death of John the Baptist (Matt. xiv. 3–12; Mark vi. 17–29).

Herod'otus, Greek historian, called the "father of history": b. at Halicarnassus in Asia Minor about 484 B.C. Before writing his history he traveled extensively, visiting the shores of the Hellespont and the Euxine, Scythia, Syria, Palestine, Babylon and Ecbatana, Egypt as far as Elephantine and other parts of northern Africa, everywhere investigating the manners, customs, and religion of the people, the history of the country, productions of the soil, etc. On returning home he found that Lygdamis had usurped the supreme authority in Halicarnassus, and put to death the noblest citizens, and Herodotus was forced to seek an asylum in the island of Samos. Having formed a conspiracy with several exiles he returned to Halicarnassus and drove out the usurper, but the nobles who had acted with him immediately formed an aristocracy more oppressive than the government of the banished tyrant, and Herodotus withdrew to the recently founded colony of Thurii, in Italy, where he seems to have spent most of his remaining life. Here, at an advanced age, we are told by Pliny, he wrote his immortal work, a statement strengthened by the fact that events are noticed in the body of the book which occurred so late as 409 B.C., while its abrupt ending proves almost beyond question that he was prevented by death from completing it. The history is divided into nine books, each bearing the name of a Muse, and is written in the Ionic dialect. The object of the historian is to narrate the conflict between the Greeks and Persians, and he traces the enmity of the two races back to mythical times. Passing rapidly over the mythical period he comes to Crœsus, king of Lydia, of whom and of his kingdom he gives a comparatively full history. The conquest of Lydia by Cyrus induces him to relate the rise of the Persian monarchy and the subjugation of Asia Minor and Babylon. The history of Cambyses and his Egyptian expedition leads him to introduce the valuable details of the history, geography, and manners and customs of Egypt, occupying the second book. The Scythian expedition of Darius causes the historian to treat of the Scythians and the north of Europe; and the subsequent extension of the Persian kingdom affords him opportunity for an account of Cyrene and Libya. In the meantime the revolt of the Ionians breaks out, which eventually brings on the conflict between Greece and Persia. An account of this outbreak and of the rise of Athens after the expulsion of the Pisistratidæ, is followed by what properly constitutes the principal part of the work, and the history of the Persian war now runs on in an uninterrupted stream until the taking of Sestos. There are English translations of his history by Macaulay (1890); Beloe, Cary, and Rawlinson, the last with important notes and dissertations. The 'Life of Homer,' attributed to Herodotus, and printed at the end of several editions of his works, is now universally believed to be a production of a later date. The best editions of the history of Herodotus are by Wesseling (1763); Schweighäuser (1806); Bähr (1855-61); Stein (1871).

Heroin, hĕr'ō-in, $C_{17}H_{17}NO_3(CH_3CO)_2$, the diacetic ester of morphine. It occurs as a faintly bitter, colorless, odorless, crystalline powder, which is nearly insoluble in water. It is soluble in dilute acids, however, and is precipitated by alkalies. Its hydrochloric dissolves freely in water and in alcohol, but is insoluble in ether. Heroin was first prominently introduced to the medical world in 1898.

Herold, Louis Joseph Ferdinand, loo-ē zhō-zĕf fĕr-dē-nań ā-rōld, French musical composer: b. Paris 28 Jan. 1791; d. Thernes, near Paris, 19 Jan. 1833. A pupil of the Conservatoire, he also studied composition under Catel, Mehul, and Cherubini, and in 1812 won the Prix de Rome with the cantata 'Mlle. de la Vallière.' His first opera, 'La Gioventú di Enrico Quinto' (1815) was received by the Neapolitan public with applause. His first serious effort as composer for the French stage was with his comic opera 'Les Rosières' (1817). This very successful work was followed in quick succession by numerous others of varying fortune. At last in 1831 appeared his 'Zampa,' and in 1832 his 'Le Pré aux Clercs,' the operas on which his fame chiefly rests, and which have gained a permanent place, the former especially being still produced with acceptance in the principal cities of the Continent. Consult: Jouvin, 'Herold sa Vie et ses Œuvres' (1868).

Heron, Matilda, American actress: b. Draperstown, near Londonderry, Ireland, 1 Dec. 1830; d. New York 7 March 1877. She was brought to the United States as a child, and appeared on the stage for the first time in Philadelphia as Bianca in 'Fazio.' Her chief parts, in which she met with great success throughout the United States, were Camille in 'La Dame aux Camélias'; and Ulah in 'De Soto.'

Herondas, or **Herodas**, Greek poet, probably flourishing about the latter half of the 3rd century B.C. Little positive information is obtainable concerning the place of his birth, but it was probably in the island of Cos. Prior to 1891 only a few fragments of his verses had been found, but in that year an Egyptian papyrus was found containing several poems (mimes or mimianibi) and these were published by F. G. Kenyon, thus bringing to light a phase of Greek life and times of which the history has been meagre. Seven of the poems are in comparatively complete form, and, besides giving an insight into Heronda's life and work, they picture the every day life of the times in extremely realistic terms, though the satirical portions of them are not personal in their nature. In composition the mimes are in choliambic verse or iambic trimeter and are written in the Ionic dialect. The latest edition containing additions by O. Crusius was published in 1898, entitled 'Untersuchungen zu den Mimiamben des Herondas.' See MIME.

Herons, wading birds of the order *Herodii*, forming, with egrets and bitterns, the family *Ardeidæ*. The family is characterized by a thin, compressed body; a long, thin neck; a straight, narrow, pointed beak; fully feathered head; longish, slender legs; three toes in front, the two outer united by a membrane, the middle claw pectinate; large, blunt wings; extensive development of powder-down tracts; and often by elongated feathers of the top of the head and other parts. Upward of 70 species of herons and their immediate allies are known, of which 14 inhabit North America. The bitterns (q.v.), with 10 tail-quills, form the sub-family *Botaurinæ*, the herons and egrets (q.v.), with 12 tail quills, the *Ardeinæ*. Egrets are simply white herons. The great blue heron (*Ardea herodias*) to which *A. cinerea* of Europe is closely related, inhabits all parts of North America and northern South America. It is a large bird with a length of about four and a spread of nearly six feet, and of beautiful slate-blue color, with the long flowing plumes black. It is to be found by the side of streams, lakes and the seashore, usually alone. Fish form the bulk of its food, but it also devours frogs, small reptiles, insects, and almost any kind of animal which it can capture. It roams in search of food mostly in the morning and evening. The heronry, or breeding-place, is usually found among high trees, and the same breeding-place is used by successive generations if they are unmolested; frequently several species of herons consort together at a favorite breeding-place. The large nest is made of twigs and sticks, and is lined with rushes, grass, and various similar materials. The eggs, usually three or four in a nest, are of a fairly uniform greenish blue color. Many nests are usually found in one heronry, and sometimes the nests are built on the ground or on a cliff. The cry is a sort of "crank, crank," uttered in a hoarse voice. In the North the blue heron is migratory, elsewhere it is resident. The little blue heron (*A. cærulea*) is found in the eastern United States from the Middle States southward and in the West Indies and Central America. It is scarcely more than one half the size of *A. herodias* and exists in two color phases, the one dark slate-blue with purplish reflections on the head and neck, the other white with traces of blue, especially constant on the unfeathered parts. This species formerly bred with other southern species in great heronries, most of which have been decimated by plume-hunters.

The little green heron or fly-up-the-creek (*Butorides virescens*) ranges throughout temperate North America and somewhat beyond southward, breeding nearly everywhere. Northward it is migratory and is the familiar heron about the streams and ponds of the Middle and New England States, where it usually nests in pairs or small communities and mostly in thick bushes or cedar trees; in other localities it sometimes breeds with larger species in heronries. The pale greenish elliptical eggs are from three to six in number. Its foods consist chiefly of small frogs, minnows and snakes, for which it searches by day as well as by night along the shallows of streams, where its harsh cry of alarm is often the first intimation of its presence. The name refers to the beautiful deep bronze green color of the upper parts.

The night-herons (*Nycticorax nævius*, and *N. violaceus*), which are closely related to the *N. grisea* of Europe, are easily distinguished from other herons by the thick, stout beak. The former, known as the black-crowned night-heron or squawk, is common throughout the United States and Canada in summer, and in the winter migrates far into South America, while the latter, or yellow-crowned species, is much less frequent and chiefly confined to the sea-coast of the warm parts of America. The squawk is about two feet long, the young brownish, the adults deep green and blue-gray above with two or three very long filamentous white occipital plumes. The night-herons are more active after dark than any other species, and are seldom seen abroad, except in the dusk or on cloudy days.

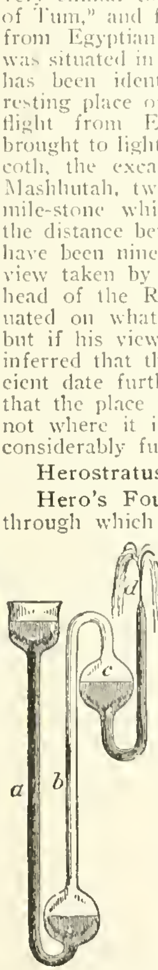
Many species of herons reside in the warm parts of Africa and Asia, among them being the largest of all, the *A. goliath*.

Consult Baird, Brewer and Ridgway, 'Water-birds of North America' (1884); Reichenow, 'Journal of Ornithology' (1877); Job, 'Among the Waterfowl' (1902). See BITTERN; EGRET.

Heroöpolis, an ancient Egyptian city found by excavation in the eastern Delta region. Maps made prior to 1880 generally located the city near the present city of Suez, but the excavations of Naville in 1883 under the auspices of the Egypt Exploration Fund tend to show that the city was farther north. Heroöpolis is given in the Septuagint version of the Old Testament as the meeting place of Joseph and Jacob. The Coptic translation is Pethom, very similar to the Hebrew Pithom, or "House of Tum," and for some time it has been known from Egyptian geographical lists that Pithom was situated in the land of Theku-t. This name has been identified with Succoth, the second resting place of the Children of Israel in their flight from Egypt. The Naville excavations brought to light the old site of Pithom and Succoth, the excavations being made at Tell el-Mashhutah, twelve miles west of Ismailah. A mile-stone which was recovered then showed the distance between Heroopolis and Clysma to have been nine miles. This would confirm the view taken by Strabo that the city was at the head of the Red Sea navigation and was situated on what he called "Heroöpolitan Gulf," but if his view be correct, then it can only be inferred that the Red Sea extended at that ancient date further north than it now does and that the place where the Israelites crossed was not where it is generally supposed to be, but considerably further north.

Herostratus. See EROSTRATUS.

Hero's Fountain, a pneumatic apparatus, through which a jet of water is supported by condensed air. A simple mode of constructing it by means of glass tubes and a glass-blower's lamp is shown in the annexed figure. The column of water in the tube *a* compresses the air in *b;* this presses on the surface of the water in *c*, and causes it to gush out at *d*.



Hero's Fountain.

Herpes, an acute, non-contagious, inflammatory disease of the skin, characterized by an eruption of one or more clusters of vesicles upon a reddened base. Several forms of the disease are recognized by dermatologists, of which the commonest are facial herpes, and herpes zoster. Facial herpes constitutes the common fever blister, or cold sore, and is usually seen about the mouth, though it also occurs on other parts of the face. There is often some slight constitutional disturbance preceding the eruption, which first makes its advent known by a sensation of burning or itching in the part, followed by reddish discoloration of the skin and after a few hours by a number of pin-head to pea-sized blisters filled with clear or turbid fluid. After a few days these dry up and form a yellowish crust, which then falls off, leaving a red spot that soon disappears. The usual duration of the disease is about a week and it shows a strong tendency to recur. Herpes often accompanies febrile conditions such as pneumonia and malaria, and a similar lesion is not rare about the genitals. Herpes occurs mostly in those whose skin is irritable or delicate, and is usually the result of some derangement of the mucous membrane of the respiratory, digestive or genito-urinary tract. It sometimes is the unfailing harbinger of the menstrual period. Cold, mental depression, and injury or irritation of the skin are other causes. The disease belongs to the class of the neuroses, and in some instances its presence can be explained only on the basis of nerve disturbance. In most cases no treatment is required, as the lesions promptly heal of their own accord, but soothing ointments or lotions tend to relieve the irritation. Herpes zoster, or shingles, is a special form remarkable for the fact that the eruption follows the course of certain nerves, and is usually disposed around one side of the body like a half belt. In rare cases it encircles the body. Its onset is preceded by stinging neuralgic pains, and by languor, lassitude, loss of appetite, shiverings, headache, nausea, quickened pulse, etc., after which the eruption appears in irregular patches. The vesicles become enlarged to the size of small peas in twenty-four to thirty-six hours, and fresh clusters occur for three or four days, completing the belt-like appearance. As the eruption recedes, by the fifth or sixth day, the vesicles become white and opaque, and the red margins grow livid or purple. Sometimes the vesicles burst, and several of the patches run together, forming irritable sores, discharging a thin serous fluid, which concretes and forms a crust that falls off as the parts beneath heal. The disease occasionally follows injuries to the nerves, and it is common in damp, cold weather of spring or autumn, when it sometimes occurs in epidemics. It is sometimes produced by sudden exposure to cold after violent exercise, and sometimes follows acute affections of the respiratory organs. The treatment consists in attention to any systematic derangement present and in the local use of soothing applications, and protective dressings to prevent rupture of the vesicles. The duration of shingles is usually from ten days to three weeks. Most cases run a favorable course and second attacks are rare.

Herpestis, a genus of dicotyledonous gamopetalous plants, of the natural order *Scrophularineæ,* of the tribe *Gratioleæ,* native to the tropical sections of both hemispheres. It may be distinguished by its calyx, as the upper segment is large and ovate, and covers the rest, the other lobes narrow or linear, its cylindrical corolla, four stamens, and two or four-valved capsule. The genus comprises about fifty species of small, creeping herbs, having opposite, or toothed leaves, and generally flowering solitary or in axillary clusters of yellow, blue or white flowers. *H. Monniera* is the common water hyssop, and the natives of India find the juice of this plant, when mixed with petroleum, of great benefit to parts of the body affected with rheumatism. *H. colubrina,* a native to Peru, is used, under the name of *yerba de culubra,* as a remedy for the bites of poisonous animals.

Herpetology, hėr-pē-tŏl'ō-jĭ, the study of reptiles. In its earlier days it included under the term "reptile" not only those now properly so named, but the amphibia (q.v.) and some other "creeping things" not in either group. Cuvier's classification, the first approach to a scientific one, put both the true reptiles and the amphibians as co-related groups under *Reptilia;* but their formal distinction was soon perceived. Huxley showed that in their descent, embryology and structural relations, the amphibians were more closely related to fishes than to the reptiles (lizards, serpents and turtles). He therefore united the two in a superior group *Ichthyopsida,* while he joined the birds to the reptiles in a group of similar rank called *Sauropsida.* Thus the limits of herpetology have been restricted to truly scientific limits,— the chordate class *Reptilia,* a definite group distinguished by the following characters:

Reptiles are cold-blooded, the temperature of the body not greatly exceeding that of the surrounding medium: the heart is three-chambered, except in crocodilians, where four chambers first occur; mostly venous blood goes from the heart to the anterior viscera, and mixed blood to the posterior region, only the head and anterior regions receiving purely arterial blood: the body is covered with scales, with which subjacent bony plates or scutes are sometimes associated: the vertebræ are absolutely gastrocentrous (biconcave); the skull articulates by a single condyle with the backbone, and the lower jaw works against the quadrate bone; the great majority are oviparous, while in some the eggs are hatched within the mother.

This characterization unites into the one class, many orders of wholly extinct types, one order represented by a single living example (the tuatara "lizard"), and the existing tortoises and turtles, lizards, snakes, and crocodiles; and none other is a reptile, properly speaking. The group occupies a central position in the vertebrate series. Above it on the scale of organization are the birds and mammals; beneath it the amphibians and fishes. Similarly reptiles stand in a middle position in geological history, as the Mesozoic, or Secondary Period, was that in which the group flourished, and of which the existing forms are, on the whole, the diminished and degraded remnants. In respect to their phylogeny: "On the one hand, there is not the slightest doubt," declares Gadow, "that they are evolved from some branch of the Stegocephali (q.v.), whilst on the other hand the reptiles, probably through some branch of the Theromorpha, have given rise to the mammals; some other reptilian branch, at present unknown, blossomed out into birds."

Classification.—The most recent classification of the reptiles, perfected since about 1875 by the enormous amount of information collected in all parts of the world, and especially in the western United States, in regard to fossil forms (see PALÆONTOLOGY), is that formulated by H. Gadow ('Amphibia and Reptiles,' 1901), expressing substantially the consensus of all specialists, and is as follows:

CLASS REPTILIA.

SUBCLASS I. *Proreptilia.*—Permian reptiles in which the components of the vertebra remain separate; well developed limbs and girdles fitted for a terrestrial life. The fragmentary remains of these animals are hard to separate definitely from the Stegocephali.

SUBCLASS II. *Prosauria.*—Chiefly extinct reptiles with deeply amphicœlous vertebræ whose parts are still unfused; movable chevron bones occur in the tail and frequently, with intercentra, in the trunk.

Order I.—*Microsauri.*—Small Carboniferous and Permian reptiles with dermal armor on the dorsal and ventral side of the trunk and tail; and ribs with head and tubercle. The armor of the skull, and the flat ischia and pubes of the pelvis resemble the condition in Stegocephali.

Order 2.— Prosauri.— Permian to recent, terrestrial, unarmored, generalized reptiles, of which one species (*Sphenodon*, or *Hatteria, Punctatum*) still persists in New Zealand (see TUATARA). This animal is distinguished from the lizards with which it was formerly placed by many skeletal characters, such as the fixed quadrate bone and the broad bony roof of the mouth.

SUBCLASS III. *Theromorpha.*— Fossil reptiles with fixed quadrate bone, only one temporal arch, and having pubes and ischia united ventrally in one broad symphysis. This group has an especial interest because it is probably the one from which mammals sprang, and flourished between the Permian and Triassic ages. See THEROMORPHA.

SUBCLASS IV. *Chelonia.*— Reptiles with an upper and lower bony shield, four feet, and toothless jaws — the turtles. There are two orders, *Athecæ* and *Thecophora*. See CHELONIA.

SUBCLASS V. *Dinosauria.*— Mesozoic reptiles, having a long tail, powerful hind legs, fixed quadrate bones, and bifurcated ribs. It is divisible into several orders. See DINOSAURIA.

SUBCLASS VI. *Crocodilia.*—Four-footed, long-tailed reptiles, with fixed quadrate bone, teeth in alveolæ and confined to jaws; ischia not united by a symphysis. The group had its origin in the Dinosauria, from which it is difficult sharply to separate it, arose in the Mesozoic era, and the early forms were marine. The strict *Crocodilia* first appeared in the lower Jura, and have evolved along two parallel lines of advance, one of which ends in the recent long, sharp-snouted gavials, and the other in the broad, short-snouted crocodiles and alligators (qq.v.). The skin is covered with horny scales or scutes which, in some fossil species formed an osseous armor. The front nasal openings lie on the dorsum of the snout near its apex, and their hinder ends are carried by the broad and deep palate far back into the throat. By this means the alligator can lie submerged with its mouth open so as to bring the nostrils to the surface and thus breath without carrying water into the windpipe. The lungs are large and of complicated structure. The heart has practically four chambers as in mammals. There are three orders: *Pseudosuchia*, early generalized forms, expiring in the Jurassic age; *Parasuchia*, extinct forms of the Jurassic and Triassic periods (See CROCODILE, FOSSIL; BELODON); *Eusuchia*, modern crocodilians. See CROCODILE.

SUBCLASS VII. *Plesiosauria.*—Mesozoic reptiles, with pentadactyle appendages adapted to life in water; fixed quadrate bones, numerous alveolar teeth, and ribs without tubercles. They apparently filled the place of the dolphins of to-day, except that the neck is in most species extremely long. See PLESIOSAURIA.

SUBCLASS VIII. *Ichthyosauria.*— Mesozoic, marine, whale-like, viviparous reptiles, with appendages transformed into paddles. The teeth are conical, lie in a groove and are very numerous. See ICHTHYOSAURIA.

SUBCLASS IX. *Pterosauria.*— Mesozoic aërial reptiles with fixed quadrate and anterior appendages forming wings — the pterodactyls. See PTEROSAURIA.

SUBCLASS X. *Pythonomorpha.*—Elongate marine cretaceous reptiles with movable quadrate bones; appendages shaped like paddles, teeth fused with jaws. Two orders, *Dolichosauri* and *Mosasauri*. See MOSASAURS.

SUBCLASS XI. *Sauria.*— Reptiles with movablt quadrate bones and transverse cloacal opening; the most recent of the reptiles, probably originating in the *Prosauria*. It contains two orders: *Lacertilia* (geckos, lizards, and chameleons); and *Ophidia* (snakes).

Bibliography.— Huxley, 'Anatomy of Vertebrated Animals' (1870); Hoffmann in Broun's 'Klassen und Ordnungen des Thierreichs' (Leipsic, in progress); Duméril and Bibron, 'Erpétologie Générale' (9 vols. Paris, 1834–54); British Museum Catalogues by Boulenger, etc.; Holbrook, 'North American Herpetology' (1836–42); Zittel-Eastman, 'Text-book of Paleontology' (1902); Gadow, 'Amphibia and Reptiles' (1901).

Herrera, Francesco de, frän-thĕs'kō dā är-rā'rä, called EL VIEJO (the Elder), Spanish painter: b. Seville 1576; d. Madrid 1656. He broke with the Italian traditions of Spanish painting and became the founder of the Spanish national school. He also worked in bronze, and it was this probably which gave rise to the charge that he was connected with counterfeiters. He had a disposition so very detestable that his pupils, of whom Velasquez was one, all left him. The Louvre contains some of his works, among others 'The Israelites Gathering the Quail in the Wilderness.' But the best are at Seville, including the 'Last Judgment,' in the Church of San Bernardo; 'Saint Peter,' in the Cathedral; and 'Moses Smiting Water from the Rock,' one of four large canvases in the archiepiscopal palace. His frescoes at both Madrid and Seville have quite disappeared.

Herrera, Francesco de, called EL MOZO (the Younger), Spanish painter: b. Seville 1622; d. Madrid 1685. He studied art under his father, Francesco, called El Viejo (q.v.) (to whom he was very far inferior as a painter), and remained some years at Rome. He was a founder of the Seville Academy (1660), and became its vice-director. Subsequently he was appointed court-painter to Philip IV. In the Seville Museum is his 'Four Doctors of the Church Adoring the Host'; in the Prado Museum, 'Saint Hermenegild.' During his residence in Italy he painted fish with such success that he was known there as 'Lo Spagnuolo dei Pesci.'

Herrera, José Joaquin de, hō-sā' hō-ā-kēn, Mexican military officer: b. Jalapa 1792; d. Tacubaya 10 Feb. 1854. He joined the Mexican army in 1809, and in 1821 was promoted brigadier-general. He aided in overthrowing Iturbide, when the latter became emperor, and was successively minister of war and president of the supreme court. President for a brief period in 1845, he again held office in 1848–51. During the war with the United States, he was aide to General Santa Anna.

Herreshoff, hĕr'rĕs-hŏf, **John B.**, American shipbuilder: b. Bristol, R. I., 1841. Under his management the Herreshoff Manufacturing Company succeeded Edward Burgess in designing and building the fastest yachts in the world. Although he has been blind since the age of 15, he has always been active in business.

Herreshoff, Nathaniel Greene, American shipbuilder: b. Bristol, R. I., 1848. He was educated at the Massachusetts Institute of Technology, and was graduated Sc. M., at Brown University. He is superintendent of the Herreshoff Manufacturing Company, and has designed many torpedo-boats and yachts, notably those sloops which have engaged in the international races of recent years.

Her'rick, Christine Terhune, American writer on domestic economy: b. Newark, N. J., 1859. She has published: 'Housekeeping Made Easy' (1888); 'The Little Dinner'; 'Liberal Living Upon Narrow Means'; 'First Aid to the Young Housekeeper' (1900); 'The Expert Maid-Servant' (1902); 'Consolidated Library of Modern Cooking and Household Recipes' (1905); etc.

Herrick, Clarence Luther, American college president: b. Minneapolis, Minn., 21 June 1858: d. 1903. He was graduated from the University of Minnesota in 1880, and after holding professorships at Denison University, Ohio, and the University of Chicago, became president of the University of New Mexico at Albuquerque.

Herrick, Myron T., American capitalist and politician: b. Huntington, Lorain County, Ohio, 1854. He studied at Oberlin College and Ohio Wesleyan University, went to Cleveland in 1875, and taking up the study of law was admitted to the bar in 1878. He soon gave up the profession of law, however, and organized the Euclid Avenue National Bank, from this time onward being prominent in financial circles. At first secretary of the Society for Savings Bank in Cleveland, he became its president in 1894, and has been connected with various railroad and other large financial enterprises. He has taken a keen interest in national and local politics from a Republican standpoint, in 1903 was elected governor of Ohio, but in 1905 was defeated by John M. Pattison.

Herrick, Robert, English poet: b. London, Aug. 1591; d. Dean Prior, Devonshire, October 1674. His father, Nicholas Herrick, was a goldsmith; through inheritance and training the son was enabled to transfer to the making of verse the exquisiteness of his father's craft. Shortly after Robert's birth the elder Herrick made his will, and two days later he died, under circumstances that suggested suicide. To his wife and his seven children he left a small property.

After a few years, perhaps at Westminster School, and a brief apprenticeship to his guardian uncle, William Herrick, also a goldsmith, the poet entered Cambridge University, at first enrolling himself in Saint John's College. Two years later he removed to Trinity Hall, intending to study law. During his residence he seems, from letters to his guardian, to have frequently needed money, and he left the university in debt. He took his degree of B.A. in 1617, and of M.A. in 1620.

Few facts remain of his next years. He went to London and associated with the poets of the time, admirers of Ben Jonson, and he himself wrote verse. The words of two New Year anthems set to music by Henry Lawes were his; through the friendly influence of prominent men at court, he may have been known to the King and Queen. By 1627, when he was chaplain of the Duke of Buckingham's expedition to the Isle of Rhé, he must have taken orders. Two years later, shortly after his mother's death, he became vicar of Dean Prior in Devonshire.

So little in Herrick's poetry suggests the priestly character that question has been made why he took orders at all; he himself spoke of his Devonshire years as pure exile from London and the world. Yet the traditions of his career at Dean Prior are entirely pleasant. His parishioners remembered him for his good humor and wit. He wrote his best poems in the little vicarage, whether in celebration of Prudence Baldwin, his housekeeper, or of Tracy, his spaniel, or of the village holiday ceremonies and superstitions, recorded with wonderful sympathy. Nothing more particular remains, save the legend of his keeping a pet pig in the house, and of his hurling a missile at an inattentive congregation—his only practical expression of ill-will towards Devonshire.

In 1647, evicted as a loyalist by Parliament, he returned to London, glad to be free of the quiet country, and set about publishing his poems. They appeared that same year, under the title of 'Hesperides, or The Works Both Humane and Divine of Robert Herrick, Esq.' The sacred poems bear the separate title, 'His Noble Numbers; or, His Pious Pieces, Wherein (amongst other things) he sings the Birth of his Saviour; and sighes for his Saviour's Suffering on the Crosse.' Nothing else is known of Herrick until 1662, when Charles II. restored him to his old place at Dean Prior. The parish register records his burial on 15 Oct. 1674.

There is almost no contemporary reference to Herrick's poems, but the frequency with which they were reprinted in collections proves the favor they found. By the end of the century, however, they were forgotten, sharing in the Augustan neglect of Elizabethan and Stuart poetry. A mention of Herrick, with some of his poems, in the *Gentleman's Magazine*, 1796, and Dr. Nathan Drake's essays and quotations in his 'Literary Hours,' two years later, revived his fame.

Herrick's literary master, as he tells us in more than one fine tribute, was Ben Jonson (q.v.). Campion and the poets of the later song-books foreshadow him, but it was through Jonson that he derived the tradition of Horace and the Latin epigrammatists, and he remained Latin in spirit, though his own carefully achieved simplicity is often near to Greek restraint. But it is not only in this literary inheritance that he belongs with Jonson; personally, if the Marshall portrait prefixed to 'Hesperides' is faithful, and if the assault upon the drowsy congregation is no fable, he illustrates with Jonson and other Elizabethans, and with Landor in later days, the paradox of violent and robust temperament reacting in fastidious art.

Herrick is first of all an artist; his merit is almost invariably a virtue of expression; he is master of the inevitable phrase. Many of his lyrics have indeed a larger perfection of form, yet he is most often concerned with the single word. His shortest poems, the numerous two-line fragments in which at first sight he would seem to scatter his genius, are frequently mere experiments in diction, usually for the sake of one word that he coins or discovers, easily recognizable for its curious awkwardness or its complete beauty. For among these trial pieces can be found some unhappy ventures, as well as astonishing verbal felicities.

This gift for language, part of the poetical equipment in general, is more marked in Herrick because of its intensity and its narrowness. It is so narrow as to be quite inflexible; far from exhibiting the Elizabethan faculty for adjusting the style to the most varied matter, Herrick subdues to one manner every subject he treats. The lines to his dying brother, the wedding songs for his friends, the epitaph on his housekeeper, and the recipes for country charms, are uttered alike in one voice and in one rigid though lovely tone. And in his choice of subjects he exercises none of the fine selection that distinguishes his diction; his conscious art is a thing of words only; in his themes he is at once almost the coarsest and the daintiest of English poets. This imperturbable manner, itself exquisite, becomes in the handling of shockingly different themes Herrick's chief limitation; here is felt a certain hardness of character, an ill-proportioned sympathy, or some deep defect of heart. But this impression is partly corrected elsewhere in his work.

The themes of Herrick's secular verse, upon which his fame rests, are given with characteristic confusion in the first poem of his book. He sings of youth and love — a Renaissance motive from which his cheerfulness or his limited sympathy subtracts most of the Renaissance sadness at the passing of beauty. He sings of his own numerous loves in the Horatian manner, leaving his admirers room to ponder whether he ever loved at all. He sings in his kindliest vein of fairy lore, and of country holidays; he identifies Renaissance Springtime motives in the native village ceremonies around him, and gives to the English May festival something of the significance it had in Provence; and he is the first writer to chronicle at length that old English Christmas spirit which Irving and Dickens recovered. No poet who writes of such subjects with such delight can be altogether unsympathetic, and in the verses which are frankly about himself there is a frequent note of human pathos that partly disarms criticism of his less felicitous themes.

It is not surprising that his 'Noble Numbers' are little read; in them as in his secular verse he is the technical experimenter, the conscious artist, where conscious art is out of place. But in the 'Christmas Carols,' in the 'Graces for Chrildren,' in the fine though fantastic 'His Saviour's Words Going to the Cross,' in the epigram 'Riches and Poverty,' and in the lines that Swinburne praised, 'Devotion Makes a Deity,' he shows feeling and thoughtfulness not unworthy of England's tradition of devout country parsons.

Bibliography.— The best editions are those by Grosart, Saintsbury (Aldine), and Pollard, with an introduction by Swinburne, in the 'Muses' Library.' For criticism, consult: 'Introductions' to the above; Gosse, in 'Seventeenth Century Studies'; Aldrich, in 'Ponkapog Papers,' and Ward's 'English Poets.'

John Erskine,
Associate Professor of English, Amherst College.

Herrick, Robert Welch, American novelist: b. Cambridge, Mass., 26 April 1868. He was graduated at Harvard in 1890, and in 1895 became professor of English at the University of Chicago. His literary style displays much finish, while his studies of character are both keen and discriminating. He has published: 'The Man Who Wins' (1895); 'Literary Love Letters and Other Stories' (1896); 'Love's Dilemmas' (1898); 'Composition and Rhetoric' (1899); 'The Web of Life' (1900); 'The Real World' (1901); 'Their Child' (1903); 'The Common Lot' (1904); 'The Memoirs of an American Citizen' (1905); etc.

Herrick, Sophie McIlvaine Bledsoe, American microscopist: b. Gambier, Ohio, 26 March 1837. She was editor of the 'Southern Review' 1875–8, and has since been connected with the editorial staff of 'Scribner's Magazine' and its successor, 'The Century.' She has published 'Wonders of Plant Life under the Microscope' (1883); 'The Earth in Past Ages'; 'Chapters in Plant Life'; 'A Century of Sonnets' (1902).

Herring. The typical fishes of the family *Clupeidæ* (q.v.), to which also belong the shad, alewife, sardine (qq.v.), and other food-fishes, the numbers of which consumed makes this the most important economically of all families of fishes. The true or sea-herrings belong to the genus *Clupea.* The common herring (*C. harengus*) of both sides of the North Atlantic swims in enormous schools containing countless numbers of individuals packed as closely as possible over areas of often 6 to 20 square miles. The herring is a migratory fish, but its movements are so complicated that much mystery still clings to them. The most satisfactory conclusions have been arrived at by a German commission appointed to study the natural history of the Baltic, etc., which concluded that the herrings live in the deep water off the coasts which they approach periodically chiefly for the purpose of spawning; that there exist a large number of distinct races, differing in size, form, times of spawning, and various other peculiarities, and that each of these races swims in separate schools, which move independently and have different seasons and grounds for spawning. Spawning takes place at various seasons, according to locality, some schools spawning in the late winter, others in the spring, and still others during the autumn months. The eggs are small and adhere in masses to seaweeds, stones, etc., on the bottom. Vast numbers are thus deposited in certain favored localities to which haddock and other fishes are attracted for the purpose of devouring them. The number of eggs produced by each fish is not especially large, being from 10,000 to 50,000, but nevertheless the natural productiveness of the herring has been sufficient to overcome inroads caused by the fisheries and the much greater destruction due to the hordes of bluefish, sharks, porpoises, gulls, and other enemies which accompany the schools in order to prey upon them. Having only few and small teeth, the herrings cannot capture active living creatures, but, as they swim with quick, nervous movements, water is being continually taken into the mouth and strained through the gill-rakers. By this means great numbers of copepods and other minute forms of life, especially larval crustaceans, annelids, and mollusks, are retained within the mouth and swallowed.

The herring fishery is of stupendous importance to the countries of northern Europe.

This is especially true of the Scandinavian countries, whose hardy fishermen take from the sea annually not less than 1,500,000,000 pounds. Scotland takes from 150,000,000 to 200,000,000 pounds, and the other maritime nations usually smaller quantities. On this side of the Atlantic the fishery is much less extensive, but is growing, and is no doubt destined to reach a great magnitude, especially in the waters of British America, which furnish each year about 250,000,000 pounds. Although found as far south as North Carolina, the herring has a commercial importance only north of Cape Cod, the New England fisheries, which are chiefly confined to Maine, yielding in 1898 64,589,000 pounds, worth $600,000. Most of these were sold fresh, either for food, or, early in the season, for cod bait; of the remainder, about 7,000,000 were salted and nearly 4,000,000 smoked. A favorite preparation is the partly smoked form of "bloaters." Large quantities of young herrings are packed and sold as sardines. In the prosecution of the American fisheries use is made chiefly of several forms of drift or gill nets and seines; under favorable conditions of great tidal movements, as in the Bay of Fundy, great numbers are captured in weirs.

A closely similar species (*C. pallasii*) is found on the Pacific coast of America, and is the object of a rapidly extending fishery. Of the anadromous river-herrings or alewives (*Pomolobus*), two species are of great commercial importance on the Atlantic coast of the United States, particularly southward, though the fisheries extend from Maine to Florida. They enter the rivers to spawn about the same time as the shad, with which they are caught chiefly in pound nets and seines. In 1896, 2,500 persons were employed in the fishery, the product of which was about 50,000,000 pounds, valued at $460,000. The greater number are smoked.

To the extensive literature of the herring the following references will serve as an introduction: Goode, 'Fishery Industries of the United States' (1884); Smith, 'Alewife Fisheries of the United States,' in Report of United States Fish Commission for 1898; Cunningham, 'Marketable Marine Fishes'; 'Report of the Commission for the Scientific Investigation of the German Seas' (a very important contribution in German); 'Annual Reports' of the United States Commissioner of Fisheries.

Herring Gull, the most numerous and widely spread of gulls, common in the breeding season throughout all the northerly parts of the world, and migrating southward in winter. The silvery sheen of white and pearl-blue plumage are indicated in its technical name (*Larus argentatus*); and its habit of following schools of fishes and picking them up gives it the name of herring-gull. The same name is often given, however, to several others of the smaller gulls. See GULLS.

Herrnhut, hĕrn'hoot, a small town or village in the kingdom of Saxony, in the circle and 18 miles southeast of Bautzen. It is situated at the foot of Hutberg Mountain, 1,054 feet above the level of the sea. It was founded by Count Zinzendorf 1722, for the use of the Moravian Brethren, and it afterward became the metropolis and centre of that sect of Christians, who, from this town, are often called Herrnhuters. (See UNITED BRETHREN.) The town is built with great regularity, and distinguished by the order, cleanliness, and stillness which prevail in it. It has a great variety of manufactures, principally of linen, calico, tobacco, and of articles in gold, tin, leather, etc. The objects of curiosity are the observatory and the burial-ground on a neighboring hill, resembling a garden, and called by the brethren "Garden of Peace." Pop. 1,200.

Her'ron, Francis Jay, American soldier: b. Pittsburg, Pa., 17 Feb. 1837; d. New York 8 Jan. 1902. He was graduated at the Western University of Pennsylvania in 1854 and on the breaking out of the Civil War commanded the Governor's Grays in the First Iowa regiment. In 1861 he was made lieutenant-colonel of the Ninth Iowa regiment. In 1862 he received the commission of brigadier-general of volunteers. Early in 1863 he joined Gen. Grant at Vicksburg and commanded the left wing of the besieging forces as major-general (1862), until the capture of the city. He subsequently captured Yazoo City, with its boats and supplies; commanded the Thirteenth army corps, and broke up the traffic along the Rio Grande, assisted President Juarez against Maximilian's forces, and in June 1865 received the surrender of the Confederate forces west of the Mississippi. In 1873 he took up his residence in New York, where he practised law until his death.

Herron, George Davis, American clergyman and social reformer: b. Montezuma, Ind., 21 Jan. 1862. He was educated at Ripon College, Wisconsin, and also studied in Europe. He became pastor of the Congregational Church in Lake City, Minn., and while there made an address ("The Message of Jesus to Men of Wealth") before a Minneapolis club, which attracted much attention; he subsequently received a number of calls from important churches, and went as pastor to Burlington, Ia. Here he organized a club for the discussion of social questions, which was largely attended, especially by workingmen. In 1893 he accepted the chair of applied Christianity at Iowa College, resigning in 1900 on account of the objection to his teachings; he then organized a religious and socialist movement known as the "social crusade." In 1901 he divorced his wife, and married a second time, an action which aroused much criticism. He has written: 'The Larger Christ' (1891); 'The Call of the Cross' (1892); 'A Plea for the Gospel' (1892); 'The New Redemption' (1893); 'The Christian Society' (1894); 'The Christian State' (1895); 'Social Meaning of Religious Experiences' (1897); 'Between Cæsar and Jesus' (1899).

Herschel, hĕr'shĕl, **Caroline Lucretia**, sister of Sir William Herschel (q.v.), German astronomer: b. Hanover, Germany, 16 March 1750; d. there 9 Jan. 1848. In her 22d year she went to England to reside with her brother, then organist in Bath. When William abandoned his former profession in favor of astronomy she became his helpmate, and when he was appointed private astronomer to George III. she discharged efficiently all the duties of an assistant astronomer, for which she was allowed a small salary. Although these duties were very arduous, she yet found time to conduct a series of observations of her own with a small Newtonian telescope her brother had made for

HERRING GULL (*Larus Argentatus*)

her. She devoted special energy to the discovery of comets, and was so successful as to be entitled to claim the priority of discovery of at least five. Several remarkable nebulæ and clusters of stars included in her brother's catalogue were described from her original observations. In 1798 her valuable work, 'A Catalogue of Stars taken from Mr. Flamsteed's Observations, with Introductory Remarks by W. Herschel,' was published by the Royal Society. On her brother's death in 1822 she returned to her native country, where she died after an unusually protracted life, distinguished by useful scientific labors. The Royal Society recognized the value of her labors by bestowing upon her in 1828 their gold medal, and some time afterward by conferring upon her the privileges of honorary membership.

Herschel, Sir **John Frederick William,** English astronomer; only son of Sir William Herschel (q.v.): b. Slough, near Windsor, 7 March 1792; d. Collingwood, Kent, 11 May 1871. He was educated at Eton and Cambridge. His first publication was 'A Collection of Examples of the Application of the Calculus to Finite Differences' (1820), but it was not until the death of his father that he devoted his special attention to those astronomical researches which have made the name of Herschel so famous. He limited his first exertions to a re-examination of the nebulæ and clusters of stars discovered by his father, and in 1824, with James South, reported to the Royal Society the position and apparent distances of 380 double and triple stars, obtained by more than 10,000 measurements. This memoir attracted the notice of the French Academy, and they voted it their astronomical prize; and two years later the gold medal of the Royal Society was awarded to each of the astronomers. The results of the re-examination were given in 1833 to the Royal Society in the form of a catalogue of stars in order of their right ascension. The catalogue contained observations on 525 nebulæ and clusters of stars not noticed by his father, and on a great number of double stars, between 3,000 and 4,000 in all. His 'Treatise on Sound' appeared in the 'Encyclopædia Metropolitana' in 1830, as did his 'Treatise on the Theory of Light' in 1831, in which year also appeared his well-known 'Preliminary Discourse on the Study of Natural Philosophy,' one of the most charmingly written books on science. In 1831 he was created a knight of the Royal Hanoverian Order. In 1833 Herschel published in Lardner's 'Cabinet Cyclopædia' a 'Treatise on Astronomy,' subsequently enlarged into 'The Outlines of Astronomy,' of which several editions have been published. Before this, however, he had undertaken a private expedition to the Cape of Good Hope for the purpose of carrying out in the southern hemisphere observations similar to those he had made in the northern. Four years were spent near Cape Town (1834–7). His great object was to discover whether the distribution of the stars in the southern hemisphere corresponded with the results of his father's labors, prosecuted mainly on the opposite side of the Galactic Circle. That the observations might be strictly comparable they were made by the same method as Sir W. Herschel, and with a telescope of the same optical power. The whole number of stars counted in the telescope amounted to 68,948, included within 2,299 fields of view. By a computation based on the star-gauges in both hemispheres relative to the Milky Way, Sir John found that the stars visible in a reflecting telescope of 18 inches aperture amounted to 5,331,572; and, more than this, the number really visible in the telescope was vastly greater, for in some parts of the Milky Way the stars were found to be so crowded in space as to defy all attempts to count them. The results of this vast labor were published in 1847, expense being borne by the Duke of Northumberland. On Herschel's return to England in 1838 he was received with every public honor, and on the queen's coronation was created a baronet. In 1848 he was president of the Royal Astronomical Society. He was buried in Westminster Abbey.

Herschel, Sir **William,** Anglo-German astronomer: b. Hanover, Germany, 15 Nov. 1738; d. Slough, near Windsor, England, 25 Aug. 1822. He went to England in 1757, and at first was employed in the formation of a military band. Although enthusiastically fond of music, he devoted his leisure hours to mathematics and astronomy; and being dissatisfied with the only telescopes within his reach, he set about constructing one for himself, in which undertaking he succeeded, having in 1774 finished a reflecting instrument of 5½ feet. Encouraged by his success he proceeded to complete larger telescopes, and from this period gradually withdrew from his musical engagements. Late in 1779 he began a regular survey of the heavens, star by star, with a 7-foot reflector, and after 18 months labor discovered, 13 March 1781, a new primary planet, named by him the *Georgium Sidus*, but now known as *Uranus*. George III. gave him a pension, enabling him to devote the rest of his life to astronomy. At Slough, he commenced the erection of a telescope of the dimensions of 40 feet, and completed it in 1787. Its diameter was 4½ feet, and it weighed 2,118 lbs. With this powerful instrument he continued to prosecute his discoveries, regularly communicating the results to the Royal Society till 1818. In 1783 he thought he had discovered a volcanic mountain in the moon, and from further observations made with his large instrument in 1787 found he was the victim of an optical illusion. He discovered two of the satellites of Saturn, and the fact that his system of rings revolved, and he measured his rotation and that of Venus, announced to the world that there were binary stars in the heavens, etc. Herschel received much assistance in making and recording observations from his sister Caroline (q.v.); and latterly his brother, a skilful optical instrument-maker, lent him valuable aid. In 1802 he laid before the Royal Society a catalogue of 5,000 new nebulæ, nebulous stars, planetary nebulæ, and clusters of stars he had discovered. See 'Herschel, his Life and Works,' by Holden (1881).

Her'schell, Farrer, Lord, English lawyer and statesman: b. London, England, 2 Nov. 1837; d. Washington, D. C., 1 March 1899. He was educated at University College, London, and the University of Bonn. He became a barrister of Lincoln's Inn in 1860; was recorder of Carlisle 1873–80; solicitor-general 1880–5; and lord high chancellor in 1886, and again 1892–5. He was a member of the Venezuela and British Guiana boundary arbitration tribunal in 1897, and was subsequently appointed one of the high joint commissioners from Great Britain, on the Anglo-American Commission, designed to settle existing differences between the United States and Canada, of which he became president. During the sitting of the commission in Washington, D. C., in February 1899, he had a severe fall, from the effects of which he died shortly after.

Hertel, hĕr'tĕl, **Albert,** German painter: b. Berlin 19 April 1843; studied at the Berlin Academy, where he became professor in 1875, and was made a member in 1901. Among his landscapes are 'Olive Harvest in Capri' (1872); 'After the Storm on the Coast of Genoa' (1878); 'Road Between Rapalla and Santa Margherita' (1892); and 'View in the Roman Campagna' (1896).

Hertel de Rouville, ār-tĕl dė roo-vēl, **Francis,** Canadian soldier: b. Three Rivers, Maurice County, Quebec, 1643; d. 1722. He was captured in 1681 and tortured by the Iroquois who were so struck by his fortitude that they adopted him into their tribe, from which he escaped and as one of Frontenac's lieutenants performed some remarkable exploits against the English from whom he captured Falmouth, now Portland. Louis XIV. tardily rewarded him with a patent of nobility.

Herter, Albert, American artist: b. New York 2 March 1871. He studied painting at Paris in the studio of Jean Paul Laurens. He has twice visited Japan and the years spent there have strongly influenced the character of his work. He is member of the Society of American Artists, of the Water Color Club, and of the Water Color Society.

Hertz, Heinrich, hīn'rĭн hĕrts, German physicist: b. Hamburg 22 Feb. 1857; d. Bonn 1 Jan. 1894. He studied at the University of Berlin, and in 1880 became assistant to Helmholtz there. In 1883 he was lecturer on theoretical physics at the University of Kiel; in 1885 was professor of physics at a technical school in Karlsruhe; and in 1889 succeeded Clausius as professor of physics at the University of Bonn. His most important work was his experiments with electricity, by which he proved that electricity can be transmitted in electromagnetic waves with the same rapidity as light, these waves showing the same phenomena of refraction, polarization, etc., as light waves. He thus further developed and attested the truth of Faraday's electro-magnetic theory of light. It is by means of the Hertzian waves also that wireless telegraphy (q.v.) is made possible.

Heruli, hĕr'ū-lī, a Teutonic tribe first heard of in history about the middle of the 3d century, who passed south from the coast of the Baltic and swept with the Goths into the eastern provinces of Rome and founded an empire on the Danube. They appear as reinforcements of Odoacer in his invasion of the western provinces of Rome in 470. Their king Rudolph formed an alliance with Theodoric the Great, but they were afterward conquered by the Longobardi. A part of them were driven toward Scandinavia, a part lingered on the borders of the Roman empire. They did good service to the Byzantine empire, but after encountering the Vandals in Africa, and the Ostrogoths in Italy, they vanished from history.

Herzel, Theodor, Jewish leader of political Zionism: b. Budapest 2 May 1860; d. 3 July 1904. He was educated in Vienna for the law, but devoted himself almost exclusively to journalism and literature. He was at first Paris correspondent and later literary editor of the *Neue Freie Presse*, and wrote comedies and dramas. In 1896 he published his 'Judenstaat,' the English translation of which ('A Jewish State') made him the political leader of the Zionist movement; and his efforts were at once centred in this propaganda. 'Die Welt' of Vienna was established by him in 1897, and in that year he planned and was elected president of the first Zionist Congress held at Basel. At every subsequent congress (the sixth having been held in August 1903) he was unanimously re-elected. In 1898 he inaugurated a series of diplomatic interviews with various sovereigns and statesmen. At the Hague Peace Conference he was received by many of the delegates. In the Zionist movement he was officially the chairman of the Grosses Actions Comité, and of the Vienna executive committee, and a member of the council of administration. Among his further works are: 'Das Neue Ghetto' (1903), directed against the Jewish element that combated his views; 'Altneuland' (1903), a fictional presentation of Zionistic ideas.

Herzegovina, hĕrt-sĕ-gō-vē'nä, Austria-Hungary, a province of the Balkan peninsula nominally belonging to European Turkey, but since 1878 administered along with Bosnia (q.v.) by Austria. It is bounded on the north by Croatia and Bosnia, on the east by Bosnia, on the southeast by Montenegro, and on the south and west by Dalmatia; length, northwest to southeast, 140 miles; breadth, 50 miles; area, 700 square miles. The surface is generally mountainous, covered by ranges belonging to the Dinaric Alps, sloping gradually to the Adriatic, which receives all its drainage chiefly by the Narenta. It contains many fertile valleys, and raises excellent tobacco. The exports consist chiefly of hides, tallow, cattle, wool, wax, and fruit. Mostar is the chief town. The province was conquered by the Turks in 1465. An insurrection, caused by Turkish misgovernment, broke out in July 1875, and was the cause subsequently of war between Russia and Turkey. In accordance with the Treaty of Berlin (1878) the province was occupied by Austrian troops, and is now ruled by an Austrian military governor. Pop. about 250,000.

Hesiod, hē'sĭ-ŏd, Greek poet: b. Ascra, a village of Bœotia, at the foot of Mount Helicon, whence it is called the *Ascræan*. But little is known of Hesiod with certainty. Even the age in which he lived cannot be precisely determined. A very common tradition relates that, in a poetical contest with Homer at Chalcis, he came off victorious. Herodotus calls him a contemporary of Homer, and says they lived 400 years before himself (about 900 B.C.). In his 'Works and Days' (172) Hesiod says that he belonged to the period immediately following the Trojan war; but there are many reasons for supposing that he lived at a later period. Of the numerous works attributed to him three only remain. These are the 'Theogony,' a collection of the oldest fables concerning the birth and achievements of the gods, arranged so as to form a connected whole. It is the most important and difficult of all his works. With it was probably connected the lost 'Catalogues of Women' (or the *Eoiai megalai*), to the fourth book of which the second fragment (the 'Shield of Heracles') must have belonged. This is evidently composed of three distinct parts, only one of which is occupied with the real description of the shield. The third fragment is a didactic poem, 'Works and Days' (*Erga*, or *Erga kai Hemerai*). It treats of agriculture, the choice of days, etc., with prudential precepts concerning education, domestic economy, navigation, etc. The Hesiodic poems are inferior to the Homeric in almost every respect. Hesiod's complete works have been translated into English verse by Elton, and Bohn's Classical Library contains a prose version.

Hesperides, hĕs-pĕr'ĭ-dēz (daughters of Hesperis), the guardians of the gold apples which Ge (the Earth) had given to Hera on her marriage. They were the daughters of Atlas and Hesperis, but their parentage is differently represented by other writers. They were four in number and their names were Agle, Arethusa, Erytheia, Hesperia, or Hesperarethusa. They were assisted in the charge of their garden by the sleepless dragon, Ladon. It was the twelfth labor of Heracles to bring the golden apples of the Hesperides to Eurystheus.

Hesperornis, hĕs-pĕ-rŏr'nĭs, a remarkable extinct form of bird, the remains of which are met with in the cretaceous deposits of Kansas. As described by Prof. Marsh, it possessed small pointed reptilian teeth, which were implanted in a deep continuous groove, somewhat like those of Ichthyosaurus. Its brain was small and more reptilian in type than that of any adult bird as yet examined. It appears to have been a large diving-bird, measuring over five feet from the point of the bill to the end of the toes. Its wings were rudimentary, its legs powerful, and its feet well adapted for rapid progression in water. The tail was broad, could move up and down, and was probably used as a rudder or swimming-paddle. The long slender jaws were united in front only by cartilage, as in serpents, and had on each side a joint which admitted of some motion, so that "the power of swallowing was doubtless equal to almost any emergency." Consult: Lucas, 'Animals of the Past' (1901).

Hesperus, hĕs'pĕ-rŭs, among the Greeks the planet Venus, when it appeared as evening star, personified as the divinity that at weddings leads the bride to the arms of her husband. He is called Phosphorus or Lucifer as a morning star, and is styled the son of Eos (Aurora) and Cephalus. He was also known as son or brother of Atlas, and brother of the Hesperidæ.

Hesperus Peak, an elevation of the La Plata Mountains, in the southwestern part of Colorado. Gold and silver have been mined in the vicinity. This peak is one of a group of high peaks in the vicinity of the State; the height is about 13,135 feet.

Hesse, hĕs, or **Hessia** (German, Hessen, hĕs'sĕn), Germany, an ancient territory inhabited in the time of the Romans by the Catti or Chatti, an old Germanic tribe. Under the Frankish kings Hesse was governed by counts, the principal of whom were the Counts of Gudensberg of the name of Giso. Philip I. the Generous, who succeeded to the sovereignty of the whole country in 1509, and who was the earnest and zealous friend of the Reformation, divided his dominions among his four sons. The eldest, William IV., obtained one half, including the capital, Cassel; Louis IV. one fourth, comprising Marburg; Philip II. one eighth, with Rheinfels; and George I. also an eighth, with Darmstadt. But Philip dying in 1583, and Louis in 1604, without children, there remained only the main branches of Hesse-Cassel and Hesse-Darmstadt (qq.v.).

Hesse, Grand Duchy of, formerly Hessen-Darmstadt, Germany, a state consisting of 13 divisions. Eleven of these are small, six surrounded by Prussian territory, and five on the borders of Baden and Wurtemberg. The other two portions, forming about nine tenths of the whole, are separated by a belt of land stretching east to west, and including part of the Prussian dominions. The more southerly of these portions forms the two provinces of Rheinhessen and Starkenburg. The northern portion, forming the province of Oberhessen, is surrounded by the Prussian province of Hesse-Nassau; area of whole grand duchy, 2,964 square miles. Oberhessen is generally mountainous; Starkenburg and Rheinhessen are also mountainous; in the southwest the Donnersberg, a northern ramification of the Vosges, rapidly subsides to the extensive plains belonging to the valleys of the Main and the Rhine. To the latter river the whole surface of the grand duchy belongs, with exception of a small portion in the north, drained by the Eder and Fulda, affluents of the Weser. The climate is greatly diversified, varying with the altitude. The soil, particularly in the provinces of Starkenburg and Rheinhessen, is fertile, and grain of all kinds is raised in large quantities. Hemp, flex, potatoes, and rape-seed also are extensively grown, and in particular districts tobacco and hops. The vine forms an important object of culture, and fruit is abundant. Horses, cattle, sheep, and swine are numerous. The minerals include iron, coal, lignite, and salt; and there are good quarries of sandstone, limestone, whetstones, basalt, and roofing-slate. The most important manufacturing industry is linen. The principal towns are Darmstadt, the capital; Mainz, Giessen, Bingen, and Worms. The grand duchy is an hereditary monarchy. The constitution dates from 1820, but was somewhat modified in 1856 and 1872. The legislative power is vested partly in two chambers—an upper, composed chiefly of nobility and citizens, appointed for life by the grand-duke; and a lower, composed chiefly of deputies from the towns, villages, and rural districts. About two thirds of the inhabitants are Protestants. Pop. (1900) 1,119,893. The grand-ducal line was founded in 1567 by George I., son of Philip the Generous. By the death of the landgrave of Hesse-Homburg, in 1866, Louis III., grand-duke of Hessen Darmstadt, succeeded to his dominions. In the German war of that year Hessen-Darmstadt joined Austria. Its army was nearly annihilated at Friedberg, and it was deprived of the newly-acquired landgraviate and other districts. In 1870 the grand duchy of Hesse entered the German empire. Louis IV., who succeeded Louis III., died in 1892. He was the husband of Princess

Alice of Great Britain, and their son, Ernest Louis, is now the reigning sovereign.

Hesse-Cassel, hĕs-käs'ĕl, or **Electoral Hesse**, Germany, a former electorate and independent member of the Germanic Confederacy, between Rhenish Prussia and Bavaria, containing 4,430 square miles, with about 850,000 inhabitants, mostly Protestants. It was founded by the eldest son of Philip the Generous, the Landgrave William IV., surnamed the Wise (1567–92). For a long period the history of Hesse-Cassel was a narrative of conflicts between the people for political freedom and the elector for absolute rule. The demands of the people were on several occasions strengthened by appeals to the elector from the Prussian government. On the outbreak of the German war of 1866, the elector joined Austria, and his territory was occupied by Prussian troops. On the conclusion of the war Hesse-Cassel was annexed to the Prussian territories, and now forms part of Hesse-Nassau (q.v.).

Hesse-Nassau, hĕs'näs'â, or **Hessen-Nassau**, hĕs sĕn-näs'sow, Germany, a province of Prussia, which includes the former principality of Hesse-Cassel (except some small districts), the greater part of the former duchy of Nassau, that portion of the former landgraviate of Hesse-Homburg which lies on the right bank of the Rhine, the territory and town of Frankfort, and some small districts ceded by Hessen-Darmstadt and Bavaria. The province is bounded by the Prussian provinces of Westphalia, Hanover, Saxony, and the Rhineland, the principality of Waldeck, the grand duchy of Saxe-Weimar, and the kingdom of Bavaria; area, 6,018 English square miles, divided into the two governments (Regierungsbezirke) of Cassel and Wiesbaden. The greater part of this province has a rugged surface, partly covered by branches of the Harz Mountains. The principal rivers are the Werra, Lahn, Ohm, Rhine, and Main. Arable land is limited, and cultivation is chiefly confined to the narrow valleys and lower hill slopes, amounting to about two fifths of the whole surface. The principal crops are rye, barley, and oats. Potatoes also are extensively grown. Fruit is tolerably abundant, and a great part of the loftier districts is covered with extensive forests, which employ a considerable number of the inhabitants, and furnish one of the most valuable sources of revenue. There are various minerals, and valuable mineral waters at Homburg, Wiesbaden, etc. The manufactures consist chiefly of woolens, cottons, and linens. The principal towns are Cassel, the capital, Wiesbaden, and Frankfort. Pop. (1900) 1,897,310.

Hessen-Darmstadt, hĕs'sĕn-darm'stat. See HESSE, GRAND DUCHY OF.

Hessian Fly. See WHEAT INSECT PESTS.

Hessians in the Revolution, The. In the 18th century Germany was divided into nearly 300 sovereignties, each maintaining a court and a military force. The possible revenue was often very limited, the burdens were almost intolerable, and the princelings were often profligate and cruel; they did not need their forces for home defense, and were glad to make money for themselves by letting out their regiments for hire, though except in one case they remitted no taxes on the people from the receipts. There was also a lingering tradition that soldiering was an honest trade like any other, and that it was useful for helping sovereigns to keep order; especially to put down insurrections, which were wicked. This, however, did not apply to rulers hiring out their troops and pocketing the money; and not only the liberal school of writers and public men, but enlightened despots like Frederick the Great, denounced it. But England had not sufficient army for the American War, and wished drilled troops rather than raw recruits, and after vainly endeavoring to hire 20,000 Russian soldiers, turned to the German princes, with some of whom she had dynastic relations, and all of whom were so eager to sell their wares that two of them offered soldiers for hire immediately after Bunker Hill, without waiting to be asked. Only those which could furnish considerable numbers were worth treating with, and all the German auxiliaries were finally hired from six states; about half being from two Hessian states, and by far the largest (more than three times greater than any other) from one. All were indiscriminately termed "Hessians," as all German immigrants were formerly called "Palatines." The first treaty was made with the Duke of Brunswick, 9 Jan. 1776, for 4,300 troops; reinforcements or replacements were sent year by year, till the total had amounted to 5,723, only 2,708 of whom ever returned. The second was with the Landgrave of Hesse-Cassel, 15 Jan. 1776, for 12,805; finally increased to 16,992, of whom 10,492 returned. The contingents from the others, under various treaties, amounted to — Hesse-Hanau, 2,038; Anspach-Baireuth, 2,353; Waldeck, 1,225; Anhalt-Zerbst, 1,152. Total sent to America, 29,867, of whom 17,313 returned; the rest either died or remained as citizens. There were about 20,000 in America at any one time after 1776. These forces cost Great Britain in subsidies and incidentals about £1,770,000; besides the lump sum, it was obliged to replace the dead, and at least in one case count three wounded men as one dead one.

About 18,000 were shipped in 1776; the commander-in-chief was Lieut.-Gen. Philipp von Heister, a veteran of the Seven Years' War. The first division of some 8,000 landed at Staten Island, 15 August; they included a body of chasseurs and grenadiers under Lieut. E. W. F. von Donop, an able and daring officer. They took a leading part in the battles of Long Island and White Plains, and all the operations for capturing New York; and stormed Fort Washington with a loss of 50 killed and 276 wounded. During this time the second division of about 4,000, under Lieut.-Gen. Wilhelm von Knyphausen, joined them. Washington's surprise at Trenton fell on Col. Rall's brigade of Germans. Rall was a regular officer whose contempt for the ragged Americans surpassed that of the most arrogant Briton, and he refused to take the most elementary precautions; he was mortally wounded. Early in 1777 Heister was superseded by Knyphausen; Howe finding the former intractable, and the Landgrave of Hesse laying the blame of Trenton upon him. Meantime the Brunswickers and a Hanau regiment under Baron von Riedesel had made a clearance of Canada; and in 1777 they were joined to the expedition of Burgoyne, in whom Riedesel had no faith. It was from this division that Baum's detachment was sent off to raid Vermont, and to meet its fate at Bennington, with Breymann's sent to support it; 365 of Baum's 374 Germans did not return, and 231 of Breymann's were killed, wounded, or captured. Riedesel and his remaining men shared in Burgoyne's surrender. Around Philadelphia, at Brandywine and Germantown, Knyphausen's command was of the first importance; and at Red Bank Donop tried to storm the American fort and was mortally wounded, his command losing 82 killed and 229 wounded, besides 60 prisoners. In the three years' occupation of Rhode Island, from the fall of 1776 to that of 1779, about half of the British corps was Hessians; and they liked, and were liked by the inhabitants,— when they departed, all persons, but especially women, were prohibited from appearing at the Newport windows, in fear that the soldiers might not wish to go. In the South, at Savannah, Charleston, Pensacola, Baton Rouge, etc., they left many dead; and shared in the bloody drawn battle of Guilford Court House. Finally, at Yorktown, they bore the brunt of the actual fighting, losing 53 killed and 131 wounded.

The Germans did their duty bravely and faithfully, with loyalty to a service they had been sold into to no profit of theirs. Very few deserted, in spite of constant inducements held out to them; a policy which Washington strongly deprecated. Probably one reason was, that they were at once recognizable from their speech. Nor were they in the least inhumane or rapacious: the charge that they were cruel barbarians was a mere political weapon of the time. In a strange country, they would have run the risk of being murdered in reprisal had they been such; but in fact they appear to have been well-meaning men. Of the 29,867 who came over, only 17,313 returned to Germany. Of the 12,554 remaining, 548 were killed; some of the total 1,652 wounded died; some disappeared; but a great number are known to have remained and settled in the country. Grants were given them in Nova Scotia, but many scattered as chance directed. See Lowell, 'The Hessians in the Revolution' (1884).

Hestia. See VESTA.

Hesychius, hĕ-sĭk'ĭ-ŭs, the author of a Greek lexicon, which has probably come to us in an abridged form, and which he partly collected from former dictionaries, and partly enlarged by many new words and examples from Homer, the dramatic and lyric poets, the orators, physicians, and historians, was a native of Alexandria, and according to the best authorities flourished about the end of the 4th century after Christ. Of the circumstances of his life nothing is known. His lexicon possesses great value, especially of an antiquarian kind, and is the most useful for the study of the Greek language of all the ancient critical writings that are extant. The best editions of his lexicon are Alberti and Ruhnken's (Leyden 1746–66, two vols. folio), and that prepared by Schmidt (Jena, five vols. 1867–68; in a smaller form, two parts, 1864; second edition, 1867).

Hetæra, hĕ-tē'ra (Greek *hetaira*, a female companion), the name given by the Greeks to a mistress, as opposed to a lawful wife. But the word had various shades of meaning, from a mistress, who might be a wife in all but the legal qualification of citizenship, down to a harlot. The beauty and accomplishments of many of the hetæræ occasioned their society to be sought by men of the highest eminence, even Plato and Socrates. No shame was attached to associating with them. Aspasia, the mistress of Pericles, is the most renowned of these hetæræ. (See ASPASIA.) Hetæræ, less intellectually famous, were Lais, whom Aristippus the philosopher loved, Ph .ne, and others. They also became famous for their connection with the works of art. Praxiteles made a marble and gold statue of the latter, and she was also the model for his statues of Aphrodite.

Heterog'amy. See METAGENESIS.

Heterogenesis, hĕt"ĕ rō jĕn'ĕ sĭs, or **Heterogeny.** See METAGENESIS.

Heteropoda, hĕt-ĕ-rop'ō-da, a group of small, pelagic, pectinibranch mollusks, which dwell together in the open sea, have the foot modified into a swimming organ, and are provided with a ventral sucker. The shells are spiral or shaped like that of an argonaut and seem as if composed of thin glass; indeed, the whole animal is beautifully transparent. Heteropods occur in enormous abundance at the surface of the sea in all the warmer parts of the world, and their dead shells sinking to the bottom form a large constituent of the abyssal ooze. They are highly organized, have well developed eyes and other organs of sense, are bisexual, and produce eggs in long cylindrical cords. The young in their development pass through a trochosphere and then a veliger stage. All are predatory, seizing and feeding on the numerous minute forms of life about them. They are most active in the early evening, darting about with twisting motions like worms, usually on their backs. They use the ventral sucking-disk for attaching themselves to any object they may encounter. Three families, containing many species, are known, and their closest affinities are with the pteropods. Consult Kingsley, 'Standard Natural History,' Vol. I. (1885).

Heterop'tera. See HEMIPTERA.

Het'man (Russian, Ataman), chief of the Cossacks, formerly elected by that people. He had the power of life and death, and was head of the army in time of war. Mazeppa in 1708 revolted against Russia, taking the side of Charles XII. of Sweden, and Peter the Great abolished in consequence the power and authority of the hetman. Catharine II. suppressed the office and title in the province of Ukraine; it still exists among the Cossacks of the Don. In Poland the commander-in-chief of the army was styled hetman, and was appointed by the sovereign. The last elective hetman of the Cossacks in Russia was Platorf 1812–14. On his death the grand duke, heir to the throne, was made hetman.

Hetty Sorrel, in **George Eliot's** 'Adam Bede' (1859), a dairymaid whose unfortunate career, condemnation to death, and final reprieve form an important part of the story.

Hevelius, Johannes, yō-hän'nĕs hā-fā'lē-oos, or hē-vē'li-ŭs, known also as JOHANNES HEVEL, Polish astronomer: b. Dantzic 28 Jan. 1611; d. there 28 Jan. 1687. After visiting the principal countries of Europe he settled in his native city, and from 1639 till his death applied himself almost exclusively to the study of astronomy. His 'Selenographia,' or description of the moon, published in 1647, was the first of numerous astronomical works of great value and authority on his favorite science. Halley, who visited Hevelius at Dantzic at the request of the Royal Society of London, of which Hevelius had been elected a member in 1664, reported favorably of the correctness of his observations. In 1661 he observed a transit of Mercury, a triumph confined to Gassendi alone of all preceding astronomers. Hevelius ranks next to Flamsteed among the men of his day as a diligent and accurate observer of the heavens.

Hewes, hūz, **Joseph,** American patriot; a signer of the Declaration of Independence: b. Kingston, N. J., 1730; d. Philadelphia, 10 Nov. 1779. He was educated at Princeton College, and about 1760 he removed to Edenton, North Carolina. He soon became a member of the colonial legislature, and was a delegate to the General Congress at Philadelphia 1774–7 and again in 1779. After taking his seat he was appointed on a committee to "state the rights of the colonies in general, the several instances in which those rights are violated or infringed, and the means most proper to be pursued for obtaining a restoration of them," and aided in the preparation of its report.

Hewett, hū'ĕt, **Waterman Thomas,** American Germanic scholar: b. Miami, Mo., 10 Jan. 1846. He was graduated from Amherst College in 1869 and has been professor of German language and literature at Cornell University from 1870. He has been general editor of Macmillan's 'German Classics' since 1895, and beside frequent contributions to periodicals has published among other works 'The Friesian Language and Literature' (1879); 'History of Cornell University' (1894).

Hewit, hū'ĭt, **Nathaniel Augustus,** American Roman Catholic clergyman: b. Fairfield, Conn., 27 Nov. 1820; d. New York 3 July 1897. He was graduated from Amherst College in 1839 and was for several years in the Episcopal ministry. He became a Roman Catholic in 1846 and joined the Order of Redemptorists. He was later one of the founders of the Congregation of Saint Paul (Paulists) taking the religious name of "AUGUSTINE FRANCIS," and subsequently becoming professor and superior in the Paulist Seminary, New York. He wrote 'Life of Princess Borghese' (1856); 'Problems of the Age' (1868); 'Light in Darkness' (1871); etc.

Hewitt, hū'ĭt, **Abram Stevens,** American manufacturer and politician: b. Haverstraw, Rockland County, N. Y., 31 July 1822; d. New York 18 Jan. 1903. He was graduated from Columbia in 1842 at the head of his class, and in 1843 he was made acting professor of mathematics there; he also began the study of law, and was admitted to the bar in 1845. He did not practise, however, but shortly after went into the iron and steel business with his father-in-law, Edward Cooper. By careful and skilful management he built up the financial success of his firm (Cooper & Hewitt); which was the first to manufacture iron girders and supports for fire-proof buildings and bridges, and also furnished the government with large quantity of material during the Civil War. In dealing with his employees, he was particularly successful, never having any serious trouble; it was his policy to keep the works running and the men employed, at least part of the time during dull seasons, though the business was sometimes carried on at a loss. At the time of his death he was recognized as one of the foremost iron masters in the country, his firm controlling the Trenton Iron Co. and the New Jersey Iron and Steel Co. He organized the Cooper Union Institute (q.v.), and as the secretary of the board of trustees largely shaped and controlled its policy for a number of years. He also gave largely to the institution. He was first active in politics at the time of the reorganization of Tammany Hall after the overthrow of the Tweed Ring. He served in Congress 1874–8, and again 1880–6 and was always especially prominent in all matters pertaining to finance, advocating a low tariff and the gold standard. In 1876 he was chairman of the Democratic National Committee, and immediately after the election issued a proclamation to his party stating that Tilden had been elected; later he supported the policy of Tilden which resulted in the appointment of the Electoral Commission (q.v.). In 1886 he was nominated for mayor of New York by Tammany and other Democratic organizations and after a hard campaign won the election over Henry George and Theodore Roosevelt. As mayor he gave the city a most efficient administration, but his independent policy often antagonized the Tammany leaders, especially his strict enforcement of the excise law. He was not renominated by his party, and was defeated as a candidate on an independent ticket in 1888. While mayor he urged in one of his annual messages the need of improvement of the city's rapid transit, and advocated municipal ownership; though his suggestions were not heeded at the time, he continued his interest in the subject, and it was largely due to his efforts that recent improvements in that direction were undertaken; in recognition of his services the Chamber of Commerce presented him with a gold medal in 1901. In February 1903 a number of prominent citizens of New York set on foot a movement to raise a memorial fund of $500,000 to be presented to Cooper Union as the "Abram S. Hewitt Endowment of the Cooper Union."

Hewitt, John Napoleon Brinton, American ethnologist and linguist: b. on the Tuscarora reserve, Niagara County, N. Y., 16 Dec. 1859. For several years he assisted Mrs. Erminnie Smith (q.v.) in the linguistic researches she was making for the Bureau of Ethnology on the Tuscarora reserve, and he is now employed in linguistic work at the Smithsonian Institution.

Hewitt, Peter Cooper, American capitalist and inventor: b. New York 1861. He is the son of Abram S. Hewitt (q.v.), was educated at Stevens Institute, Hoboken, and Columbia College. He entered business with his father and invented improvements in the processes of the Peter Cooper glue factory, which the Hewitt firm controls. Turning his attention to electricity he invented the Cooper Hewitt lamp and static converter. The lamp in its present form consists of a glass tube of any desired shape with a bulb at one end which contains a small quantity of mercury. All air is exhausted from the tube, which thereupon fills with vapor from the mercury in the bulb. Electrodes are provided at each end of the lamp, the negative electrode in the bulb of mercury and the positive electrode at the opposite end. On passing a direct current through the lamp the vapor which fills the tube is rendered incandescent and gives off a steady, blue-white light. Owing to the great resistance at the negative electrode to the initial flow of current, it is necessary to use a high voltage to start the lamp. This is commonly done by passing a spark from a «choking» coil through the negative electrode, which when once penetrated offers but slight resistance to the flow of current. If for any reason the current is interrupted, the high resistance is immediately resumed and must be broken down again before permitting further flow of current.

The light given off by this lamp is entirely lacking in red rays, and consequently does not reveal the real color of the objects it falls upon. It is, however, of great value as a photographic illuminator being rich in actinic rays, which most affect the photographic plate. Mr. Hewitt is investigating with a view to discover means to turn some of the rays of the incandescent vapor into red rays. This discovery will be a means of great economy, because the Cooper Hewitt lamp is probably the cheapest artificial light in the world. The mercury vapor lamp consumes one half watt per candle-power, as against 3½ watts in the incandescent lamp.

Hewlett, hū'lĕt, **Maurice Henry**, English author: b. London 22 Jan. 1861. He was the son of Henry Gay Hewlett, a writer of some little note, and was educated at the London International College, Isleworth. He was admitted to the bar in 1891, and in 1896–1900 was keeper of the land revenue records and enrolments. His reputation was made as an interpreter of the more recondite phases of the life and thought of the Middle Ages, especially in Italy. His style is a skilful medium for his purpose, but frequently so archaized as to be somewhat difficult. His books are: 'Earthwork out of Tuscany' (1895), a collection of Italian studies; 'The Masque of Dead Florentines' (1895); 'Songs and Meditations' (1897); 'Pan and the Young Shepherd' (1898); 'The Forest Lovers' (1898), his first popular success; 'Little Novels of Italy' (1890); 'Richard Yea-and-Nay' (1900); 'New Canterbury Tales' (1901); 'Fond Adventures' (1904).

Hexam'eter (from the Greek ἕξ, six, and μέτρον, a measure), a verse of six feet. It is the heroic or epic measure of the Greeks and Romans, the finest examples of which are the two poems ascribed to Homer, the Iliad and the Odyssey, and the Æneid of Virgil. The sixth foot is always a spondee (two long syllables) or a trochee (a long and a short). The five first may be all dactyls (one long syllable and two short), or all spondees, or a mixture of both. The scheme of this verse then is —

—⏑⏑, —⏑⏑, —⏑⏑, —⏑⏑, —⏑⏑, — —
— —, — —, — —, — —, — —, — ⏑

with all the varieties which the mingling of the two kinds of feet, as mentioned, affords; as,

—⏑⏑, — —, — —, —⏑⏑, —⏑⏑, — —
Forte sub arguto consederat ilice Daphnis;

or, —⏑⏑, — —, —⏑⏑, —⏑⏑, —⏑⏑, — —
Qui Bavium non odit amet tua carmina, Mævi;

and so on. The variety of which the hexameter is susceptible, its great simplicity, its harmony, and its numerous pauses, constitute the charm of this verse, and adapt it to the most various subjects. A spondee is rarely used in the fifth foot, and then in Latin the word with which the verse ends is generally composed of four syllables, and the fourth foot at least must be a dactyl; as,

Cara deûm soboles, magnum Jovis incrementum.

The prevalence of the dactyl or spondee in the hexameter depends much upon the genius of the language; thus the dactyl is more frequent in Greek than in Latin, and in German than in Greek. It is evident that the hexameter cannot be formed in such languages as Italian, French, Spanish and English, whose prosody is regulated by the accent and not by the *quantity* of the words.

The French and Italian writers, however, early attempted the hexameter, as well as Sidney and Southey in English; but without success. More recent English poets have also tried it, as Clough and Kingsley. Longfellow has made use of the hexameter in his 'Evangeline.' But in no modern European language have hexameters become naturalized, except in German, to which this measure seems as well adapted as to the Greek. Fischart attempted the German hexameter in the 16th century. In the middle of the 18th century it was used by Klopstock, Uz, and Kleist. Goethe's hexameters are very often as poor as their sense is beautiful. John Henry Voss improved the German hexameter by the excellent translation of Homer and his valuable 'Zeitmessung der deutschen Sprache' (Königsberg 1802).

Hexapoda, hĕk-săp'ō-da, a group name for the six-footed arthropods, or true insects (*Insecta*), excluding spiders, myriapods and other forms often included in the term «insects.»

Hexateuch. See PENTATEUCH.

Hexoic Acid, an organic acid having the formula $C_6H_{12}O_2$, or $C_5H_{11}.COOH$, and occurring in fats, in cheese, among the products of the butyric fermentation of sugar, and in the fruit of *Heracleum sphondylium* and in the flowers of *Satyrium hircinum*. It is best prepared by the fractional distillation of crude fermentation butyric acid. It is an oily substance, very clear and mobile, solidifying at about 29° F., and boiling at 400° F. It has a specific gravity of 0.95, and is oxidized by nitric acid to acetic and succinic acids. It is also known as «caproic acid,» and its salts are sometimes called caproates, and sometimes hexoates.

Heyse, Paul, powl hī'zė, German poet and novelist: b. Berlin 15 March 1830. He studied classics in his native city, in 1852 traveled in Switzerland and Italy, and two years later he settled in Munich on the invitation of King Maximilian II. of Bavaria, who granted him a pension. He has lived mainly in Munich ever since, devoted almost exclusively to literature. His first work was 'Jungbrunnen, Märchen eines fahrenden Schülers' (Tales of a Traveling Scholar) (1850); and to the same year belongs his tragedy 'Francesca da Rimini.' 'Die Brüder' (1852) and 'Urica' (1852), were narrative poems, and formed part of the volume entitled 'Hermen' (1854), later 'Novellen in Versen,' which did much to establish his reputation. Heyse's genius has found its most perfect expression in his tales or novelettes (Novellen), and in this department of literature he holds almost a unique place among German writers. His work is almost throughout highly finished and artistic, and shows a rich imagination and great fertility in invention. His tales have been published in more than 20 collections, and a selection appeared in 1890 under the title 'Auswahl furs Haus.' His early successes in narrative verse were followed by such works as: 'Die Braut von Cyperin' (1856); 'Thekla' (1858); 'Rafael' (1863); 'Syritha' (1867); 'Der Salamander' (1879); 'Die Madonna im Ölwald' (1879); 'Liebeszauber' (1889). His best plays are those of his third period, and some of them, especially 'Hans Lange' and 'Kolberg,' have been acted with great success. 'Mary of Magdala' was well received in America. Among them are: 'Die Hochzeit auf dem Aventin' (1886); 'Gott schütze mich vor meinen Freunden' (1888); 'Hans Lange' (1866); 'Kolberg' (1868); 'Die Weisheit Salomos' (1887); 'Weltuntergang' (1889); 'Die schlimmen Brüder' (1891); 'Wahrheit?' (1892); and 'Jungfer Justine' (1893). His larger novels, 'Kinder der Welt' (1873); 'Im Paradiese' (1875); 'Merlin' (1892); and 'Über allen Gipfeln' (1895), have met with great success. Among other works are: 'Skizzenbuch' (1877); 'Verse aus Italien' (1880); 'Spruchbuchlein' (1885); 'Gedichte' (Poems, 5th ed. 1895; and 'Neue Gedichte und Jugendlieder' (1897).

Heyward, hā'ward, **Thomas, Jr.**, American patriot: b. St. Luke's Parish, S. C., 1746; d. there 6 March 1809. He was of much prominence in North Carolina during the Revolution, was a delegate to the Continental Congress 1775–8 and one of the signers of the Declaration of Independence. In later years he was a judge in his native State.

Heywood, John, English dramatist of the first half of the 16th century. He was a paid musician at the court of Henry VIII., with whom he became a favorite on account of his skill in music. Heywood's dramatic works may be classed as interludes, standing between the miracle-plays and the drama proper. The earliest of them, 'A Merry Play between the Pardoner and the Frere, the Curate and Neybour Pratte,' was written before 1521. Another famous piece is 'The Four P's,' an interlude in which figure a Palmer, a Pardoner, a Potycary, and a Pedlar.' His allegory of the 'Spider and the Fly' (1556) fully reveals Heywood's religious proclivities. By spiders, the Protestants are meant; by flies, the Catholics.

Heywood, Thomas, English dramatist b. Lincolnshire. He was educated at Cambridge and appears to have been writing plays as early as 1596. Of all the old dramatists he was the most prolific. We learn from the preface to 'The English Traveller' that down to 1633 he had "had either an entire hand, or at the least a main finger," in the composition of 220 plays" and he continued for some years after that date to write for the stage.

Twenty-four of Heywood's plays have been preserved. The best is 'A Woman kilde with Kindnesse' (1607). His work is usually distinguished by naturalness and simplicity; but he wrote at the beginning of his career one absurdly grandiose play, 'The Foure Prentises of London' (1615), which was parodied in Beaumont and Fletcher's 'Knight of the Burning Pestle.' 'The Rape of Lucreece' (1608) is chiefly noticeable for its songs; 'Love's Maistresse' (1636), dealing with the story of Cupid and Psyche, is fanciful and ingenious; and there is much tenderness in 'A Challenge for Beautie' (1636). 'The Captives, or the Lost Recovered,' an interesting play, acted in 1624, was first published in 1885.

Hezekiah, hĕz-e-kī'a (*Hizkiyah*, generally *Hizkiyahu*, strength of Jehovah), the 12th king of Judah. At 25 he succeeded Ahaz about 720 B.C., about 698 B.C. He had no sonner mounted the throne than he initiated a system of reform, on the injunctions of Isaiah, and broke up the idolatrous customs into which the people had fallen during the life of his father. He also endeavored to repair the injury done by national defeats and losses. He purged, repaired, and reopened the temple with magnificent sacrifices and a splendid ceremonial. So extreme was his indignation against idolatry that he destroyed the brazen serpent which was said to be the one used by Moses in his miraculous healing of the Israelites. With patriotic zeal he assumed the aggressive against the Philistines, and not only rewon the cities lost by his father, but dispossessed them of most of their own. In the 14th year of Hezekiah's reign he had a dangerous illness, which threatened serious complications, and the kingdom was in a difficult crisis, for the king had no heir, Manasseh not being born till long afterward. The greater part of the Scripture records bearing on the reign of Hezekiah is occupied by the two invasions of Sennacherib. Several of the Psalms are supposed to allude to the discomfiture of Sennacherib, for example, xlvi.-xlviii., lxxvi. Hezekiah did not long survive this deliverance, dying after a reign of nearly 29 years. Among the many highly useful works executed by him, the aqueducts of Jerusalem are of especial importance.

Hiawatha, hī-a-wä'ta or -tha, the hero of an American Indian legend known by this name among the Iroquois and among the other tribes. He is mentioned in various works on the aborigines, and in 1855 was immortalized in the poem, 'Hiawatha,' by Longfellow.

Hiawatha, Kan., city, county-seat of Brown County; on the Saint Joseph & G. I. and the Missouri P. R.R.'s; about 70 miles northwest of Kansas City and 55 miles north of Topeka. It is situated in a rich agricultural region. Its chief manufactures are flour, foundry products and agricultural implements. Its trade is principally in wheat, corn, fruit, livestock, flour, and lumber. It has the Morrill Public Library and an academy. The city owns and operates the waterworks and an electric-light plant. Another electric-light plant is owned by a private corporation. Pop. (1900) 2,829.

Hib'bard, George Abiah, American writer of short stories: b. Buffalo, N. Y., 1858. He has written 'Iduna, and Other Stories'; 'Nowadays'; 'The Governor'; etc. His work is marked by finished style and much insight into character.

Hib'ben, John Grier, American logician: b. Peoria, Ill., 19 April 1861. He was graduated from Princeton 1887 and is now professor of logic there. He is author of 'Inductive Logic' (1896); 'The Problems of Philosophy' (1898).

Hiberna'tion, the winter sleep of warm-blooded animals. Under this term is also included the torpidity of frogs, toads, reptiles, certain fishes, insects, the horseshoe crab and snails, which is mainly due to prolonged cold. Among the mammals which hibernate are the bear, dormouse, badger, bat and hamster; a number are incomplete hibernators, as the prairie dog, while squirrels fall into a winter sleep during the coldest weather, but may be seen in warm spells in winter. The males of the black and white bear are more or less active during the winter months, while the females are hibernating. The same species, like the skunk, may in the southern portion of its range not hibernate at all. Neither do the hibernators all retire to their holes or dens or under fallen trees at the same date, but the time varies with the temperature, and different degrees of torpidity are exhibited. It also appears that continuous hibernators do not lay in a supply of food, as do intermittent ones like squirrels; yet the Arctic fox is said to store up a supply of dead lemmings, ermines, geese, etc.

Hibernation is like sleep, and has been compared with trance. During this period the animal functions are nearly suspended, the excretions are greatly diminshed and in the bears the rectum is closed by a resinous plug, called by the Swedes "tappen," and by American hunters "seal." The animal heat is lowered to that or nearly that of the air, the action of the heart being slight; there is an increased muscular irritability, and the animal loses from 30 to 40 per cent of weight.

Snakes, lizards, the toad, frogs, salamanders, and certain fishes hibernate, burying themselves in the earth below the reach of frost, the aquatic forms digging into the mud at the bottom of streams. The few fishes which are known to lie dormant and take no food sink into the mud of streams or of the sea. The horseshoe crab burrows in the mud beyond the reach of oyster dredges in November, remaining in deep water until the middle of spring. Most insects hibernate in the larva or pupa state, a few as moths or butterflies. Caterpillars hide under moss, the bark of trees, etc., but they freeze solid and may be broken into two pieces like an icicle. They gradually thaw out in spring; when the changes are sudden, great numbers die. Spiders and snails hibernate under stones, moss, etc., while slugs bury themselves in the mud, and those mussels and other mollusks living in streams and lakes descend into the mud.

Estivation.— In the tropics there is a corresponding period of torpor during the hot, dry season, when food is scarce, and vegetation is taking a rest. Alligators, snakes, certain mammals, as the tauree, insects and land snails become dormant, the latter closing the mouth of their shells with a membrane-like substance (epiphragm), leaving a small opening in it for the admission of air in breathing, yet after a prolonged shower they become active. Thus it is seen that heat, dryness and the lack of food operate in causing estivation, while cold and famine appear to be the cause of hibernation; though all species are by no means affected alike. Among the lowest organisms the dormant vitality of resting spores, seeds of plants, winter eggs of sponges, of polyzoa, the dormancy of certain adult forms, are connected with a lowered temperature, and a resting period is necessary both in plants and animals. The simultaneous shedding of the leaves of deciduous trees is certainly connected with if not caused by cold, and it is undoubtedly true that changes of temperature as well as lack of food, and the need of rest, cause hibernation and summer dormancy.

Hibernia, the ancient name applied to Ireland (q.v.).

Hiber'nians of American, Ancient Order of, an Irish-American secret society founded in 1836. It has one general or national board, with 2,002 subordinate divisions. There were 139,453 members in 1902. The benefits disbursed the same year amounted to $429,000. National president (1902), J. T. Keating, Chicago, Ill.

Hibiscus, hī-bĭs-kŭs, a genus of plants of the mallow family (q.v.), distinguished by a double calyx and fruit of three or more many-seeded carpels united into a many-seeded capsule. The species are numerous, natives of warm climates, some trees or shrubs, but most of them large herbaceous plants. Many bear very beautiful flowers, much used in the South Sea Islands in wreaths, etc., for personal adornment. The rose-of-Sharon (*Hibiscus syriacus*), a native of Syria and Carniola, has long been in cultivation as an ornamental shrub. Several other species have become favorite hothouse plants. The scarlet hibiscus (*H. coccineus*) and the rose-mallow (*H. moscheutos*) are among the most striking and beautiful of North American wild flowers, glowing among the reeds of marshes in late summer in flame-color and pink. The characteristic mucilaginous and fibrous properties of the Malvaceæ are very strongly developed in this tribe. The fruit of *H. esculentus*, called gumbo, okra, etc., is in general use for food in the East and West Indies and the United States. It is an annual plant, with a soft herbaceous stem, three to five feet high, crenate leaves, axillary sulphur-colored flowers, and pyramidal, somewhat podlike capsules. The fruit is used in an unripe state, and is generally much esteemed, but is disliked by some on account of its viscidity. It enters as an important ingredient into the pepper-pot of the West Indies, or is used in soups. It also produces a coarse fibre. The bark of *H. tiliaceus*, a tree 20 feet high, with a very thick bole, abounds in mucilage. This tree is one of the most abundant trees of the South Sea Islands; and the wood, being light, tough, and durable, is much used for many purposes. From its fibre the Tahitians manufacture matting. Many other species yield fibres, some coarse, some fine and beautiful, which are used in different countries: but the most important in this respect is *H. cannabinus,* the Deccan hemp of western India (see Hemp). *H. sabdariffa* is very generally cultivated in warm countries, on account of its calyx, which, as the fruit ripens, becomes fleshy, and acquires a very pleasant acidity. It is much used for making tarts and jelly, and a decoction of it, sweetened and fermented, affords a refreshing beverage, well known in the West Indies as sorrel cool drink, the plant being called red sorrel; and in Madras it is used for similar purposes, and is named rozelle or rouselle. Musk-seed (*H. abelmoschus*) is cultivated for its seeds, which have a fragrance between that of musk and that of amber. They are much used by perfumers, and are called *graines d'ambrette.* In Egypt and Arabia they are mixed with coffee, and stimulant and stomachic qualities are ascribed to them. The petals of *H. rosa-sinensis* possess astringent properties, and they are also used by the Chinese to stain their eyebrows and their shoes black.

Hic'cup, or Hiccough, is a spasmodic affection of the diaphragm caused sympathetically by the irritation of structures supplied by nerves communicating with the phrenic nerve. Though generally a slight and passing inconvenience, its occurrence in the last stages of acute disease is a grave symptom, indicating general collapse of the nervous system. It may last only a few minutes or may continue for weeks without being capable of being subdued by any kind of treatment. Fasting or a stimulant suddenly swallowed is one of the commonest causes of hiccup, which generally passes off of its own accord. Nothing removes it more effectually than some active emotion of the mind suddenly excited. Hiccup is a common attendant of dyspepsia, and is often observed in abdominal diseases when terminating fatally, and is especially a symptom in some forms of hernia. Many remedies have been suggested for it, such as holding the breath as long as possible, tying a belt tightly round the waist, and the frequent swallowing of small rounded pieces of ice.

Hi h'born, Philip, American naval officer: b. Charlestown, Mass., 1839. In 1869 he entered the United States navy as assistant constructor, in 1875 was made constructor, and in 1881 a member of the naval advisory board. From 1893 until his retirement 4 March 1901, he was chief constructor, and as such was identified with the reorganization and enlargement of the new United States navy. He attained rear-admiral's rank, and published a valuable report on foreign dockyards.

Hich'ens, Robert Smythe, English journalist and novelist: b. Speldhurst, Kent, 14 Nov. 1864. He was educated at Clifton College and the Royal College of Music, and after a short career as a musician turned to journalism. In 1893 he visited Egypt for his health, and there conceived the idea which materialized in the 'Imaginative Man' (1895). 'The Green Carnation' (1894), however, epigrammatic and keenly satirical in tone, first brought him into public notice. Later works of his are: 'After To-Morrow' (1895); 'New Love' (1895); 'The Folly of Eustace and Other Stories' (1896); 'The Londoners' (1897); 'Byeways' (1897); 'The Prophet of Berkeley Square' (1901); etc.

Hick'ey, Emily, English poet: b. Macine Castle, County Wexford, Ireland, about 1845. She was co-founder in 1881 of the Browning Society with F. J. Furnivall (q.v.) and has lectured on English literature. She has published among other volumes 'A Sculptor and Other Poems' (1881); 'Verse Tales, Lyrics, and Translations' (1889); 'Our Lady of May and Other Poems' (1902). Her verse has been highly praised by critics.

Hickey Plot (1776), a conspiracy of the British officials and Loyalists of New York to end the Revolutionary war by the murder or capture of its leaders and the seizure or destruction of its supplies. The heads and probable devisers of it were Governor Tryon, who had fled from the city but remained on a man-of-war in the harbor, and sent supplies of money for bribery, etc.; and Mayor Mathews. The scheme was to kill or seize the patriot generals, and at all events to deliver Washington alive to Sir William Howe, blow up the magazine and secure the passes to the city. Several hundred New York Loyalists were involved. Two of Washington's guard were bought, but a third pretended to accede and revealed the plot. Mathews, a gunsmith named Forbes, and a dozen others were arrested and sent to Connecticut, Mathews carrying the mayoralty flag with him. Thomas Hickey, one of the treacherous guards, was hanged in New York 27 June 1776, the first military execution in the American army.

Hick'man, Ky., town, county-seat of Fulton County; on the Mississippi River, and on the Nashville, C. & St. L. railroad; about 35 miles below Cairo, Ill. It has steamboat connections with the river ports. It is the seat of Hickman College. Its chief industrial establishments are a flour-mill, wagon-factory, two spoke-factories, saw- and planing-mills. Its trade, in addition to its own manufactured articles, is principally in grain and tobacco. Pop. (1900) 1,589.

Hick'ok, Laurens Perseus, American metaphysician: b. Danbury, Conn., 29 Dec. 1798; d. Amherst, Mass., 6 May 1888. He was graduated at Union College in 1820, was licensed as a preacher in 1822, and was pastor successively at Newton and Litchfield, Conn., till in 1836 he was elected professor of theology in the Western Reserve College, Ohio, where he remained eight years. He was professor in the Auburn Theological Seminary 1844–52, and then became professor of mental and moral science, and vice-president in Union College. In 1866 he was formally made president of that institution of which, however, he had been in sole charge for eight years previous. His publications include among other works 'Rational Psychology' (1848); 'Moral Science' (1853); 'Empirical Psychology, or the Human Mind as Given in Consciousness' (1854); 'Rational Cosmology' (New York 1858), in which he attempts to demonstrate *a priori* the laws of the universe; 'Creator and Creation' (1872); 'Humanity Immortal' (1872); 'Logic of Reason' (1875).

Hick'ory (formerly Hickory Tavern), N. C., town in Catawba County; on the Southern railway; near the headwaters of the Catawba

River; about 43 miles northwest of Charlotte and 50 miles west of Salisbury. The chief manufactures are flour, foundry products, wagons, lumber, leather, boots and shoes. It has several private educational institutions: Claremont Female College, opened in 1880; Saint Paul's Lutheran Seminary; Lenoir College, opened in 1891, under the auspices of the Lutheran Church. Pop. (1900) 2,535.

Hickory, a group of trees of the walnut, forming the genus *Hicoria*, and exclusively North American. They are large strong trees, 60 to 80 feet high, with close shaggy bark and large pinnately divided leaves, pistillate flowers on a terminal peduncle and staminate flowers in long, drooping aments. The fruit is a thick-shelled nut in a tough green husk. There are about 10 species, all natives of the eastern United States and Canada except a Mexican species. The best known of these are the following: Shag-bark, shell-bark or white hickory (*H. ovata*), leaflets 5 to 7, whose bark scales off in great plates curving outward at both ends, and whose nuts are sweeter and better than those of any other species; the northerly "big shag-bark" or king-nut (*H. laciniosa*), leaflets 7 to 9, with narrower "shags," darker wood and big nuts in husks often three inches long; white-heart, or fragrant hickory, or mocker-nut (*H. alba*), noted for the hardness and toughness of its wood; the pignut or broom hickory (*H. globra*), leaflets 3 to 7, which represents a group of moisture-loving species whose nuts are thin-husked, elongated and bitter and estringent to the taste. Associated with these is the pecan (*H. pecan*), of the Southern States, whose oblong, thin-shelled nut is one of the most delicious of all nuts, and is now being cultivated in a few places in order to supply the increasing demand. The water hickory (*H. aquatica*) is sometimes called the bitter pecan.

Uses of Hickory-wood.—As timber this wood is of great value for articles requiring great strength with lightness and elasticity; but it is liable to quick decay when exposed to the atmosphere, and for this reason is little used in building, and should be painted. It was the most serviceable of all woods to the aboriginal Americans; and the axe, pick, and tool handles made from it are exported to all parts of the world. It enters into the manufacture of rakes, cradles, and many forms of farm-implements; is largely used in carriage-making, especially for thills, shafts, and the parts of racing-sulkies, the lighter American vehicles owing their acknowledged pre-eminence largely to the availability of this wood. The wood of the various species differs in quality, however; that of the pecan is hard and brittle, and the water hickory soft and comparatively light. The wood of the others is exceedingly strong and tenacious, and weighs about 50 pounds to the cubic foot.

Insect Pests.—A. S. Packard recorded in 1890 170 species of insects attacking the hickories; and Chittenden declared in 1903 that this number could be easily doubled. Hickory appears to be an especial favorite of borers. Prominent among them are the painted hickory-borer, one of the long-horned beetles (*Cyllene picta*); the hickory twig-girdler (*Oncideres cingulata*), twig-pruner (*Elaphidion villosum*), and hickory-bark beetle (*Scolytus quadrispinosus*). This bark-borer is the most important economic species, and during recent years has been the cause of considerable injury in hickory forests in the State of New York. Consult Packard, 'Insects Injurious to Forest and Shade Trees,' published in 1888 as the fifth report of the United States Entomological Commission.

Hickory Shad. See GIZZARD SHAD.

Hicks, Elias, American preacher of the Society of Friends: b. Hempstead, L. I., 19 March 1748; d. Jericho, L. I., 27 Feb. 1830. While a youth he manifested a talent for public speaking, and at 27 was a well known preacher. For many years he labored zealously in advancing the generally accepted doctrines of the Friends; but having as he believed discovered errors in these tenets, put forth views of his own which he defended with energy and ability. To advance these views he traveled extensively in the United States and in the British provinces, attracting large congregations by his oratory. The result was a schism in the body of Friends; those adhering to the old doctrines being specially termed orthodox, while the followers of Hicks were called after him Hicksites. (See FRIENDS.) He was an active abolitionist and with others was instrumental in inducing the State of New York to pass an act which, on 4 July 1827, liberated all slaves within its borders. He was the author of 'Sermons' (1828); 'Observations on Slavery' (1811); 'The Letters of Elias Hicks' (1834); etc. See 'Elias Hicks, Journal of his Life and Labors' (1828).

Hicks, Thomas, American painter: b. Newton, Pa., 18 Oct. 1823; d. 1890. He studied at the Philadelphia Academy, at the National Academy, New York, and afterward in Paris under Couture. Settling in New York he became one of the favorite portrait painters of his day. His pictures in the rooms of the New York Historical Society form an interesting gallery of historic figures, executed with more than ordinary artistic skill.

Hicks, Thomas Holliday, American politician: b. Dorchester County, Md., 2 Sept. 1798; d. Washington, D. C., 13 Feb. 1865. After successively occupying the positions of sheriff, member of the State legislature, member of the State electoral college, and member of the Governor's council, he was in 1858 elected governor of the State. When war was threatened between North and South, although sympathizing with the South and condemning the North's attitude on the slavery question, he sided with the party of neutrality in Maryland and opposed the secession of that State. When there were rumors of a plot formed by 6,000 men of his State to prevent Lincoln's inauguration and seize the city of Washington he suspended the writ of habeas corpus, and planned the arrest of suspected persons. He was the only prominent State official who stood by the Federal government, and at the expiration of his term as governor the new Legislature passed resolutions thanking him for having saved the State from joining the Confederates. In 1862 he was appointed to the senate of the United States and served in it till his death.

Hicks-Beach, SIR Michael Edward, English politician: b. London 1837. He was educated at Eton and Oxford, entered parliament in 1864, and was made chief secretary for Ireland in 1874, and secretary of state for the colonies in 1898. In 1885 he was appointed chancellor of the exchequer and leader of the Conservative party in the House of Commons. He was president of the board of trade from 1888 to 1892. On the fall of the Gladstone ministry in 1895 he again became chancellor of the exchequer. In October, 1902, he caused a sensation by charging the Balfour government with wasteful expenditure of war appropriations, and in 1903 ably defended the British policy of free trade.

Hick'son, Sydney John, English zoologist: b. London 25 June 1859. He was educated at Cambridge and has been professor of zoology at Owens College, Manchester, England, from 1894. He has published 'A Naturalist in North Celebes'; 'The Fauna of the Deep Seas'; 'The Story of Life in the Seas' (1898).

Hidalgo y Costilla, Miguel, mē-gĕl' ē-dăl'-gō ē kōs-tēl'ya, Mexican revolutionist, first leader in the Mexican war of independence: b. State of Guanajuato 8 May 1753; shot in Chihuahua, Mexico, 27 July 1811. He was a priest, and in earlier life was simply a man of great acquirements, anxious to promote industry in Mexico, and noted for conscientious fulfilment of his ecclesiastical functions. He is said to have introduced the silkworm into Mexico, and did much to promote the culture of the vine. This conflicted with the policy of the Spanish government, which was to discourage all manufactures or agriculture which could interfere with the revenue, and the vines Hidalgo had planted were destroyed. This drove him to rebellion. Possessing much influence among the Indians, he formed the plan of a general insurrection, which was to take place 1 Nov. 1810; but the plot having been disclosed by one of the conspirators, some of his party were arrested, and he was obliged to precipitate his movements. On 10 September having been joined by three officers of the garrison of Guanajuato, he raised the standard of revolt. His eloquence had a remarkable effect on the multitude who heard him, and when after his oration he unfurled a rude copy of the picture of Our Lady of Guadalupe, the patroness of Mexico, the war assumed the character of a crusade. On 29 September with an army of 20,000 men, mostly Indians, he captured Guanajuato. He took Valladolid and several small places, and soon after was proclaimed generalissimo of the Mexican army, and advanced against Mexico; but finding himself almost without ammunition, was obliged to retreat. During this war the government party declared that the ordinary rules of warfare need not be observed as regarded the insurgents, while the latter retaliated with the most horrible atrocities. On one occasion Hidalgo is said to have massacred 700 prisoners because they were Europeans. After several defeats the insurgents were left at Saltillo under charge of Rayon, while Hidalgo and others went to the United States to obtain arms and military aid. On their way they were captured by a former friend, and finally shot in Chihuahua. He was after his death regarded as a saint by the people, and within a few years the place of his execution was shown to travelers as a holy spot. The town of Goliad, Texas, was named in his honor, the H, as silent in pronunciation, being omitted and the other letters rearranged. At the founding of the town the name of Hidalgo was still proscribed by the Spanish rulers and the transposition of the letters of his name was made in order to avert the attention of the authorities.

Hid'denite, a yellowish-green or emerald-green, transparent variety of spodumene, discovered by W. E. Hidden, in 1880, in Alexander County, N. C. The emerald-green varieties have been used as gems. They resemble the emerald, but show a greater wealth of color on account of their pleochroism.

Hides and Leather. There are few arts, among the many that are used for the benefit of mankind to-day, that are of such ancient origin as that of tanning. It is only necessary to study the carvings upon the monuments that the modern archæologist has unearthed to ascertain the fact that the old Egyptians were not only acquainted with several processes of tanning and working in leather, but that its preparation was one of the most important branches of Egyptian industry. So far as our knowledge of their methods of work extends, we know that these ancient workmen prepared their tan in earthen vessels and that they were able to preserve skin either with or without the hair attached. Among the Hebrews, who undoubtedly derived their knowledge of the art of preparing leather from the Egyptians, the trade of the tanner was despised, largely because of the bad odor connected with it, and those who followed this source of livelihood were obliged to locate their working places outside the limits of the city. Often they were situated by the side of streams, or on the shore of the sea, as was the case in Joppa, where the building said to have been the house of Simon the Tanner was located on the shore south of the city.

According to the most authentic records the first tannery to be operated in this country was established in Virginia, about the year 1630. A year or two later another tannery was established in New England, in the village of Swampscott, or Lynn, Mass., by Francis Ingalls, a colonist who had learned his trade in Lincolnshire, England. As it was impossible not to recognize the importance of the industry it was greatly encouraged by the colonial authorities, in evidence of which fact there are many laws on the old statute books regulating, not only the manufacture of leather, but the saving of skins needed by the tanners, under serious penalties for noncompliance. For example, a law was passed in Massachusetts, in 1646, prohibiting the exportation of raw hides, or unwrought leather, under heavy penalties which not only affected the shipper, but reacted upon the master of the vessel that attempted to sail with such freight, for these were the days when the small tanners who had shops scattered throughout the country were entirely dependent upon the surrounding neighborhood for their hides, but so effective were the restrictions placed upon importations of skins by the authorities, that leather was relatively more plentiful in the American colonies than it was in England.

One of the most prominent leather manufacturers of the old days was Colonel William Edwards, who sent the first tanned leather to the Boston market in 1794. Beginning his business in Hampshire about 1790, when he was less than 20 years of age, he immediately inaugurated a series of improvements in the mechanical branch of the art, which, as they were afterward adopted and extended by others, were the means of infusing a much-needed spirit of enterprise into the business. In fact, it was the new ideas in mechanism and in the arrangement of the tannery which he evolved that paved the way for the most important improvements which have since been made in the manufacture of leather. The first company in the business to be incorporated also owed its existence to Colonel Edwards' enterprise, for it was his extensive tanneries at Northampton, Cummington, and Chester that were purchased by the men who incorporated the Hampshire Leather Manufacturing Company of Massachusetts, with a capital of $100,000 in 1809. These works then had a capacity of 16,000 full-grown hides per annum.

By 1810, the tanning industry had extended so widely that there were tanneries in operation in almost every portion of the country. Bark was so plentiful that it was much cheaper than in England, and, as the result, it was not long before the exportations of American leather had attained an aggregate of 350,000 pounds per annum, while the importations were confined to morocco, and some peculiar kinds of English leather which could not then be produced in this country. At this time (1810) the value of all the manufactures of hides and skins was stated by the census office to be $17,935,447, but, owing to the fact that the census at that time was so crudely conducted that it was very incomplete, it is safe to say that $20,000,000 would be much closer to the correct figure. From that date, however, the business increased, slowly at times, perhaps, but steadily, until, in 1840, it was reported that there were about 8,000 tanneries in the country, with a capital of $16,000,000, and employment for fully 26,000 hands. By 1850, the capital had increased to more than $20,000,000, while the value of the annual product had reached the quite respectable figure of $38,000,000. In 1860, this product, including the making of morocco and patent leather, had almost doubled, being in excess of $72,000,000, while, in 1870, the 7,569 establishments in the country were employing no less than 35,243 persons, at an aggregate wage of $14,505,775, to produce an annual output that was valued at $157,237,597. At this time the capital invested in this business was reported as being more than $61,000,000.

As the establishments engaged in the making of leather were enumerated very differently by the census of 1890 and 1880, it is quite impossible to obtain a reliable basis of comparison from the published statistics. In preparing the census of 1880, the government's enumerators not only counted all the smaller businesses, but they must have reckoned twice all that were engaged in both tanning and currying, with the result that they were able to make an aggregate of 5,628 establishments. As the later census enumerators have confined their attention solely to the large establishments the discrepancy is too great to be readjusted by estimate. Thus, for example, the 1890 census reports 1,787 establishments, while the 1900 census has but 1,306. The other census figures follow:

THE LEATHER INDUSTRY, 1880 TO 1900.

	1880	1890	1900
Capital	$73,3[illegible],911	[illegible]	$173,977,421
Number of employees	40,282	42,3[illegible]	52,109
Wages paid	$10,5[illegible],826	$21,249,98[illegible]	$22,[illegible]1,092
Cost of material used	156,384,117	132,04[illegible],741	155,[illegible],004
Value of product	[illegible]	17[illegible],130,0[illegible]2	[illegible]4,[illegible]8,127

Among the first patents taken out for the application of any special process in the making of leather was in 1823, when an inventor patented a method of forcing the tanning liquor through the skin by hydrostatic pressure. In 1831, William Drake devised a modification of this method. According to his process two skins were sewed together and the liquid, which was placed in the receptacle thus formed, was permitted to remain until the tanning had been completed. Some years prior to that time a patent had been issued for a method which provided for the suspension of the hides in a closed vessel, in which their conversion into leather would be much accelerated by the removal of

LEATHER PATENTS.

Purpose for which Issued	Date of First Patent	Approximate Total Number of Patents to Date
Processes and apparatus for leaching and making extracts from tan-bark	Aug. 10, 1791	100
Bark-mills	July 19, 1794	100
Processes employing apparatus for tanning leather	July 9, 1808	100
Leather-splitting machine	July 9, 1808	75
Unhairing machine	July 12, 1812	75
For rolling leather	Oct. 19, 1812	25
Scouring and setting machine	Nov. 21, 1831	70
Tanners' vats and handling appliances	Jan. 9, 1834	75
Machines for boarding and graining leather	March 25, 1835	35
Compounds for depilating hides and skins	June 30, 1836	60
For fleshing machines	June 17, 1837	25
Compounds for bating hides and skins	Feb. 3, 1838	40
Whitening, buffing, and shaving leather	May 10, 1838	30
Compounds and materials for tanning and tawing leather and preparing raw hides	July 12, 1838	175
Processes for tanning leather	Aug. 1, 1838	275
For currying leather	Aug. 1, 1838	25
Machines for stoning, polishing, finishing, glassing, glazing, flinting, creasing, and dicing leather	March 15, 1845	75
Compounds for coloring and polishing leather	Oct. 9, 1847	40
Methods for manufacturing enameled, japanned, and patent leather	Jan. 9, 1855	20
For stuffing leather	Feb. 6, 1[illegible]	20
For pebbling leather	May 6, 185[illegible]	30
For employing mineral substances for tawing hides and skins	Aug. 4, 1857	20
For stretching leather	Feb. 8, 18[illegible]	40
Bark-rossing machines	Jan. 9, 18[illegible]	10
For preserving hides	Sept. 11, 18[illegible]	15
Machines for shaving or making leather of uniform thickness	Sept. 24, 1867	5
Apparatus for blacking leather	Sept. 20, 1870	15
Measuring-machines	Aug. 28, 1877	25
Striking-out machines	March 27, 1883	4

all the air by an air-pump. To enumerate all, or even the most important of these inventions within any brief space would be impossible, but the preceding table gives the date when the first patent was issued for each of the details which enter into the manufacture of leather, as well as an estimate of the number of patents that have been issued in each division of the endustry up to the present time.

Hides, as the term is generally accepted today, may be conveniently divided into three classes: (1) Hides proper, which consist of the skins of the larger and more common animals, such as oxen, cows, and horses; (2) kips, which comprise the skins of small, or yearling cattle, which are too large to be classified as calfskins, and (3) skins, including those of calves, sheep, goats, deer, pigs, seal, and the various kinds of fur-bearing animals, many of which, including most of the latter, retain their hair after tanning. The heavy hides are converted into sole, belt, and harness leather; the calfskins are chiefly used for material for the manufacture of the uppers for leather shoes and boots, and are also in much demand by bookbinders; the sheepskins are used for a large variety of purposes, including linings for shoes, aprons, cushions, and covers, gloves, women's shoes, bellows, whips, etc.; the goatskins are used almost exclusively in the making of gloves and ladies' shoes—the morocco leather so extensively manufactured until recent years having now given place to the cheaper and more durable "glazed kid"; the hogskins are utilized in the making of saddle-leather, traveling bags, etc., while dogskins, because of their thin and tough characteristics, are particularly useful in the manufacture of gloves. The durability of the porpoise-skin has recommended its use in the making of shoe-strings, while the buffalo, alligator, kangaroo, deer, elephant, hippopotamus, rhinoceros, walrus, and shark, are among the many other creatures whose skins are utilized in various fields of manufacture after they have left the hands of the tanner.

There is probably no vegetable growth containing tannin that has not been tried by those who are interested in discovering the best and most economical methods of tanning leather, but, while nearly all of them have met with some favor, oak-bark is now held to be the best agent obtainable for this purpose. Among the other tannages that have been utilized with success, however, one may mention hemlock-bark, union, Dongola, alum, chrome, combination, electric, sumac, and gambier.

Practically the only change that has taken place in the tannage process of sole-leather is represented by a slight diminution in the time required for the work, but as experiments are constantly being made along these lines it is believed that the day will come when such leather will be turned out in as many days—perhaps hours—as it now takes weeks. The change that has already been made along these lines in the preparation of the lighter skins has been almost as radical. The introduction of Dongola kid, in 1880, completely revolutionized the manufacture of kid or morocco. It was the discovery of James Kent, of Gloversville, N. Y. The system of tanning, or tawing by the use of chromium compounds, was discovered as early as 1856 by a German chemist, but each of the many experiments which followed this discovery had failed because there was no known method by which the tannage could be made permanent. At last it was found that hyposulphite of sodium contained the long-sought remedy, and by this process the tannage was made lasting. It was due to this discovery, and to its successful application, that some of the largest and best equipped leather manufactories in the world have since been established in the United States.

Hierarchy, hī'ē-rär-kĭ (From Gr. *hieros*, sacred, and *arche* government), sacred government or "the administration of sacred things," first used by the pseudo-Dionysius in the 5th century in his work on the Celestial and Ecclesiastical Hierarchies. It is now generally used to signify the body of officials in the Church organically graduated in their ranks and orders from the supreme head to those in the most subordinate position. In the Roman Catholic Church a threefold distinction is recognized: (1) A hierarchy of divine right, which embraces, under the primacy of the popes, bishops, priests, and deacons. This hierarchy is held by Church to be of divine institution. (2) A hierarchy by ecclesiastical right, consisting of the Roman pontiff and the three original divine orders and of the five minor orders (two in the East), subdeacons, acolytes, exorcists, lectors, and porters (ostiarii). (3) A hierarchy of jurisdiction, which includes all the judicial and administrative authorities, ordinary and delegated, charged with the maintenance of the faith among Christians, its union, its discipline, and its general care and supervision. All its powers proceed from the pope as primate, either expressly or by implication. In this category are ranked cardinals, patriarchs, exarchs, metropolitans, and archbishops, and as deriving their powers from these, archpriests, archdeacons, rural-deans, vicars-general, etc. The Anglican Church also recognizes a hierarchical rank in its body, comprising bishops, priests, and deacons. The other Protestant bodies practically reject hierarchical government.

Hiero, I., hī'ē-rō, king of Syracuse in Sicily: d. Catania, 467 B.C. He was brother and successor of Gelon. Hiero's reign, though less glorious than the preceding, was marked by a peculiar splendor on account of his generous encouragement of learning. Though some blemishes tarnish the first years of Hiero's reign, he compensated for his first faults by the noble actions which signalized the remainder of his life. A long sickness was the main cause of this alteration. Since he could no longer occupy himself with the cares of royalty, he collected around him a society of learned men, and thus becoming acquainted with the pleasures of learning, he never afterward ceased to value it. His court became the rendezvous of the most distinguished men of his time. The names of Simonides and Pindar appear among those of his most constant companions, and when Æschylus left Greece, he betook himself to Hiero, to close his days in his kingdom. He was several times victor in the Grecian games.

Hiero II., king of Syracuse: b. before 306 B.C.; d. 216 B.C. He was the son of Hierocles, a noble Syracusan, who claimed a descent from the family of Gelon. During Hiero's reign began the first Punic war, and he was able, by his adroitness, to preserve the friendship of both Romans and Carthaginians. The glory of Hiero and the prosperity of Syracuse culminated in the period which intervened between the first Punic war and the second; for in that season of peace Hiero enacted wise laws, and was devoted to the happiness of his subjects. His encouragement of agricultural pursuits enriched him and doubled the revenues of the state. He left the crown to his grandson Hieronymus.

Hieronymus. See JEROME, SAINT.

Hieroglyphics, hī″ē-rō-glĭf′ĭks (from Gr. *hieros,* sacred, and *glypho,* engrave), the inscriptions sculptured on buildings in Egypt, with the implication that the writing was confined to sacred subjects, and legible only by the priests. The term has also been applied to picture-writing in general, such as that of the Mexicans and the still ruder pictures of the North American Indians. Two different modes of hieroglyphic writing were used by the ancient Egyptians,, the hieratic, and the demotic. Pure hieratic writing is the earliest, and consists of figures of material objects from every sphere of nature and art, with certain mathematical and arbitrary symbols. Next was developed the middle hieratic or priestly writing, the form in which most Egyptian literature is written, and in which the symbols almost cease to be recognizable as figures of objects. Hieratic writings of the third millennium B.C., are extant. In the demotic or enchorial writing, derived directly from the hieratic, the symbols are still more obscured. The demotic was first used in the 9th century B.C., and was chiefly employed in social and commercial intercourse. Down to the end of the 18th century scholars failed in find a clue to the hieroglyphic writings. In 1799, however, M. Bouchard, a French captain of engineers, discovered at Rosetta the celebrated stone which afforded European scholars a key to the language and writing of the ancient Egyptians. It contained a trilingual inscription in hieratics, demotic characters, and Greek, which turned out to be a decree of the priests in honor of Ptolemy V., issued in 195 B.C. The last paragraph of the Greek inscription stated that two translations, one in the sacred and the other in the popular Egyptian language, would be found adjacent to it. In deciphering these inscriptions the discovery of an alphabet was the first task. The demotic part of the inscription was first examined by De Sacy and Akerblad, and the signification of a number of the symbols ascertained. The hieratic part was next carefully examined and compared with the demotic and Greek. At last after much study Champollion and Dr. Thomas Young, independently of each other, discovered the method of reading the characters (1822), and thus provided a clue to the decipherment of the ancient Egyptian writing.

Cartouche of Cleopatra, i.e. Kleopatra.

Cartouche of Ptolemy, i.e. Ptolemaios.

Hieroglyphic characters are either ideographic, that is, using well-known objects as symbols of conceptions, or phonetic, that is, representing words by symbols standing for their sounds. The phonetic signs are again divided into alphabetical signs and syllabic signs. Many of the ideographic characters are simple enough; thus the figure of a man, a woman, a calf, indicate simply those objects. Others, however, are less simple, and convey their meaning figuratively or symbolically. Water was expressed by three zigzag lines, one above the other, to represent waves or ripples of running water, milk by a milk-jar, oil by an oil-jar, fishing by a pelican seizing a fish, that is, fishing; seeing and sight by an eye; and so on. The nature of the phonetic hieroglyphs, which represent simply sounds, will be understood from an explanation of the accompanying cuts.

(1) The first hieroglyph in the name of Kleopatra is a knee, which is *kne* or *kle* in Coptic, and represents the K of Kleopatra. (2) The second hieroglyph in Kleopatra is a lion couchant, which is *laboi* in Coptic, and *labu* in the old Egyptian, and represents the L of both names. In Kleopatra it occupies the second place, and in Ptolemaios the fourth. (3) The third hieroglyph in Kleopatra is a reed, which is *aké* in Coptic and *aak* in the old Egyptian, and represents the E of Kleopatra. The reed is doubled in Ptolemaios and occupies the sixth and seventh places, where it represents the diphthong *ai* of Ptolemaios. (4) The fourth hieroglyph in Kleopatra is a noose, which represents the O of both names and occurs in the third place of Ptolemaios. (5) The fifth hieroglyph in Kleopatra is a mat, which represents the P of both names, and is the initial of Ptolemaios. (6) The sixth hieroglyph in Kleopatra is an eagle, which is *akhoom* in Coptic, and represents the A, which is found twice in the name of Kleopatra. (7) The seventh hieroglyph in Kleopatra is a hand, which is *toot* in Coptic, and represents the T of Kleopatra, but does not occur in Ptolemaios, where it might be expected to occupy the second place. The second place of Ptolemaios is occupied by a semicircle, which is found at the end of feminine proper names, and is the Coptic feminine article T. The researches of Champollion satisfied him of the existence of homophones, or characters having the same phonetic value and which might be interchanged in writing proper names. (8) The eighth hieroglyph in Kleopatra is a mouth, which is *ro* in Coptic, and represents the R of Kleopatra. (9) The ninth hieroglyph in Kleopatra is the eagle, which is explained in No. 6 above. (10) The semicircle is the T of Ptolemaios, which with (11) the egg found at the end of proper names of women, is a feminine affix. In the name of Ptolemaios there is still the M and the S to account for. The fifth hieroglyph in the cartouche of Ptolemaios is a geometrical figure, consisting of three sides of (probably?) a parallelogram, but now called a hole, because the Coptic *mu* has that signification, and represents the M. The hook represents the S of the word Ptolemaios. Vowels were only regarded by the Egyptians as they were needed to avoid ambiguous writing. There are groups of hieroglyphs of which one element is an ideographic sign, to which a phonetic complement is added to indicate the pronunciation of the ideographic sign. The

words of a text could be written in hieroglyphs in three ways—(1) by phonetic hieroglyphs; (2) by ideographic hieroglyphs; and (3) by a combination of both. According to Ebers, in the perfected system of hieroglyphics the symbols for sounds and syllables are to be regarded as the foundation of the writing, while symbols for ideas are interspersed with them, partly to render the meaning more intelligible, and partly for ornamental purposes. Consult: Brugsch, 'Egyptologie' (1891); Erman, 'Life in Ancient Egypt' (1894); and 'Egyptian Grammar' (1894).

Hierosolyma. See JERUSALEM.

Hig'gins, Anthony, American politician: b. Red Lion Hundred, Del., 1 Oct. 1840. He was educated at Yale and after studying law at the Harvard Law School was admitted to the Delaware bar in 1864. From 1869 to 1876 he was United States attorney for Delaware, and becoming interested in politics was chairman of the Republican State Convention in 1868. In 1881 he secured the vote of the Republican members of the Delaware legislature for the National Senate and in 1884 was defeated as a Republican candidate for Congress. He was United States Senator 1889–95.

Hig'ginson, Ella Rhoads, American novelist and poet: b. Council Grove, Kan., 1862. She was married to R. C. Higginson and has passed her life mainly in the vicinity of Puget Sound, Wash. She has contributed much to periodicals, and her work, which has a distinctly original flavor, has attracted much attention from its vigorous presentation of life on the upper Pacific slope. Her most noteworthy book is 'Mariella, or Out West,' an extremely strong novel (1902); and other works of hers are 'The Flower that Grew in the Sand' (1896); 'From the Land of the Snow Pearls' (1897); 'A Forest Orchid' (1897); and several collections of poems.

Higginson, Francis, English clergyman in colonial America: b. 1587; d. Salem, Mass., 6 Aug. 1630. He was educated at Cambridge, England, and subsequently became rector of a parish in Leicester, but becoming gradually a Nonconformist, was deprived of his benefice, and was employed among his former parishioners as a lecturer. While apprehending a summons to appear before the high commission court, he received an invitation from the Massachusetts Company to proceed to their colony, which he accepted. He embarked in May 1629, and it is related by Cotton Mather that as the ship was passing Land's End, he called the passengers about him and exclaimed: "We will not say, as the Separatists were wont to say at their leaving of England, 'Farewell, Babylon; farewell, Rome!' but we will say, Farewell, dear England! farewell, the church of God in England, and all the Christian friends there. We do not go to New England as Separatists, though we cannot but separate from the corruptions of it. But we go to practise the positive part of church reformation, and propagate the gospel in America." He arrived at Salem 29 June, and on 20 July was chosen teacher of the congregation established there. Subsequently Higginson drew up "a confession of faith and church covenant according to Scripture," which on 6 August was assented to by 30 persons, who associated themselves as a church. He wrote 'New England's Plantations, or a Short and True Description of the Commodities and Discommodities of the Country' (1630), and an account of his voyage, printed in Young's 'Chronicles of the First Planters' (1846). Consult: T. W. Higginson, 'Life of Francis Higginson' (1891).

Higginson, Francis John, American rear-admiral: b. Boston 19 July 1843. He was graduated from the United States Naval Academy in 1861 and served in the United States navy during the Civil War becoming lieutenant-commander in 1866. He was commander of the Massachusetts during the Spanish-American War 1898, was promoted commodore that same year, and rear-admiral in March 1899.

Higginson, Henry Lee, American banker: b. New York 18 Nov. 1834. He was educated at Harvard, studied music abroad and served in the Federal army during the Civil War and was brevetted lieutenant-colonel. He has been long connected with the Boston banking firm of Lee-Higginson & Co., and has contributed large amounts toward the organization and support of the Boston Symphony Orchestra.

Higginson, Mary Thacher, American author, wife of T. W. Higginson (q.v.): b. Machias, Maine, 27 Nov. 1843. She has written 'Seashore and Prairie' (1876); 'Room for One More' (1879); and 'Such as They Are' (1893), poems written in collaboration with her husband.

Higginson, Sarah Jane Hatfield, American writer: b. Philadelphia 15 Jan. 1840. With her first husband, a Dutch jurist, she lived for several years in the Dutch East Indies, and after his death returned to the United States, where she was married to Stephen Higginson, a former American consul in the Dutch East Indies. She has written: 'A Princess of Java: a Tale of the Far East' (1887); 'Java, the Pearl of the East,' a book of travel (1890); 'The Bedouin Girl.'

Higginson, Thomas Wentworth, American author: b. Cambridge, Mass., 22 Dec. 1823. He is descended from Rev. Francis Higginson (q.v.) and was graduated from Harvard in 1841, and from Harvard Divinity School in 1847. He became pastor of a Unitarian church in Newburyport, Mass., in 1847, but resigned from the pastorate in 1850, his anti-slavery views being unacceptable to his congregation. In the year last named he was the unsuccessful "Free Soil" candidate for Congress, and he was pastor of a Free (unsectarian) church at Worcester, Mass., 1852–8. In the interim he had been prominent in anti-slavery agitation, and for his share in the attempted rescue of the fugitive slave Anthony Burns (q.v.), was indicted for murder in 1854 with Wendell Phillips, Theodore Parker and others, but owing to a flaw in the indictment the defendants were discharged. He also aided in the Kansas Free State efforts, and during the Civil War was captain of the 51st Massachusetts regiment of volunteers, becoming colonel in November 1862, of the 1st South Carolina volunteers, the earliest regiment of freed slaves in the Federal service. He resigned from the army in October 1864, by reason of disability, and has since given his attention to literature, residing at Cambridge, Mass., since

1878. He has been almost a life-long advocate of woman suffrage and of the higher education of woman, and was a member of the Massachusetts legislature 1880–1, serving on the State board of education, also, 1881–3. He is a polished, graceful speaker, and has frequently appeared on the lecture platform, his latest appearance being as Lowell lecturer on American literature in Boston in 1902. As an after-dinner or occasional speaker he is especially happy, his felicitous sentences being almost always illuminated by the play of a very delicate humor. He is president of the Round Table, a social Boston club, and vice-president of the Boston Authors Club, as well as a member of many other organizations, social and literary. He has been for a generation a constant contributor to periodicals of the highest class and has figured in literature as essayist, novelist, poet, and historian. His principal work in fiction is 'Malbone' (1869), in which his first wife is outlined as Aunt Jane. As an essayist he is perhaps seen at his best, the essay form seeming peculiarly adapted to his genius. Among collections of essays by him may be cited: 'Outdoor Papers' (1863); 'Atlantic Essays' (1871); 'Women and Men' (1887); 'The New World and the New Book' (1891); and 'Concerning All of Us' (1892). His 'Young Folks' History of the United States' (1875) has been widely popular, and other histories by him are 'Larger History of the United States' (1885); 'English History for Americans' (1893); 'Massachusetts in the Army and Navy, 1861–5' (1895–6). His verse is included in 'The Afternoon Landscape' (1889); 'Such as They Are' (1893). Yet other important works by him are 'The Monarch of Dreams,' a strikingly original sketch (1886); 'Army Life in a Black Regiment' (1869); 'Cheerful Yesterdays' (1898); 'Old Cambridge' (1899); 'Contemporaries' (1899); and lives of Margaret Fuller (1884); Francis Higginson (1891); Henry W. Longfellow (1903); John Greenleaf Whittier (1903); 'History of the United States' (1905). He translated the complete works of Epictetus (1865, revised edition 1891). With Samuel Longfellow (q.v.) he completed a well-known anthology of seaside verse, 'Thalatta' (1853), and with Mrs. E. H. Bigelow 'American Sonnets' (1890). Several of his works have been translated into French, German, Italian, and even modern Greek. He was the friend of very many of the older New England writers and has been especially helpful to many of the younger ones, not a few of whom owe him much in the way of kindly criticism or suggestion, the fruit of ripe scholarship.

High Church, a term applied to a faction in the Church of England. It was applied first to the younger clergy during the latter part of the reign of Elizabeth who asserted that Calvinism was inconsistent with the ancient doctrine and constitution of the primitive church, and who claimed a divine right for episcopacy. Bishop Andrews was the chief writer of this faction, and Laud became its most active leader. The term now generally refers to those who exalt the authority and jurisdiction of the church, and attach great value to ecclesiastical dignities and ordinances, being more or less identified with the ritualistic party. See RITUALISM.

High Bridge, Engagement at. See FARMVILLE.

High-Frequency Oscillating Current. This term is especially applicable to electrical currents, the high frequency interruptions of which are obtained by means of condenser discharges in contradistinction to those produced by a disrupted static current, without the interposition of a metallic condenser in series with one or both terminals. The latter differs in several characteristics and is essentially a high potential current, 10,000 to 50,000 volts, with a minimum amperage, usually about .0005.

To generate a high-frequency current it is usual to charge two Leyden jar condensers with a high potential current, the source of which may be a static machine or induction coil, shunting the two wires with a spark-gap for the purpose of disrupting the current. The external armatures of the condensers are short-circuited through a solenoid or helix consisting of a few turns of coarse copper wire (D'Arsonval). The helix may be substituted by a straight copper bar (Sheldon). By prolonging the helix from 50 to 100 turns, this constitutes the resonator of Oudin. The upper part of the helix resonates in unison with the lower, when properly in tune, as would a tuning-fork resonate with another of the same pitch. The office of the extended helix is to amplify the current.

Another arrangement is after Tesla: The primary of a specially constructed induction coil is energized by an alternating current. The secondary terminals, giving a potential of 15,000 volts, are connected, one to each side of a suitable condenser. From each of these terminals a shunt is taken. One leads to one end of the primary of a Tesla coil; the other, broken by a spark-gap, is connected to the second terminal of the primary. The frequency obtained from the Tesla apparatus is fabulously high — millions a second. The potential may be hundreds of thousands or millions of volts. The amperage is sufficient to light to full candle-power several incandescent lamps. The primary of the induction coil consumes 15 to 25 amperes. For maximum high frequency effects this type of apparatus seems to be essential. The brush discharge from the terminals may be 20 or even 50 inches in length. There are many modifications of this apparatus.

The one characteristic of the high-frequency oscillating current is its lack of power to excite the motor, and, aside from a slight sensation of warmth, the sensory nerves at the point where the electrode touches the body. The accepted explanation for this fact is, that the nerves respond to certain frequencies of stimulus; for the motor nerves, reaction takes place up to about 5,000 frequencies; if these are gradually increased muscular contraction diminishes and finally ceases. This theory is in line with reasoning as to the cause for action of the special senses — sight and hearing.

At the terminals of a working high-frequency apparatus is seen a beautiful brush discharge or effluve of a peculiar blue color, which will leap to any object brought near it. Interpose a plate glass one half inch thick (or more), and the effluve will penetrate it. If the object be a vacuum tube it will glow almost as brightly as if nothing intervened. It is an ideal current for igniting Geissler and low-vacuum X-ray tubes; only one terminal need be connected.

The high-frequency discharge is a rich ozone generator, and, applied to unhealthy granulations and various skin diseases, acts as an oxidizer, antiseptic, and disinfectant. Applied to the skin before incision, it will render the site aseptic.

For general effect the patient is placed upon an auto-condensation couch or in the centre of an auto-conduction cage. In the treatment of sub-acute and chronic rheumatism, sciatica, neurasthenia, etc., it is most useful.

John M. Garratt, M.D.

High Priest, the head of the Jewish priesthood. In the books of Moses the holder of this dignity is simply designated the priest, the epithet high occurs on one or two occasions, but as a distinctive epithet it appears to have been added subsequently. The formal consecration of Aaron, the brother of Moses, together with his sons, to a hereditary priesthood, is recorded in Ex. xxviii. The high-priesthood continued in the line of Aaron, sometimes in one, and sometimes in another branch of it, until the coming of Christ. After the subjugation of the Jews by the Seleucidæ, the Ptolemies, and the Romans, it was often arbitrarily conferred by the foreign masters. The dignity of the priest's office is indicated by the splendor and costliness of his garment, which was among the most beautiful works of ancient art. To the high priest belonged the regulation and superintendence of the worship of God, the declaration of the oracles of Jehovah to the people (he alone being permitted to consult them on important public occasions), and the preservation of the national sanctuary. Although the administration of justice was committed to particular judges, yet to him the last appeal was made in difficult cases, even in temporal affairs, and nothing important in war or peace could be undertaken without his assent.

High Schools, the term applied in the public school system of the United States to the institutions for secondary and higher education preparatory to a college course. They were generally established at public expense between 1820 and 1850, to correspond in grade to the academies or schools maintained by endowment or at private expense in which young men were prepared for college.

The European representatives of the American high schools are the public schools and colleges of Great Britain, the lyceums of France, Spain, and Italy, and the gymnasia of Germany; the universities in Germany are officially called high schools (Hochschulen).

The term 'high school' was applied as early as the 16th century to a celebrated educational establishment of a liberal character, a grade below the university, in Edinburgh, Scotland.

In 1647 the Massachusetts Colony enacted a law that every town of 100 families should maintain a school, the teacher of which should be "able to instruct youth, so far as they may be fitted, for the university." This law, though imperfectly obeyed, introduced very early into Massachusetts and New England a small number of classical schools, and subsequently prepared the way for the endowment of a few academies in which young men were prepared for the colleges. Of these especially endowed academies, many of which rendered eminent service, the more notable are the Hopkins Grammar Schools of Hartford and New Haven, Conn.; the Hopkins Academy in Hadley, and Phillips Academy at Andover, Mass.; Phillips Exeter Academy at Exeter, N. H., and Amherst Academy, Mass. Among the public schools of the country, the Boston Latin School, a colonial foundation, was for a long time almost the only classical school supported by public taxation at which students could be prepared for college. It was pre-eminent alike for the thoroughness of the education which it gave, and the freeness with which this was proffered to all the residents of Boston. In 1821 the English High School, supplementary to the Latin School, was established in Boston. In Philadelphia the corresponding institution still bears the name of the Central High School, while in New York city the original Free Academy has developed into the College of the City of New York. With the reorganization of the public school systems of the older States, and the foundation of such systems almost simultaneously with the redemption of the soil from the forest and wild prairie in the newer States, provision was made for a system of high schools, to give a thorough preparation for the college curriculum. These high schools are now in vigorous operation from one end of the United States to the other. See Education, Secondary.

High Seas. Among maritime nations both in ancient and modern times the necessity for some international regulations to govern their communications by sea has been found a necessity. The views of jurists on this subject have fluctuated between two opposite principles. Nations possessing a powerful marine, are disposed to push their privileges to the utmost, and to claim exclusive accession to, or a superiority and protective rights over, extensive tracts of the ocean highway. The weaker maritime nations, on the other hand, and the commercial rivals of these most especially privileged, have contended for the liberty of the seas. The most memorable instance of this controversy occurred in connection with the claims arising out of the great maritime discoveries of the Portuguese at the close of the 15th century. Under the grant of Pope Alexander VI. the Portuguese claimed the right to exclude other nations from the seas between the eastern coast of Africa and the coasts of India. Against this claim Grotius wrote his celebrated treatise, the 'Mare Liberum,' which appeared in 1609. The English, who had their own claims of jurisdiction, were not then, or for long after, prepared to admit the liberty of the seas. The general principle of international law now accepted is that the jurisdiction of maritime nations extends only for three miles, or within cannon range of their own coasts; the remainder of the seas being high seas, accessible on equal terms to all nations. Inland seas and estuaries, of course, are excepted.

High Treason (Fr. *trahison*, betrayal), is defined in English law as the most heinous of all offenses against the law, and consists in imagining or devising the death of the ruling monarch, or proposing to kill, maim or restrain the king or queen; or levying war against him; adhering to his enemies; killing his wife or eldest son, or heir; violating his wife, or daughter, or heir's wife; killing the lord chancellor; killing the chancellor of the exchequer, or a justice in office. High treason against the United States consists in levying war against them; adhering to their enemies, or giving their enemies aid and comfort. Treason against a State is generally defined as hostility to a State only. The former punishment of treason in English law was death by hanging, drawing and quartering. The penalty is now hanging or imprisonment. This crime is punishable in the United States according to the act of 1862 by death or imprisonment with hard labor for a period of not less than five years, a fine of not less than $10,000 and a perpetual disability to hold any office under the United States. The act of 1862 adds: "No person shall be convicted of treason unless on the testimony of two persons to some overt act, or on confession in open court. The Congress shall have power to declare the punishment of treason, but no attainder of treason shall work corruption of blood (q.v.) or forfeiture except during the life of the person attainted."

Highbinders, a name given to a secret organization among the Chinese in the United States which has caused much bloodshed in the Chinese quarter of San Francisco, Cal., necessitating intervention on the part of the authorities. The Chinese call these societies "hatchet" societies, and the members "hatchet men." The organization seems to be an offshoot of the Six Companies (q.v.), though some claim that it is merely a revival of one which originated over 200 years ago in China.

Higher Criticism, The. The higher criticism is a science whose aim is the determination of the literary history of books and writings. It sets forth the facts and principles by which we must determine, in the case of any writing, its literary form, its unity, its date, the place of its composition, its authorship, the method of its composition or construction, its integrity, and the amount and character of any subsequent editing it has received, so far as these matters can be discovered by the use of such internal evidence as is presented in the writing itself. It is thus the science for ascertaining the literary form and the literary history of any writing by means of internal evidence. These same matters may also be determined, in part or in whole, by external evidence in many cases; that is, by history or tradition. This latter method will not necessarily be either better or worse than the method which employs internal evidence. The greater probability of the result, in every case, will depend upon the amount and the character of the evidence which is attainable. Sometimes external evidence may be more abundant and trustworthy than the internal evidence, and sometimes the reverse may be true.

The science under consideration is termed higher criticism to distinguish it from the related science of lower, or textual, criticism. This latter science has for its object the ascertaining of the history of writings as the work of penmen and printers. It seeks to determine just the words and the letters which the author himself wrote, and what are the changes which his work has suffered in transmission. Since the literary history of a writing is, on the whole, of more importance than the history of the written or printed text, the science of the literary history is justly termed the higher criticism.

The higher criticism is a science which is equally applicable to all literatures. It may be used to determine the literary history of a writing of any age, language, or people. But, of late, it has been especially brought into notice in its application to the literature of the Bible. On this account, it is sometimes spoken of as if it were a science belonging to Biblical study only. But the fact is that Biblical higher criticism is only one department of higher criticism in general.

As employed in Biblical study, higher criticism adopts the following method: (1) it sets forth the principles by which, according to the teachings of general literary criticism, we may correctly determine the literary form, the unity, the date, the place of composition, the authorship, the method of composition or construction, the integrity, the amount and character of subsequent editing, of each of the Biblical books and writings; (2) it then presents the evidential facts to be found in each of the Biblical books and writings, to which these principles will apply; and (3) finally it gives the conclusions which result from the application of these principles to the evidential facts. In practice, however, different schools of Biblical higher critics come to very different conclusions upon the same basis of evidential facts, while using the same principles of criticism. This results from the varying opinions held by these critics in relation to the value and significance of the evidential facts, due to their differing views about the history of Israel, and their philosophical convictions concerning the place of the supernatural in that history. Those critics who refuse to allow the existence of any supernatural element in the history of Israel, and hold that this history was the product of only those forces which shape and determine all human history, so that it was exactly like the history of every other people, cannot put the same value and meaning upon the historical testimony and references to be found in the Biblical books, as those critics must who believe that the history of Israel was, to no inconsiderable extent, a supernatural history, and, therefore, different from the history of every other people. In the case of the Old Testament, for example, some critics hold, because of their philosophical opinions in regard to the supernatural, and the universality of the working of the evolutionary forces of history, that the historical material of the Old Testament, as we now have it, is not to be accepted as the true basis of Old Testament history, and that this history must be constructed out of this material, under the guidance of some philosophical theory. Other critics accept the historical material which is now to be found in the Old Testament, as furnishing in itself the true Old Testament history. Since the evidential facts used in higher criticism receive their value and meaning from their evident relation to a previously determined history, it is clear that each of two so different histories cannot be a basis for the same critical conclusions. But it is to be noted that the determination of the histories is not a work of higher criticism, but is a matter which results from the philosophical opinions held by historians. The consequence of these facts is that the only results which have thus far been reached by Biblical higher criticism, which all schools of critics would accept, seem to be: (1) The existence of different documents in the Pentateuch, which have been used in its compilation, although there is, among critics, quite a little difference of view in relation to the age of these documents and the time of their compilation into the Pentateuch: (2) the plural authorship of the books of the Old Testament known as the books of Isaiah and Zechariah: and (3) the fact that older sources have been used in the making of the synoptic gospels and the book of Acts. From all that has been said, it will be seen that it is not the duty of higher criticism to assert or deny anything in relation to the inspiration of the Scriptures, or their authority for belief or conduct. With these matters this science has absolutely nothing to do.

S. Burnham, D.D.,
Dean of the Hamilton Theological Seminary, Colgate University.

Higher Law, a famous phrase used by William H. Seward (q.v.) 11 March 1850, in the United States Senate, on the admission of California as a State, which was held up by the Southern element to force the Congress to admit it as a slave State, or at least to divide it on the line of the Missouri Compromise (q.v.). Seward denied that the principle of compromise applied only to slavery, which was only one of many institutions, and held it equally applicable to the Territories, which were a possession to be enjoyed and administered in common by the States; and declared that the older States had no arbitrary power over them. He went on: "The Constitution regulates our stewardship; the Constitution devotes the domain to union, to justice, to defense, to welfare, to liberty. But there is a higher law than the Constitution, which regulates our authority over the domain, and devotes it to the same noble purposes. The territory is a part . . . of the common heritage of mankind, bestowed upon them by the Creator of the universe. We are his stewards, and must so discharge our trust as to secure in the highest attainable degree their happiness." And to Webster's assertion that it was absurd to re-enact the laws of God, he answered that "there is no human enactment which is just that is not a re-enactment of the law of God." It was his first set speech in the Senate, and at once made him the recognized leader of the radical section. The conservatives denounced it as treasonable, implying that no one was under any obligation to support the Constitution if he believed it in opposition to the law of God, and making the execution of any laws impossible.

Higher Plane Curves. See Curves, Higher Plane.

High'land Cattle, a variety of small, rough-coated, usually red or black cattle, with upturned horns, kept half wild upon the moors of the Scottish Highlands, and believed to represent in part the cattle of the aboriginal Britons, which are replaced in the south of Great Britain by the short-horned breeds introduced by the Roman conquest. Compare White Cattle.

Highlanders, Scotch, in the United States. After the Jacobite risings in England in 1715 and 1745, in favor of the Old and Young Pretenders, which were zealously supported by the Highlanders (who indeed formed their backbone), the English government exerted itself to drain their strength by colonizing them elsewhere: and many who were in danger of vengeance came to America voluntarily. The chief movement was after 1745, when the government thoroughly reorganized the Highlands, broke up the clans, and deported large numbers to the colonies: but after 1715 many, in bands or as individuals, had come over, especially to the Carolinas. Some settled in western South Carolina, as farmers or Indian traders; a considerable body near Fayetteville, N. C., where their descendants still speak Gaelic in preference to English, and have their church ministrations in that language; and a number of different colonies in the future Georgia, where Oglethorpe found them when he came over in 1733 with a patent for a new colony. Especially he won the hearts of a settlement at Darien, under a Capt. Mackay. These Highlanders gave him priceless help in his incessant fights with the Spaniards and constant negotiations with the Indians: but they strongly opposed the slave trade or the introduction of slaves into Georgia. Some Highland companies sent to the Mohawk Valley, during the French and Indian war, were disbanded there, and remained as settlers, a recognizable element during the Indian troubles of the early Revolution.

Hil'da, Saint, Anglo-Saxon abbess: b. about 614; d. 680. She was consecrated as a nun by Bishop Aidan, and was successively head of the abbey of Hartlepool, and of the famous monastery founded by her in 657 at Whitby, Yorkshire. This continued for several centuries a religious house of great power and influence, in the time of its founder perhaps the strongest in Great Britain. Cædmon (q.v.), the Anglo-Saxon poet, was attached to the monastery during her rule, and it was there that the celebrated synod took place in 664 in which the Celtic ritual was condemned. Consult: Bede, 'Ecclesiastical History.'

Hil'debrand. See Gregory VII., Pope.

Hil'dreth, Richard, American historian: b. Deerfield, Mass., 22 June 1807: d. Florence, Italy, 11 July 1865. He was graduated at Harvard in 1826, studied law at Newburyport, entered practice in Boston, and abandoned it in 1832 to become editor of the 'Boston Atlas.' In this position a series of articles by him in 1837, relative to the separation of Texas from Mexico, did much to stimulate the resistance which that movement encountered in the free

States. In 1834 his anti-slavery novel, 'The Slave,' was written. This work was republished and favorably received in England, and in 1852 an enlarged American edition appeared under the title of 'The White Slave: Memoir of Archy Moore' (1837). In 1837–8 he was Washington correspondent of the 'Boston Atlas,' and resumed his editorial post as an advocate of the election of General Harrison, of whom he wrote a campaign biography. He then abandoned journalism, and in 1840 published, under the title of 'Despotism in America,' a volume on the political, economical, and social aspects of slavery, to which in the edition of 1854 was appended a chapter on the 'Legal Basis of Slavery.' In 1840–3 he resided in Demerara, British Guiana, and at Georgetown edited two free labor newspapers. Later, for several years, he was a member of the New York *Tribune* staff, and in 1861 was appointed United States consul at Triest. His best known work is his 'History of the United States' (1849–56), which extends from 1492 to the end of President Monroe's first term. The author sought an authentic presentation of the conspicuous figures of earlier American history. His work is accurate and careful, though with a Federalistic viewpoint; but so uninteresting in manner as to be ill-adapted for continuous reading. Hildreth also wrote: 'Theory of Morals' (1844); 'Theory of Politics' (1853); 'Japan as it Was and Is' (1855); and 'Atrocious Judges' (1856).

Hilgard, hĭl'gärd, **Eugene Woldemar,** German-American chemist and geologist: b. Zweibrücken, Bavaria, 5 Jan. 1833. He came to the United States in 1836, returned to Europe for purposes of study and was graduated (Ph. D.) at Heidelberg, 1853. In 1858 he became State geologist of Mississippi, in 1873 was appointed professor of geology and natural history in the University of Michigan, and in 1875 was made professor of agricultural chemistry and director of the agricultural experiment station in the University of California. He received the Liebig medal from the Munich Academy of Sciences in 1894, and his investigations into the chemistry and physics of soils have done much to promote agricultural science.

Hill, Adams Sherman, American educator: b. Boston, 30 June 1833. He was graduated from Harvard College 1853 and Harvard Law School 1855, and in 1875 became Boylston professor of rhetoric and oratory at Harvard University. He has written: 'Principles of Rhetoric' (1878); 'Our English' (1889); 'Foundation of Rhetoric' (1892).

Hill, Ambrose Powell, American military officer: b. Culpeper County, Va., 9 Nov. 1825; d. 2 April 1865. He was graduated at the United States Military Academy 1847; served in the Mexican War, but resigned from the army in March 1861, and was made colonel of the 13th Virginia regiment of the Confederate army. Having distinguished himself in service, he was promoted major-general in May 1862, and lieutenant-general 20 May 1863, and placed in command of one of the three corps of the army of Northern Virginia. He led his corps at Gettysburg and later at Bristow Station and the assault on the Weldon railroad in 1864. He was killed in the attack on Petersburg, Va.

Hill, Benjamin Harvey, American legislator: b. Jasper County, Ga., 14 Sept. 1823; d. 16 Aug. 1882. He was graduated at the State University of Georgia in 1844 and chose law as a career. In 1851 he was elected to the State legislature. He in vain attempted to withstand the secession sentiment of his State, but at last yielded to the movement, and was elected to the Provisional Confederate Congress, and from the assembly promoted to the Confederate Senate. He supported Greeley for the presidency in 1872, and was defeated for the United States Senate the following year, but after being elected to the House of Representatives in 1875, was given a seat in the United States Senate 1876 and held it for the remainder of his life.

Hill, Daniel Harvey, American military officer: b. Hill's Iron Works, York district, S. C., 12 July 1821; d. Charlotte, N. C., 24 Sept. 1889. He was graduated at the United States Military Academy in 1842, and served in the Mexican War; became professor of mathematics and military tactics in Washington College, Va., in 1849, professor of mathematics in Davidson College, N. C., in 1854; and was made president of the North Carolina Military Institute in Charlotte in 1859. At the outbreak of the Civil War he entered the Confederate army as colonel; was promoted to lieutenant-general in 1863, and commanded a corps at the battle of Chickamauga. After the close of the war he resumed his educational work, and in 1877 became president of the Arkansas Industrial University, where he remained until shortly before his death.

Hill, David Bennett, American lawyer and politician: b. Havana, N. Y., 29 Aug. 1843. He entered a law office in Elmira, N. Y., as clerk and student in 1862, and after admission to the bar in 1864, rapidly built up a law practice and was an acknowledged leader of the local bar. He was active in politics, and acquired a leadership there also, through his genius for organization. He was a member of the State assembly 1870–1, and president of the Democratic State convention in 1877 and 1881. In 1882 he was elected mayor of Elmira, and lieutenant-governor in the same year, with Cleveland as governor. In 1885, when Cleveland resigned to take up his duties as President, Hill became governor. He was subsequently twice elected governor, serving till January 1892, when he took his seat in the United States Senate. During his first administration as governor, the legislature was Republican, and he was involved in a number of partisan struggles. As senator, he opposed on some issues the policy of President Cleveland; he was also opposed to the income tax clause of the Wilson Tariff Bill. In 1892 he was a prominent candidate for the presidency at the Democratic National convention, and at the convention of 1896 was one of the chief leaders of those who favored the gold standard and were opposed to radicalism in the party. In 1894 he was again candidate for governor of New York State, but was defeated by Levi P. Morton. In 1902 he practically dominated the Democratic State convention, and was active throughout the campaign.

Hill, David Jayne, American educator and diplomat: b. Plainfield, N. J., 10 June 1850. He was educated at Bucknell University, where he became professor of rhetoric 1877–9, and then president of the institution. He was elected president of Rochester University, N. Y., in 1888, resigning to spend three years in Europe studying international law and diplomacy. He became first assistant United States secretary of state in October 1898, and in 1903 was appointed United States minister to Switzerland. He has written biographies of 'Washington Irving' (1879); and 'William Cullen Bryant' (1879); 'Principles and Fallacies of Socialism' (1885); 'International Justice'; 'A Premier of Finance'; etc., and several school and college text-books.

Hill, Frank Alpine, American educator: b. Biddeford, Maine, 12 Oct. 1841; d. Brookline, Mass., 12 Sept. 1903. He had long been prominent among New England educators, and after being head-master of high schools in Milford, Chelsea, and Cambridge, Mass., became secretary of the Massachusetts State Board of Education in 1894. He was a trustee of the Massachusetts Institute of Technology, of the State Agricultural College at Amherst, and of the Boston Museum of Fine Arts, as well as a commissioner of the State School Fund.

Hill, Frank Pierce, American librarian: b. Concord, N. H., 22 Aug. 1855. He was graduated from Dartmouth in 1876. In 1881 he became librarian of the Lowell public library, and in 1885 he organized the first free public library in New Jersey at Paterson. He also organized the Salem public library, and the Newark library in 1889. At Newark a new building was erected under his administration and the library brought to a high degree of efficiency so that it is recognized as one of the model public libraries. In 1901 he was appointed chief librarian of Brooklyn, under the new system established upon the receipt of Mr. Carnegie's gift.

Hill, Frederic Stanhope, American sailor and author: b. Boston, 24 Aug. 1829. He went to sea when a boy, and during the Civil War was an officer in the United States navy. He was with Farragut at the capture of New Orleans and Vicksburg, and was also in command on the Texas coast and in the Mississippi squadron. He has written: 'Twenty Years at Sea' (1893); 'Story of the Lucky Little Enterprise'; 'Twenty-six Historic Ships' (1903); and has been editor of the Cambridge 'Tribune.'

Hill, George Birbeck, English educator and author: b. Tottenham, Middlesex, 7 June 1835; d. Hampstead, London, 24 Feb 1903. He was a nephew of Sir Rowland Hill (q.v.), was educated at Oxford, and was head-master of Bruce Castle School 1859–76. Since the latter date he had devoted his attention to literature and was well known in the United States through his 'Harvard College, by an Oxonian' (1894). Other works by him are: 'Talks about Autographs' (1896); 'Dr. Johnson: his Friends and his Critics' (1878); 'Life of Sir Rowland Hill' (1880); 'Foot-steps of Dr. Johnson in Scotland' (1890); 'Memoirs of the Life of Edward Gibbon' (1900).

Hill, Henry Wayland, American lawyer: b. Isle La Motte, Vt., 13 Nov. 1853. He was graduated from the University of Vermont in 1876, was principal of Swanton, Vt., union school 1877–9, and of Chateaugay, N. Y., academy 1879–83. He was admitted to the bar at Albany, N. Y., in 1884, and entered upon the practice of his profession at Buffalo. He was a member of the New York assembly 1896–1900, and has been State senator since 1901, representing each time a constituency in Buffalo. He is the author of several constitutional provisions and of several general statutes now in force. During his public career he has secured for Buffalo large State appropriations for the new 74th and 65th regiment armories, for the Historical Society building, for harbor improvement and other public purposes. He also advocated measures designed to provide home rule for cities, reform in election methods, etc., and many important State measures, such as the Primary Election law, the Civil Service law, the Franchise Tax law, the Pharmacy law, and the Canal Improvement referendum of 1903. He has made a study of waterways in this and other countries, and contributes the article on that subject in this encyclopedia. He is the author of 'The Development of Constitution Law in New York,' and a contributor to the 'Bibliophile Edition of the Odes and Epodes of Horace.'

Hill, James J., American capitalist: b. near Guelph, Ont., 16 Sept. 1838. At 18 in the village of St. Paul, Minn., he became check-clerk and caretaker of freight at the steamboat landing. At that time there was not a mile of railroad in the State. In 1862 the first 10 miles of railroad were finished from the levee in St. Paul to the riverside in St. Anthony, and known as the St. Paul and Pacific railroad, of which Hill later became the agent. After the Civil War, Hill clearly discerned the great resources and possibilities of the Red River country — Western Minnesota and Eastern Dakota. He went East, contracted for his boilers and machinery, and on the bank of the river built a flat-bottomed steamer called The Selkirk, which in the summer of 1870 began to run between Winnipeg and the head of navigation, to rival the line operated by the Hudson Bay Company. The same year, 1872, Hill consolidated his transportation interests with those of the Hudson Bay Company, forming the Red River Transportation Company. The St. Paul and Pacific railroad now reached the western boundary of the State at Breckenridge. For several years the St. Paul and Pacific system of railroads, consisting of 437 miles of completed track, was in poor condition. The stockholders, mostly Holland capitalists, were weary with delay and misfortune. Because of his faith in the future of the region Hill formed a syndicate of five persons which soon gained possession of the road, and in June 1879, the system was consolidated into a single ownership as the St. Paul, Minneapolis and Manitoba Railroad Company. In 1880 the road was extended to the Pacific coast, traversing vast tracts of land without human habitation. The track was well laid, but the stations were often only freight cars, remote from one another, and from other human settlements. The road is now known as the Great Northern. Coal fields were discovered, a branch road carried their product for the use of the main line and settlements formed for preparing the lumber for shipment. To ship valuable lumber eastward was an excellent plan: but to send empty cars after it was out of the question; and Hill conceived the idea of shipping grain for the Japanese steamers to carry to the Orient. An agent was sent to China and Japan to find out what the price of wheat must be to compete with rice, and the result was that the Japanese Navigation Company, the third largest steamship company in the world, began to carry large shipments of grain to China and Japan. Large docks for these steamers were built at Seattle, Wash., the western terminus of the road. The original 437 miles of completed road of which Hill took charge as manager, developed into the Great Northern system of 6,000 miles. In 1883 he became president of the company. The road extends from Puget Sound to St. Paul, or during the season of navigation to Duluth and Superior, where it connects for Buffalo with its own steamers. A fleet of six freight vessels are added to these. The grain ships moving through the "Soo" give that canal rank over the Suez in point of tonnage.

In developing this scheme the plan increased enormously in the process. Besides laying the foundation of a great fortune, it opened a very rich and vast new country, reached out to new markets for many American products, and brought benefit to great numbers of people. All along the line of the road Hill encouraged the most diversified and productive farming, and introduced new methods and labor-saving devices.

Hill, Octavia, English social reformer: b. about 1838. She began work among the London poor under F. D. Maurice (q.v.); and in 1864, supported by Ruskin, began her great work of improving the homes of workingmen in the slums of London. Her methods were based upon the principle of teaching the people to help themselves, by inculcating in them right notions of cleanliness, order, and self-respect. Her efforts have been crowned with great success; the houses which have been improved yield a good percentage on the money spent in effecting the improvements; and through her hundreds have been helped to lead more comfortable and better lives. She has written 'Homes of the London Poor' (1875); 'Our Common Land and other Essays' (1878).

Hill, Robert Thomas, American geologist: b. Nashville, Tenn., 11 Aug. 1858. He was graduated from Cornell University in 1886; and was immediately given a position on the United States Geological survey. He was also a lecturer in the school of economics at the University of Michigan, and professor of geology at the University of Texas for two years, which position he resigned to return to the United States Geological Survey. He has been engaged in geological and geographical explorations in the southwestern States, Mexico, Central America, and the West Indies. His work in the two last-mentioned localities has been the investigation of the origin of the land forms, and the problem of the union of the continents. Among his most valuable contributions to geological science have been the proof of the existence of the lower cretaceous formation in the United States and the announcement of the possibility of artesian wells in Texas. In May 1902 he was sent by the National Geographical Society at the head of the expedition to investigate the volcanic eruption of Mount Pelée in Martinique. His publications include 'On Occurrence of Artesian and Other Underground Waters in Texas' (1892); 'Cuba and Porto Rico with other Islands of the West Indies' (1898); and numerous contributions to the bulletins of the geological survey and periodicals.

Hill, Rowland, English popular preacher: b. Hawkstone, Shropshire, 13 Aug. 1744; d. London 11 April 1833. He was ordained in the Anglican Church, but embracing the views of the Calvinistic Methodists, soon began to preach in barns and meeting-houses, and when they were too small or too distant, or not to be procured, in streets, fields, and highways. In 1783 he laid the foundation of Surrey Chapel, Blackfriars Road, London, where he preached with great success every winter for about 50 years, making summer excursions to the provinces, where his eloquent but eccentric preaching attracted immense crowds. He published sermons and other theological works, of which the best known are his 'Village Dialogues.'

Hill, Rowland, Viscount, English soldier: nephew of Rev. Rowland Hill (q.v.); b. Prees, Shropshire, 11 Aug. 1772; d. near Shrewsbury, England, 10 Dec. 1842. He entered the army in 1790 and served with distinction from Toulon to Waterloo. In 1812 he was made a K. B., and in 1814, a peer by the title of Baron of Almaraz and of Hawkstone. At the battle of Waterloo, Lord Hill commanded the right wing of the British. In 1828 he was appointed general commanding-in-chief of the British army. This important office he continued to hold under several successive ministries, and only resigned it a few months before his death. He was made a viscount in 1842. He was often styled "the right arm of Wellington." See Sidney's 'Life of Lord Hill' (1845).

Hill, Sir Rowland, English postal reformer: b. Kidderminster, 3 Dec. 1795; d. 27 Aug. 1879. He was engaged as a schoolmaster till 1833, shortly after which he was appointed secretary to the commissioners for the colonization of South Australia. In 1837 he published a pamphlet recommending the adoption of a low and uniform rate of postage throughout Great Britain and Ireland. The scheme was approved by a committee of the House of Commons, and early in 1840 the penny postage system, which seems to have been originally proposed by James Chalmers of Dundee, was carried into effect with the assistance of Rowland Hill, who, for this purpose, received an appointment in the Treasury. In 1846 he received a public testimonial of the value of upward of £13,000. In 1846, he was made secretary to the postmaster-general, and in 1854 chief secretary to the Post-office. In 1860 he became K. C. B.

Hill, Thomas, American Unitarian clergyman and mathematician: b. New Brunswick, N. J., 7 Jan. 1818; d. Waltham, Mass., 21 Nov. 1891. Left an orphan at 10 years; at 12 he was apprenticed to the printer of the 'Fredonian' newspaper, where he remained four years. He then entered an apothecary's shop, after a year's attendance at school, and served in it several years. He was graduated from Harvard College in 1843; and from the Divinity School in 1845, and was settled as pastor at Waltham the same year. He was president of Antioch College, Ohio, 1859–62. He accompanied Agassiz on his expedition to South America and was pastor of the Unitarian Church at Portland, Maine, 1873–91. He published 'Elementary Treatise on Arithmetic' (1845); 'Geometry and Faith' (1849); 'First Lessons in Geometry' (1855); 'Treatise on Curves' (1855); 'The Natural Sources of Theology' (1875); 'In the Woods and Elsewhere', verse (1888); etc.

Hill, Thomas, American painter: b. Birmingham, England, 11 Sept. 1829. He came to the United States in 1841. Returning to Europe he studied under Paul Mayerheim for several months, but is practically a self-taught artist. He painted the 'Yosemite Valley' which was chromo-lithographed by Prang. He has continued to confine himself to the grander aspects of American scenery, and notable among his productions are 'The Home of the Eagle'; and 'Grand Cañon of the Sierras.'

Hill, Walter Barnard, American lawyer and educator: b. Talbotton, Ga., 9 Sept. 1851; d. Athens, Ga., 28 Dec. 1905. He was graduated from the University of Georgia in 1870, and from the law school in 1871, with the degree of A.M. He was admitted to the bar, and practised law in Macon, Ga., from 1871 to 1899. He was a member of the Georgia Bar Association, and was its president in 1888; a member also of the American Bar Association and the chairman of the committee on judicial administration. He also was actively interested in educational progress, being trustee of Vanderbilt University at Nashville, Tenn. In 1899 he was appointed chancellor of the University of Georgia; as an educator he strongly approved the work of the Tuskegee and similar institutions for the negro. He wrote articles on legal and educational subjects and compiled the law code of Georgia (1873, 1882).

Hill, Walter Henry, American Roman Catholic priest and educator: b. near Lebanon, Ky., 21 Jan. 1822. He was graduated from St. Mary's College in 1843, was tutor there for a time, and also studied medicine at St. Louis University. In 1847 he became a member of the Jesuit order, taught at St. Joseph's College and at St. Louis University and completed his theological studies. In 1861 he was ordained a priest; in 1865–9 he was president of St. Xavier College at Cincinnati; he was socius of the provincial at St. Louis University in 1869 and professor of mental and moral philosophy there in 1871. From 1884 to 1896 he was pastor of the church of the Sacred Heart in Chicago, and in 1896 retired from all active duties. He has written 'Elements of Philosophy, comprising Logic and Ontology' (1873); 'Ethics of Moral Philosophy' (1877); 'Historical Sketch of St. Louis University' (1879); and valuable contributions to the 'American Catholic Quarterly.'

Hill River. See HAYES RIVER.

Hillard, hil'ard, **George Stillman,** American author and lawyer: b. Machias, Maine, 22 Sept 1808; d. Boston 21 Jan. 1879. He was graduated from Harvard in 1828, and from the Harvard Law School four years later. He was a member of the Massachusetts senate in 1850, where his policy as a legislator was warmly commended by Daniel Webster; a member of the Massachusetts constitutional convention in 1853; and United States district attorney in 1866–70. Though successful as a lawyer his tastes were largely literary; he was well known as a lecturer; was editor of the 'Christian Register' with George Ripley, and associate editor of the Boston *Courier;* wrote 'Six Months in Italy' (1853); 'Life of George Ticknor' (with Mrs. Ticknor); 'Life of George B. McClellan' (1864), and edited a series of school readers which bore his name, and the works of Spenser.

Hillebrand, Karl, kärl hĭl'lĕ-bränt, German critic and historian: b. Giessen, 17 Sept. 1829; d. Florence 19 Oct. 1884. For participation in the insurrection in Baden (1849) he was imprisoned, but escaped to France, where he was graduated at the Sorbonne, and in 1863 became professor of foreign languages at Douai. On the outbreak of the Franco-Prussian War, he removed to Italy and passed the remainder of his life there. Among his publications in French, German, Italian, and English, are: 'On Good Comedy' (1863); 'Contemporary Prussia' (1867); 'Italian Studies' (1868); 'Times, Peoples, and Men' (1875–85); 'History of the Government of Normandy' (1863–73); 'Public Instruction in the United States' (1869); 'Lectures on German Thought during the Last Two Hundred Years' (1880). Consult Homberger, 'Karl Hillebrand' (1884).

Hil'legas, Howard Clemens, American journalist and author: b. Pennsburg, Pa., 30 Dec. 1872. He was graduated from Franklin and Marshall College, Lancaster, Pa., in 1894, and after being connected with several Pennsylvania journals was war correspondent of the New York *World* in South Africa 1899–1900. He has published 'Oom Paul's People' (1899); 'The Boers in War' (1900); 'With the Boer Forces' (1900).

Hillern, Wilhelmine von, vĭl-hĕl-mē'nė fōn hĭl'ĕrn, German novelist: b. Munich 11 March 1836. In early life she was an actress at Coburg, and in 1857 married Baron von Hillern who died in 1882. Her novels began to appear in 1862 and became rapidly popular. Among them are: 'Double Life' (1865); 'A Physician to the Soul' (1869); 'The Geyer-Wally' (1873). Translations of her novels have been widely circulated in America. Her efforts as a dramatist have not endured, but one or two of her novels have been adapted for the stage.

Hill'house, James, American politician: b. Montville, 21 Oct. 1754; d. New Haven, Conn., 29 Dec. 1832. He was graduated in 1773 at Yale, of which institution he was treasurer from 1782. He studied law, and took an active part in the struggle of the Revolution; was a Federalist member of Congress in 1791, and in 1795–1810 a member of the United States senate. He was also a member of the Hartford Convention of 1815. It was chiefly through his initiative in the planting of trees that New Haven came to obtain the title of 'Elm City.'

Hillhouse, James Abraham, American poet: b. New Haven, Conn., 26 Sept. 1789; d. near there 4 Jan. 1841. He was the son of James Hillhouse (q.v.). He was graduated at Yale College in 1808, entered commerce in New York, and published in London his drama of 'Percy's Masque,' reprinted in New York with changes in 1820. In 1822 he removed to a country seat near New Haven, where he passed the remainder of his life. In 1825 he published his second drama, 'Hadad'; and in 1839 a collected edition of his writings appeared under the title of 'Dramas, Discourses, and other Pieces.' His dramatic writings, once greatly praised, now appear grandiose and dull.

Hilliard, hĭl'yard, **Henry Washington**, American lawyer: b. Fayetteville, N. C., 4 Aug. 1808; d. Atlanta, Ga., 17 Dec. 1892. He was graduated at South Carolina College in 1826, was admitted to the bar in 1829, in 1831–4 was a professor in the University of Alabama (Tuscaloosa), in 1838 was chosen to the Alabama legislature, in 1842–4 was United States *chargé d'affaires* in Belgium, and in 1845–51 represented an Alabama district in Congress. Though opposed to secession, he became a brigadier-general in the Confederate army. He was United States minister to Brazil, in 1877–81. He wrote: 'Speeches and Addresses' (1855); 'De Vane, a Story of Plebeians and Patricians' (1865); and 'Politics and Pen Pictures' (1892).

Hillis, hĭl'ĭs, **Newell Dwight**, American Presbyterian clergyman: b. Magnolia, Ia., 2 Sept. 1858. He was educated at Iowa College and Lake Forest University, studied theology at McCormick Theological Seminary, entered the ministry of the Presbyterian Church, and held pastorates at Peoria, Ill. (1887–90), and Evanston, Ill. (1890–4). In 1894 he was appointed pastor of the Central Church, Chicago, an independent congregation, and in 1899 of Plymouth Church of Brooklyn. He became known also as a lecturer, and has published: 'The Investment of Influence'; 'A Man's Value to Society'; 'How the Inner Light Failed'; 'Foretokens of Immortality'; 'Great Books as Life Teachers'; 'The Influence of Christ in Modern Life'; 'The Quest of John Chapman' (1904); and many other books.

Hills'boro, Ill., city, county-seat of Montgomery County; on the Cleveland, C., C. & St. L. railroad; about 45 miles south by west of Springfield, and 52 miles northwest of East Saint Louis. Its chief manufactures are flour, furniture, woolen goods, carriages and wagons, and dairy products. There is a coal-mine nearby. It is the commercial centre of an agricultural section of the State. Pop. (1900) 1,937.

Hillsboro, Ohio, village, county-seat of Highland County; on the Norfolk & W. and the Baltimore & O. S. R.R.'s; about 60 miles southwest of Columbus and 50 miles east by north of Cincinnati. It is in an agricultural and stock-raising region. The chief manufactures are furniture, foundry products, flour, lumber, dairy products, and cigars. It is the trade centre for a large part of Highland County. It has a public library containing about 8,000 volumes, and a number of fine public and private buildings. The city owns and operates the waterworks. Pop. (1900) 4,535.

Hillsboro, Texas, city, county-seat of Hill County; on the Missouri, K. & T. and the St. Louis S. R.R.'s; about 52 miles southwest of Dallas and 38 miles north of Waco. It is situated in an agricultural and stock-raising region. Its chief manufactures are cottonseed-oil, cotton goods, hosiery, flour, candy, men's clothing, agricultural implements, and lumber. The trade is largely in live stock, cotton, hides, grain, hay, and lumber. It has cotton-gins, cotton-compresses, planing-mills, and hay presses. The city owns and operates the waterworks. Pop. (1890) 2,541; (1900) 5,346.

Hills'dale, Mich., city, county-seat of Hillsdale County; on the Lake Shore & M. S. railroad; about 88 miles southwest of Detroit and 60 miles west of Toledo, Ohio. The first permanent settlement was made about the year 1840. It is situated in a rich agricultural region in which are raised large quantities of fruit. The chief manufactures are flour, fur garments, screens for doors and windows, wagon-wheels, tables, furnaces, furniture, and canned fruits. The trade, in addition to the manufactures, is chiefly in grain, fruits, vegetables, and live-stock. Baw Beese Park, outside the city limits, is owned by the city. Hillsdale is the seat of Hillsdale College (q.v.). The electric-light plant and the waterworks are owned and operated by the city. Pop. (1900) 4,151.

Hillsdale College, a coeducational institution founded in 1855 under the auspices of the Free Baptist Church, in Hillsdale, Mich. Since its establishment it has graduated about 1,000 students. The number of professors and instructors in 1903 was 24, the number of students 350. Special attention is given to the classical and scientific work, but the modern languages are not neglected.

Hilo, hē'lō, Hawaii, town on the Hilo Bay, on the eastern coast of the island; about 38 miles from Mauna Loa, 36 miles from Mauna Kea (the highest peak of the group), and 28 miles from Kilauea. Hilo is the second town in size in the Hawaiian Islands. It has the best harbor belonging to the group. The lighthouse in the harbor can be seen many miles. Large lava-fields are near; on the northwest side of the town and in the vicinity are extensive forests. The craters of Loa and Kilauea, the largest in the world, are visited annually by many tourists who land at Hilo. The inhabitants of the town include many races; but people from the United States who have engaged in business in Hilo are quite prominent. Hilo has good schools to which attendance is compulsory. The population of the town, which is co-extensive with the district of the same name is (1900) 19,785.

Hilongos, hē-lŏng'ōs, Philippines, pueblo of Leyte, on the southwest coast at the mouth of the Salog River, 62 miles southwest of Tacloban. It has a good harbor. Pop. 13,813.

Hilprecht, Herman Volrath, hĕr'män fōl'-rät hĭl'prĕHt, American Assyriologist: b. Hohenerxleben, Germany, 28 July 1859. He was graduated at Leipsic in 1883 and was curator of the Semitic section of the museum of the University of Pennsylvania, to which he presented the greater part of the 27,000 original cuneiform inscriptions which it contains. He was made professor of Assyrian and Comparative Semitic philology in the same institution 1886. In 1888–89 he was Assyriologist and scientific director of the University of Pennsylvania's expedition to Nippur, Babylonia, and editor-in-chief of its publications. Among his works may be mentioned: 'Old Babylonian Inscriptions, chiefly from Nippur'; 'History of the Babylonian Expedition of the University of

Pennsylvania to Nippur'; 'Recent Researches in Bible Lands'; 'Explorations in Bible Lands during the 19th Century' (1903).

Hilton Head, an island, at the mouth of the Broad River, off the southeast coast of South Carolina; a part of Beaufort County. Fort Walker, a Confederate fortification, was erected here during the Civil War. On 5 Nov. 1861, the fort was attacked by a Union fleet, under Commodore Dupont; Commodore Tatnall, with a Confederate flotilla, or "mosquito fleet," assisted Fort Walker, but it was captured by Dupont. The reports gave Union loss 8 killed and 23 wounded; Confederates, 10 killed and 10 wounded.

Himalaya, hĭm-ā'lā-ya or hĭm-a-lā'ya (from the Sanskrit signifying the abode of snow), a mountain system of Asia containing the highest peaks in the world, the principal mass of which is near the southern edge of the central section of the continent, between lon. 65° and 110° E., and lat. 28° and 37° N. The system extends approximately from northwest to southeast for about 2,000 miles, while its breadth varies from 100 to between 500 and 600 miles. The elevated plateau of Tibet, between the Himalaya proper and its extension, the Kuen-Lun range, is the widest part of the system. While the term Himalaya is usually confined to the range forming the northern barrier of India, the Hindu-Kush, on the northwest, and the Karakoram with the Kuen-Lun to the north are not distinct chains as frequently represented, but are all portions of the same connected mountain mass, having very little to distinguish them from the rest of the elevated system to which they belong. The Himalaya is connected on the east with the mountains of China and the Indo-Chinese peninsula, and on the west with the mountains of Baluchistan and Afghanistan. The Pamir Plateau described as a "huge boss or knot" north of the Hindu-Kush connects the Himalayas with the Thian-Shan, another mountain system which extends northeastward for about 1,200 miles. From the Ganges-watered plain of northern India which has an elevation of about 1,000 feet above the sea, the Himalayas ascend by successive slopes. The transition from this plain to the ascent of the range is marked in the northwest by a belt of dry, porous ground, broken up into numerous ravines. East of this is the "Terai," a belt of sloping marshland covered with forest and jungle, very malarious and crowded with wild animals. Beyond this lies the "Bhabar," a belt of gravelly and sandy nature covered with forests of valuable timber trees. The "duns," "marls," or "navars," longitudinal valleys partly cultivated and partly yielding forest growth, occupy the space between the Bhabar and the slopes of the Himalayas. The principal passes are the highest in the world and include the Ibi-Gamin pass in Garhwal 20,457 feet, the Mustagh 19,0[illegible]0 feet, the Parangla 18,500 feet, the Kronbrung 18,313 feet, and the Dora Ghat 17,750 feet. The greatest elevations of the Himalayan system are Mt. Godwin-Austen 28,250 feet in the Karakoram range, and in the Himalayas proper the Gaurisankar or Mount Everest 29,002 feet, the highest peak in the world, Kunchinjinga 28,170 feet, and Dhawalagiri 26,826 feet. On the north the limit of the snow line is 17,400 feet, on the south 16,200 feet. From the southern slope of the central portion of the great chain flow the various streams which unite in the Ganges; from the southern slope of the northwestern portion spring the rivers of the Punjab or "Five Waters," which unite to swell the Indus which rises on the northern slope and flows southwestward to the Arabian Sea; also on the northern slope not far from the source of the Indus springs the Brahmaputra which flows east, southwest, and south to the Bay of Bengal; and also from the plateau of Tibet north of the main Himalayan range flow the Salwin, Mekong and other rivers of the Indo-Chinese peninsula, the Yangtse, Hwang-ho, and other rivers of the Chinese Empire. The whole system is of granitic formation associated with gneiss and mica-slate, followed in descending by metamorphic and secondary rocks, until the alluvial deposits are reached. Minerals abound; copper and lead have been mined from ancient times, iron more recently, coal is found at the foot of the mountains, gold in the beds of the mountain torrents, zinc, sulphur, plumbago and salt are also obtained, and there are numerous mineral springs. The vegetation is luxuriant; rhododendrons are in rich profusion, and there are forests of pine, spruce, silver-fir and deodar cedar at varying altitudes. Consult Schlagintweit, 'Scientific Mission to India and High Asia'; Waddell, 'Among the Himalayas.'

Hinckley, Thomas, American colonial governor: b. England, about 1618; d. Barnstable, Mass., 25 April 1706. In 1635 he emigrated to America, and settled at Scituate, but four years later removed to Barnstable. He was deputy governor of Plymouth Colony in 1680 and afterward governor.

Hincks, Sir Francis, Canadian statesman: b. Cork, Ireland, 14 Dec. 1807; d. Montreal, 18 Aug. 1885. He went to Canada in 1831, set up in business at Toronto, and there became editor of the 'Examiner.' In 1841 he entered the first United Parliament as a prominent Liberal. He undertook the editorship of the 'Pilot' of Montreal in 1844. From 1851 to 1854 he was Canadian premier, and as such developed the railway facilities and mining resources of the country, and negotiated a treaty of commerce with the United States. In 1855–62 he was governor of Barbadoes, in 1862–9 of British Guiana, later minister of finance, and from 1873 editor of the Montreal 'Journal of Commerce.' Among his publications are: 'Canada: Its Financial Position and Resources' (1849); 'The Political History of Canada between 1840 and 1855' (1877); 'The Boundaries Formerly in Dispute between Canada and the United States' (1885).

Hind, hīnd, **John Russell**, English astronomer: b. Nottingham 12 May 1823; d. Twickenham 23 Dec. 1895. In 1840 he obtained a situation in the Royal Observatory at Greenwich. He was a member of the commission appointed to determine the exact longitude of Valencia (1844), and on his return was appointed the observer in Bishop's Observatory, Regent's Park. There he calculated the orbits of more than 70 planets and comets, noted several new variable stars and nebulæ, and discovered 10 minor planets. In 1851 he obtained from the Academy of Sciences at Paris the Lalande medal, and was elected a corresponding member; and in 1852 received the Astronomical

Society of London's gold medal, and a pension of $1,000 a year from the British government. In 1857–91 he was director of the 'Nautical Almanac,' and in 1880 president of the Royal Astronomical Society. He wrote: 'The Solar System' (1846); 'Astronomical Vocabulary' (1852); 'The Comets' (1852); 'Elements of Algebra' (1885); 'Introduction to Astronomy' (1871), and other works.

Hindman, hīnd'man, **Thomas Carmichael,** American soldier: b. Tennessee 1818; d. Arkansas 1868. He studied law, entered practice in Mississippi, fought in the Mexican War as a lieutenant of Mississippi volunteers, and in 1858–61 was a Democratic representative in Congress. Not long after the outbreak of the Civil War, he was commissioned brigadier-general, was defeated at Newtonia and Prairie Grove, was promoted major-general at Shiloh, and later served in Arkansas.

Hin'doos, in American history, a nickname given in New York State in 1854 to the American (q.v.) or Know-Nothing Party, from a charge that its candidate for governor, Daniel Ullmann, was born in Calcutta. He was in fact a Delaware man and a graduate of Yale.

Hinduism, in its widest sense, the religion and religious philosophy of the inhabitants of Hindustan, which is professed by nearly half of mankind. Hinduism, historically considered, presents three periods of development. The first is the Vedic age. The Vedas (q.v.) are hymns of worship, and the study of them reveals very clearly the nature worship of primitive Hindustan. In these hymns the elements of nature are addressed as divine beings. Agni, fire, lightning; Surya, the sun; Indra, the cloudless firmament; Maruts, the winds; Ushas, the dawn, are the principal deities of this poetic pantheon. They are addressed in high and sometimes beautiful language, as the senders of temporal blessings. Offerings of delicious viands are made to them; but they are not to be propitiated by bloody sacrifices of beasts, much less by human sacrifices. Libations are poured to them of soma, an exhilarating drink, made from the fermented juice of the soma (q.v.) or milk-plant. Throughout the Vedic hymns runs the under-notion of a supreme being, the creator and ruler of all. This is less discernible in the Brahmana or the Veda than in the Upanishads (q.v.). The Brahmana is a later class of Vedic hymn in which the henotheism suggested in the Upanishads has given place to a highly artificial classification of the divine powers, with a careful estimate of the rank of each. In the Upanishads, Agni, Indra, and Surya become symbols whose united significance may help the mind to understand the existence of one supreme and absolute being, and in this class of Vedic hymn we see the principles of the most enlightened form of native religion in India. The one world soul, in all its manifestations, is reflected in the soul of man, whose destiny is to be reunited with it. The moral responsibility of man, and the judgment of the supreme being against wrong-doing, are plainly taught in these hymns; but there is no trace in them of the later doctrine of moral purification through reiterated metempsychosis.

The second period in the development of Hinduism may be called the epic period. It receives full illustration in the great epic poems, the Ramayana, and the Mahabharata. Side by side with the pictorial teaching of these poems, in which an attempt is made to present the working of the divine economy in relation to specific human lives, there rises a philosophical system, rudimentary indeed, but laying foundations for the later Sankhya, Nyaya, and Vedanta systems. In the Mahabharata, with all its episodes and fantastic incidents, is vividly put forth the doctrine that the union of the human soul with the great, divine soul of the world is aided and expedited by penances of various sorts, such as are detailed with systematic prolixity in the Yoga. In the epic period the doctrine of metempsychosis is clearly enunciated. The soul, after the death of its temporary possessor, must be born again in some material semblance, in order that it may complete the work left unfinished in some previous state of existence, and must repeat the same experience until its task be accomplished and perfection be attained. A decided change is apparent in the popular Hinduism of the third or Puranic period (see PURANAS; TANTRAS). In the Puranas there is almost a Götterdämmerung discernible; no longer do peace and concord prevail in the pantheon where Brahma, Vishnu and Siva still reign supreme, but all is discord, confusion, and destruction. The legends of the epic poems are amplified with childish variations. The simple ideas of the Vedic hymns have vanished. The unbridled imagination of imitators and commentators has overstepped the limits of reverence, dignity, and even poetic beauty in the Puranas, which do not show any advance even in philosophical earnestness, acuteness, or profundity. Worship has become an empty ceremonial. The Vedanta philosophy is now the intellectual creed of the thoughtful and learned (see VEDANTA), and this philosophy is a sort of Deistic agnosticism, only slightly more definite than that of Herbert Spencer, as propounded in his 'First Principles.' For it is the main tenet of the Vedanta that there is one supreme divinity, but, however imagination and speculation may seek to invest this first principle with all the perfections which the human mind is capable of conceiving, the essence of the one divine being lies far beyond the grasp of human thought.

The philosophical creed and henotheism of the educated Brahmin is a sort of esoteric Hinduism which has not supplanted among the general people the influence of a wild polytheism. While it is said that the inferior gods of India make up a pantheon of 330,000,000 divinities, the most important among them are but few in number. These are styled "Guardians of the World," and comprise the elemental gods worshipped in the Vedic hymns. Next in rank to Vishnu, Siva, and Brahma, the supreme triad, are Indra, Agni, Yama (the god of hell), Surya, Varana (the god of water), Purana (the god of wind), Kuvesa (the god of wealth), Soma or Chandra (the moon god), etc. Among sacred animals are bulls: snakes, whose union with the demigods produced monkeys, and some birds, such as the ganada. Among trees, the banyan is held to be divine.

The sects of Hinduism are numerous, and their existence illustrates a principle which is found to have prevailed in the mythological religion of Greece. Each of these sects worships a particular divinity, and teaches that this divinity possesses all the attributes of a supreme being. Thus polytheism does not mean in India, generally, the worship of many gods by each devotee, but very often merely the worship of one god under many names. For example, the Saivas worship Siva; the Sauras, Surya the sun; the Ganapatyas, Ganesa, the god of wisdom, and so on to an almost indefinite length. They ask from each of these gods the same gifts, and the exercise of the same powers. Other sects are Buddhists, Jainas (q.v.), and Sikhs (q.v.). These last profess a pure theism, yet blended with all the absurdities of Hindu mythology and the monstrous fables of Islam; nevertheless they despise Hindus and Mussulmans alike and do not recognize the distinctions of caste. They reject all the Hindu sacred books and look upon warfare as a religious deity. This sect was founded at the beginning of the 16th century A.D. by Nanak Shah.

The philosophy of Hinduism is almost altogether occupied with those questions for which a religious solution is generally sought, namely, the origin and destiny of man, and his relation to the supreme being or the absolute. There are six schools of this philosophy, namely, the Nyaya, Vaiseshika, Sankhya, Yoga, Mimansa, and Vedanta. They all agree in essential points. Their object is to prescribe rules by which man may be delivered from the bondage of ignorance, and be absorbed into the deity. Their doctrine of the soul as something eternal and inextinguishable, distinct from mind, senses, and body, yet sharing in the merit or guilt of good or bad deeds, the latter of which are caused by ignorance of what is best and highest, is identical. They all teach the doctrine of metempsychosis and accept the authority of the Vedas. There is complete agreement among them as to how ignorance is to be gradually illuminated and right apprehension acquired: to this end the Scriptures must be studied and clearness of intellect and heart secured by sacrifices, alms giving, pilgrimages, the repetition of sacred words. The Sankhya are atheistic in their belief, but all the other schools teach the existence of one supreme being.

Hindustan, hĭn-doo-stän', **Hindostan**, hĭn-dō-stän', or **Indostan**, signifying "the land of the (river) Indus," a word of Persian derivation, formerly applied to India (q.v.).

Hingham, hing'am, Mass., town in Plymouth County; on Massachusetts Bay, and on the New York, N. H. & H. railroad; about 15 miles southeast of Boston. In the town are the villages of South Hingham, West Hingham, and Hingham Centre. The first permanent settlement was made in 1633, and it was then called Barecove. In 1635 it was incorporated under its present name. Its chief manufactures are awnings, cordage, wooden-ware, toys, boot-heels, furniture, leatherette and upholstery. It has a meeting-house which was built in 1681. It contains a public library and is the seat of Derby Academy. Some of the noted people who have lived in Hingham are John A. Andrew, John D. Long, Benjamin Lincoln, and James Hall, the famous geologist who for a number of years was State geologist of New York. Joshua Hobart, the Puritan ancestor of the Hobarts of New York State, lived in Hingham. Pop. (1900) 5,059. Consult: 'History of the Town of Hingham.'

Hink'son, Katherine Tynan, Irish novelist and poet: b. Dublin, Ireland, 3 Feb. 1861. She was educated in a convent at Drogheda and since her marriage to H. A. Hinkson in 1893, has lived in Ealing, a suburb of London. She is a voluminous writer of prose and verse, and her books are well known in the United States. Among them may be named: 'Shamrocks,' verse (1887); 'The Way of a Maid' (1895); 'Oh! What a Plague is Love' (1896); 'Three Fair Maids' (1900); 'That Sweet Enemy' (1901).

Hinman, Russell, American editor of text-books: b. Cincinnati 23 Jan. 1853. He was educated at Antioch College, Ohio, went into business as a civil engineer; and later became editor of geographical text-books for Messrs. Van Antwerp, Bragg & Co. of Cincinnati. Since 1890 he has been in charge of the editorial office of the American Book Co. He has written 'Eclectic Elementary Geography'; 'Eclectic Complete Geography'; 'Eclectic Physical Geography.'

Hinoyossa, hē-noi-ōs'sä, **Alexander d'**, Dutch colonial governor in America: b. and d. Holland. He came to America in 1650 as lieutenant in a small military force sent to accompany 150 immigrants. In 1659 he became director of Nieuer Amstel, a Dutch colony on the eastern bank of the Delaware River. Although, owing to disagreements and illness, this colony was not at first a success, it was greatly developed by Hinoyossa's wise rule. Hinoyossa was for a time involved in a conflict of authority with Director Petrus Stuyvesant of New Amsterdam, who had general superintendence of the commissioners constituting the government of Nieuer Amstel. In 1663 he obtained authority over all the settlements on the Delaware. The Swedish colonists submitted, and Stuyvesant relinquished his control. Upon the conquest of New Netherland by England, Hinoyossa returned (1674) to the continent where he fought in the Dutch army against the French invasion by Louis XIV.

Hin'ton, Richard Josiah, American author: b. London, England, 25 Nov. 1830; d. 20 Dec. 1901. He settled in the United States in 1851; studied topographical engineering at the Columbia School of Mines; and removing to Kansas in 1856 became a supporter of the cause of John Brown. He served in the National army in 1861–5; and was the first white man appointed to raise and lead colored troops. After the war he engaged in newspaper work in Washington, New York, and San Francisco. He was the author of 'Life of William H. Seward'; 'Life of Gen. P. H. Sheridan'; 'John Brown'; etc.

Hip, that part of the trunk comprised between the abdominal wall and the lower limb, particularly the region over the hip-bone (the crest of the ilium).

Hip Joint, the joint of the upper leg or thigh (femur where it joins the trunk. It is a ball and socket joint, formed by the sinking of the smooth globular cap into the deep hollow, called acetabulum (vinegar bowl), of the os innominatum. Its movements are controlled by five ligaments: the capsular; the ilio-femoral; the teres; the cotyloid; and the transverse. These movements are more wonderful than even those of the arm, being flexion, extension, abduction, adduction, and rotation inward and outward. It is the most powerful joint in the body and hardest to dislocate.

Hip Joint, Disease of, a disease of the ball and socket of the hip. It often results from scrofula; comes on in children or young persons, from very slight causes; is often traced to a long walk, a sprain in jumping, or a fall. In the early stage of the disease the whole of the structures of the joint are inflamed and after proper treatment may be sometimes subdued with no worse consequences than a more or less rigid joint. Usually, however, abscesses form around the joint, and often communicate with its interior; and the acetabulum and the head and neck of the thigh-bone become disintegrated, softened, and gritty. In a still more advanced stage, dislocation of the head of the thigh-bone commonly occurs, either from the capsular ligament becoming more or less destroyed, and the head of the bone being drawn out of its cavity by the action of the surrounding muscles, or from a fungous mass sprouting up from the bottom of the cavity, and pushing the head of the bone before it.

As the disease advances, abscesses occur around the joint. True shortening of the limb now takes place, which at the same time becomes adducted and inverted. From this stage, if the health is pretty good, and the lungs are sound, the patient may be so fortunate as to recover with an anchylosed (or immovable) hip-joint; but the probability is that exhaustion and hectic will come on, and that death will supervene, from the wasting influence of the purulent discharges occasioned by the diseased bone.

Hipparchus, hĭ-pär'kŭs, Greek astronomer: b. Nicæa in Bithynia. He lived about 160–125 B.C.; resided for some time at Rhodes, but afterward went to Alexandria, then the great school of science. A commentary on Aratus is the only work of his extant. He first ascertained the true length of the year, discovered the precession of the equinoxes, determined the revolutions and mean motions of the planets, prepared a catalogue of the fixed stars, etc.

Hipparion, hĭ-pā'rĭ-ŏn, a genus of fossil three-toed *Equidæ*. See HORSE, EVOLUTION OF.

Hippel'ates, a genus of midges to whose agency is ascribed the spread in many instances of the southern ophthalmic disease of cattle called pink-eye. See FLIES; PINK-EYE.

Hippocrates, hĭ-pŏk'ra-tēz, Greek physician, the father of medicine: b. in the island of Cos 460 B.C.; d. Larissa, Thessaly, 357 B.C. Besides practising and teaching his profession at home he traveled on the mainland of Greece. His writings, which were early celebrated, became the nucleus of a collection of medical treatises by a number of authors of different places and periods, which were long attributed to him, and still bear his name. The best edition is that of Littré (in 10 vols Paris, 1839–61). He has the great distinction of having been the first to put aside the traditions of early ignorance and superstition, and to base the practice of medicine on the study of nature. He maintained, against the universal religious view, that diseases must be treated as subject to natural laws; and his observations on the natural history of disease, as presented in the living subject, show him to have been a master of clinical research. His accounts of phenomena show great power of graphic description. In treating disease he gave chief attention to diet and regimen, expecting nature to do the larger part. His ideas of the very great influence of climate both on the body and the mind, were a profound anticipation of modern knowledge. He reflected in medicine the enlightenment of the great age in Greece of the philosophers and dramatists.

Hippodrome (from the Greek, *Hippos*, a horse, and *Dromos*, a race course), the name given by the Greeks to places where races were held. This included both chariot and single horse racing, but the hippodrome later took the form of a circus, other games, such as wrestling, boxing, running, etc., being added, and for a short time after the introduction of Roman customs and manners it became the scene of gladiatorial combats, but as sights of this nature did not find favor in the sight of the Greeks, these combats were eventually eliminated and the main feature of the games, as in the beginning, was the chariot race. To the brutal taste of the Roman populace flowing blood acted as an elixir, but to the more refined Eastern people the amphitheatre was abhorrent. Though numerous amphitheatres were scattered throughout western Europe very few were ever built within the limits of the Eastern empire and then only where the influence and manners of the Romans were most powerful.

The first mention of a hippodrome is made by Homer, but it is believed that the term then applied to any course over which a race of any kind was run and that it did not necessarily have a fixed location. As the chariot-racing became the national game, the proper courses for the holding of such events became necessary, as in these races, though much of the success depended upon the courage and skill of the driver, the loss of life was often great, through collision, the overthrow of the chariot in turning caused by rough ground, the breaking of an axle, or numerous other accidents. The hippodrome was built for the purpose of avoiding, as much as possible, the possibility of such mishaps, by providing a wide and smooth track, thus leaving plenty of space for the contestants. Of the ancient hippodromes (as distinguished from circus, amphitheatre, etc.), probably the most famous are those of Olympus and of Constantinople, and while the Circus Maximus of Rome may to a great extent have been more of a circus than race course, it was planned after the Greek race courses, was used by the Romans for this purpose, and thus may properly be classed with the other two.

The origin of the hippodrome at Olympus tradition gives to Hercules, but the only description of it obtainable is found in the passages of Pausanias (v. 15 ¶ 4; vi. 20 ¶ 7 foll.) though from the explorations of the German archæologists the ground plans of most of the structures described by Pausanias have been traced. Of its length and breadth there is no precise information, the overflow of the Alphus River having washed away the indications of its limits, though probably the distance from the starting place of the races to the goal, or from one goal to the other, was 770 metres or 4 Olympic stradia, and it was about one fourth as wide, or the same as each side of the starting place.

In general form the hippodrome was an oblong, one end of which was semicircular; on three sides having seats for the populace and on the fourth, where the races were started, seats for the royalty and nobles. The right side, formed by an artificial mound, was a little longer than the left side, which was built on the natural slope of a hill, the base of the fourth side being formed by the portico of Agnaptus, named after its builder. The form of the starting place was not unlike the prow of a ship, each side being 400 feet long, and containing stalls for the chariots and their horses. In the arena were two goals around which the chariots passed several times to complete the race; one of these goals having a bronze statue of Hippodameia upon it, the other an altar dedicated to "Taraxippus, the Terror of the Horses." The principal difference between the Greek hippodrome and the Roman circus was in the width of the arena, in the latter only four chariots being able to race at one time; there was also some slight difference in the arrangement of the carceres.

The erection of the hippodrome of Constantinople was due to two Roman emperors, Septimus Severus and Constantine the Great, who each in turn captured Byzantium by storm. About six years after its capture by him (197 A.D.) Severus commenced operations a little to the west of Byzantium, but in that year was called away by a rebellion in the West and never returned to the city For over a hundred years it remained untouched, until 323, when Constantine, having conquered the city, pushed the work to completion after changing the details in the original plans. On 11 May 330 it was inaugurated.

The external appearance of the hippodrome was imposing for its vastness, its height, and even for its beauty. The walls were of brick, laid in arches, and faced by a row of Corinthian columns 260 in number and standing 11 feet apart. There were four entrances from the city each flanked with towers, but of the stairways leading to these entrances no description has come down to us.

Some idea of the immensity of this prodigious structure may be given by the fact that its dimensions were 1,400 feet in length by 400 feet in width, covering an area of 535,866 square feet, or 12.3 acres. On the north was a structure containing the apparatus for the games, the servants' and attendants' apartments, the chariots and horses, the arsenal, etc., called by the Romans the *carceres* and by the Greeks *μάγγανα*. This apartment was separated from the arena by pillars with latticed gates, 12 in number. Next to these gates was the little church or oratory, where the rival contestants prayed before the games.

The ground story was 20 feet high. On it rested the palace of the Kathisma or Tribunal, in the centre of which, supported upon 24 marble pillars was the platform in Kathisma proper, on the front of which was the emperor's throne. On either side and a little below the emperor were the seats for courtiers, ambassadors, etc. Far down the western side of the hippodrome and nearly opposite the built column was the gorgeous chamber of the empress, this supported upon four porphyry pillars and hence called the tetrakion.

The eastern, western, and southern portions were occupied by parallel rows of seats, appropriated to the spectators according to their rank. Behind these rose tier upon tier of benches until nearly half way to the top where was a broad promenade bounding the entire extent of the hippodrome except on the northern side. This promenade was without roof or covering, and, standing nearly 40 feet above the ground, protected by a solid marble railing reaching to the breast, the spectator had a spacious avenue 2,766 feet long. It is estimated that the hippodrome would seat 60,000 persons and have comfortable standing room for 20,000 more, while with a little crowding 100,000 might be accommodated.

The arena was 211 feet wide by 1,190 feet long and was bounded by a narrow walk called the Euripus, paved in tesselated stone. The semicircular southern portion of the arena, that included in the curve of the Sphendone, was reserved for the criminals and there too was the place for executions. In the centre of the arena and lying parallel to it was the Spina: a stadium, 607 English feet in length, it marked and governed the beginning, duration, and end of each course of a race. At each end of the Spina was a high, narrow framework, surmounted by seven poles, on one group being placed seven fish, on the other seven eggs; one of each was taken down upon the completion of each circuit during the race until the race finished. Toward the southern end of the Spina was the Phiale, a broad basin of running water devoted to the victims of accidents. The space between the northern goal and the carceres was called the Stama, where wrestlers and acrobats performed.

Many additions to the works of art already gathered by Constantine were made during the 700 succeeding years, but in 1203 the hippodrome was sacked by the Franks and Venetians and all were either carried off or destroyed. The most famous of these was the 'Four Golden Steeds,' which was stolen by the Venetians and which in turn was brought to Paris by Napoleon, and is now standing guard over the main entrance of the cathedral of Saint Mark. Among the others are the statues of Hercules, the She-wolf and Hyæna, the Virgin Goddess Diana, the Brazen Ass, the Caledonian Boar, Helen of Troy, the God of Wealth, and eight Sphinxes, beside the statues of the early Roman emperors, martyrs, teachers, philosophers, etc In the early days of the city games were of frequent occurrence, but as time went by they became less and less frequent owing probably to the great cost (it is estimated that a single celebration cost 1,000,000 francs) and at last were celebrated only on 11 May and 25 December, the birthdays of the city and Christ respectively.

It is not known precisely when this hippodrome was entirely destroyed, but as there is no definite reference to any chariot race later than the reign of Isaac Angelus, who was dethroned

in 1195, and as the place was sacked in 1203-4 it is probable that it did not survive the beginning of the 13th century.

The Circus Maximus at Rome was for a long time the only structure of its kind in the world, taking its form from the Greek hippodrome and furnishing the model for all later *circi*. In the Vallis Murcia, between the Palatine and Avantine hills, wooden seats were first constructed by Tarquinius Priscus (Liv. I., 35); were frequently burned and rebuilt until the time of Julius Cæsar, when the steps were constructed of stone and greatly improved. At that time it probably accommodated about 100,000 people. After its destruction by fire in 31 B.C. Augustus completely restored it, making several magnificent additions. The upper tier of seats on the Aventine side was again destroyed by fire in 36 A.D., but Claudius not only restored these, but greatly enlarged the entire circus. These additions were supplemented by others made during the reigns of Trajan and Constantine until it was estimated that the circus held 385,000 spectators, while the 'Notitia' places the possible number at 485,000.

The general plan of the Circus Maximus compared favorably with the Greek hippodromes, the main difference being in the arena around which Cæsar had constructed a moat 10 feet wide and 10 feet deep to prevent beasts from injuring the spectators, and in the width of the arena as before stated. Before the reign of Augustus the circus was used for gladiatorial fights with wild beasts and other forms of butchery, but after the erection of the amphitheatre of Statilius Taurus the circus was no longer used for such purposes. The popularity of this as of the Greek hippodrome also declined and it gradually decayed, now only a few of the remains standing.

The term hippodrome has also been applied to race tracks in England and on the continent, the most famous of these so called hippodromes being those at Vincennes, Longchamps, Chantilly in France, Newmarket and Epsom in England, and Curragh in Ireland. The modern hippodrome, or indoor circus, had its beginning in Paris, where the first was constructed in 1845. It was built entirely of wood, the arena was 108 metres long and 104 wide, and it had a seating capacity of 15,000 persons. This was destroyed in 1870 by fire. The word hippodrome was first utilized in this country when Franconi conducted a circus where now stands the Fifth Avenue Hotel, at 23d Street and Fifth Avenue, New York.

The first hippodrome of the accepted type to be built in America was the New York Hippodrome, which occupies an entire block on Sixth Avenue, between 43d and 44th streets. This structure was begun on 1 July 1904 and finished in five months, the opening performance occurring 12 April 1905. The main façade has a length of 200 feet, and the building extends 240 feet east on 43d and 44th streets. It is built of brick, marble, and steel, and rises to a height of 72 feet on Sixth Avenue, and 110 feet in the rear, the total cost being $1,750,000. It is the largest playhouse in the world, having a seating capacity of 5,200.

In the interior decorations the general scheme of coloring is a Roman red as a background, with all the structural features done in ivory, gold, and silver. The carpetings are of the same color, and the wall hangings, draperies, and upholstery are executed in a Roman red velvet enriched with heavy gold and silver embroidery and tassels.

The auditorium is about 160 feet long and 160 feet wide in the first story, and the balcony and gallery occupy the building in front of the stage above the first story. At the rear of the balcony is the mezzanine floor, below the rear seats of the balcony being the wide segmental promenade with main entrances and flights of shallow stairs at each end leading to the street. Behind the promenade the space, 20 to 50 feet wide and 200 feet long, is occupied by smoking rooms, parlors, waiting rooms, and cloak rooms. The promenade and lobbies are finished in marble and cæn-stone, relieved by rich illuminations of the ornamented parts in gold and silver. A special feature of the auditorium is the arrangement and construction of cages for animals of the feline kind. Their dens are arranged in a segmental curve in the promenade floor, and have plate glass fronts with iron bars behind.

The chief point of interest in the hippodrome centres the stage and the entirely novel mechanical arrangements for operating the movable platforms, filling and emptying the tank, raising and lowering the stage, and handling the scenery. The depth of the stage from the extreme front to the back wall is 110 feet, or 50 feet from the back wall to the proscenium opening and 60 feet from the arch to the front of the stage. This latter part of the stage lying forward of the proscenium arch is known as the "apron." It is large enough to contain two regulation circus rings, each 42 feet in diameter. Beneath the "apron" is built a huge steel and concrete tank, over 14 feet in depth, and large enough for the whole "apron" to sink within it. When aquatic performances or naval pageants are given the tank is filled with water and the movable "apron" is submerged below the water to the bottom of the tank.

Bibliography.—As before stated, the only description of the Olympia as it originally stood is contained in 'Pausanias' (v. 15 Φ 4; v. 120 Φ 7 foll.). From results of excavations the best descriptions of the old hippodromes of the world may be had in the following: Curtius, 'Olympia' (Berlin 1852); Grosvenor, 'Hippodrome of Constantinople' (London 1889); Lehndorf, 'Hippodromos' (Berlin 1870); Pollack, 'Hippodromica' (Leipsic 1890). For descriptions of chariot races consult: Homer's 'Iliad,' and Livy, and "Lew" Wallace, 'Ben Hur' (New York 1880). Of the New York Hippodrome probably the best description is contained in the 'Scientific American' (Vol. XCII., No. 12: 25 March 1905). For a study of the architectural features of the structures of those times consult Sturgis, 'European Architecture' (New York 1896).

Hippopot'amus, the generic and popular name of a great amphibious ungulate, allied to the swine, of which two species are known. One (*H. amphibius*) is common throughout the greater part of Africa; the other (*H. liberiensis*) is not only smaller, but has other important differences, and is found only in the African west coast rivers, and those flowing into Lake Tchad. The former species has a thick and square head, a very large muzzle, small eyes and ears, thick and heavy body, short legs terminated by four toes, a short tail, two ventral teats, skin about two inches thick on the back and sides, and without hair, except at the extremity of the tail. A curious feature of the skin is the reddish exudation which pours from its pores when the animal is excited or in pain. It is called "bloody sweat," but the blood has no part in it. The incisors and canines of the lower jaw are of great strength and size, the canines or tusks being long and curved forward. These tusks sometimes reach the length of two feet and more, and weigh upward of six pounds. The animal is killed by the natives partly as food, but also on account of the teeth, their hardness being superior to that of ivory, and less liable to turn yellow. The hippopotamus has been found as much as 14 feet long, and nearly 5 feet high, but usually measures much less. It delights in water, living in lakes, rivers, and estuaries, and feeding on water-plants or on the herbage growing near the water, where it can walk as well as swim. It often leaves the water after nightfall, and goes, sometimes long distances, to grassy pastures to feed; regular paths are worn through the reeds, and here the Africans often arrange pits, deadfalls, or other traps for their capture. These animals are quick of sense, timid and anxious to escape danger; but when brought to bay or enraged prove formidable antagonists and often destroy canoes. They are excellent swimmers and divers, and can remain under water eight or ten minutes. The behemoth of Job is considered to be the hippopotamus. Several extinct species are found in Old World Tertiary formations, and modern species formerly inhabited not only Madagascar, but southern Europe and India, where they were contemporary with the men of the Stone Age.

Hippuric (hĭ-pū'rĭk) **Acid**, an organic acid, $C_9H_9NO_3$, existing in the urine of herbivorous animals, and, in small quantities, in that of human beings. It is increased by a vegetable diet, and by the disease called diabetes, and may be caused to appear in the human urine in considerable quantities by the administration of benzoic acid with the food. It is most conveniently prepared by boiling horse urine with milk of lime, filtering, neutralizing with hydrochloric acid, and evaporating to about one eighth of its volume. The concentrated urine is then acidified with hydrochloric acid and allowed to stand, when impure hippuric acid comes down as a yellowish-brown precipitate. To purify the crude product, it is heated to 212° F. with not quite enough water to entirely dissolve it, and chlorine gas is passed through the solution until the unpleasant smell has entirely disappeared. The solution is then filtered while hot, and the crystals which separate upon cooling are isolated and subjected again to the same treatment, the chlorine being passed through the solution, in this second treatment, until the solution is bright yellow. When thus prepared, hippuric acid crystallizes from water in the form of large prismatic plates, belonging to the trimetric system. Its crystals are colorless or white, free from odor, and have a slightly bitter taste. Hippuric acid has a specific gravity of about 1.308, and melts at 360° F.; it begins to boil at about 465° F., giving off benzoic acid and benzonitrile. It is insoluble in benzene, carbon disulphid, and cold chloroform, and is but slightly soluble in ether and in cold water. It is very soluble, however, in boiling water, and in hot alcohol. With bases, hippuric acid forms salts that are remarkable for the beauty of their crystalline forms. When boiled with dilute hydrochloric, sulphuric, nitric or oxalic acid, it yields benzoic acid and glycocoll.

Hiram College, a coeducational institution, founded in 1850, in Hiram, Ohio, under the auspices of the Christian Church. It was first called the Eclectic Institute, but was incorporated as a college in 1870. In 1903 there were in attendance about 400 pupils in the departments of oratory and music and in the preparatory department and college. There are about 6,200 volumes in the library.

Hiroshima, hē-rō-shē'mä, Japan, a town on the island of Hondo, about 100 miles from Kobe, and after Osaka the most important port on the inland sea. Pop. (1899) 122,306.

Hirsch, hĭrsh, **Emil Gustav**, American rabbi: b. Luxemburg, Germany, 22 May 1852. He studied at the University of Pennsylvania and at Berlin, was rabbi successively in Baltimore, Md. (1877) and Louisville, Ky. (1878–80), and in 1880 was chosen minister of the Sinai congregation of Chicago, Ill. In 1880–7 he was editor of the 'Zeitgeist' of Milwaukee, Wis., and later became editor of the 'Reform Advocate' of Chicago. He was appointed professor of rabbinical literature in Chicago University in 1892. He appeared as an orator on various patriotic and other occasions, and wrote several monographs on religious and Biblical topics. He was also prominent in Republican State politics, and in 1896 was presidential elector-at-large for Illinois.

Hirsch, Maurice, Baron de (Baron Maurice de Hirsch de Gereuth), Austrian Jewish capitalist and philanthropist: b. Munich 9 Dec. 1831; d. Ogyalla, Hungary, 21 April 1896. His fortune was computed to be $200,000,000, and his yearly income at about $20,000,000. His benefactions equaled nearly $100,000,000, the most of this sum being directed toward the improvement of the condition of the Jews in all parts of the world. The De Hirsch trust for the United States is a fund of $2,500,000 for the Americanizing and education of Rumanian and Russian Jews. Other large gifts were those of $5,000,000 for the endowment of schools in Galicia, and of $50,000,000 to the Jewish colonization association for the establishment of colonies in Argentina. In 1888 he offered to the Russian government $10,000,000 for schools, with the condition that in the distribution of the amount no discrimination as to race or religion be made. This offer was not accepted. Baron de Hirsch made extensive sums through the construction of railways in Turkey.

Hirth, hērt, **Friedrich**, German-American educator: b. Grafentonna, Saxe-Coburg, Germany, 1845. He studied at Leipsic, Berlin, and Greifswald, entered the Chinese customs service in 1870; retired in 1897, and in 1902 was called to the newly created professorship of Chinese in Columbia University. In the summer of 1902 he was in St. Petersburg, cataloguing a collection of manuscripts taken at Peking. He made a valuable collection of Chinese porcelains, now in the museum at Gotha, and one of printed

HIPPOPOTAMUS (*Hippopotamus Amphibius*).

books and MSS., now in the Berlin Royal library. Among his publications are: 'China and the Roman Orient' (1885); 'Ancient Porcelain' (1888); 'Chinesische Studien' (Vol. I., 1890); and 'Ueber fremde Einflüsse in der Chinesischen Kunst' (1896).

His'cock, Frank, American legislator: b. Pompey, Onondaga County, N. Y., 6 Sept. 1834. In 1855 he was admitted to the bar, in 1860-3 was district attorney of Onondaga County, and in 1867 a member of the State constitutional convention of New York. He was a Republican representative in Congress in 1879-87, and obtained recognition as a party leader and speaker. In 1887 he was United States senator from New York and then returned to professional practice.

Hispania, hĭs-pā'nĭ-a̤. See SPAIN.

Histol'ogy, the science of animal and vegetable tissues. It investigates by means of the microscope the various tissues of man, animals and plants in their anatomical relations and compositions. Topographical histology considers the more minute structures of the organs and systems of the body; normal histology deals with the healthy tissues; and pathological histology investigates the changes they undergo in disease. Marie François Xavier Bichat (1771-1802) is generally credited with the foundation of the science of histology. Unfortunately the imperfect condition of the microscope in his time prevented Bichat and his contemporaries from carrying their investigations to the point which Schleiden, Schwann, Johann Müller, Virchow, Von Recklinghausen, Cohnheim, etc., have reached. It has been found that all structures however complex are made up of cells, and that the parts of a body may be resolved into a small number of elementary tissues now grouped as: (1) epithelium, which lines almost all the cavities of the body and is directly or indirectly in communication with the atmosphere; (2) the nervous tissues, which as nerve cells originate and as nervous fibres transmit all nervous impulses; (3) muscle, which produces motion whether voluntary or involuntary; (4) glandular tissue which consists of cells standing in close relation with the blood-vessels which take from the blood certain substances and secrete them; (5) connective substances which support and hold together the more delicate and important structures, especially forming the cartilages and bones. See CELL; ANATOMY, COMPARATIVE; ANATOMY OF PLANTS.

Many tissues have the power of repairing injuries that happen to them. This power is called regeneration, and is found especially in the lower animals, in polyps, worms, and in many amphibious creatures and reptiles. In other cases the lesion is supplied by a new growth of connective substance. In diseases the tissues undergo many changes and many of these diseases in the organism are shown also by the changing of color. The science of such changes is generally called pathological histology. It is a comparatively young science and has been cultivated by Virchow, who was the founder of cellular pathology.

Vegetable histology is that department of botany which deals with microscopic phytotomy or the anatomy of plants, especially investigating the plant cells and plant tissues. It is properly subordinate to morphology and is a distinctively descriptive science. It deals with the question in what relation the cells or forms of tissue stand to the vital activity of plants, what functions they perform, and in what respect they are constituted for the fulfilling of those functions. (Compare CYTOLOGY.) Owing to the excessive minuteness of the cells which form the tissues of all plants the investigation relies almost entirely on the microscope, and naturally has made its advance in proportion as the microscope has been made more perfect. Microscopes that are now used magnify at least 1,000 diameters, and the materials used have to be carefully prepared and mounted. Many of them have to be colored with hæmatoxylin, fuchsin, saffranin, and other alcoholic or aqueous dyes. Consult Delafield and Prudden, 'Handbook of Pathological Anatomy and Histology' (1901).

Historical Societies in the United States. John Pintard, of New York, deserves the credit of being the first who endeavored to organize historical societies in the United States. He was born 18 May 1759, received his education at Princeton College, and became actively identified with several military expeditions in the War of the Revolution, being also deputy commissary for American prisoners. He was especially zealous in the study of American history, and appreciated the need of preserving the literature, muster-rolls, private and public documents, relics, and other material of the colonial period, at that time uncollected. In 1789 he visited the Rev. Jeremy Belknap, in Boston, who writes: "When Mr. Pintard was here he strongly urged forming a society of antiquarians." In August 1790 Mr. Belknap, following this suggestion of Mr. Pintard, drew up an outline for such a society, in which was the following clause, "Letters shall be written to gentlemen in each of the United States requesting them to form similar societies and a correspondence shall be kept up between them for the purpose of communicating discoveries and improvements to each other," and quaintly concludes, "When ye societie's funds can afford it salaries shall be granted to the secretaries and other officers." In February 1791 Mr. Belknap writes: "We have now formed our society and it is dubbed, not the Antiquarian, but the Historical Society. It consists at present of only 8, and is limited to 25. We intend to be an active, not a passive, literary body; not to be waiting like a bed of oysters for the tide (of communication) to flow in upon us, but to seek and find, to preserve and communicate literary intelligence, especially in the historical way." In 1794 the membership was increased to 60, and by act of legislature in 1857, the limit of resident members was placed at 100. Associated with Jeremy Belknap in the new society were Rev. John Eliot, Rev. James Freeman, James Sullivan (later governor of Massachusetts), Rev. Peter Thatcher, William Tudor, the noted lawyer, Thomas Wallcut, the antiquary, James Winthrop, for years librarian of Harvard, Dr. William Baylies, a physician of Dighton, and George R. Minot, the author. The position held to-day by the Massachusetts Historical Society is so well recognized at home and abroad that it would be futile to attempt to describe either its valuable contributions or its stimulating example to similar societies, during its unqualified success of over 100 years. Its officers in 1903, were: President, Charles Francis Adams; vice-presidents, Samuel Abbott Green, M.D., Thomas Jefferson Coolidge; recording secretary, Edward James Young; corresponding secretary, Henry Williamson Haynes; treasurer, Charles Card Smith; librarian, Samuel Abbott Green, M.D.; cabinet-keeper, Henry Fitch Jenks.

To John Pintard is due the credit for the first meeting, 20 Nov. 1804, of the New York Historical Society. Those present included John Pintard, Judge Egbert Benson, DeWitt Clinton, Rev. Wm. Linn, Rev. Samuel Miller, Dr. David Hosack, Rev. John M. Mason, Rev. John N. Abeel, Samuel Bayard, Peter G. Stuyvesant and Anthony Bleecker. These patriotic founders organized "for the purpose of discovering, procuring, and preserving whatever may relate to the natural, civil, literary, and ecclesiastical history of the United States in general, and of this State in particular." The valuable library of John Pintard was acquired in 1807, thus forming the nucleus of the 100,000 volumes owned by the society in 1903. The first gift from outside sources, recorded in the minutes of the Society, came in 1810, when 10 volumes of the publications of the Massachusetts Historical Society were presented. The society is now erecting a new home on Central Park West, 76th and 77th streets, where its thousand members may more adequately enjoy its collections; including the galleries of American portraits and old masters; the famous Egyptian collection of Dr. Henry Abbott, the Nineveh sculptures presented by James Lenox, the original Audubon water colors, together with countless original papers, engravings, prints, broadsides and relics of the Colonial and Revolutionary periods. Meetings are held the first Tuesday of each month, October to June inclusive, at which papers, dealing with American history, are read. The society established a fund for printing its proceedings and collections; 28 volumes have been issued since 1868, as follows:

Vol. I.— 'The Continuation of Chalmer's Political Annals of the American Colonies' (1685–96); 'The Colden Letters on Smith's History of New York' (1759–60); 'Documents Relating to the Administration of Jacob Leisler' (1689–1769).

Vol. II.— 'The Clarendon Papers, Relating to New York and New England' (1662–7); 'The Destruction of Schenectady' (1690); 'Montague's Arguments on Acts of New York Assembly' (1701); 'Colden's Letter on Smith's History of New York' (1759); 'Plowden's New Albion' (1632–50); 'Gardiner's History of East Hampton, New York' (1798); 'Collection of Evidence and Vindication of the Rights of New York to the New Hampshire Grants.'

Vol. III.— 'Territorial Rights of New York Against the Government of New Hampshire,' a brief by James Duane; 'Old New York and Trinity Church' (1730–90); sermon by the Rev. Francis Makemie (1707).

Vol. IV., Vol. V., Vol. VI., Vol. VII.— 'The Papers of Major-General Charles Lee' (1754–1811).

Vol. VIII.— 'Letters of General Pattison, Commandant of New York City' (1779–80); 'Letters to General Lewis Morris (1775–82).

Vol. IX., Vol. X.— 'Official Letter-Books of Lieutenant Governor Cadwalader Colden' (1760–75).

Vol. XI.— 'Papers of Charles Thomson, Secretary of the Continental Congress' (1765–1816); 'Letters of Colonel Armand' (1777–91); 'Letters to Robert Morris' (1775–82).

Vol. XII.— 'Trial of General Schuyler' (1778); 'Trial of General Robert Howe' (1781); 'Journal of Commissary Rainsford, Enlistment of Hessian Troops' (1776–78).

Vol. XIII.— 'Trial of General St. Clair' (1778); 'Journal of Occurrences at Quebec' (1775–76); 'Case of William Atwood, Chief Justice of New York' (1703); 'Vesey's Sermon in Trinity Church, at the Funeral of Lord Lovelace' (1709); 'Letter of Dominie Michaelius, First Minister in New Netherland' (1628); 'Records of the Court of Lieutenancy, New York Militia' (1686–96).

Vol. XIV.— 'Journals of the Engineer Officers, Colonel James and Captain John Montressor, of Services in America' (1757–78).

Vol. XV.— 'Journal of Lieutenant Von Krafft, of the Hessian Army' (1776–84); 'Letter-Book of Captain Alexander McDonald, of the Royal Highland Emigrants' (1775–79).

Vol. XVI., Vol. XVII.— 'Papers of Lieutenant-Colonel Stephen Kemble, Adjutant-General of the British Army in America, Journals and Correspondence' (1775–89); 'General Orders of the British Army in America' (1775–8); 'Journals, Documents, and Correspondence of the Expedition to Nicaragua' (1780–1).

Vol. XVIII.— 'The Burgher Right and Roll of Burghers of New Amsterdam' (1648–61); 'Roll of Freedom of New York City' (1675–1866); 'Register of Indentures of Apprentices of New York City' (1694–1708).

Vol. XIX. to XXIII.— 'The Deane Papers, Correspondence, Official and Private, of Silas Deane' (1774–89).

Vol. XXIV.— 'Muster Rolls of New York Provincial Troops' (1755–64).

Vol. XXV.— 'Abstracts of Wills on File in the Surrogate's Office, City of New York' (1665–1707).

Vol. XXVI.— Same (1708–29), with Appendix.

Vol. XXVII.— Same (1730–44).

Vol. XXVIII.— Same (1744–).

The officers of the New York Society for 1903 are: President, Samuel Verplanck Hoffman; first vice-president, Frederic Wendell Jackson; second vice-president, Francis Robert Schell; foreign corresponding secretary, Archer Milton Huntington; domestic corresponding secretary, George Richard Schieffelin; recording secretary, Sydney Howard Carney, Jr., M.D.; treasurer, Charles Augustus Sherman; librarian, Robert Hendre Kelby.

Following in the steps of these two oldest societies hundreds of a similar character exist to-day. Indeed, hardly a city or county in each State of the Union but has had its own local historical society. A casual glance at a few local societies in Massachusetts and New York will give an idea of the spirit which prevails for the preservation of the historic past:

The American Antiquarian Society, Worcester, Mass., was incorporated 24 October 1812; this inland city being selected as less exposed to possible invasion from the sea, with the consequent loss of historical collections.

The Essex Historical Society, Salem, Mass., was originally started by Dr. Edward A. Holyoke, of Salem, and incorporated in 1821. Some 15 years later the Essex County Natural History Society was incorporated, and in 1848 both of these societies united, forming the Essex Institute. Of other societies in Massachusetts a few will suffice. The New England Historic Genealogical Society, Boston; The Quoboag Historical Society, Brookfield; Historical Society, Nantucket; Old Residents' Association, Lowell; Old Colony Historical Society, Taunton; Pocumtuck Valley Memorial Association, Deerfield; The Pilgrim Society, Plymouth; The Rumford Historical Society, Woburn. Rehoboth, Watertown, Westborough, Weymouth, and Winchester have each local societies.

In New York State mention may be made of the Long Island Historical Society, Brooklyn; Suffolk County Historical Society, Sag Harbor; Oneida Historical Society, Utica; Onondaga Historical Association, Syracuse; Rochester Historical Society; Buffalo Historical Society; Westchester Historical Society, and Tarrytown Historical Society. In many States the various religious denominations have historical societies and there was organized recently the American Jewish Historical Society, New York.

The various organizations in the several States have assumed so much usefulness that there now exists an "American Historical Association," organized at Saratoga, N. Y., 10 Sept. 1884, incorporated by Act of Congress, approved 4 Jan. 1889, and reports annually to Congress through the Smithsonian Institution. The more recent patriotic societies, such as the Sons of the Revolution, Society of Colonial Wars, Mayflower Society, Daughters of the Revolution, Colonial Dames, and Huguenot Society, are largely indebted to the historical societies for their existence. Indeed, the Sons of the Revolution was formed in the hall of the New York Historical Society.

The following list of historical societies existing in 1903, is arranged in alphabetical order of States, with the information furnished, in so far as replies have been received, from the secretaries of States, or officers of historical societies:

Alabama.— The Alabama Historical Society, organized 8 July 1850 at Tuscaloosa, Chancellor Alexander Bowie being first president. Incorporated by Act of the General Assembly 5 Feb. 1852. During Civil War all work was suspended, many documents being lost. 1874 revived by Dr. Joshua H. Foster, its first secretary. 10 Dec. 1898; The Alabama History Commission was created at Montgomery, Hon. Thomas M. Owen being secretary and treasurer.

Alaska.— Society of Alaska, Natural History and Ethnology, incorporated 11 April 1888 at Sitka. Alaska Historical Library and Museum incorporated 6 June 1900, at Sitka.

Arizona.— The Arizona Pioneer Historical Society, located at Tucson, was established some years ago.

Arkansas.— There are two historical societies in the State, both styled "Arkansas Historical Society," one at Little Rock, Fay Hempstead, secretary; the other at the University of Arkansas, Fayetteville, J. H. Reynolds, secretary.

California.— The California Historical Society, organized in 1886, San Francisco.

Colorado.— The State Historical and Natural History Society, Denver; incorporated 11 July 1879. Charles R. Dudley, secretary.

Connecticut.— The Connecticut Historical Society, Hartford, organized 1825; revived by the general assembly 1839; Albert C. Bates, secretary; New Haven Colony Historical Society, New Haven, 1862; New London County Historical Society, New London, 1870; Fairfield County Historical Society, Bridgeport, 1881; and the Middlesex County Historical Society, Middletown, 1902.

Delaware.— The Historical Society of Delaware, Wilmington, incorporated 1868; Hon. Chas. B. Lore, president; Wm. Hall Porter, recording secretary.

District of Columbia.— The Columbia Historical Society, organized 9 March 1894; Mrs. Mary Stevens Beall, recording secretary; and also the American Historical Society.

Georgia.— The Georgia Historical Society, Savannah; Hon. William Harden, secretary.

Idaho.— The Historical Society of the State of Idaho, Boise City; Hon. Wm. A. Goulden, secretary.

Illinois.— The Illinois State Historical Society, organized 30 June 1890. Local organizations in the State cooperate with the Society. The last legislature made the society a part of the Illinois State Historical Library, which library has heretofore issued publications of the society. Mrs. Jessie Palmer Webb, librarian of State Historical Library, and secretary and treasurer State Historical Society.

Indiana.— The Indiana Historical Society, organized 1830.

Iowa.— The State Historical Society of Iowa, Iowa City; organized 1857; present articles of incorporation date April 1892; F. E. Horack, secretary. The historical department of the State Library, Des Moines, should not be confused with this society.

Kansas.— The Kansas State Historical Society, Topeka; organized 14 Dec. 1875; Geo. W. Martin, secretary; "this library contains 24,424 books; 72,789 pamphlets; 25,926 volumes of newspapers; 25,977 manuscripts; 6,696 relics; 5,751 pictures; and 5,129 atlases and maps.

Kentucky.— The Kentucky Historical Society; organized 1839–40. The legislature donated rooms to the society 1879–80. In August 1902 it became a department of the State. Gov. J. C. W. Beckham, president; General Fayette Hewitt, first vice-president; W. W. Langmoor, second vice-president; Mrs. Jennie C. Morton, secretary and treasurer.

Louisiana.— The Louisiana Historical Society; organized 15 Jan. 1836; Judge Henry A. Bullard, president; reorganized 1846 with Judge F. X. Martin, president; incorporated 1847 and a new charter given 30 April 1877, transferring it from Baton Rouge to New Orleans. From 1860 to 1888 Judge Charles Gayarré, president, being succeeded by Judge W. W. Howe. Since 1894 Prof. Alcée Fortier has been president.

Maine.— The Maine Historical Society, Portland; organized 1822; H. W. Bryant, recording secretary; The Bangor Historical Society, Bangor; The Kennebec Antiquarian Society, Augusta; York Institute, Saco; The Sagadaboc Historical Society, Bath; The Lincoln County Historical Society, Wiscasset; The Skowhegan Historical Society, Skowhegan; The Waterville Historical Society, Waterville; and The Eliot Historical Society, Eliot.

Maryland.— The Maryland Historical Society, Baltimore; Geo. W. McCreary, librarian; The Frederick County Historical Society, Frederick; The Harford County Historical Society, Belair, Dr. Archer, president.

Massachusetts.—See data previously given.

Michigan.— The Michigan Pioneer and Historical Society, Lansing; organized 22 April 1874; issues each year a volume of historical collections; Henry R. Pattengill, secretary.

Minnesota.— The Minnesota Historical Society, St. Paul, is the only society in that State.

Mississippi.— The Mississippi Historical Society; organized 1898; Dr. F. L. Riley, secretary; Dunbar Rowland is director of the department of archives and history of the State of Mississippi, Jackson. This department was created 26 Feb. 1902 and is under the auspices of the historical society.

Missouri.—The Missouri Historical Society, St. Louis; chartered in 1875; The State Historical Society, Columbia, in 1899.

Montana.— The Montana Historical Society, Helena; organized December 1864; incorporated February 1865 and is a part of the State Library; Miss Laura E. Hovey, secretary and librarian.

Nebraska.— The Nebraska State Historical Society, Lincoln.

New Hampshire.— The New Hampshire Historical Society, Concord.

New Jersey.— The New Jersey Historical Society, Newark; organized 1845; William Nelson, corresponding secretary; Bergen County Historical Society, Hackensack, 1902; New Brunswick Historical Club, New Brunswick, Hunterdon County Historical Society, Flemington; Salem County Historical Society, Salem; Princeton Historical Association, Princeton; Woodstown and Pilesgrove Historical Society, Woodstown.

New Mexico.— The Historical Society of New Mexico; incorporated 5 Feb. 1881; home office, Santa Fe.

New York.— See previous references.

North Carolina.—The Historical Society of North Carolina was chartered in 1833; rechartered 22 March 1875; Dr. K. P. Battle, department of history University of North Carolina, Chapel Hill, secretary; The North Carolina Literary and Historical Society, Raleigh; W. J. Peele, secretary; and The Trinity Historical Society, Durham; Dr. J. S. Bassett, secretary.

North Dakota.— The North Dakota Historical Society; incorporated 8 March 1895; Col. C. A. Lounsberry, secretary, Fargo.

Ohio.— The Ohio State Archæological and Historical Society, Columbus; incorporated 13 March 1885, E. O. Randall, secretary. There are many local societies in Ohio: The Western Reserve Historical Society, Cleveland; The Fireland Historical Society, Norwalk; The Ohio Philosophical and Historical Society, Cincinnati; and others.

Oklahoma Territory.— The Oklahoma Historical Society, founded by the Oklahoma Press Association at Kingfisher, May 1893. By act of territorial legislature 21 Feb. 1895 it became trustee of the Territory "for the care, collection and preservation of all kinds of historical matter, and for the expending of any appropriation made by the Territory for such historical purposes, and located the society at the University building at Norman." In June 1901 the society accepted the offer of the entire upper floor of the Carnegie Library, Oklahoma City, pending the erection of a capitol building. Lincoln McKinlay, president; Sidney Clark, custodian.

Oregon.— The Oregon Historical Society, organized 17 December 1899; F. G. Young, secretary, University of Oregon.

Pennsylvania.— The Historical Society of Pennsylvania, Philadelphia; organized 1824; John W. Jordan, librarian; Bucks County Historical Society, Doylestown; Montgomery County Historical Society, Norristown; York County Historical Society, York; Lancaster County Historical Society, Lancaster; Wyoming Historical and Geological Society, Wilkes-Barre; Washington County Historical Society, Washington; Lebanon County Historical Society, Heilman Dale; Chester County Historical Society, West Chester; Delaware County Historical Society, Chester; Berks County Historical Society, Reading; Tioga Point Historical Society

Athens; and the Presbyterian, Baptist, and Methodist Historical Societies, Philadelphia.

Rhode Island.— The Rhode Island Historical Society, Providence; founded in 1822; The Newport Historical Society, Newport, R. I.

South Carolina.— The South Carolina Historical Society, Charleston; organized 1855; Gen. Edward McCrady, president; A. S. Salley, Jr., secretary.

South Dakota.— The Department of History in the State of South Dakota; administered by the State Historical Society; was organized by act of legislature 21 Jan. 1903; located at Pierre; Doane Robinson, secretary.

Tennessee.— Tennessee Historical Society, Nashville; Robert T. Quarles, corresponding secretary.

Texas.— The Texas State Historical Society; organized 2 March 1897; Hon. John H. Reagan, Palestine, president.

Utah.— The State Historical Society of Utah; organized 31 Dec. 1897; Salt Lake City.

Vermont.— The Vermont Historical Society; organized 1838; Montpelier; Joseph A. Deboer, recording secretary.

Virginia.— The Virginia Historical Society, Richmond; organized 1831; William G. Stanard, corresponding secretary and librarian.

Washington.— The Washington State Historical Society, Tacoma; Hon. Ezra Meeker, president; E. N. Fuller, secretary.

West Virginia.— State Historical Society, Charlestown.

Wisconsin.— The State Historical Society of Wisconsin, Madison; organized 1849; re-organized 1853, this latter date being considered the real date of organization.

Wyoming.— The Wyoming Historical Society; organized 1895; Robert Morris, secretary, Cheyenne.

Sydney H. Carney, Jr., M.D.

History is a record of events which have occurred among mankind; embracing an account of the rise and fall of nations, and other great mutations which have affected the political and social condition of the human race. In a more limited sense, history is a record of the progress of mankind in civilization; and, therefore, deals especially with those nations which have performed great achievements and exerted a commanding influence upon the fortunes of the human race.

History is generally divided into three great epochs — Ancient History, Mediæval History, and Modern History. Ancient History begins with the first appearance of historic records, and ends with the fall of the Western Roman Empire 476 A.D. Mediæval History, or the History of the Middle Ages, extends from the fall of Rome 476 A.D., to the discovery of America 1492 A.D. Modern History embraces the period from the discovery of America to the present time. Sometimes, however, the world's history is divided into only two great periods — Ancient and Modern; Ancient History embracing the whole period before the fall of Rome, 476 A.D., and Modern History comprising the entire period since that event.

The three sources of history are written records, architectural monuments and fragmentary remains. Several races of men have disappeared from the globe, leaving no records inscribed upon stone or parchment. The existence and character of these people can only be inferred from fragments of their weapons, ornaments and household utensils, found in their tombs or among the ruins of their habitations. Among these races were the Lake-dwellers of Switzerland; the prehistoric inhabitants of the Age of Stone and the Age of Bronze of the British Isles; the builders of the shell-mounds of Denmark and India; and the Mound-builders of the Mississippi Valley.

The discovery of monuments of great antiquity has aided vastly in ascertaining the date of ancient events. The Parian Marble, brought to England from Smyrna by the Earl of Arundel, contains a chronological arrangement of important events in Grecian history from the earliest period to 355 B.C. The Assyrian Canon, discovered by Sir Henry Rawlinson, the great English antiquarian, consists of a number of clay tablets, constructed during the reign of Sardanapâlus, and containing a complete plan of Assyrian chronology, verified by the record of a solar eclipse which must have occurred 15 June 763 B.C. The Fasti Capitolini, discovered at Rome, partly in 1547 and partly in 1817 and 1818, contains in fragmentary records a list of Roman magistrates and triumphs from the beginning of the Roman Republic to the close of the reign of Augustus. The Rosetta Stone, discovered by a French military engineer during Bonaparte's expedition to Egypt in 1798, contains inscriptions in the Greek and Egyptian languages, the deciphering of which has led to the discovery of a key to the meaning of the hieroglyphic inscriptions on the Egyptian monuments. The fragmentary writings of Sanchoniathon give us some light on Phœnician history; those of Berosus on Babylonia and Assyria; Manetho's lists of the 30 dynasties of Egyptian kings afford us valuable information; and the works of Herodotus, the «Father of History,» have given us a graphic account of the ancient nations — their annals, manners, and customs, as well as a geographical description of the countries which they inhabited.

Herodotus was the first of Grecian historians. Other Greek writers of history were Thucydides, the great philosophic historian; Xenophon, the writer of charming historical romances; Ctesias; Diodorus Siculus; Polybius; and Plutarch, the charming biographer of antiquity. Ancient Rome produced Livy, Tacitus, Sallust, and Cornelius Nepos, who have given us the facts of Roman history. For the history of the ancient Hebrews we are indebted to the books of the Old Testament and the works of Josephus, the celebrated Jewish historian, who wrote a complete history of his countrymen in Greek. Among early Christian Church historians were the Roman Eusebius and the Anglo-Saxon, the Venerable Bede. The Frenchmen Comines and Froissart were celebrated chroniclers of the Middle Ages. The Italian Macchiavelli achieved fame by his historical writings. Among modern historians have been many who have acquired celebrity by their works. Such were the great trio of British historians — Hume, Gibbon, and Robertson, whose works have always been regarded as standards. England has produced many famous writers of history; such as Macaulay, Carlyle, Grote, Thirlwall, Froude, Lingard, Arnold, Allison, Freeman, Rawlinson, Green, Knight, Merivale, Milman, Hallam, and others. France produced Rollin, Voltaire, Thiers, Guizot, Sismondi, Mignet, Michelet, and the brothers Thierry. Germany has given the world a great ecclesiastical historian in the person of Mosheim; and a number of German historians have given the world the benefit of their scholarly researches, among whom we may mention Niebühr, Neander, Rotteck, Heeren, Schlosser, Mommsen, Curtius, and Leopold von Ranke. Among American historians the most renowned have been Hildreth, Prescott, Bancroft, Motley, Lossing, and Parkman.

The origin of nations has been involved in obscurity, which has only quite recently been removed by the diligent study and the patient research of modern European scholars. Investigation into the affinities of the various languages has given us some new knowledge upon this interesting and important subject. Comparing the languages of most of the modern European nations with those spoken by the ancient Romans, Greeks, Medes, and Persians, and Hindus, we observe that all these languages had a common origin, entirely different from those spoken by the ancient Chaldees, Assyrians, Phœnicians, Hebrews, Arabs, and Egyptians; these latter being related to each other, but not to those of the nations previously named. The former of these languages are called *Aryan*, the latter *Semitic* and *Hamitic;* while the Central Asian Tartar nomads have a language called *Turanian.*

The Aryan branch is called Japhetic, because it has been supposed to be descended from Japheth; while the Semitic branch is regarded as the posterity of Shem, and the Hamitic branch as the children of Ham. The name Aryan means "tiller of the soil"; wherein this race has differed from the Turanian, or nomadic races of Central Asia.

In the course of time nations became divided into civilized and uncivilized, as their intellectual development was furthered by talents and commerce, or retarded or cramped by dullness and by isolation from the rest of mankind. Uncivilized nations are either wild hordes under an absolute and despotic chief who wields unlimited power over his followers, or wandering nomadic tribes, guided by a leader, who, as father of the family, exercises the functions of lawgiver, governor, judge and high priest. Neither the wild hordes under their despotic chiefs, occupying the unknown regions of Africa (negroes), the steppes and lofty mountain ranges of Asia, the primeval forests of America (Indians), and the numerous islands of Oceanica (Malays), nor the nomadic races with their patriarchal government, find any place in history.

The oldest civilizations were those found in the Tigris-Euphrates and Nile valleys, in the Hindu peninsula, and in the remote empire of China. The exact origin of the ancient nations and civilizations is lost in the dimness of their remote antiquity. These regions were richly endowed by nature with the resources necessary for sustaining a dense population; and the oldest historic empires accordingly took their rise in the rich alluvial lands watered by the Tigris and the Euphrates in southwestern Asia and by the Nile in northeastern Africa.

Historical Asia is southwestern Asia; where the great Hamitic and Semitic empires of Chaldæa, Assyria, and Babylonia successively flourished, in the Tigris-Euphrates valleys; where the Hebrews and the Phœnicans played their respective parts in the world's historic drama; and where the Aryan race finally came upon the scene in the appearance of the great Median and Medo-Persian empires and the Græco-Macedonian empire of Alexander the Great and his successors, followed by the Parthian, Eastern Roman, and new Persian empires; after which the Semitic race again prevailed in the sudden rise of Mohammed's religion and the great empire founded by his successors; followed by the conquests of the Seljuk Turks from Tartary, the two centuries of warfare between Christendom and Islam for the possession of the Holy Land as represented in the Crusades, the terrible scourges of the conquering Mongol and Tartar hordes of Genghis Khan and Tamerlane; and, lastly, the rise of the now-decaying Mohammedan empires of the Ottoman Turks and the modern Persians.

Southern Europe was the seat of the greatest two nations of antiquity—the Greeks and the Romans—the former by their literature and philosophy and their political freedom, and the latter by their laws and political institutions influencing all future European nations. The other nations of ancient Europe were barbarians, many of whom were conquered and civilized by the Romans. The overflow of the Roman dominion in the 5th century after Christ entirely changed the current of European history by a redistribution of its population through the migrations and conquests of its vast hordes of northern barbarians, who 14 centuries ago laid the foundations of the great nations of modern Europe. America and Oceanica were wholly unknown to the ancient inhabitants of the Old World, and have only occupied the field of history since their discovery and settlement by Europeans within the last four centuries.

The cradle of civilization — if not the cradle of the human race — was the fertile alluvial Tigris-Euphrates and Nile valleys, where, with the dawn of civilization, flourished the old Chaldæan and Egyptian empires—the most remote of historical states of antiquity. History begins with Egypt, the oldest of historical nations.

Asia is the birth-place of the great religions and the home of absolute despotism. The two great pantheistic religions — Brahmanism and Buddhism; also the great monotheistic religions — Judaism, Christianity, and Mohammedanism — arose in Asia; while Asiatic governments today are what they have been from time immemorial — absolute monarchies, or despotisms; no republic or constitutional monarchy ever having flourished on Asiatic soil.

Europe, on the contrary, inhabited by the progressive Aryan race, has carried political institutions to the highest state of development; civil, political, and religious liberty having had a steady growth. Asiatic civilization has been stationary, while European civilization has been progressive. The Asiatics are passive, submissive, given to contemplative ease and disinclined to active exertion. The Europeans are active, energetic, vigilant and aggressive. Europe has also colonized other portions of the globe; the greater part of the present populations of North and South America being the descendants of Europeans who settled in the New World, and drove away, or assimilated with, the aborigines; while Europeans have also settled in portions of Africa, Asia, and Oceanica. The Asiatics, on the other hand, do not colonize.

History, Ancient. Objectively history is a succession of past events connected with one another as cause and effect; subjectively it is a record of such events as determined by the processes of investigation included in historical method. The history of mankind treats not so much of individuals as of the progress and decline of communities and states with especial reference to morality, religion, intelligence, social organization, economic condition, refinement and taste, government, and the peaceful and military relations of governments to one another (cf. Andrews, 'Institutes of General History,' p. 3). Strictly there are no periods; the life of mankind flows continuously, never wholly changing the direction of its current at any definite time. But for the convenience of study history is more or less arbitrarily divided into periods, during each of which the resultant of changes in the life of mankind, or of a particular part of it, is supposed to be a determinable movement of progress or decline which the historian takes as characteristic of the period.

The familiar division of general history into ancient, mediæval, and modern may be accepted as the most practical, though it is exceedingly difficult to define these long and complex ages. Most obvious is the geographical characteristic. Leaving out of account India and the farther East, which have contributed little to the progress of the rest of the world, ancient history has to do (1) with the fertile river-valleys adjoining the east end of the Mediterranean; (2) with the Mediterranean basin itself; for the few outlying countries which had a share in ancient history depended upon this area for their civilization. Or taking race and religion as the basis of division, we may define ancient history as the development of pagan, non-Germanic civilization; for with the thorough establishment of Christianity and the coming of the Germans the Middle Age begins. Although ancient history includes many nations and numberless movements of growth and decay, it shows nevertheless remarkable unity. From simple though diverse beginnings the various peoples of the area above defined developed into the one complex political and social organization known as the Roman empire; and when with the wreck of this system the ancient world passed away, there began under new conditions that fresh life of mankind which in its earlier stage we call mediæval and in its more mature growth modern.

History does not concern itself with ultimate origins; it begins with man in the lowest condition in which it actually finds him, and with the help of anthropology, archæology, and kindred sciences it traces his improvement from that point upward through the earlier known stages of his existence. The prehistoric age, which precedes contemporary written records, is taken into account in so far as, by furnishing relative beginnings, it affords an explanation of later developments. Even when the historian reaches the period of contemporary documents and literature, he continues to use all available auxiliary sciences, principally epigraphy, archæology, numismatics, philology, and geography. In testing the genuineness and the historical value of sources he makes use of critical principles which are becoming more and more definite and effective with the growth of historical method into a science.

Nowhere has source material accumulated so rapidly in recent years as in the Orient. As a result of continued explorations there our knowledge of Oriental life has been vastly increased, and the beginnings of Oriental history have been pushed much farther back into the past. We are now able to study the Egyptians of the paleolithic age (cf. Petrie, 'History of Egypt' (4th ed. i. p. 5 ff), although no date can yet be assigned to that primitive culture, nor have yet been discovered all the links which connect it with the historic age. Beginning with the earliest appearance of written records in the Orient, we may divide ancient history into the following periods:

I. *The Dawn of Civilization; the old Egyptian Kingdom and the Chaldean and Syrian City-States, 5000–3000 B. C.*—Whether mankind first emerged from the Stone Age in the valley of the Nile or in that of the Tigris and Euphrates rivers is disputed, and the date of this event has not been even approximately determined. There can be no doubt, however, that early in the fifth millennium B.C. civilization in both these regions had reached a comparatively high development. People irrigated their fields, built cities, in which they lived under kings, and were acquainted with the elements of practical science as well as with the art of writing. The Egyptian alphabet of this period was hieroglyphic, the Chaldean cuneiform. Egypt achieved political unification under a monarch near the beginning of the period; Chaldea and Syria remained divided among rival city-states.

Through the most brilliant part of the period the Egyptian capital was Memphis, whose Pharaohs of the fourth dynasty (about 4000–3725 B.C.) constructed the great pyramids at Gizeh. This epoch is unique in the world's history for the bold attempt to surpass nature in the grandeur and strength of its buildings, which at the same time indicate the high centralization in the hands of the monarch. The people of Egypt, devoted to agriculture and the industrial arts, were peace-loving, submissive to authority, and intensely religious. Prominent among the Chaldean cities were Ur, Nippur, Agade (Accad), and Babylon, under independent kings who strove with one another for the mastery. In spite of their military occupation the people, like the Egyptians, engaged their best thought and energy in creating the elements of civilization. Among their early achievements were the science of astronomy, the calendar, and a system of weights and measures, which with some modifications afterward passed to Europe. Early in the fourth millennium Chaldean civilization began to affect Syria.

II. *The Middle Kingdom of Egypt; the Political Unification of Chaldea; the Neolithic and Æneolithic Ages in Greece, about 3000–2000 B. C.*—In the beginning of the period Thebes supplanted Memphis as the political centre of Egypt. The most brilliant dynasty was the twelfth (about 2775–2550 B.C.). The Pharaohs of this family with a firm hand controlled the feudal lords who since the sixth dynasty had been growing strong over all Egypt, and to whom most of the famous rock-graves of the period belong. The same dynasty conquered Ethiopia (Nubia), carried on a lively trade with Syria, and had commerce with countries as far west as Crete. They built splendid temples, and regulated the waters of the lower Nile by means of a great reservoir in the Fayûm. Their utilitarian works contrast strikingly with the grand though selfish idealism of the pyramid-builders. Meanwhile in Chaldea the strife among the cities continued till the whole country was unified under Babylon (2250 B.C.).

In the industries both nations reached a high stage of technical skill. The Egyptians excelled in inlaid work, the Babylonians in the engraving of gems. The architecture was massive, the Chaldean in brick, the Egyptian in stone. The sculpture, too, though lacking grace, showed great strength. The literature was looked upon by after ages as classic. In government we find a centralized monarchy with a bureaucratic administration regulated by written law (cf. the Code of Hammurabi (q.v.), about 2250 B.C.). The family was monogamic, and society was definitely organized in classes. The prime motive power in life was religion, which, manipulated by the priests, was already reducing the activities of man to a system of conventions and thus putting an end to originality.

In the region about the Ægean Sea the period is represented by the first settlement at Troy, of neolithic culture (3000–2500 B.C.), and by the second or "burnt" city, which was æneolithic (2500–2000 B.C.). Crete, in communication with Egypt, seems to have taken the lead in the civilization of this region.

III. *The Earliest Empires and Their Struggles; the Beginnings of Assyria, Phœnicia, and the Hebrews; the Bronze Age in Greece, 2000–1000 B. C.*—After the twelfth dynasty Egypt weakened; from the beginning of the second millennium the Hyksos (q.v.) a barbarous people from Asia, controlled the lower Nile valley for several, possibly five, centuries. After their expulsion the Egyptians became a conquering people. The eighteenth dynasty (about 1600–1325 B.C) extended their dominion on the south to the centre of Ethiopia and on the northeast to the Euphrates River. Cyprus and the "isles of the Great Sea" sent as tribute and gifts vases of Mycenæan manufacture.

Chaldea, ruled by Cossæan — Kassite — kings (1717–1140 B.C.), was not only unable to prevent these conquests, but even lost her hold upon Assyria, which now began a long winning struggle with Babylon for supremacy. Both countries courted the favor of the powerful Pharaohs. For the first time in history we have great states in relations of war and peace with one another — the beginning of diplomacy and "world-politics." Assyria (1125 B.C.) suddenly created an empire which extended northward to the sources of the two rivers and westward to the Mediterranean. She advanced beyond Egypt in the organization and administration of conquered countries, but her empire soon fell to pieces, partly from internal exhaustion and partly because of invasions from Arabia.

Before the rise of the Assyrian empire the Hittites had conquered eastern Asia Minor and had wrested northern Syria from Egypt; but their power was as speedily overthrown by swarms of invaders of unknown race from Asia Minor, who then made a fierce assault upon Egypt.

Before the end of the millennium the Phœnicians had planted many trading-stations on the islands and coasts of the Mediterranean and had created a "world-commerce." Sidon was at first the leading city, and afterward Tyre. Their civilization, with that of all Syria, was fundamentally Chaldean, affected to some extent by Egyptian commerce and conquest. About 1000 B.C. the Greeks adopted their phonetic alphabet.

Among the immigrants from Arabia into the civilized districts of Hither Asia were the Aramæans, who established themselves in northern Syria with their capital at Damascus, and the Hebrews, who conquered the country in southern Syria now known as Palestine (1150 B.C.). At first their government was a theocracy represented by prophets and "judges," but soon (about 1050 B.C.) they established a kingship.

In this period the creative energy of the Egyptians had exhausted itself. Life became artificial; wealth, flowing in from conquests, substituted magnificence for taste, and in the end enfeebled the national spirit. On account of the wars the military class came into great prominence; the king, more than before, became the proprietor of the state, and the priests gained control of the material as well as of the spiritual activities of the nation. In Hither Asia, also, artistic and industrial civilization suffered through the decline of Chaldea; for the Assyrian genius was chiefly political and military rather than artistic or intellectual. The Hebrews, however, were moving in the direction of monotheism, and Phœnicia was spreading Oriental civilization abroad over the Mediterranean lands.

Of enormous importance for history was the development of civilization in the Ægean region. The beginnings of the Bronze Age — proto-Mycenæan — are represented by the third, fourth, and fifth cities at Troy (2000–1500 B.C.), followed by the fully developed Mycenæan civilization, represented by the sixth city at Troy, by Tiryns, Mycenæ, and many other cities on the Greek peninsula, in Crete and the Ægean islands. Characteristic of the civilization are massive fortifications, large palaces, immense tombs, wonderfully skilful work in gold, in vase-making, gem-cutting, and inlaying with precious metals, also excessive ornamentation of apparel and effeminate luxury. Toward the close of the millennium this culture began rapidly to decline.

Parallel to this development in the Ægean, yet little affected by it, the Etruscans of central and northern Italy were creating a peculiar civilization,— less artistic and less grand than the Mycenæan,— which did not reach its height till the following millennium.

IV. *The Growth and Decline of the Syrian Kingdoms; the Rise of the Assyrian Empire; the Epic Age in Greece, 1000–700 B. C.*— Tyre, taking the place of Sidon, became the centre of the world's commerce. Under king David the Hebrews developed a great political power; but after the death of Solomon they split into two kingdoms, Judah and Israel. Damascus, which had belonged to the realm of David, again became the capital of an independent Aramæan kingdom. Near the end of the period, however, all Syria excepting Tyre fell under the Assyrian yoke. The people of Damascus (about 730 B.C.) and Israel (722 B.C.) were carried into captivity, and Judah became tributary. Babylon, too, was definitely conquered (728 B.C.). Egypt, again declining, divided into many small principalities, while Ethiopia rose to a power of the first importance. Her king conquered the Nile valley to its mouth in 728 B.C. But the greatest political event of the period was the rise of the Assyrian empire. Through persistent warfare carried on by a line of able kings for crushing frequent rebellion as well as for new conquests, the empire reached the height of glory, though not yet its widest extent, under Sargon (722–705 B.C.).

Great progress was made in civilization. The Hebrews, afflicted by Assyria, were purging themselves of polytheism, and under the lead of inspired prophets were learning to look upon Jehovah as the only God, almighty, pure, and jealous, who demanded of his worshippers not only ceremonial exactness but clean hearts and spiritual devotion. With the Assyrians, notwithstanding their strong religious nature, political motives were dominant. For strengthening their empire they adopted the plan (1) of recruiting their armies partly from conquered peoples, (2) of transplanting populations from one part of the empire to another, to break up local attachments and weaken the power of resistance, (3) of organizing some of the conquered countries into provinces ruled by Assyrian officials, though many were still left under their native rulers. In government and administration, accordingly, Assyria was at this time the most progressive of nations.

The centre of interest in the growth of civilization, however, shifted to the Ægean region, where in this age the Ionic Greeks produced the first European literature — the 'Iliad' (q.v.) and the 'Odyssey' (q.v.) Colonists in a strange country, the Ionians were not in a condition to cultivate the Mycenæan arts, but drew their subsistence from grazing, agriculture, and war. With a high degree of refinement, mixed with barbarity, they possessed remarkably virile, elastic minds. In contrast with the slavish Orientals, the Greeks, represented by the Ionians, were in spirit free. To them neither nature nor religion was terrible: their gods were intensely human, generally the helpers, never the implacable enemies of man. Combined with this intellectual liberty and boldness was a rare sense of fitness and proportion, manifested in the Homeric poems referred to above. In Greek manhood, virility, freedom, intelligence, and taste combined to produce a civilization which was already rapidly advancing beyond that of the Orient.

V. *The Fall of Assyria and the Rise of the Persian Empire; in Greece Colonial Expansion and the Awakening of a National Consciousness; the Struggle Between Asia and Europe, in which Greece Becomes the Centre of Interest in the World's Politics; in the Central Mediterranean Region the Political Growth of Carthage and Etruria; at Rome the Primitive Kingship and the Beginning of the Republic, 700–479 B. C.*— Early in the period Lydia became a conquering state, and reached the height of its imperial power under Crœsus (560–546 B.C.), who ruled nearly all Asia Minor west of the Halys River. Egypt fell under the Assyrian power (664 B.C.); but soon throwing off the yoke, it enjoyed a long period of independence (645–525 B.C.). Before the loss of Egypt the Assyrian empire reached from Thebes on the Nile nearly to the Caspian Sea, and from the Persian Gulf nearly to the Black Sea — the greatest extent of country yet united under one ruler. In Nineveh, their new capital, the kings built magnificent palaces of brick, adorned with representations of their wars in sculptured reliefs. They established libraries, too, of Babylonian learning. But they had already ceased to make political progress, and they failed to give their empire an organic unity, and to inspire the conquered nations with loyalty to the central government. Suddenly the empire was overthrown by a combination of the Babylonians and the Medes, who destroyed Nineveh in 606 B.C. With this event Assyria disappeared from history.

Two empires — the Median and the Babylonian — divided between them the Assyrian domain. The former lay in the north of Hither Asia, the latter in the south. Under Nebuchadnezzar (606–562 B.C.), Babylon became the largest and wealthiest city in the world, a brilliant seat of industry and commerce. He destroyed Jerusalem, carried Judah into captivity (586 B.C.), and conquered Tyre. Of the other empire the ruling people were the Medes, who inhabited the plateau between the Tigris Valley and the Caspian Sea. Their sway extended westward, on the north of Babylonia, to the Halys River, and southward over their Persian kinsmen. Both empires, however, were short-lived: in 550 B.C. Cyrus, an Elamitic prince, at the head of a Persian revolt, established himself master of the Median realm. This event made the empire Persian. After conquering Lydia (546 B.C.) and Babylon (538 B.C.), Cyrus proceeded to subdue the countries to the east and northeast of Persia: so that at his death (529 B.C.) his empire extended from the Ægean Sea to the Indus River, and from the Persian Gulf to the Jaxartes River — an area perhaps five or six times as great as that of the Assyrian empire. His son and successor Cambyses added Egypt (525 B.C.), and Darius, the following king (522–485 B.C.), completing an organization begun by Cyrus, divided the empire into twenty satrapies (provinces), each under a governor termed satrap. This magistrate, appointed by the king, exercised full military and civil authority over his province, subject to royal regulations and commands. Though checked by the continual presence of a royal secretary and by the occasional visits of the king's «eye» (inspector), the satrap enjoyed the splendor and nearly all the power of a sovereign. Darius also built roads throughout the empire, distributed the taxes equitably, and established a system of gold and silver coins. He annexed Thrace to his empire, and made an unsuccessful attempt to conquer Greece.

In the beginning of this period the Greeks were extending the sphere of their influence through colonization. About 750 B.C. they had begun to settle in southern Italy and Sicily: and for two centuries the movement of expansion continued, till their settlements extended from Naucratis, Egypt, to the Pillars of Hercules, and from the northern coast of the Black Sea to Libya. With colonial enterprise the industries and commerce kept full pace. They manufactured armor, artistic bronze-ware, and tastefully painted vases. From Lydia they learned the art of weaving and dyeing fine woolens as well as of coining money; from Egypt they derived the elements of astronomy, of surveying, and of the other practical sciences. Great intellectual progress took place; lyric poetry flourished in all parts of Greece — a kind of poetry which shows that the Greeks were actively thinking on all subjects suggested by their expanding environment. They made a beginning of geography, history, and philosophy. Thinking led to religious and moral progress; the Greeks began to exercise self-restraint and moderation in life. Their sympathies widened with their intelligence; they discovered that they were all of one blood, one speech, and one religion, and began to call themselves by the common name of Hellenes. They became aware, too, of the differences between themselves and foreigners, whom they termed "barbarians," and of their own superiority to all other races. Conflicts with foreigners made the Greeks feel that they ought to combine for mutual defense. In the preceding age (1000–700 B.C.) their whole country was divided among a multitude of small city-states, each under an independent king. While in the more progressive parts of the nation in the period now before us the government was rapidly developing from kingship through aristocracy, oligarchy or timocracy, and tyranny in the direction of democracy, a corresponding movement was going on toward political unity. The city of Sparta, after uniting by conquest Laconia, Messenia, and Cynuria in the strong military state of Lacedæmon, built up the Peloponnesian league with herself as leader. The basis of her superior military organization was the phalanx. Under the fear of Persian invasion this power expanded into an Hellenic league of all the loyal Greek states on the peninsula and on the neighboring islands. In Sicily a similar league grew up under Syracuse for defense against two formidable powers, Etruria and Carthage. The Etruscan dominion extended from the Alps to the vicinity of the present Naples, and probably included the then insignificant city of Rome, which after having been ruled from the earliest times by kings set up a republic in 509 B.C. The Etruscans, now at the height of their development, were equally powerful by land and sea. Even more formidable to the Greeks was Carthage, the greatest Phœnician colony, which united under its leadership all the other Phœnician settlements in the western Mediterranean region. By means of enormous wealth, accumulated through commerce, this city recruited a vast army of mercenaries, with which she hoped to overwhelm the western Greeks.

Checked by the growth of foreign powers, Greek colonial expansion came to an end about 550 B.C. Then the boundary of free Hellas on the east was pushed back by the Lydian and Persian conquests in Asia Minor. A revolt of the Ionians against Darius,— in which the insurgents were aided by the mother country,— precipitated between Asia and Europe a conflict destined to affect the whole future history of the world. An army sent into Greece by Darius, was beaten back by the Athenians at Marathon in 490 B.C. Ten years afterward, Xerxes, son and successor of Darius, led a vast host into Greece, hoping to overwhelm the free little country by the sheer force of numbers. But his fleet was shattered in the battle of Salamis (480 B.C.) and his army destroyed at Platæa by the forces of the Hellenic league (479 B.C.). Meantime at Himera, Sicily, the despot of Syracuse destroyed the invading mercenary army of Carthage (480 B.C.). The Greeks met with brilliant success both in the East and in the West: those of their race in Asia Minor were liberated; all were relieved from fear of foreigners; Greek civilization was free to develop without the restraint of alien rule; Greece came out of the struggle strong, proud, self-conscious, ready for great achievements in peace and in war.

VI. *The Culmination and Decline of Greek Political Power and of Greek Civilization; the Hellenization of the Orient; the Unification of Italy Under Rome, 479–264 B. C.*—The splendid naval force which Athens furnished for the war, together with superior statesmanship, placed her at the head of a new league of maritime Greek states, known as the Delian Confederacy (organized 477 B.C.). Rivalry for the headship of Greece between democratic Athens and oligarchic Sparta led to the Peloponnesian war, which involved a great part of the Greek world (431–404 B.C.), and which ended in the establishment of Spartan supremacy (404–471) over eastern Greece, while nearly all western Greece was united under Syracuse. Oppression on the one hand, and on the other the love of the Greeks for city-autonomy, caused the downfall of both political powers. For a short time under Epaminondas (371–362 B.C.) Thebes attempted to take the place of Sparta, but in vain; the Greek state-system,— consisting of leagues and hegemonies of cities,— was rapidly crumbling. Meanwhile Macedon, a territorial state under King Philip, taking advantage of the political disunion and mutual jealousies of the city republics, began to encroach on free Hellas. After defeating the combined forces of Athens and Thebes at Chæronea (338 B.C.) he imposed his protectorate upon the Hellenic state-system. His son Alexander the Great in a series of brilliant campaigns (334–331 B.C.) conquered the Persian empire, and afterward extended its boundaries to the northeast and the east. His empire was the largest the world had known. Among his improvements was the specialization of administrative functions, financial, judicial, and military. When he died, the empire after a long struggle among his generals ultimately divided into three great states,— Egypt, Asia (the Seleucid empire), and Macedon, including Greece. To regain and preserve their liberty many of the cities of eastern Greece entered into two federal unions, the Ætolian and the Achæan. These institutions, though long known to the Greeks, came into favor too late to save them from the domination — not of Macedon but of Rome. The western Greeks, however, were first to meet their fate.

After adopting a Republican constitution Rome engaged with her neighbors in a long, desperate struggle for existence (509–431 B.C.). Then by securing the headship of Latium (431–406 B.C.) and by the conquest of Veii she became one of the strongest powers in Italy. A series of wars with the Latins, Samnites, and Italiot Greeks (343–290 B.C.) gave her control of all Italy south of the Rubicon River. The success of the Romans was due to their improvement on the Greek phalanx, their strict discipline and obedience to authority, their laborious patience in fortifying acquired territory, and their liberality in the treatment of conquered peoples. The political system which in this period they gradually built up on the basis of Italian nationality recognized various gradations of rights and obligations among the communities of the system from the tributary subjection of the Gauls to the full Roman citizenship. Though partly federal, the system left to Rome absolute control of foreign and military affairs. At the close of the period (264 B.C.) Rome and Carthage were the great powers of the western Mediterranean; those of the East were Macedon, Egypt, and the Seleucid empire.

The century and a half (479–322 B.C.) following the Græco-Persian war was in some respects the most brilliant in the history of civilization. The tremendous energy roused in Greece by the war displayed itself under the guidance of taste and reason in every field of activity. A wave of independence, overthrowing tyrannies and oligarchies, established popular governments in many cities, and intensified the democracies already existing. In Periclean Athens, which depended economically upon the labor of slaves and tributes from dependent allies, the citizens enjoyed a more liberal education and a wider range of political and social privileges than have ever fallen to any other community known to history. In close relation with this political and social development architecture, sculpture, and literature reached ideal perfection. The fifth century produced the Attic drama (Æschylus, Sophocles, Euripides, and Aristophanes), the noblest historical writing (Herodotus and Thucydides), and the inimitable Parthenon and Erechtheum. But the Peloponnesian war exhausted the energy and resources of eastern Greece. The growing refinement and love of peace which characterized the following century is indicated by the fact that the inhabitants of the city-states shirked military service, so that war came largely into the hands of mercenaries drawn from the less cultured territorial states. Thought prevailed over action; and in art strength was to some extent sacrificed to beauty and finish. While poetry declined, oratory and philosophy reached the height of their development in Demosthenes, Plato, and Aristotle, who brought classic Greek literature to a close.

Following the conquests of Alexander, commerce, colonization, and administrative policy spread Hellenic civilization over the Orient. In the post-classic period (after 322 B.C.) Pergamum and Alexandria became the most famous seats of Hellenistic culture, which was distinguished for painstaking scholarship rather than for creative power. The West, too, was falling under Hellenic influence. Rome adopted from the Greeks not only the phalanx, but also various deities and religious ideas, the alphabet,— either directly or through the Etruscans, — and other rudiments of civilization. From the Etruscans chiefly came the impetus to the building of public works,— temples, sewers, roads, bridges, fortifications,— in which the Romans showed creative genius. But to the end of the period they paid little attention to learning; they were without literature and had few if any schools. A realistic, practical people, they were narrow and unamiable in private and business relations, but excellent warriors and citizens. Duty and Discipine were the great commandments to which the family and society, citizens and soldiers, yielded religious obedience. These heroic virtues were not the least important factor in the creation of their empire.

VII. *The Expansion of the Roman Power over the Mediterranean World; the Growth of Plutocracy and the Decline of the Republic, 264–27 B. C.*—The extension of the power of Rome over the peninsula brought her into collision with Carthage, which had occupied nearly the whole of Sicily and was now threatening southern Italy. Not only did Rome feel bound to protect Italy, but her growing commercial class desired by conquest to extend its opportunities for trade and speculation. The First Punic War (264–241 B.C.) may be compared in character and importance with the recent war between the United States and Spain, which resulted in the occupation of the Philippine Islands by the former power. To meet the Carthaginians on their own element, Rome built a navy, and thus equipped herself for transmarine conquests. As a result of the war, Carthage surrendered Sicily to Rome in addition to paying a heavy indemnity. This island became the first Roman province (227 B.C.). Sardinia and Corsica, acquired soon after the war, were organized into a second province. Then by conquering the Gauls in the north of Italy (225–222 B.C.) the Romans extended their sway to the Alps. In the Second Punic War (218–201 B.C.) the Carthaginian Hannibal, one of the most eminent generals of all time, invaded Italy, defeated one Roman army after another, desolated the country, and came near wrecking the power of Rome. Her preservation was due to the wisdom of the senate, to the solidity of Roman character, and to the tie of common interests and of kindred blood which bound the Italians together against the alien intruder. This war of defense shows Rome at her best. Peace brought her two provinces in Spain and the destruction of her rival's navy. So greatly superior was now her strength that the conquest of the civilized world had become merely a question of a few years. In another series of successful wars (200–146 B.C.) she acquired Macedon, Greece, Asia Minor, and the country about Carthage. Corinth and Carthage were destroyed, and most of the acquired territory was organized into provinces. At this date (146 B.C.) Rome was the only great power in the entire Mediterranean basin. The further growth of her empire consisted mainly in the conversion of protected and dependent countries into provinces and an occasional conquest. To Pompey belongs the subjugation of Syria (65–62 B.C.), which alone remained of the Seleucid empire, and to Julius Cæsar the more important conquest of Gaul (58–50 B.C.). Egypt, long dependent, became a province in 30 B.C. The Roman empire, consisting of provinces and dependent allies, now included the whole circuit of the Mediterranean.

Some advantages came to the world from Roman rule: while in the East Græco-Oriental culture continued undisturbed, Latin civilization, which was falling more and more under Hellenic influence, gradually permeated the provinces of the West; throughout the empire the cities retained their own laws and self-administration under the government of their wealthy class; all parts but the frontiers enjoyed lasting peace. The evil effects of the system, however, soon began to outweigh its advantages. To secure a monopoly of commerce for themselves, the Romans restricted or even prohibited trade among the subject communities. Over all the empire they acquired vast estates, which they worked by slave labor, thus destroying everywhere the free peasantry. Their policy of farming the taxes was also unjust and oppressive.

The governors, too, with rare exceptions made office a means of amassing fortunes. In these ways the administrative and capitalist classes recklessly exploited the provinces for their own profit. At the same time commercial restrictions and the competition of slave labor were ruining the farmers and business men of Italy, and a worthless, dangerous mob was growing up in the capital.

The early government of Rome by magistrates, senate, and assemblies, although admirably adapted to a small community, proved unequal to its new and complex functions. The assemblies, now becoming corrupt, were in the hands of magistrates, ministers of the senate, which as a whole was controlled by a small knot of members, the curule ex-magistrates. This inner circle formed in the beginning a nobility of merit; it saved the state from Hannibal and conquered the Mediterranean world. But it soon transformed itself into an hereditary caste, which, monopolizing the domestic and imperial offices, used them as a means of absorbing the wealth of the world. In brief the nobility degenerated into a corrupt, self-seeking plutocracy. As to the general condition of the world at this time it should be noted that the want of competition, such as exists among nations of approximately equal power, by reducing the vitality of mankind, stopped progress, and decay was already setting in. Thorough reform was needed even to postpone the collapse of ancient civilization.

The Gracchi sacrificed their lives in a vain attempt to regenerate the peasantry and to restore Italy to its old condition of economic health; at the same time they showed the enormous power of the plebeian tribunate for purposes of reform or revolution. Far preferable to government by the corrupt aristocracy or by the mob, which Gaius Gacchus organized, would be the strong rule of one man; and the task of creating in the army a solid foundation for a government of the kind was accomplished by Gaius Marius. After him the governor (proconsul) of a military province employed his position as a means of acquiring an army for political use; and the proconsuls became rivals for the mastery of Rome. Finally Gaius Julius Cæsar, an aristocrat by birth but a champion of the people, allying himself with the tribunes, overthrew the republic and created a virtual monarchy. By radical reform of the entire administration this great creative statesman arrested the decay of civilization and gave the institutions of the ancient world a new lease of life. The assassination of the monarch, far from restoring the republic, was followed by a war of succession, in which his grand-nephew Octavius — after 27 B.C. Augustus — won the imperial prize (31 B.C.).

VIII. *The Empire at Its Height, 27 B. C.–180 A. D.*— Instead of recurring to the autocracy of Cæsar, Augustus hit upon a compromise between republic and monarchy (27 B.C.). The senate through its magistrates and promagistrates was still to govern Rome, Italy, and the peaceful provinces, while Augustus as holder of the military authority (*imperator*, hence emperor) was to rule directly the exposed and unquiet provinces and to exercise supervision even over those administered by the senate; the republic was to continue for Italy, the monarchy was established for the subject countries. In Rome Augustus held the tribunician power, and was sometimes elected to republican offices; but his chief influence over the home government was exercised not through office but in the capacity of political "boss,"— a position which the Romans dignified with the name of *princeps* (foremost citizen). The prince and the senate had not only their separate fields of administration but also separate treasuries and separate sets of officials. Augustus concealed the independent position of the prince; Tiberius brought the dyarchic antithesis into bold relief; the Claudian and Flavian princes, by gradual encroachment on the senatorial prerogatives, aimed to convert the dyarchy into a monarchy. As the senate declined, the officials of the prince, originally his friends and household servants, developed into an imperial bureaucracy. After the tyranny of Domitian the "Good Emperors" (96–180 A.D.), in reconciling the nobility to the principate, laid more firmly the constitutional basis of their power. The government may now be termed a monarchy, although some elements of the dyarchy remained, and though the senate, with its republican traditions, continued to be a material check upon the powers of the prince.

The emperors made few permanent conquests,— chiefly Britain and the Danubian provinces. Their fundamental task was to extend Latin civilization to the un-Hellenized parts of their dominion. In Africa west of Egypt, notwithstanding the survival of the Phœnician language in private life, Latin civilization took deep root. Spain and southern Gaul became perhaps even more thoroughly Latinized. Northern Gaul was less affected, and Britain still less, by the Romans, while the northern provinces east of Gaul varied greatly in their receptivity of Latin culture. The principal factor in the work of civilization was the city; in most of their European domains the Romans superseded the old tribal organization by the Italian municipal system, which gave the nations the refining and disciplining influence of comfortable homes, useful and artistic public works, schools, courts of justice, and local self-government. Each city was a centre from which Latin modes of life and Latin ideas radiated. Imperial rule cured most of the ills of republican administration. Abolishing the farming of direct taxes, it placed their collection in the hands of imperial officials, and distributed them on the basis of a careful census. The governors, now drawing their salaries from Rome, and deprived of their former unlimited opportunity for extortion, were held responsible to the emperor. The armies, placed under strict discipline and controlled by one will, no longer wasted the empire by civil wars. For the vast extent of the frontier the soldiers were few, and the burden of their support was light. The republic had looked upon the provinces as its estates; in the 2d century A.D. the emperor came to regard himself as the parent of the subject peoples, whom he was in duty bound to treat with love as well as with justice. Though oppression was not wholly eradicated, the imperial government was in a high degree efficient, just, and humane. The progress of civilization was followed by the extension of the Roman citizenship. The liberal policy of Claudius in bestowing it was continued by his successors, till shortly after the period under discussion all freemen of the empire became Romans by the edict of Caracalla (212 A.D.).

In this period was tried the experiment of maintaining profound and lasting peace over the large area comprising the interior provinces. Prominent among the results was a material prosperity far greater than has ever blessed those countries in any other age. Another result was the development of the "feminine virtues." Men "became chaste, tender-hearted, loyal, religious, capable of infinite endurance in a good cause" (Seeley, 'Roman Imperialism'). They began to regard women as their equals, to treat children and slaves humanely, to show kindness even to animals, and in spite of gladiatorial contests, to abhor bloodshed. Morals, at their lowest ebb in the Rome of Nero, were rapidly purified by the coming in of the best families from the provinces, so that under the Good Emperors morality in the capital reached a high level. The spirit of the age expressed itself not only in the private and social virtues, but also in the Civil Law, which rested upon the principles of justice, kindliness, and equality among men.

The unimaginative Romans failed to produce a literature of the highest rank. In the late republic lived Lucretius, a poet of real genius, and Cicero, the versatile author of orations, philosophic works, and private correspondence. The Augustan age created the epic and rural poetry of Virgil, the 'Odes' and 'Satires' of Horace on social and moral topics, and Livy's stately history of the republic. The most splendid Latin writers of the age of the Good Emperors were the satirist Juvenal and Tacitus, the historian of the early empire. Among the most famous writers in the Greek language at this time were Pausanias, author of a 'Tour of Greece,' Appian, the historian, and Plutarch, the biographer of eminent men. Hellenism continued to be the chief liberalizing and refining force in the empire. Its highest intellectual product from Roman soil was Stoicism, which found its best expression in the writings and character of Marcus Aurelius.

IX. *From Limited Monarchy to Despotism; the Reorganization of Diocletian and Constantine; the Barbarian Invasions and the Decline of the Empire, 180–500 A. D.*— Writers generally agree in making the decline begin with the reign of Commodus (180–192 A.D.), though disintegrating forces had long been in operation and though for generations afterward the empire at times, as under Septimius Severus and Diocletian, showed great recuperative power. The century which intervened between the death of Marcus Aurelius and the accession of Diocletian (180–284 A.D.) we may regard as a period of revolution. The happiness of the Roman world under the Good Emperors had been chiefly due to the wisdom of a succession of rulers who were able to secure the good will of the senate and of the populace of Rome, the subordination of the pretorians and of the army, and the respect of surrounding nations. The weak, brutish Commodus allowed these nicely adjusted forces to conflict, and the result was civil war and anarchy. The revolution, sweeping away the influence of pretorians, populace, and senate, almost of Rome itself, brought new principles of government into play. The emperor was to be a despot of the Oriental type,— a God on earth,— who surrounded himself with stately splendor, and governed through a complex bureaucracy. He appointed a colleague, and two Cæsars were named as heirs of the emperors, all four dignitaries being men of eminent military ability. The empire was reorganized in prefectures, dioceses, and provinces under appropriate magistrates. These arrangements, chiefly the work of Diocletian (284–305 A.D.) and Constantine (sole emperor 324–337 A.D.), were in the main permanent. In making better use of the resources of the empire for the purposes of defense the new organization brought fresh strength, but rivalry between the emperors again caused civil wars with all their evil consequences. Under Constantine, who removed the capital to Byzantium, thereafter called Constantinople, the two imperial offices were again vested in one person, and were not definitely separated till the accession of Arcadius and Honorius, sons of Theodosius (395 A.D.). Even then the theory of a single empire ruled by two colleagues continued; and when in 476 A.D. Romulus "Augustulus" was deposed at Rome and the imperial trappings were sent to Constantinople, people understood merely that the collegial government had once more given way to monarchy.

Meanwhile from the heart outward through every limb the empire was falling to decay. The underlying cause, already referred to, was declining vitality, fundamentally due to lack of interest in the welfare of the state, of the community, of future generations. As the civilized part of the human race lost love of life and hope for the future, it began to die out. A related cause was slavery, which long before Marcus Aurelius had been destroying the free population; in his time the plague, and after him foreign and civil wars, continued to waste life, while the burden of taxation, always increasing, made life every day more wretched. The wealth of the empire flowed to the East in exchange for useless luxuries; and for want of gold and silver the coinage was debased; at the same time the cost of living became excessive. Then, too, the growing splendor of the imperial courts added to the burden. With their scant means many found it impossible to support families, and even the slaves grew fewer. In these conditions most of the lower population, free and slave, became hereditary serfs — *coloni* — bound to the soil and to the payment of fixed dues to their lords. But it was not only the poor who suffered. The municipalities had once enjoyed freedom in local affairs, each governed by a senate, whose members — *decuriones* — were the wealthier men of the community. Gradually the emperors encroached upon the liberty of these cities, till they had converted even the privileges of the senators into intolerable burdens. For as these officials were responsible for the taxes due from their districts, many of them, unable to wring the required amount from the poorer classes, were themselves reduced to poverty. Nevertheless they could in no way shirk their duty, but were held for life by an iron hand to the unenviable task of collecting and of paying oppressive taxes. Artisans and traders, too, were bound strictly to their hereditary vocations, in order that the government might be sure of the dues to which they were subject. In brief, society was forced into a rigid caste-like system, which crushed freedom and made the life of rich and poor, bond and free, almost equally wretched. As under these circumstances the population grew unwarlike, the government found it more and more necessary to make up the armies of Germans, who consequently settled in the empire in ever increasing numbers. Although they readily adopted Roman civilization, their independent spirit, out of harmony with the conditions above described, acted as a new disintegrating force. Another power, which while aiming to make the world over on its own model tended to destroy ancient ideas and institutions,— including the empire itself,— was Christianity. Rome, essentially polytheistic, always tolerated the religions of the nations which she conquered; in the adoption of their gods into her pantheon she found a means of political centralization. Judaism, however, she regarded with disfavor, and attempted to suppress Christianity. These exceptions to her policy of toleration were due to the irreconcilable conflict between monotheism and polytheism and to the leveling tendency of the Christian religion. The apostles of Christ taught that the gods of Rome were demons, that the worship of the emperor was sinful, that all men from the emperor to the slave were equal before God, that the heaping up of wealth was an abomination; in brief their religion seemed to the Romans subversive of all the principles on which the empire rested. But although Christianity and Germanism were disintegrating the empire, they were destined in combination to make the old world new. The estimate of their value as creative agencies belongs to the mediæval period.

In appearance more formidable than internal decay were the hostile nations outside the empire. In the 3d century the Germans, who had long been threatening, began to break through the northern frontier. The Franks flung themselves upon Gaul; the Goths occupied Dacia and crossed the Danube, to defeat and kill an emperor. In the East, too, a new danger appeared; on the ruins of the old Seleucid power had arisen the Parthian empire, which in the 3d century was supplanted by a new, vigorous Persian empire. The warlike Persian monarchs nearly made good their threat to drive the Romans from Asia.

Early in the 5th century the Germans began to establish their states within the empire,— the Visigothic kingdom in Gaul and Spain (415 A.D.), that of the Vandals in Africa, and of the Burgundians in the Rhone valley. About the middle of the century the Angles and Saxons began to overrun Britain; a little later the Franks, who long before had crossed the Rhine, began the conquest of Gaul (486 A.D.); and in 493 A.D. the Ostrogoths conquered Italy. Before the end of the century the western branch of the empire had fallen into the hands of Germanic chiefs, who while vaguely recognizing the emperor at Constantinople as their lord were in reality sovereign kings of the countries they ruled. Here ancient history ends; the interaction between Roman and German life under Christian influence is the subject of mediæval history.

Literature.— For the method of history see Bernheim, 'Lehrbuch der historischen Methode' (4th ed., Leipsic 1903); for an elementary sketch, Botsford, 'Ancient History' (New York 1902), a philosophic view may be found in Andrews, 'Brief Institutes of General History' (6th ed., Boston 1900); by far the best detailed work is Meyer, 'Geschichte des Altertums' (I.–V., reaching to the middle of the 4th century B.C., Stuttgart and Berlin 1884–1902); for a satisfactory treatment of the period following this date it is necessary to depend on the histories of special countries and periods, for example, Holm, 'History of Greece' (III., IV., translated from the German, New York 1896–8); Mommsen, 'History of Rome' (translated from the German, 5 vols., conformed to the 8th ed., New York 1895); 'Provinces of the Roman Empire,' 2 vols. (New York 1886); Duruy, 'History of Rome' (8 vols., Boston), valuable for the imperial period; cf. also Duncker, 'Geschichte des Altertums' (3d–6th ed., 9 vols., Leipsic 1874–86); 6 vols. translated by Abbott (London 1877–86); Oncken, 'Allgemeine Geschichte in Einzeldarstellungen,' by various authors (Berlin 1878–90); Helmholt, 'History of the World' (Vols. I.–IV., New York 1902); Philippson, 'Das Mittelmeergebiet: seine geographische und kulturelle Eigenart' (Leipsic 1904), valuable for physical environment; Cunningham, 'Western Civilization in its Economic Aspects' (Cambridge 1898); Webster, 'General History of Commerce' (Boston 1903); Perrot et Chipiez, 'Histoire de l'Art dans l'Antiquité' (8 vols., Paris 1882–1903); for general tendencies, Freeman, 'Chief Periods of European History' (New York 1886); especially fresh and suggestive are the articles by E. Meyer, Diels, Wilamowitz-Möllendorff, Soltau, and Hirschfeld in the 'Historians' History of the World,' III.–VI. (New York and London 1904); the best encyclopedias for Greece and Rome, containing much information also regarding the Orient, are Daremberg et Saglio, 'Dictionnaire des Antiquités grecques et Romaines' (3 vols. ready, Paris 1873–1904); Pauly-Wissowa, 'Real-Encyclopädie der cl. Altertumswissenschaft' (4 vols. ready, Stuttgart 1894–1901); the best periodical is 'Beiträge zur alten Geschichte,' edited by Lehmann (Leipsic 1901—); for bibliography past and current, 'Jahresbericht über die Fortschritte der cl. Altertumswissenschaft,' including 'Bibliotheca philol. cl.,' edited by Bursian (Berlin); for bibliographies of special countries see the articles on Egypt, Chaldea, Babylonia, Assyria, Greece, and Rome.

George Willis Botsford,
Adjunct Professor of Ancient History, Columbia University.

History, Mediæval. *Definition.*— Mediæval history may be most easily defined as the middle period between ancient and modern history. Some scholars have wished to do away with the term entirely, and to use only two divisions, ancient and modern. In fact, in Oriental history there is no mediæval period. But most students prefer to keep to the threefold division for European history. This is due largely to the fact that the mediæval period can be presented with greater unity than either ancient or modern.

Mediæval history began with the disintegration of the Roman Empire in the 5th century, the ruin of paganism, and the migrations. Without arguing the merits of the various dates which may be assigned for the end of the Middle Ages (q.v.), we shall here discuss the history to about 1500 A.D. During this period of one thousand years, the most marked characteristic is the dominant influence of the Church. The most important peoples are the Germanic races, who emerged slowly from barbarism, and gradually assimilated some of the features of the Roman civilization. Based upon the ruins of the older rose a new civilization, which caused a radical transformation in political, social, and religious ideals.

Contrast Between Romans and Germans.— The Romans had a highly developed and very complex civilization. From their Greek subjects, they had acquired the knowledge of art, literature, science, and philosophy. Under the Roman peace, an active commerce had grown up throughout the empire, supplying to each province the products of all of the others. In law and administration the Romans had reached such excellence that we still imitate them. Moreover, Christianity had become the state religion.

The Germans were barbarians, having the virtues and vices of their savage state, and resembling, in many respects, the North American Indians. But they were a vigorous race, with a great capacity for learning. Some of them had been converted to Christianity before they entered the Roman Empire, but most of them were still pagans.

Migrations.— The Roman Empire had for centuries held the barbarians in check, by the prestige of its name, by the payment of tribute, or by the policy of exciting dissension among its enemies. This last is well summed up in the Roman proverb, *Divide et impera*, which may be paraphrased, "Cause divisions and strife among those whom you fear and thus rule over them." In the latter part of the 4th century, however, the terrors inspired by the advance of the Huns (q.v.) into Europe, the knowledge of the weakness of the Roman Empire, and their own desire for more fertile lands, caused the Visigoths (q.v.) to enter upon their great migration. Their example was followed by other German tribes, and the movement continued throughout the 5th and 6th centuries. By the year 600, all the European portion of the Western Empire, except a few positions in Italy, was held by the Germans.

During the period of the migrations, there was a great destruction of life and property. But the conquered inhabitants were neither exterminated nor driven out. The German invaders were relatively few in number, and, in many sections, they found unoccupied lands sufficient for their needs. The conquerors and the conquered lived in constant contact with one another, and the resultant civilization was partly Roman and partly German. See MIGRATIONS.

Fusion of the Two Civilizations.— The 7th and 8th centuries were the period of fusion. By the year 800, the terms *Roman* and *Barbarian* were no longer used. The inhabitants formed a single people, with a civilization much lower than the Roman but much higher than that of the Germans when the latter had entered the Empire. In this new composite civilization, the Roman influence was greater in language, mechanical arts, business arrangements, and municipal, intellectual, and ecclesiastical affairs. The German influence was greater in military matters and judicial procedure

The fusion was practically completed by the time of Charles the Great. He realized clearly the task of the Middle Ages, and did all in his power, on the one hand to retain all that was best of the older German customs, and, on the other hand, to introduce from Italy such Roman customs as his subjects were able to adopt. He did much to foster education, which followed Roman models. By his wars, he brought under his sword all of the German peoples.

The New Empire.— In 800, Charles's services received fitting recognition in his election as emperor of the Roman Empire. The idea of a Roman empire which embraced all Christians had never been lost. After 476, when Romulus Augustulus was deposed by Odoacer, the people in the West, Germans and Romans alike, had regarded the emperor at Constantinople as the head of the Christian world. Even barbarians like Clovis (q.v.) had been proud to secure recognition and obtain a title from the emperor. The popes had looked to the emperors for support. In the last years of the 8th century, the East was ruled over by Irene (q.v.), who was both despised because she was a woman and for her crimes and heresy, so that it seemed to many that the imperial office was vacant. Consequently, Charles was crowned emperor and was considered the successor of Augustus, Trajan, and Constantine (qq.v.). Under his strong rule, the Western world was governed firmly, and the western nations were held together.

Disintegration of the Empire.— After Charles's death, his son was unequal to the task of ruling the empire. Under the combined effects of civil strife and constant invasions by the Northmen, the Mohammedans, and the Slavs (qq.v.), the central power was weakened, and the last Carolingian rulers were unable to protect their subjects. The whole frontier was exposed to attacks and the raids of the enemy even extended far into the interior. In each district the strongest man came to be regarded as the natural leader and protector. Sometimes it was a royal official, holding a fortification; sometimes it was an abbot or a bishop; at other times, a bold adventurer, who usurped authority. In the absence of a strong central government, each leader had to police his land and administer justice. Naturally, he demanded to be paid for his services, and exacted tribute from all under his control.

Because of the lack of money, the Carolingians (see CARLOVINGIANS) had always furnished to their counts and other official estates from which they obtained their living. Under the weak kings, the temporary grants of both land and office became hereditary, with or without the rulers' consent. The rulers, however, soon recognized the necessity of allowing this, and sought merely the recognition of their own overlordship and ultimate ownership of the lands. Consequently, they granted the benefices to the heirs and conferred, in addition, the immunity, or right of independent jurisdiction. Thus almost all land and power came to be held feudally. See FEUDALISM.

Feudal Anarchy.— There was constant warfare as each strong lord sought to obtain greater power or a more independent position. On the other hand, each king or suzerain tried to increase his own feudal holdings by conquest or marriage. Every vassal was anxious to avoid all the feudal services that he could, and, at the same time, to exact as much as possible from the people subject to him. Commerce was burdened with excessive tolls in each fief and exposed to the depredations of the robber barons. Little attention was paid to maintaining roads and bridges, consequently travel was difficult as well as dangerous. As a whole, the feudal régime tended to isolate each fief and to reduce the peasantry to misery. It is significant that the term "Dark Ages," formerly applied to the whole of the Middle Ages, is often used now for the 9th and 10th centuries.

The Church.— The great cohesive and educating force was the Church. Soon after they entered the Roman Empire, each tribe of Germans had been converted to Christianity. In every barbarian kingdom the bishops were important officials. They often obtained great wealth, and ruled over vast estates. On their possessions, the serfs were treated somewhat better than on the lay fiefs. Monasteries had been founded throughout Western Europe, and often these served both as schools and as model farms. Boniface did much to bring the tribes of Germany into direct connection with Rome, and he held frequent church councils at which the clergy and nobles of a whole district came together. These councils were very important for their effect in unifying the Church and making its work more effective.

From this time the Church gained steadily in power and influence. Charles the Great did much to increase its wealth by enforcing the payment of tithes. He insisted that the clergy should be better educated themselves and should do more for the education of the people. In the 9th century the growing power of the papacy and the weakness of the kings enabled the popes to bring the bishops more directly under their own control. Thus the clergy of Western Christendom were brought into intimate association with Rome. Latin was the common language of all churchmen. Their feeling of membership in the Church was frequently stronger than any local attachment. Consequently the more able men were equally at home in every country and the Church had a greater unity than any lay power. This all-pervasive Church was the great unifying element amid the divisions of the feudal period.

Investiture Struggle.— After periods of weakness in the first half of the 10th and again in the first half of the 11th century, the Church at Rome was purified and strengthened by the support of the German emperors. About the middle of the 11th century, the strong personalities of Pope Leo IX. (q.v.) and of Hildebrand (later Gregory VII.) (q.v.) led to a great reform movement, and also to an effort to make the pope's power more effective. One feature of this movement was an attempt to secure entire control of appointment to church offices. This brought the papacy into conflict with the kings who considered that they had a right to nominate the bishops in their own kingdoms. The struggle was most acute between the German emperors and the popes, and resulted in the long investiture conflict, which was ended in 1122 by a compromise. See INVESTITURE.

Roman Empire of the German Nation.— But the investiture struggle was only a single phase in the relations between the empire and the papacy (q.v.). In order to understand this it is necessary to study the fortunes of the empire after Charles the Great. Under his successors, the emperors had gradually lost their power, so that by the end of the 9th century, the title of *emperor* had become almost a meaningless designation, either conferred by a pope on anyone of whom he wished to make use, or else usurped by any ruler who chanced to be temporarily the strongest personality in Italian affairs. This continued to be the fate of the imperial title until Otto the Great (q.v.) was summoned to Italy, because of the discord reigning among the various Italian nobles. In 963 he was crowned emperor, and became the ruler of both Germany and Italy. Under his son and grandson, Otto II. and Otto III., "the Roman Empire of the German nation" was a very effective power in controlling both the imperial lands and the papal policy. After the death of Otto III. in 1002, the German rulers paid little attention to Italian affairs until 1046, when Henry III. was summoned to Rome because of the contest which was being waged between three rivals for the papal office. For 10 years he wielded a power similar to that of the Ottos. But at his death, as the heir was a young child, the reformed and strengthened papacy was able to assert its independence. When Henry reached manhood and desired to regain his father's power, the contest began and took the shape of the already mentioned investiture struggle. After the Concordat of Worms (q.v.) there was a truce which was broken by the accession of Frederick Barbarossa (q.v.), who was determined to be emperor in fact as well as in name.

Empire and Papacy.— On the other hand, the papacy was strong and was determined to assert its paramount authority. There ensued a struggle of one hundred years between the Hohenstaufen emperors and the popes. In spite of the ability of the rulers and the brilliancy of their reigns, the popes triumphed, largely by means of the assistance of the Lombard cities, which had grown rich and powerful and claimed to be independent of the imperial control. The death of Frederick II. in 1250 really marks the end of the mediæval empire, as a strong international power, although it continued, under a changed form, to be a factor in European politics for centuries longer, and came to a close only in the 19th century.

The Crusades.— The increasing power of the popes was also marked by their desire to extend their authority over the Eastern Church as well as the Western. This was in part the cause of the crusades, which were the most important manifestation of the strength and influence of the Church. The spirit of asceticism (q.v.) had long been inculcated as the most distinguishing mark of Christianity. The consciousness of their own sins and the teachings of the Church led many to do penance. One of the favorite forms, especially for heinous crimes, was a pilgrimage to some hallowed spot. The most difficult pilgrimage and the one to which greatest sanctity attached was the journey to Jerusalem. In the 11th century, one hundred and sixteen separate pilgrimages to Jerusalem are recorded, and, in some of these expeditions, hundreds and even thousands took part. Thus attention was directed to the Holy

Land. Moreover, in spite of the disorders of the feudal régime, the population was increasing, especially in France. The people were hard-pressed to get food, and were anxious for a change of any kind. Consequently, when the Emperor Alexius appealed for aid and Pope Urban II. preached the crusade at Clermont thousands took the cross. The movement spread rapidly and affected every country in Europe. Although Jerusalem was in the possession of the Christians for little more than a century, the crusades to the Holy Land, which continued for 200 years, produced great results. In order to understand these, it is necessary now to take up the Byzantine and Muslim civilizations. See CRUSADES.

Byzantine Civilization. — Until a half-century ago, the Byzantine history was misunderstood. It was looked upon as the long death struggle of a society in which all progress had ceased, and despotism, tempered by assassination, crushed out all vitality. Gibbon styled the history «a tedious and uniform tale of weakness and misery.» It is known now that this was unjust. The most striking fact about the Byzantine Empire is its «constant vitality and power of recuperation.» It was threatened by invaders, but it repelled them all. At times it lost some of its most fertile provinces, but at other periods it would rise triumphantly and recover its lost possessions. Throughout the period between 700 and 1100, Constantinople was the bulwark of Europe, against which the waves of invasions rolled in vain. In addition to being a bulwark, Constantinople was, throughout the Middle Ages, the great storehouse of the Greek and Roman civilizations, where it was preserved until the European nations were sufficiently advanced to profit by it. Constantinople (q.v.) was also the most important commercial centre of the Middle Ages. The city was marvelously wealthy and excited the admiration of every traveler. Most of the crusaders passed through Constantinople and the Greek lands on their way to Jerusalem; by them the influence of its civilization was widely spread throughout the West. See BYZANTINE EMPIRE.

Muslim Civilization. — No less important was the influence of the Mohammedans. After the death of the prophet in 632, his followers had conquered with wonderful rapidity the greater part of the civilized world. From Persia and India they held all Asia to the Hellespont. Egypt and the whole north coast of Africa, Spain, and about one third of Gaul, were under their sway within a century. Their advance in civilization was equally rapid. The Arabs had wonderful acquisitive ability and were taking almost the first step in their education. In each country they learned the arts and sciences known by the inhabitants, and they carried this knowledge wherever they ruled. The Greek philosophy, which they acquired from the peoples in the lands formerly under Greek sway, the mathematical knowledge of India, the irrigation practised in Egypt, are illustrations of their acquisitions, which enabled them in the 10th and 11th centuries, to develop a civilization far in advance of any other, with the exception of the Byzantine. From Bagdad to Spain this culture was spread throughout the Mussulman world. In Syria, the crusaders were in contact with this civilization for two centuries. By their agency and by the association of Christians and Mussulmans in Spain, Sicily, and other points, much of the Muslim learning was conveyed to the Christians of Western Europe.

Changes in the 12th and 13th Centuries. Enrichment of Europe. — In addition to this fructifying intercourse with other civilizations, many elements in their own contributed to cause a rapid advance in the 12th and 13th centuries. Among these may be noted the increase in population, the cultivation of waste lands, the revival of commerce, the general progress along educational lines, and the rise of strong kingdoms. But as it is impossible to isolate each factor and to determine the part which it played, the results will be considered as a whole and the changes which took place in Western Europe after 1100 will be described.

The hundreds of thousands of crusaders had to procure large sums of money for their equipment and journey. Consequently the precious metals which had been hoarded came into circulation as money. Instruments of credit were devised and the money circulated rapidly. Contact with other civilizations gave birth to new tastes and these were gratified by means of a greatly increased commerce which extended to all parts of Europe and even to the extreme East. The merchants became numerous and prospered. Cities increased rapidly in population and new ones were founded. The Italian cities, because of their position, prospered the most of all. The merchants became an important class because of their wealth, and by the end of the 13th century became a political factor which was recognized by their inclusion in the new parliamentary bodies.

Intellectual Advance.—The investiture struggle had caused scholars to study history in order to find precedents in support of the imperial or the papal claims. The contact with other peoples broadened the intellectual horizon of the Western people. The new points of view with which they became acquainted led them to question the traditions which had ruled their lives. The new books, especially the works of Aristotle (q.v.), which fell into their hands, were studied eagerly. The new wealth gave leisure. Students flocked to the centres where teachers were to be found, and gradually universities arose. Roman law was fostered by the emperors; canon law, by the Church. Scientific knowledge, especially in medicine, was acquired from the Greek and the Arabic works. Gothic cathedrals of exquisite beauty were built in western Europe. The deeds of the crusaders furnished new material to literature. The old tales were re-worked and given a literary form.

Growth of Monastic Orders. Temporal Power of the Popes.—No less marked were the changes in the Church. At the close of the 11th century a great wave of asceticism spread over western Europe. The idea of sacrifice caused thousands to enter monasteries, and many new orders of monks were founded. These orders vied with one another in austerity and asceticism. Their reputation for sanctity and their services to the community brought to them great donations from the pious. Their knowledge enabled them to increase their wealth. But this wealth led many to enter the monasteries from unworthy motives, and thus caused a gradual decline in their lofty morals. The wealth of the Church, as a whole, caused many, both monks and laymen, to attack it as having departed from its Christian ideals. Heretics became numerous and had to be repressed by persecutions and the inquisition. In the 13th century the mendicant orders became prominent, partly as a protest against the wealth of the Church, and partly as an agency to combat heresy. The ideal of service to others for which they stood became dominant in monasticism, and later orders were founded, almost universally, for some special service. See MONACHISM; ORDERS, RELIGIOUS.

The papacy, engaged in a struggle with the monarchs, felt the need of temporal power and strove for it. Innocent III. had monarchs as his vassals, and wielded a temporal authority greater than that of any previous pope. After the popes had triumphed over the Hohenstaufens they seemed to have achieved success. Their struggle with the French king, at the beginning of the 14th century, however, led to defeat and to the "Babylonian captivity" at Avignon. Then ensued the schism and the conciliar period when many felt that the general councils and not the popes should be supreme. Finally the papacy emerged triumphant, but with a changed ideal, laying less stress upon temporal power (q.v.) than upon control over the conscience of the individual.

Chivalry. Decadence of the Knights.—In the 12th century, the clergy and the knights formed the aristocracy. The latter, too, had their period of great splendor. The ideals of chivalry, which became prominent in the 12th century, were inculcated by the Church, and the knights were often likened to the clergy as a class specially set apart by their religious vows. These ideals were also inculcated by the new literature, which glorified not only bravery and loyalty, but also generosity and luxury. The latter led to the ruin of many of the knights. Their income, arising from feudal dues, was relatively fixed. As their tastes expanded and they expended more upon luxuries, they fell into debt. The rate of interest was ruinous and they were unable to pay. Consequently many were compelled to alienate their fiefs, the monarchs and other lords of large fiefs absorbed the lesser fiefs, and there was a tendency for the knights to become retainers of the more wealthy. Their consequence as a class declined in comparison with the growing importance of the merchants. The development of strong infantry forces finally deprived them of their pre-eminence in military matters. See CHIVALRY.

Rise of the Nations.—The contact with other peoples led to the rise of a national consciousness. In the earlier days, when each feudal castle or village was practically isolated and often at strife with its neighbors, there had been little feeling of common interests. Association with foreigners brought a sense of national feeling in opposition to the foreigners. This is very marked in the armies of the second and third crusades. This movement was coincident with, and one cause of, the growth of the strong monarchies. The merchant class was also an important element in the development of the king's powers. Commerce was heavily burdened with feudal tolls and exposed to depredations by the knights. The merchants sought privileges and protection from the kings. In return they furnished them money, which aided them in extending their power at the expense of that of their nobles. The kings came to depend largely upon the cities for support in all struggles with the nobles. By their wealth the citizens were able to rival the nobles in luxury and ostentation. The sons of the merchants frequented the universities and developed into officials of the kings. More and more the kings came to depend upon the third estate and to withdraw power from the nobles.

The French Monarchy.—The development of the monarchical power took different forms in the several countries, but took place about the same time in the leading nations. In France, the Capetian kings (see CAPET) had at first little power. They had only a small territory directly under their control, and consequently only a small income. But by fortunate marriages and by confiscations they enlarged their feudal domains. Several of the kings had long reigns and the evils of a minority or a change of dynasty were avoided. Gradually all the fiefs were brought under the control of the king, and feudal usages were made the basis for the assertion of a really monarchical power. Under Saint Louis (1226–1270) and his successors France was centralized and the kings became supreme. The prosperity of France was checked for a time by the Hundred Years' war (1328–1461). This was due in part to a failure of male heirs in the direct line, which enabled the English kings to make a claim to the throne on the ground that they were the most direct heirs. But France finally emerged triumphant and England lost all her territory in France. The kings, supported by the third estate, became practically absolute.

The English Monarchy.—In England the Norman Conquest (q.v.) made William supreme lord. Following the Norman feudal usages, he insisted upon an oath from each one of his subjects, and did not allow the intervention of the feudal nobles. In spite of the civil wars of the 12th century, Henry II. was able to retain the supreme control. The tyranny and incompetence of John led to a revolt on the part of the barons and the extortion from him of the Great Charter. (See ENGLAND — *Civil History.*) The efforts of the kings to evade the provisions of the charter caused the union of the nobles and third estate, the distinctive feature of the English constitution as contrasted with that of France or of Germany. The loss of its continental possessions really strengthened England and enabled it to develop a strong government in its own island.

The German Monarchy.—Germany was a kingdom made up of great duchies. The king was strong only when he had all these duchies under his immediate control. The imperial title which he held was usually a source of weakness, because of the necessity of maintaining his authority outside of Germany. Those kings who neglected the imperial interests in Italy and Burgundy were strongest at home. Frederick Barbarossa, Henry VI., and Frederick II. (qq.v.), who attempted to build up strong empires, were compelled, as the price of support from their German subjects, to make constant concessions. Thus they bartered away most of their German lands and royal rights. The towns and cities, in particular, acquired privileges and practical independence in payment for their support in men and money. On the extinction of the Hohenstaufen house, Germany was divided up into many separate entities, varying in size from a duchy to a village or to a knight's fee, all claiming independence of all control except the imperial. The weak emperors of the 14th and 15th centuries were unable to maintain any effective control or order. Each emperor was intent only upon retaining his position and securing such property for his family as he could. Consequently Germany became a prey to internal dissension and division.

The Other Monarchies.—The other countries were more backward. In Spain, the Christian kings were engaged in conquering Muslim territory or else in warring with one another. These movements were going on for several centuries, and culminated just at the close of the Middle Ages. In 1492, the Moors were conquered in Granada, their last stronghold. The two most powerful kingdoms, Castile and Leon, had already been united, and 20 years later the Spanish portion of Navarre was added. In Scandinavia powerful monarchies were growing up. In the eastern portions of Europe new Christian kingdoms had arisen, especially Russia and Hungary, which were destined to play an important role in the later centuries.

The Period of the Renaissance: Discoveries.—The last period of the Middle Ages is often spoken of as the Age of the Renaissance (q.v.). The name is to a certain extent a misnomer. But it is sanctioned by general usage, and there are certain factors that may be brought together, which serve to mark the transition from the mediæval to the modern world.

The travel and commerce of the 12th and 13th centuries caused an interest in foreign lands which never abated. In particular, the taste for spices, which had become common, led to attempts to secure these more easily and more cheaply. After the loss of the Christian possessions in Syria, the importation of spices into Europe was burdened with heavy tolls by the Muslim rulers through whose territories they had to be carried. To the men of the 15th century there seemed to be two possible routes by sea to the spice islands, one by sailing around Africa, the other by sailing directly west to India. Attempting the latter led to the discovery of America; attempting the former, to the doubling of the Cape of Good Hope. The result of these discoveries was to make the nations on the ocean the leaders in commerce. The Mediterranean ceased to be the centre of the world's commerce and the Italian cities lost their pre-eminence as commercial centres.

Inventions: Compass, Printing-press, Gunpowder.—This exploration was possible only by the use of the compass (q.v.). This had been known in the West by the 12th century; in the East, centuries earlier. But it was perfected as a real aid to navigation only in the 14th century. About the middle of the 15th century came an even more important invention, that of printing (q.v.). This resulted at once in increasing enormously the number of books in existence and in cheapening their cost to one fifth or less, so that books were readily accessible to a much larger number than before. At about the same time the manufacture of gunpowder was being perfected. Compositions similar to gunpowder (q.v.) had long been known in the East, and the knowledge of the composition of "Greek fire" had been brought to the West. But it came into general use only in the 15th century, and the guns long after that were held by many to be inferior to the cross-bow. But gunpowder, before 1500, was revolutionizing the art of war and rendering the mediæval knight obsolete.

Classical Literature and Pagan Spirit.—Contemporary with these discoveries and inventions was the awakening of an interest in classical literature. In the 12th century there has been at some centres an eager study of the Latin classics, but, in the 13th, this had been superseded to a great extent by the branches considered more practical, especially law, mathematics, and science. In the 14th and 15th centuries men turned again to the classics, and Greek, which had long been neglected, became a favorite study. Along with the study of the pagan authors developed a new feeling for art, which resulted in the wonderfully natural works of the Renaissance artists. Other sides of this new activity were manifested in the more scholarly spirit of criticism and in scientific study. In fact, with the period of the Renaissance modern history had dawned.

Bibliography.—Lavisse et Rambaud, 'Histoire Générale du IVe siècle à nos jours' (Paris 1893 ff.; the first three volumes form the best general history of the Middle Ages); Gibbon, 'Decline and Fall of the Roman Empire' (edited by Bury, 7 volumes, London and New York 1896–1900); Milman, 'History of Latin Christianity' (9 volumes, 1867; a general favorite). Of the many Church histories, two may be mentioned: Alzog, 'Manual of Universal Church History' (3 volumes; a scholarly treatise from a Roman Catholic standpoint); Schaff, 'History of the Christian Church' (4 volumes, to Gregory VII.; voluminous, scholarly, from a Protestant standpoint). Three volumes in the 'Periods of European History'; Oman, 'Dark Ages'; Tout, 'Empire and Papacy'; Lodge, 'Close of the Middle Ages' (New York 1893–1901), furnish a detailed, but somewhat uninteresting, summary of the political history. Hodgkin, 'Italy and Her Invaders' (8 vols.), and Bury, 'Later Roman Empire' (2 vols.), are the best guides for the periods before 800. Bryce, 'Holy Roman Empire' (new ed. 1904; wonderfully compact and useful); Symonds, 'Renaissance in Italy' (7 vols.); Burckhardt, 'Civilization of the Italian Renaissance'; Voigt, 'Wiederbelebung des classischen Alterthums' (2 vols., 3d edition); these works are to be commended for the period of the Renaissance. For special subjects: Montalembert, 'Monks of the West' (6 vols.); Lea, 'History of the Inquisition' (3 vols.; the masterpiece of a great historian); Oman, 'History of the Art of War' (Vol. II.), for military matters; Heyd, 'Geschichte des Levantehandels im Mittelalter' (2 vols.), very important for the commerce; Levasseur, 'Histoire des classes ouvrières avant 1789' (2 vols.), admirable for economic conditions; Gregorovius, 'Rome in the Middle Ages' (8 vols.), very scholarly and interesting; Rashdall, 'History of the Universities of Europe in the Middle Ages' (2 vols.), the best treatise on the subject; Saintsbury, 'Flourishing of Romance,' the best brief account of the literature in the 12th and 13th centuries; Munro,

'Syllabus of Mediæval History' (3d ed., 1903), contains references by topics to about 250 works, mainly in English.

Professor of History, University of Wisconsin.

History, Modern.—*General Characteristics.*—When History is divided merely into Ancient and Modern, the term Modern applies to history subsequent to the 4th century A.D. The *Americana,* however, keeps to the more usual triple division into Ancient, Mediæval, and Modern; and with this classification Modern History begins about the year 1500.

At that date, as for several centuries preceding it, the scene of human progress was confined to Western Europe, and the actors were the Latin and Teutonic peoples. Nations, in the proper sense, were not made; and the political map bore faint resemblance to that of to-day. There was one Latin Christendom, binding in feeble union the several geographic units. But most of the units themselves were broken into fragments under local rulers; and these fragments, sometimes of widely separated lands, were recombined, with kaleidoscopic confusion, in loose, shifting aggregates which possessed not even permanent names. Out of this feudal chaos, strong monarchies were just emerging, to organize states, in France, England, and Spain; but there was hardly a prophecy of a Germany or an Italy. Except for Poland with its Latin church and borrowed German culture, Eastern Europe was outside the pale of civilization. The barbarous northern Slavs seemed doomed to Tartar domination, and the somewhat less barbarous southern Slavs with the neighboring Magyars were enslaved by the Turk. From the devouring victorious march of the Turk even Central Europe was in imminent peril.

This dismal political picture had its counterpart in social and economic conditions. Society was hopelessly aristocratic and predominantly militant, and it was crystallized in strata. The skilled industry of the towns was managed upon the guild system; and agricultural labor, except in England and some other small districts, was carried on by serfs.

But Europe had been astir with dim impulses to change for four hundred years,— ever since the Crusades broke the torpor of the Dark Ages and prepared the way for the rise of towns and the Renaissance. Near the close of the 15th century the tendency to progress became more pronounced, and the lines of activity more varied. Louis XI. in France, the Tudors in England, Ferdinand and Isabella in Spain, prepared the way for new consolidated political societies, and for new principles of government; the invention of printing made possible the preservation and utilization of the recently rediscovered Greek learning and the rapid dissemination of new ideas; the discoveries of Columbus and Vasco da Gama set free undreamed-of energies among the lands of the Atlantic seaboard, and summoned commercial Europe to a right-about from east to west; the adoption of gunpowder in the wars between Francis I. and Charles V. marked the passing of the military superiority of the knight in armor, and undermined the citadel of aristocracy in politics; the opening of the Protestant Reformation (1520) shattered the old unity of Christendom, and, together with the Catholic Counter-Reformation called out new energies in the fields of morals and intellect. Within two generations, the one just before and the one just after the year 1500, there stood revealed not merely a new physical hemisphere and new continents in the old one, but also a new universe of thought and feeling. Europe had passed into a new age.

The four centuries of Modern History have been a period of constant, marvelous, increasingly rapid transformation,— intellectual, political, industrial. The stage itself has widened from a corner of the smallest continent into wellnigh the whole surface of the globe. The actors have multiplied, until they promise in the near future to include all branches of the human race. The drama has become infinitely complex, with the interaction of countless streams of influence. As compared with Ancient or Mediæval History, Modern History deals with a brief time, but with vast spaces, complex relations, and accelerated progress. The separate movements that make up the bewildering maze are discussed severally in some detail, under appropriate headings, in the *Americana.* This article attempts only to marshal them in such order as to bring out the essential relations between them.

It is convenient to divide the four centuries of Modern History into the *age of monarchic states* and the *age of nation-states.* The American and French Revolutions make the transition from one to the other, and the most satisfactory dividing date is 1789.

From the Reformation to the French Revolution.—*Monarchic States.*—The constant warfare of the 16th, 17th, and 18th centuries is the simplest thread by which to connect the other movements of the age. Speaking broadly, the contests of the first half of the period, to 1648, are "religious wars," Catholic against Protestant, while after 1648 the struggles grow out of dynastic and commercial rivalries.

The declaration of the war which split Christendom into opposing camps for over a century came in 1520, when Luther burned the Pope's bull. The Diet of Worms at once pronounced against the rash monk the ban of the Empire; and the decree would have been enforced, and Protestantism stifled at its birth, if the young Emperor, Charles V., had had a free hand. But Charles had just become involved in strife with Francis I., over the claims of Spain and France in Italy, and he was kept busy with war against France and the Turks until 1544. For a generation, therefore, the new faith was left to spread itself unchecked over Germany and Scandinavia, while during the same period the English church cut itself off from Rome, and Presbyterian heresy made headway in France and Switzerland. For a time, indeed, Protestantism threatened to conquer even the south of Europe; but the Catholic Counter-Reformation, with equal zeal and superior skill, finally saved the Romance lands to the old faith.

Religious Wars, 1546–1648.—Meanwhile, entangled in his strife for European sovereignty, Charles could not strike at Protestants in Germany until 1546. It was then too late. In 1555, after brief struggles, the princes of the Schmalkald League forced upon him the Peace of Augsburg; and, though troubled with incessant bickerings, Germany had no further civil war for sixty years. Just that period, however, was filled with terrible religious contests in the Netherlands and France; and then the age of religious wars closed with another civil war in Germany,— the most destructive in European history. The century of strife from the opening of the Schmalkald War to the close of the Thirty Years' War (1546–1648) did not materially alter religious frontiers. Catholicism, to be sure, made some conquests with the sword, — Bohemia, South Germany, and the southern Netherlands,— but in most of these districts, as in the Latin countries of Southern Europe, the Counter-Reformation was making rapid gains before war began.

The close of the period of religious war is marked by the decay of Spain, the continued disruption of the Holy Roman Empire, and the rise of France and of the Dutch Republic. To explain these changes it is needful to dwell somewhat further upon the wars.

In 1556–7, after his failure in Germany, Charles V. resigned his crowns,— the Austrian possessions passing to his brother, and the Spanish to his son, Philip II. Despite the division, Philip was far the most powerful monarch in the world. Each year the "gold fleet" filled his coffers from the exhaustless wealth of the Americas, and in 1580 Portugal with her East India empire fell into his hands. This was the power,— supreme in Europe and sole mistress of the New Worlds east and west,— against which the petty, disunited Netherland provinces dared to rebel. Beginning as a political revolt in 1568, the struggle soon became a religious war; and it was waged for more than forty years with a relentless fury which made it a byword for ferocity even in that brutal age. The ten southern provinces finally returned to Spanish allegiance; but the northern provinces,— Dutch in blood and Protestant in religion,— fought on with desperate courage until they won independence. At the same time they preserved political and religious liberty for the world. Midway in the struggle, Elizabeth of England sent some tardy aid. Philip then turned upon England; but the destruction of his "Invincible Armada" in the splendid sea-fight in the Channel not only saved England at home but also paved the way for the English colonization of North America. The war closed in 1609. Spain had sunk into a second-rate power, never again to play an important part in European politics; but the United Provinces, through the stage of the desolating war, had grown prosperous. They drew wealth, not from the wasted land, but from the sea, plundering the new possessions of Spain in the East Indies and building there a colonial empire for themselves. For most of the century, in intellectual, commercial, and industrial activities, the Dutch held the first place in Europe.

In France the Edict of Nantes (1598) closed the wars of religion by guaranteeing toleration and handing over certain garrisoned towns to the Huguenots as security. During the next half century, under the wise administration of Henry IV. and then of Richelieu, the industry of the people restored prosperity with marvelous rapidity. Richelieu crushed the feudal nobles and recaptured from the Huguenots their garrisoned towns. In other respects, however, he kept toward the Protestants the pledges of the Edict of Nantes; and as he warred upon the Protestants within France in order to strengthen the royal power, so he aided the Protestants of Germany in the Thirty Years' War in order to make France supreme in Europe. France had long been in real peril from the Hapsburg powers of Spain and Austria, which ringed her about in hostile embrace; but the failure of Spain against Holland and Richelieu's policy of weakening Austria in the German war removed the peril, and, as Spain declined from the first place in Europe, France stepped into it.

Meantime the Thirty Years' War (1618–48) was desolating Central Europe. The princes of North Germany proved timid and incapable; and the cause of Protestantism was saved only by foreign intervention, by Denmark, by Sweden, and finally by Catholic France. At the close of the struggle, the first European Congress reorganized Europe. By the Peace of Westphalia, France received most of Alsace and some other Rhine districts. The independence of Switzerland and of the United Provinces was formally recognized. Sweden, already reaching down both west and east shores of the Baltic, secured much of the south shore also, with command of the mouths of the German Oder, Elbe, and Weser. On the other hand, the Empire lost more than territory. The political rearrangements within that state reduced the imperial Diet to the level of a useless debating society and put an end to whatever had persisted of national unity. From this time until it vanished, a century and a half later, the Holy Roman Empire was a meaningless survival, cumbering the earth, and the Hapsburg "Emperors" derived their only real importance from their position as hereditary archdukes of Austria. To most of Germany the war had brought blasting ruin. Half the population and two thirds the movable property were swept away. Land tilled for centuries became waste, and men became savages. Not till the middle of the nineteenth century did large districts again contain as many homesteads and cattle as in 1618; while the low position of the German peasantry, until 1850, was due in great measure to this war.

American Colonization.—Before the religious wars closed, the continent of Europe had ceased to be the sole scene of important historical development. American colonization was well advanced, and political liberty had received a remarkable development both in England and in English colonies. These topics demand attention before the student enters upon the consideration of the next period of European wars.

Spain made her first settlement upon the American continent at the Pearl Coast in 1513. Then sweeping to north and south, she took swift possession of all South America except Brazil, all Central America, and of the Floridas and Californias, far up both coasts of North America, while plans were afoot to plant her flag over the rest of that continent. But the ruin of the Armada, together with Spain's decay at home, came in time to leave room for other colonization. France seized upon the mouths of the Mississippi and the St. Lawrence, the apparent gateways to the continent; and English colonies stretched themselves in patches along the fringe of the North Atlantic coast. The Dutch spent their colonizing energies mainly in the Orient; and, despite some ambitious beginnings, Sweden soon grew too weak to be a serious factor in North America. Thus that continent was left in dispute between Spain, France, and England. The contest was to be interwoven with the European wars of the last half of the seventeenth century and of the eighteenth century, and the outcome was big with consequence to the world. All European countries except England governed their colonies on despotic plans. The English colonists took to the New World institutions and principles of freedom, and soon gave them a wider development there than had been possible even in the old home. Besides the rights of free speech and jury trial and *habeas corpus*, each English colony had from the first, or very quickly inaugurated, a representative legislature with full parliamentary privileges and with control over taxation. In several colonies, local government also was conducted on extreme democratic principles. Not until two hundred years later did any of these free principles appear in the colonies of any other people,— and then only because of the success of the English colonies.

England in the Seventeenth Century.— In England itself the seventeenth century saw an important development in free government. Through the Stuart period, from 1603 to 1688, England was engaged in a critical struggle between the royal claims of "Divine Right" government and the rising spirit of popular government. Except for brief intervals the conflict was parliamentary, not military, but it was constant and stubborn. Much of the time it was confused with ecclesiastical questions, which, to the men of the time, often seemed the chief issue; and it was fortunate, indeed, that the stern heroism of Puritanism became engaged on the side of political liberty. During this century, too, England was the last remaining battle ground in Europe for free government. In the other large states,— in Spain, France, Austria, in the Scandinavian lands, even in the petty principalities of Italy and Germany, — despotism was triumphant. In England, popular principles not merely maintained themselves against the Stuart attack; they came out of the conflict with increased vitality. The great experiment of a Puritan Commonwealth failed; but after the Stuart Restoration it became apparent that the body of the monarchists themselves were now thoroughly devoted to parliamentary government, and the attempt of the later Stuarts to set up a personal absolutism called forth the "Glorious Revolution" of 1688, which established the supremacy of Parliament over the king.

Dynastic and Commercial Struggles, 1648–1783.— We now return to the general development of Europe after 1648. On the continent the period from the Peace of Westphalia to the French Revolution (1648–1789) is marked (1) by absolutism within the several states and (2) by dynastic interests in their foreign relations,— with incessant selfish war, as the result. The famous phrase ascribed to Louis XIV. of France, —"I am the State,"— might have been used appropriately by any monarch of the time outside of England. A few great rulers dominate the period. Indeed the stage is largely filled by three monarchs,— Louis XIV. (1643–1715), Peter the Great (1689–1725), and Frederick the Great (1740–86). The influence of Peter was restricted for the most part to Russia; but the other two belong to all Europe, and the period divides itself naturally into the Age of Louis XIV. and the Age of Frederick II. The chief aim of statesmen was to prevent any one country from becoming too strong for the safety of its neighbors. The Peace of Westphalia had transferred political predominance from the Hapsburgs to the Bourbons. Thus, during the first half of the period France threatened the "balance of power," and league after league of other powers was organized against her. International morality, however, was low; and commonly rulers were willing to let a strong power rob a weaker one if they could find "compensation" by robbing some other state themselves. In the last wars of Louis XIV., just before and after 1700 (known in American history as King William's War and Queen Anne's War), the dynastic interests of European ruling families became merged in a titanic, century-long struggle between France and England for world dominion,— though neither country was yet fully conscious of the import of the strife.

In Europe, France was no longer in peril, as she had been in the period preceding Richelieu; and Louis the Fourteenth's half-century of war was merely a struggle to enlarge his dominions. For a generation the victories of Turenne dazzled Europe; and France annexed some important strips of territory on the east, at the expense of Spain and of the decaying Empire. But in the closing period, when the Allies also had found great generals, in the English Marlborough and the Austrian Prince Eugene, even success in the field deserted Louis; and to a comprehensive view his failure was profound. Exhausted France was crushed by taxation to pay the interest of the war debt; while, in attacks upon petty provinces in Europe, she had wasted energies and opportunities that might have made her supreme in Asia and America. Within, the economic reforms of the great Colbert were abandoned; and the revocation of the Edict of Nantes (1685) drove into exile more than two hundred thousand of the best citizens of France. The effect corresponded in a measure to the effect upon Spain of the expulsion of the Moriscoes somewhat earlier. The Huguenots had comprised the skilled artisans and the enterprising merchant classes; and their flight added to the terrible economic demoralization and deprived France of all chance at industrial leadership.

To men of the time, however, the failure was partially disguised by the glamor that surrounded the court of the *Grand Monarque*. French literature, brilliant and sparkling, was in its first splendid period; and French intellectual leadership survived for more than a century. Until after 1800, the court of Louis XIV. remained the model for every court in Europe; and French thought, French fashions, and the French language were the common property of all polite society.

The Treaty of Utrecht (1713), while it left France still one of the three greatest powers, marks her recession from predominance. Spain resigned her territories and claims in Italy and on the Rhine, and, except for her decaying colonies, withdrew finally within her own peninsula. England gained Newfoundland and Nova Scotia from France, and in Europe she secured command of the Mediterranean by the conquest of Gibraltar and Minorca. By the same treaty and by the rearrangements that immediately followed, the old Spanish Netherlands, the Duchy of Milan, and the Kingdom of Naples and Sicily fell to Austria. The Duke of Savoy (one of the faithful allies against France) acquired Sardinia, with the title of a kingdom for his enlarged state. A little before, in 1701, the Elector of Brandenburg had secured the title of King of Prussia. Thus, out of the wars of Louis, at the beginning of the eighteenth century, arose the two kingdoms, Prussia and Sardinia, which in the latter part of the nineteenth century were to make modern Germany and modern Italy against the will of modern France.

About 1700, other important changes took place in the map of Europe. For three centuries, Austria had been one of the chief bulwarks of Christendom against Mohammedanism. In 1683 Vienna had been besieged by the Turks, and had been saved only by the arrival of the gallant Sobieski with his Polish chivalry. But thereafter Austria took the offensive. She won back Hungary, and then, step by step, extended her dominions down the Danube valley and the Illyrian coast. In the latter part of the reign of Louis XIV., the Austrian Hapsburgs, turning away from the Rhine, definitely adopted a Danubian policy and sought to aggrandize themselves by seizing Slav territory from Turkey.

This new policy of Austria gave Louis XIV. a freer hand on the Rhine than he otherwise would have had, and so helped on the decline of Holland. In 1640, Dutch vessels carried the commerce of the world,— even the greater part of that between England and her colonies. Soon after that date, however, England attacked the Dutch commercial supremacy by navigation laws, and at last by war. Fearful of French conquest, and deserted or timidly defended by Austria, Holland had no choice but to ally herself to her commercial rival. After 1689 in particular (when William of Orange became King of England), Holland followed the lead of England in politics, while that country drew to herself the Dutch carrying trade.

In the north of Europe the former great powers, Sweden and Poland, were declining before the rise of Russia and Prussia. Peter the Great (1689–1725) consolidated the government in Russia, introduced a veneer of Western civilization, and started his country on its deliberate march toward distant seas, west, south, and east. Peter himself secured the western "window" by seizing from Sweden the southeastern Baltic provinces. In the middle of the century, the Empress Elizabeth (1741–62) robbed Sweden of the rest of the Baltic coast up through southern Finland. The northern half of Finland remained Sweden's until Alexander I. seized it in the Napoleonic wars; but toward the close of the eighteenth century, under Catherine II., Russia began her advance along the Black Sea at the expense of Turkey. Under the same ruler occurred the Russian gains in the partitions of Poland,— a story which can be understood only in connection with the rise of Prussia

For three centuries the Hohenzollern Margraves of Brandenburg had been patiently adding scrap by scrap to their realms. Soon after 1600 these dominions lay mainly in three widely separated groups,— Cleves on the Rhine, Brandenburg on the Elbe, and East Prussia beyond the Vistula. The object of Hohenzollern politics was to consolidate these provinces by acquiring intermediate territory. Toward the close of the Thirty Years' War, Frederick William, the Great Elector, made important headway in this respect and accomplished still more for his country after the close of that struggle by persistently maintaining peace and fostering industry. It was his son who in 1701 secured the title of King. The second king of Prussia built up a magnificent army and reared a son who was to use it magnificently. Frederick II. ascended the throne in 1740 and began his long reign by an unjust but profitable war. The Hapsburg realms had just fallen to a woman, and, disregarding solemn treaties, Frederick took unscrupulous advantage of the supposed weakness of the Archduchess, Maria Theresa, to seize from Austria the rich province of Silesia. The heterogeneous Hapsburg realms seemed about to fall to pieces; and Spain, France, Savoy, and Bavaria hurried to join Prussia in dismembering the carcass. But England and Holland threw themselves into the struggle on the Austrian side, and the Treaty of Aix la Chapelle (1748) closed the War of the Austrian Succession without further territorial changes. Frederick kept Silesia, reaching far down into the heart of Germany, and Prussia stood forth as one of the great powers.

The significance of the contest, however, lay in its wide extension into India and America. Indeed, colonial war between England and Spain had already begun before Frederick appeared on the stage, and France must soon have joined Spain in any event. In the New Worlds, too, the Peace restored the former boundaries; but the war marks a clear consciousness in England and France that the two were rivals for vast realms outside Europe. The family interests of monarchs as a cause for war were giving place to the commercial interests of English and Dutch merchants as opposed to those of French and Spanish merchants, while back of these selfish motives lay the mighty question, big with consequence to the world, whether French or English political ideas should hold the New World.

In 1756, Austria fortified herself by alliance with Russia, Sweden, and even her old enemy France, and prepared to destroy Prussia. Frederick's supreme military genius saved his country for the moment, and the next year England came to his aid. During the brief interval between the European wars, England and France had practically remained at war in America; and now that France had joined Austria, England was constrained to support Prussia. In all the period from 1689 to 1815, no matter what the origin of the wars, England and France soon became the chief factors; and though they were at one time or another on every side of every question, they were never on the same side at the same time.

This Seven Years' War (1756–1763), or Great French War, as it is commonly known in

America, was literally a world-wide struggle. Red men fought by the Great Lakes of North America, and black men fought in Senegal, while Englishmen and Frenchmen grappled in India as well as in Germany, and their fleets engaged on every sea. The showy battles took place in Germany, and on the whole the European conflict determined the wider results. Pitt, with vision fixed upon a coming British empire, declared that in Germany he would conquer America from France. This he did. England furnished the funds, and her navy swept the seas. Frederick, supported by British subsidies, furnished the generalship and most of the troops for the German battlefields. The striking figures in the struggle are (1) Pitt, the English imperialist and the directing genius of the war; (2) Frederick, the military genius, who won Pitt's victories in Europe; (3) Wolfe, who won French America from the great Montcalm; and (4) Clive, the East India Company's clerk, who laid the basis for England's supremacy in India.

Changes in the World-Map; the American Revolution.— The Treaty of Paris (1763) left Europe without change; but in India France lost all except a few unfortified trading posts, while in America England received Florida from Spain, and Canada and the eastern half of the Mississippi valley from France. France ceded to Spain the western half of the Mississippi valley, in compensation for the losses Spain had incurred as her ally; and, except for her West India islands, she ceased to be an American power. Spain still held South America and half North America; but her huge bulk was decaying day by day. Holland, too, with widespread empire, was plainly in decline. England, having dispossessed France in both Asia and America, stood forth as the leading world-power.

The American Revolution, a few years later, did not lessen this pre-eminence; but it had other results of supreme significance. The war came because the American colonies had really become a nation, and because the English government unwisely insisted upon managing American affairs after the Americans were quite able to take care of themselves. English interference in economic matters had long been irksome, and the danger of interference in ecclesiastical matters was feared. England had just relieved the colonies from fear of French conquest. External bonds were gone, and internal ties were dissolving. Then George III. and his ministers supplied the necessary jar to effect separation by trying to raise revenue in America by Acts of Parliament. Astute patriots rallied the majority of the Americans by an old English shibboleth; and after a bitter eight-years conflict (1775–83), the thirteen English colonies became the first free American nation.

The Revolution «split the English race and doubled its influence.» It paved the way for a more enlightened economic science, since, contrary to all expectations, the trade of free America from the first proved more valuable to England than that of colonial America had been. It reacted upon England, so that, when the great wars were over, both that country and its remaining colonies made new advances in political liberty. It set up the standard of independence for the states of Spanish America in both continents. But its supreme importance lay in the birth into the family of nations of the United States itself, though the full significance of the new nation hardly began to impress Europe for more than two generations.

England's European enemies had seized the opportunity to attack her in a war of revenge. England came out of the contest with glory little tarnished. She had been fighting, not America alone, but France, Spain, and Holland, as well; and though she had lost the best part of her old American empire she was not without compensating gains. She seized Dutch colonies at will; she strengthened her grasp upon India; she won back the undisputed sovereignty of the ocean by shattering the navy of France; she rebuffed all assailants from the rock of Gibraltar, the key to the Mediterranean; and in some measure she made good even her American loss by the acquisition of Australia just afterward.

The Partitions of Poland.— To return to continental Europe in the closing half of the Age of Frederick the Great:— one more territorial change calls for attention. Poland had fallen into anarchy under its elective, figurehead king and its oligarchic nobles. This anarchy gave the neighboring powers excuse for plunder. Catherine II. determined to seize a large part of the country. Frederick II. persuaded his old enemy, Austria, to join him in compelling Russia to share her booty. The First Partition of Poland (1772) pared off a deep rind. The Second and Third Partitions, which «assassinated the kingdom,» had not even the pretext of misgovernment in Poland, for the Poles had earnestly taken up the work of reform. These final divisions took place in 1793 and 1795, after the death of Frederick, amid the wars of the French Revolution. Prussia gained large extent of territory, with valuable sea coast; and, most important of all, the additions brought the principal Prussian provinces,— formerly scattered,— into a compact body. But Russia gained far the greatest part of the territory, and she now bordered Germany on the east, as France had come to do earlier on the west, after the destruction of the Burgundy of Charles the Bold. The wise policy of the Germans, early and late, would have been to support the buffer states against the greed of Russia and France. Failure to do so has left Germany exposed ever since to direct attack by powerful enemies, and has compelled her to build up artificial frontiers of fortresses and bayonets, and to accept an undue militant character for all her civilization.

The Beneficent Despots of the Eighteenth Century.— In foreign relations, the Age of Frederick the Great saw little improvement over that of Louis. In the government within the several states, however, there was a beneficent and significant change. Frederick of Prussia, Catherine of Russia, Charles III. of Spain, Leopold of Tuscany, Ferdinand of Naples, Joseph II. of Austria, all belonged to a new class of «crowned philosophers» and «benevolent despots» who sat upon the thrones of Europe in the latter half of the eighteenth century. In Sweden and Portugal, also, great ministers sought to impose a liberal policy upon the monarchs, as

Turgot succeeded in doing for a while, even in France. A remarkable school of French writers,— Diderot, Voltaire, Rousseau,— had created a new, enlightened sentiment in the ruling classes, and a new sense of responsibility. Government was no more *by* the people than before, but despots did try to govern *for* the people, not for themselves. Sovereigns spoke of themselves no longer as privileged proprietors, but, in Frederick's phrase, as "the first servants of their states." All these rulers planned far reaching reforms,— the amelioration or abolition of serfdom, the correction of abuses in the church, the building up of popular education. In Prussia, for a time, much was accomplished. The condition of the peasantry was improved: the administration was rendered economical and efficient: and wealth and comfort began to increase by bounds. But these happy results were secured only by the tireless energy of one of the world's greatest geniuses. On the whole the liberal monarchs made lamentable failures. One man could not lift the weight of a nation. It remained to see what the people could do for themselves. The age of enlightened despots was the prelude to the French Revolution.

THE AGE OF NATION STATES.— *The French Revolution, 1789–99.*—In the latter part of the Middle Ages, Italy had given the world an intellectual revolution; Germany began Modern History with a religious revolution; and France now introduced the last great division of the Modern period by a political and social revolution. Pre-eminently among political revolutions, the French Revolution deserves the name. The English Revolution of 1688 swept away temporary interference with ancient principles of English politics; the American Revolution made the Americans politically independent, but did not directly change the character of their society; the French Revolution cut loose from the past, and started France, with all the world, upon new lines of growth.

But if it destroyed the old, it also built the new. The work of destruction was needlessly horrible and bloody; but as a whole the Revolution was a vast and fruitful reform. The really significant thing is not the temporary mob-rule and bloodshed; the significant thing is the great national awakening which swept away an absurd society, founded on ancient violence and warped by time, to replace it with a simpler social system, based more nearly on equal rights.

The chief institutions of France were: (1) a monarchy, centralized, despotic, and irresponsible; but in weak hands, incumbered by complex survivals of ancient local institutions, and hampered by its respect for the good opinion of the privileged classes; (2) an aristocracy, wealthy, privileged, corrupt, skeptical; and (3) an established church, wealthy and often corrupt. Below these spread the masses, a necessary but ugly substructure. Over the continent, similar conditions held sway. In France the nobles had fewer duties, the peasantry had more completely risen out of serfdom, and more of a middle class had grown up, than in the other large countries of the continent. Feudal society was more decayed, and industrial society more advanced. The great European revolution broke through at the weakest spot.

The fundamental cause of the Revolution was the unjust privileges of the favored classes and the crushing burdens of the masses. The evil was no greater than for centuries, but the consciousness of it was greater. The masses began to demand reform; and the privileged classes had begun to distrust their rights.

The Revolution is usually dated from the meeting of the States-General in 1789. The king had summoned that body, hoping to induce the privileged orders to give up their exemptions from taxation, and so relieve the bankrupt treasury. The Third Estate, representing the middle class, and the liberal nobles and clergy had assembled with the determination to secure far-reaching reforms and to establish a "constitution." A sharp contest, with a brief period of anarchy, left power in the hands of these liberal elements, where, despite some attempts at counter-revolution and some danger of mob predominance, it remained for two years. The Constitution fashioned during this period provided for a weak kingship and abolished nobility and all special privileges before the law; but it carefully entrenched middle-class supremacy against democracy by graded property qualifications and a complex system of indirect elections.

Further changes were inevitable; but, if France had been left to herself, they might have come about as quietly as these first ones. Instead, foreign war gave the movement a new character. War was inevitable. Emigrant nobles gathered their forces on the Rhine under the protection of German princes. The Emperor, Leopold, brother-in-law of Louis of France, called upon the sovereigns of Europe to recognize the cause of Louis as "the cause of kings," and demanded from France such changes in her government as should protect Europe against the spread of revolution. This presumptuous dictation in their internal affairs roused a tempest of righteous wrath in the French nation; and in 1792 war began between "the cause of kings" and "the cause of peoples." For twenty-three years Europe was engaged in strife, upon a greater scale than ever before in history.

France was girdled with foes. The Empire, Prussia, and Sardinia, were at once in arms. Naples and Spain joined the coalition. Sweden and Russia both offered to do so, if needed. Ere long England and Holland were added to the enemies who expected to partition France. Vast armies invaded France; and the French forces were demoralized by treachery of officers and by fear of royalist plots. If France was to be saved, it could not be done by half-measures, nor with a king in secret alliance with the enemy. Control fell to extremists; and, while the mighty Danton roused and organized the national energies, the frenzied mob, unhindered, answered the victories and boastings of the invaders by the attack on the Tuileries and the Massacres. In September, the Convention established the French Republic with extreme democratic features and with manhood suffrage. Then revolution within revolution transferred power to more and more radical factions. The defeated Girondists raised the provinces against the capital; and for a time Paris and a score of central departments faced the remaining three fourths of France and united Europe. Out of this crisis, in 1793, grew the great Committee of Public Safety, which ruled France for a year with despotic power. The Revolution now became constructive, and never has the French genius for organization shown itself more triumphantly. The Committee deliberately adopted a policy of "Terror" to crush plots and dissension and to secure united action. Revolt was stamped out. A million soldiers were sent to the front. The invaders were rolled back in rout, and the ragged but devoted French armies swarmed victoriously across all the frontiers, to sow civil liberty over Europe with fire and sword. France was not again in serious danger from foreign foes until the fall of Napoleon, twenty years later.

Meantime, while the grim, crime-stained men of the Committee in war and tumult were organizing order within and victory abroad, the Convention was laying anew the foundations of French society and advancing the progress of the human race. It adopted the projects of Cambarcérès for the codification of French law, and the plans of Condorcet for a system of national education; it accepted Argobast's metric system of weights and measures; it abolished slavery in the French colonies, created provision for the public debt, instituted the first Normal School, the Polytechnic School, the Conservatory, the Institute of France, the National Library, and began the improvement of prisons and hospitals, and the reform of youthful criminals. Meantime the peasants had become free landholders, and the whole laboring class was rising rapidly in standard of living.

In 1794 the Jacobins split into factions, and these turned the "Terror" upon one another. The following year a conservative reaction gave the Republic a new constitution, which restored property qualifications and indirect voting. But the new plural executive (the Directory) proved incompetent and corrupt, and kept itself in power only by a series of *coups d'état*. It was assailed by conspiracy, radical and royalist; and France breathed more easily, when, in 1799, Bonaparte overthrew it with his troops and set up a firm military despotism, veiled by plebiscites.

Napoleonic Period, 1800–15.—For fifteen years, as First Consul (1800), Consul for Life (1802), and Emperor of the French (1804–14), Napoleon was sole master of France. He preserved the principle of civil equality and all the economic gains of the Revolution, but political liberty for a time was lost. True, his rule was a denial of the old doctrine of Divine Right: each new usurpation received the sanction of a popular vote, and he boasted that he was chief by will of the people. But every form of constitutional opposition was crushed or muzzled. The legislative chambers existed only to speak when and as he chose; free speech, free press, and all security for personal liberty were suppressed by a system of spies and secret police and by arbitrary imprisonment of suspects; local administration was centralized more highly than even under the old monarchy, "nor did there exist anywhere independent of him authority to light or repair the streets of the meanest village in France."

This all-pervading absolutism was directed by the penetrating intelligence and indomitable energy of the world's most "terrible worker"; and it conferred upon France great and rapid benefits. Order, precision, symmetry were introduced into every branch of the administration. The interrupted work of the Convention was resumed. Education was organized; law was simplified and codified; the church was again brought into alliance with the state; industry was fostered, and magnificent public works were carried out. But in all this, Napoleon was merely the last and greatest of the beneficent despots. And in the outcome, his rule fixed more firmly than before in the mind of the nation the dangerous willingness to depend upon an all-directing central power; so that in our own day, after many revolutions, the supremely difficult task of the Third Republic has been to create the spirit of local self-government.

No doubt, in 1800, when Napoleon came into power, he sincerely desired peace, in order to reconstruct France. By the brilliant victories of Marengo and Hohenlinden he dissolved the hostile coalition, and a series of treaties, closing with the Treaty of Amiens (1802), gave Europe a breathing spell. But soon Napoleon again desired war. His victories in Italy, as a general of the Directory, had first brought him to the world's notice, and only military glory could keep France from murmuring at his rule. Moreover, he aspired frankly to European empire. On the other hand, the nations felt that there could be no lasting peace with him except by complete submission to his will. In 1803, England and France renewed their strife, and between these powers there was to be no more truce until Napoleon's fall, eleven years later. In that time Napoleon fought also three wars with Austria, two with Prussia, two with Russia, a long war with Spain, and various minor conflicts. From 1792 to 1802, the unceasing European wars belong to the Revolutionary movement. From 1803 to 1815, they are properly Napoleonic wars, due primarily to the ambition of a great military genius. In the first series, Austria was the chief opponent of the Revolution; in the second series, England was the relentless foe of Napoleon.

Napoleon's insight readily divined his true enemy; but Nelson's great sea fight put an end to all possibility of directly invading England. On the continent, however, victory followed victory. After Austerlitz (1805), Austria gave up her remaining Italian and Illyrian territory, and many of her possessions in Germany. After Jena (1807), humiliated Prussia was reduced half in size, thrust beyond the Elbe, and bound to France by a shameful treaty. Less decisive conflict with Russia was followed by the diplomatic victory of Tilsit (1807). Emperor and Tsar entered into friendly alliance. France was to have a free hand in Western Europe; Russia was to be permitted to aggrandize herself at the expense of Sweden, Turkey, and Asia; and the two were to join in ruining England by enforcing Napoleon's "continental system."

The refusal of Portugal to obey Napoleon's command for the confiscation of English commerce led to the seizure of that state. Then followed a like seizure of Spain, out of which grew the long Peninsular War, which, as Napoleon confessed afterward at St. Helena, was really the canker that destroyed him. At the time, however, it seemed trivial, and for five years after Tilsit Napoleon was master of the continent. At its greatest extent the huge bulk of France filled the space from the ocean to the Rhine, including not only France as we know it, but also Belgium, half of Switzerland, and large strips of Germany, while from this central body two outward-curving arms reached toward the east, one along the North Sea to the Danish peninsula, and the other down the coast of Italy past Rome. The rest of Italy and half the rest of Germany were under Napoleon's protection, ruled as vassal states by his brothers and generals. Denmark and Switzerland were his willing allies, and Prussia and Austria were unwilling ones. Sweden and Russia, though nominally his equals, were allowed that dignity only because they upheld his policy. Only the extremities of the continent,— the islands of Sicily, Sardinia, and England, and the mountainous Spanish peninsula,— kept their independence, at the cost of wasting war.

The period was filled with important rearrangements for Europe, territorial, political, and social. Many of these were designed in selfishness: but nearly all were to bear good fruit. In particular, the Germany and Italy of to-day were made possible by Napoleon's fearless clearing away of old institutions, and by the vigorous impulse he gave to the new forces of political unity and social reform.

In Germany, even the territorial rearrangements paved the way for later national unity. Not only the twelve hundred anarchic territories of the "knights," but also the three hundred petty, scattered, despotic principalities, ecclesiastical states, and oligarchic city-republics (with a few exceptions) were absorbed in larger neighbors: so that the multitudinous, ill-governed states of the vanished "Empire" were consolidated into less than forty. Most of these reorganized states, outside Austria and Prussia, were further combined in the Confederation of the Rhine: and in this Confederation, as well as in the German and Italian territory annexed to France, and in the various vassal states over Europe, serfdom and feudalism were abolished and civil equality and the Code Napoleon were introduced. The administration of justice was made cheap and simple, and the old clumsy and corrupt methods of government gave way to order and efficiency.

Most important of all, similar reforms were adopted in Prussia, not from French pressure, but by the influence of the Prussian minister, Stein, who sought to make his country strong enough to throw off the French yoke and to regenerate Germany. Napoleon's insolence had at last forced part of Germany into a new national patriotism: and that patriotism began to arm itself by borrowing weapons from the arsenal of the Revolution.

Napoleon's "continental system," if embarrassing to England, was ruinous to Europe. Moreover, Tsar Alexander began to suspect Napoleon of intriguing against him in Finland and Turkey: and in 1811 he refused longer to follow Napoleon's commercial policy. Napoleon declared war. The destruction of his Grand Army amid Russian snows was the signal for the rising of the peoples of Central Europe in the Wars of Liberation. Napoleon, like a desperate gamester, refused all terms, and finally was crushed and deposed. The Bourbon dynasty was restored to the throne of France, and the powers met in the Congress of Vienna (1814–15) to reconstruct the map of Europe.

The Congress of Vienna.— In its desires, that Congress stood for reaction. Says Fyffe, "It complacently set to work to turn back the hands of time to the historic hour at which they stood when the Bastille fell." It ignored peoples, and considered only princes. Its work, therefore, had to be slowly undone through the next half-century.

Still, its power for restoration was less than its wish; and even its most selfish work contained seeds of progress. Nobody thought of restoring the old ecclesiastical princes, nor of undoing the consolidation of Germany. That country was left in thirty-eight states, and Italy in twelve. Austria, which had lost territory in Central Europe, received its compensation in Italy, so that its despotic energies were more than ever drawn away into Italian and Danubian questions. Renovated Prussia, in return for Slav lands, which it ceded for the Tsar's new Kingdom of Poland, received German territory,— half of Saxony, the Pomeranian sea coast, and German provinces on the Rhine taken from France. Thus, reaching down into the heart of Germany, and with distant isolated districts to defend on the Rhine and on the Niemen, Prussia stood forth the natural champion of Germany against Slav and Gaul. In like manner, Sardinia's gain of Genoa was one more step in the consolidation of Italy. In return for the vast national debt incurred in supporting coalitions against Napoleon, England added still further to her colonial supremacy by holding South Africa, Cyprus, Malta, and other important stations. Despite its brief welcome to Napoleon at his return from Elba, France was wisely left with the boundaries she had when the Revolutionary wars began. The most serious disappointment to the liberals was the failure to secure a national union in Germany. Reactionary Austria secured instead the Germanic Confederacy — a loose league under Austrian presidency, with a Diet which was merely a meeting of ambassadors,— "a polite and ceremonious means of doing nothing."

It was worth much to Europe merely to recognize that it had common interests which could be arranged by a peaceful congress. Even this gathering of despots was an advance from eighteenth century politics toward a better international organization. Some of its work, moreover, was distinctly progressive, such as the declaration against the African Slave Trade, the opening to commerce of the rivers flowing between or through different countries, and especially the neutralization of Switzerland under the protection of the powers.

From 1815 to the Revolutions of 1830.— For more than thirty years after the Congress of Vienna, reaction held sway. The restored princes, who "had learned nothing and forgotten nothing," strove to ignore the progress from 1789 to 1815. In Sardinia, serfdom was restored; in Spain and the Papal States, the Inquisition and other mediæval institutions; in some places, even street lamps were abolished along with other hateful French reforms. Five states,— Russia, Austria, Prussia, England, and

France,— determined the policy of Europe. The first three were divine-right despotisms; and though the Tsar and the King of Prussia played for a time at liberalism, the first disorders enabled Austria to draw them over to her own frankly reactionary program. At first, France and England were not much better than these Eastern powers. Louis XVIII. had found it necessary to give France a charter; but in that document itself the theory of divine right was preserved, until the revolutionary changes of 1830. That theory could have no place in England; but even there the government was for many years in the hands of an extreme Tory party. The evil genius of the whole period was the subtle Austrian statesman, Metternich, with his motto, "Government is no more a matter for debate than religion is." The one good thing to be said for Metternich's long supremacy is that he permitted no great war; and this was because he felt it necessary to hold the powers in friendly alliance, so as better to arrest progress within the lines drawn at the Congress of Vienna.

However, beneath the tide of reaction, the principles of the Revolution survived. The two positive forces in politics for the 19th century were to be democracy and nationality. The league of princes compelled them to work underground; but before the middle of the century they emerged in three series of revolutions — in 1820, 1830, and 1848.

The revolutions of 1820 started in Spain, to re-establish the Constitution of 1812, which had been adopted first during the war for Independence. Completely successful there for the time, the movement spread swiftly over the southern peninsulas — to Portugal and to the states of North and South Italy, while it stimulated the Greek rising against the Turks. Metternich found a weapon of repression ready. After Waterloo the four great allies, Russia, Prussia, Austria, and England, had agreed to preserve their union against revolutionary France by holding occasional congresses. Metternich now summoned these powers to the Congress of Troppau. Here the despotic masters of Russia, Austria, and Prussia signed an agreement to unite in putting down revolution against any established government. England protested and withdrew from the alliance; but her place was taken by France, and the united despots, popularly known as the "Holy Alliance," proceeded to carry out the Troppau programme. With overwhelming armies they crushed constitutionalism in Naples and Piedmont, and a little later, in Spain. England's fleet preserved the little sea-coast country of Portugal from attack; and the Tsar's sympathy for his Greek coreligionists held Metternich from aiding Turkey. Portugal and Greece were the only European lands to reap good from the widespread risings of this period.

American Progress.— Greater gain there was, however, outside Europe. The "Holy Alliance," successful in Spain, wished to restore monarchic control over revolted Spanish America. Here they failed. When Napoleon seized Spain (1808), the Spanish colonies, nominally loyal to the old Spanish dynasty, began to taste the sweets of economic and political freedom. They were powerfully influenced, too, by the success of the United States; and soon they began, one after another, to avow independence not only of Napoleon, but also of the mother country. The United States had recognized their independence. England had not done this; but now she interposed her sea-power to shield them against the proposed attack by the "Holy Alliance." England, indeed, urged the United States to join in a formal alliance to protect Spanish America. The United States chose to act separately, but it did act along the same line: in 1823 President Monroe's message announced that this country would oppose any attempt of the despotic powers to extend their political system to America. Thus was born a group of new nations. For more than fifty years, it is true, the best of the new states manifested anarchic tendencies; but before the close of the nineteenth century some of them began to make steady and promising progress in government and society. Their constitutions have been modeled generally upon that of the United States.

Before returning to Europe, brief attention should be given to the progress of the United States itself in the generation following the French Revolution. The Constitution of 1787 saved the thirteen States of that time from falling apart into jangling, insignificant units, and gave the world an advanced type of federal government. The Louisiana Purchase (1803) doubled the territory of the country and confirmed its destiny as the home of a mighty continental nation. During the closing Napoleonic struggles, the contemptuous disregard of England for the rights of neutrals, together with the treacheries of Napoleon, involved America in war with England; but, beyond this, except for the enunciation of the Monroe Doctrine, the United States, busied with its marvelous growth at home, had kept free from foreign complications. At the moment of the European revolutions of 1820, the great American Republic was entering on the forty years of anti-slavery debate which preceded the Civil War.

Revolutions of 1830.—The year 1830 is one of the notable dates in the 19th century. In America the victory of Jackson had just marked a fresh advance in popular government. In England the First Reform Bill began its two-year struggle in Parliament. On the continent of Europe, revolution struck a new blow at the system of Metternich. This time the movement started in France, where the July Revolution replaced the divine-right Bourbon monarchy with the constitutional, bourgeois monarchy of the Orleanists. Explosions followed over Europe. The Belgians rose against their Dutch masters; the Poles against Russia; Italian risings seemed for a moment to have some chance in the papal states and the duchies; and, while Russia and Austria were busied in Poland and Italy, liberal gains were secured in several German states. But soon Metternich, his hands free once more, set himself patiently to restore the old order in Germany. France, it is true, was lost to the "Holy Alliance," and joined England in defending liberal Belgium against despotic intervention. But in the final result, France and Belgium were the only gainers from this period. It was to take the third great "year of revolutions," to sweep away Metternich's shattered system.

To appreciate in any measure the wonderful progress of the remaining two thirds of the 19th century, it is needful to grasp the conditions of the world of 1830, or, we may say, of 1837, when the Victorian era began. It was still a small, despotic world, far more remote from the great, progressive world of 1900 than from the world of 1600. Civilization held only two patches on the globe,— western Europe and eastern North America. In the latter, the real frontier of the United States reached less than one third the way across the continent, and politics and society were dominated by the slave power. Europe knew "Germany" only as a pious aspiration of revolutionaries, and "Italy" as a "geographical expression." Metternich stood guard over central Europe. On the east hung Russia, an inert mass, in the chains of her millions of serfs. Under the contemptible Orleans monarchy, France was taking breath between spasmodic revolutions. England herself had only begun to stir under the long oligarchic rule of her landlord class. The rest of the globe hardly counted; a fringe of Australia held a convict camp; eastern Canada was a group of jealous, petty provinces, learning to agitate in disorderly fashion for self-government; Spanish America, prostrate in anarchy, gave as yet little hope of the coming renaissance; Japan was to sleep a generation longer; while the two largest continents were undisturbed in their native barbarism, except for England's grasp upon the hem of India and South Africa.

England in the 19th Century.—In Europe, England was to lead the van of progress; and in England, almost alone in Europe, reform was to come without revolution. But the England of 1830 was still mediæval. During the great French wars from 1690 to 1815, except for the one development of ministerial government, England had retrograded politically and socially. Her society was marked by extreme inequalities between rich and poor, intensified by cruel class legislation; her government, superficially representative, had really fallen into the hands of a selfish landlord class; her boasted local self-government was intensely aristocratic; her established church was aristocratic and unspiritual. In the last half-century had come an industrial revolution — the growth of the factory system — with marvelous increase of population and growth of city life, calling imperatively for new adjustments; but the great Tory party met all calls for reform with sullen denunciation and repressive legislation which made free speech a crime.

Under the system of rotten and pocket boroughs, more than half the House of Commons were the appointees of less than 200 landlords, while most of the rest represented small fantastic constituencies. Thus, reform necessarily began with Parliament itself. This parliamentary reform was accomplished by three great measures: that of 1832 placed power in the hands of an intelligent middle class, the landed and mercantile interests; 35 years later, the Second Reform Bill (1867) gave power to the artisan class of the towns; and the bill of 1884 once more doubled the electorate and left England a democracy.

The Reform Bill of 1832 was followed at once by social reform, in response to the swelling tide of humanitarianism in literature and society. Legislation swept away negro slavery in the colonies, and the hideous white slavery of women and children in English factories and mines; reformed the barbarous and fantastic criminal code; abolished the worst abuses of the pauperizing poor-law; began the protection of workmen in factories against carelessness or wilful neglect of capitalists; gave women legal rights; adjusted taxation more equibly; swept away the corn laws and introduced the free-trade era; removed the press gang, and brought in the penny post; enlarged the self-government of the colonies; and established a wonderfully efficient system of democratic self-government in cities at home. Subsequent political reform, despite the Irish difficulties after 1870, added to the rate of social reform. In particular should be noticed the complex industrial legislation, and, for dependencies where the nature of the population forbids self-government, the adoption of efficient, unselfish colonial administration, in which England has set an example for all world powers. Even India and Egypt, with their tremendous difficulties, have been touched with new life; while the great provinces of the English-speaking colonies, Canada and Australia, have organized themselves into two mighty federal states (1867 and 1901). In the rural units of England, too, the local government bills of 1888 and 1894 established true democracy.

Revolutions of '48.—Meantime, on the Continent, the next great progress after 1830 came with the revolutions of '48. A general explosion had been preparing; but again the signal was given by France. The Orleans monarchy had become reactionary; and the socialistic February revolution set up the Second Republic. March saw Metternich himself a fugitive, escaping from Vienna in a laundry cart, while thrones were tottering everywhere between Russia and Turkey on one side and England on the other. Even England trembled with a Chartist movement and the threat of an Irish rebellion. The kings of Holland, Spain, Denmark, and Sweden made constitutional concessions. In Germany and Italy there were complex movements, working (1) for constitutional liberty and social reform within the several states; (2) for the union of the fragments of the German race into a nation; and (3) for the independence of Italians, Slavs, and Hungarians, held in subjection by Austria.

The third movement resulted in wars, out of which Austria finally emerged triumphant; and her victorious army was a ready tool to restore absolutism at home. In Germany the undisciplined Liberals had wasted opportunity, Austria dispersed the Frankfort National Assembly, and, after humiliating unready Prussia at Olmütz, restored the old confederation (1850). A year later (1851) the *coup d'état* of Louis Napoleon closed the revolution in France and prepared the way for the Second Empire of the next year.

But there had been great gains. Feudalism and serfdom were gone forever, even from Austria. Sardinia, Prussia, and the minor German states kept their new constitutions. Switzerland had become a true federal republic upon the American type. Sardinia, by her sacrifices, and Prussia, in spite of the past mistakes of her timid government, were clearly marked out as the champions of Italy and Germany against Austria. Victor Emanuel of Sardinia recognized his mission to unite and free Italy; and Prussia, so recently shamed, had statesmen who would see that next time she should be ready.

Europe from 1850 to 1880.—The next 25 years (1850–75) saw not only the advance toward democracy in England, the victory of nationality and the abolition of slavery in the United States, the formation of the federal Canadian Dominion, on the American model, and the awakening of Japan under American constraint, but also a new federal German Empire, a united, constitutional Italy, a stable French republic, a constitutional Spain, and a constitutional, federal Austria-Hungary. The period was one of "blood and iron." Napoleon III., who had drawn England into the Crimean war (1854) to humiliate Russia, was himself drawn by the statesmanship of Cavour into the Austrian war of 1859 to help free Italy. Within a year after the resulting campaigns in Italy had closed, the American Civil War began; and before it ended, Bismarck had entered upon his trilogy of wars. In 1864 he robbed Denmark of the Schleswig-Holstein duchies, with the great harbor of Kiel for Prussia's projected navy, and so made trial of the new army he was at once to use (1866) in driving Austria out of Germany by the Six Weeks' War. The North German Confederation, then formed, was expanded into the German Empire by the Franco-Prussian war (1870–1), into which Bismarck next tricked French vanity and the despairing ambition of the decaying French government. These struggles completed also the unity of Italy. In 1866 Italy recovered Venetia from Austria, and in 1870, when France could no longer interfere, it at last marched its troops into its ancient capital, Rome. Even for conquered countries, during this period, did reform grow out of war. The Crimean catastrophe struck the chains from Russia's serfs; the shock of defeat in '59 and '66 woke Austria to constitutional progress; only when Germany shivered the sham of the Second Empire did France enter upon true republican life; and it was in the ashes of her old social system that our own South found regeneration.

Out of the Russian-Turkish war of 1877–8 a new group of Balkan nations was born, mainly Slav in blood, with at least the forms of constitutional government. But since 1871 political progress for the most part has been peaceful. The various monarchies of Europe, except Russia and Turkey, had already all adopted constitutions modeled upon the English government, though in none of them were the ministries so truly dependent upon popular will as in England. Indeed, in some states the formal constitutional monarchy really merges into a practical despotism. Progress in politics since 1871 has been of two kinds: (1) a growth in ministerial responsibility, and (2) rapid extension of the franchise toward a manhood basis. Actual administration, in most European countries, is still highly aristocratic; but in the matter of ultimate control democracy is generally triumphant, and it is training itself everywhere, by compulsory school systems, for the closer management of affairs.

International Relations Since 1880. Europe in Africa and Asia.—International relations since 1880 require brief statement. France longing to recover her lost provinces from Germany in a war of revenge, drew close to Russia. Bismarck offended Russia by supporting Austria in the Balkans. Italy was angered by the French seizure of Tunis in 1880. Thus new combinations of the powers appeared. In 1881, Germany, Austria, and Italy (all old enemies) leagued in the Triple Alliance; while a little later, France and Russia formally adopted a dual alliance. The Continent was thrown into two hostile camps, and has rested ever since under an armed peace. France became "the tail to the Russian kite." England, unwilling to join the Triple Alliance, as Bismarck wished, has been left in a position her statesmen have chosen to characterize as one of splendid isolation.

In the '90s, all these arrangements were threatened by the active appearance, in the field of international politics, of two non-European powers. The Chinese war of 1894 revealed Japan as a modern and powerful state; and the Spanish-American War (1898) made it apparent that the United States had abandoned its exclusively American policy. Moreover, since about 1880, European politics had been merging more completely than ever before in world politics. The questions at issue ceased to be Rhenish or Danubian, and became African and Asiatic. The 19th century, indeed, had been one of expansion of civilized powers, but that expansion had hardly been conscious of its own importance. The United States had quietly filled its borders from ocean to ocean with a homogeneous population. Russia had spread across northern Asia to the Pacific, and was reaching down in the Trans-Caspian region toward the Persian Gulf. And England had continued annexation of the keys to empire in waste spaces of the earth. These three were the world-powers. Far behind came France, with some important possessions in North Africa and some ancient claims in southeast Asia. Until 1884 Germany had no thought of colonial empire.

About 1880 a new, conscious greed for colonial territory seized Europe. Africa, some Pacific islands, and the helpless Asiatic empires of Persia, Turkey, Siam, and China were the only unappropriated lands. There followed a swift, peaceful division of Africa. In 1880, only patches here and there on the coast were European; in 1891, except for the native states of Abyssinia, Liberia, and Morocco, the continent was mapped out between European claimants. The three important African powers are England, France, and Germany, though Belgium, Spain, Portugal, and Italy are also represented. England is far in the lead. Her ambition has been to unite her two main possessions, in the Nile Valley and in South Africa, by acquiring intermediate territory; but the Congo Free State and German East Africa were thrust between too soon. France comes second in extent of territory; but, except for Algeria and Madagascar, her districts are less valuable than those of England or Germany. France would have liked to join her holdings on the east and west of the continent; but she found English territory thrust in between. German ambition was frustrated in similar manner. The three powers seem to have mutually stale-mated one another's attempts to dominate Africa.

The occupation of Asia by European states has proceeded more slowly, but has moved with increasing rapidity in recent years. England, Russia, Japan, and France are the chief powers concerned though Germany has shown an active disposition to take a hand in any partition, and though the commercial interests of the United States make it certain that that country will be an important factor in any further changes.

In 1894, Japan and China engaged in war over the control of Korea. With amazing rapidity, Japan overcame her bulky antagonist: but Russia, backed by France and Germany, stepped in to rob her of the fruits of her victory. Japan, owning not even one modern ship of war, was forced to yield — to spend all energies for the next 10 years in preparing for further conflict. Russia secured from China the right to extend her Siberian railroad through Manchuria, and in 1898 she also obtained the powerful fortress of Port Arthur. Germany and England then compelled China to grant them important districts, which, like the Russian acquisitions, seemed to command the heart of China and to doom that power to partition. In 1900 the Chinese resentment against "western barbarians" culminated in the Boxer massacres. The powers sent armies to rescue their beleaguered embassies at Peking; but, largely through the policy of the United States, no territorial indemnities were demanded. During the campaign, however, Russia occupied Manchuria, and, despite repeated solemn promises, it soon became plain that she meant to keep it. The powers apparently acquiesced; but when Russia in 1903 encroached also upon Korea, Japan foresaw danger to her own independence, and, in 1904, she began war. The struggle has been tremendous, almost beyond parallel; but Japanese victory has been swift and overwhelming, and has changed the whole face of world politics. Russian aggression in the East has been checked for a long period. See MANCHURIA; PORTSMOUTH, TREATY OF.

Summary.—The three mighty agents in the 19th century transformation have been democracy in politics and industry, humane sentiment in morals, and scientific progress. The first of these has been the main theme of the latter part of this article. The gentler spirit of recent society, likewise touched upon, has abolished slavery, ameliorated law, and brought about organized, zealous, and intelligent effort to lessen misery and crime. But perhaps the most marvelous phase of the "Wonderful Century" is the scientific advance. Since the primitive inventions of making fire, of the bow, of domesticating animals, of smelting iron, and of the alphabet, all the inventions of man up to the year 1800 probably count for less than those since that year. In civilized lands, life has been lengthened over a fourth, and the population of the civilized world has trebled. This larger amount of life has been lifted to a higher level. Wealth is more abundant; and the laboring masses, though still getting too little of it, get far more than formerly. The area of civilized life has been wonderfully expanded, but steam and electricity bind the most scattered portions together more closely than adjacent villages were joined in the near past. And this new solidarity is not merely in material interests: it has its intellectual and moral side. There is a growing unity of sympathy and opinion.

The picture, of course, has its dark side. Crowded populations live and work under conditions of misery and disease and often of sin. Civilized nations show callous disregard for the rights of weaker or barbarous people. And over the civilized world itself there still broods the danger of annihilating war, more terrible because of the inventions of this scientific age.

Happily this survey may close with a chronicle of a great step toward removing this last danger. The Hague Conference of 1899, called in the interests of peace, did not find it possible to make any advance toward disarmament, but it did provide for a permanent international tribunal for arbitration between such nations as may choose to avail themselves of it. It is of supreme consequence that machinery is ready so that two nations at difference may escape war without loss of dignity, if they both desire. Even more significant and hopeful, however, is a long series of arbitration treaties between nations, two and two, beginning with the Anglo-French treaty of 1903. Despite the terrible Russo-Japanese war, the first years of the 20th century have seen remarkable progress toward the federation of the world.

Bibliography.—Within the space at command, no detailed bibliography is possible. Since the dawn of the scientific study of history, writers have shunned the attempt to cover the complex field of modern history except in co-operative "series." Of such series the most important in English are 'The Cambridge Modern History,' edited by Ward (1903, 12 vols., of which only 5 have appeared by 1905); and 'Periods of European History,' edited by Hassall (1890–2. 8 vols., of which the last 5 belong to our period). Andrews' 'Historical Development of Modern Europe' (1896), Fyffe's 'Modern Europe to 1878' (1884), and Seignobos' 'Europe Since 1814' (1899) deal with the 19th century. Cunningham's 'Western Civilization' (1900), and McVey's 'Modern Industrialism' (1904) treat special phases. For further references the reader may consult the special bibliographies at the close of the articles on leading countries and movements. West's 'Modern History' (a high-school manual, 1904) in an appendix gives a classified bibliography of 150 standard English works.

WILLIS MASON WEST,
Professor of History, University of Minnesota.

History, Logic of. The relation of history to the problems of the philosopher has been mostly confined to those questions which are treated in the philosophy of history. The object of this discipline is to interpret the meaning of mankind's historical development and to comprehend the progress of humanity in the setting of a metaphysical system. It is only in recent times that philosophy has recognized clearly the importance of an entirely different relation. If the philosopher studies in the science of logic the ways of thought and the special methods by which the different special sciences are able to reach the truth it must be logical and thus, ultimately, a philosophical task to examine the methods of historical investigation. The special schemes of the historian's technique belong to historical science proper. But as soon as the attitude which the historian has to take towards the world is in question, we stand before a logical problem which is most nearly connected with the general problem of the meaning of truth. A rich literature devoted to this circle of problems has grown up during the last decade, partly through the activity of philosophers and psychologists, partly from the interests of historians and economists themselves.

Of course, it is possible to take the skeptical attitude and to deny the existence of a particular problem here. We can say that all science has the same kind of task, and that the logical problems are thus not other for history than for the natural sciences. Yet this attitude may lead to two different standpoints. The first is the most popular one. From that it would appear that history is not a real science at all. It collects a mass of material just as the zoölogist collects his specimens; but that kind of treatment which makes zoölogy a real science, the study of the common characteristics and of the underlying laws, is not in question for the historical material. Instead of this an art enters into play, the art of historical presentation. The works of the great historian are thus in first line works of art parallel to the great epic narratives, with only the difference that the epic poems follow the lines of imagination while the historian reconstructs the facts as they may have happened. Scientifically history would thus stand on the lowest level, as a mere collection of facts without that real scientific treatment which makes the value of the other sciences. The best which can be hoped, then, is that it may be brought to a kind of scientific height by introducing as much as possible the results of other sciences such as physics, biology, anthropology, geo-physics, etc., into the explanation of historical happenings. The influences of climate, of race disposition, of technical inventions, and so forth, then become predominant in the scholarly treatment of historical events. It may be said that this low opinion of the pure scientific character of history has been prevalent throughout the whole history of science.

But those who consider the natural sciences as the only type of real scientific work may be led, and have been led frequently in recent times to still another standpoint. They may say that history has the greatest possibility of being a full-fledged science. The only step it has to take is that from the merely descriptive to the law-seeking attitude. The real task of the historian, they say, would be to find the common features which belong to the growth of every nation and to the political and social, artistic and scientific, economic and religious movement of the different periods and of the different communities. As long as isolated processes are described, history indeed remains on a pre-scientific level, but as soon as we recognize characteristic types of development, we reach general laws like those of the biologist or the chemist. The interest concentrates itself then on the psychological factors which moulded the fate of the nations, and especially the life of the masses becomes a true historical agency. That which is unique then becomes insignificant and accidental as compared with the great typical processes which repeat themselves under similar conditions in the most different countries. A kind of natural science of historical nations thus becomes the logical goal.

Those modern movements, however, which have forced the problems of the logic of history to public attention object to both these standpoints because they refuse to admit the first presupposition. They deny that the natural sciences are the only type of a real science. They claim, rather, that this is a prejudice which has been suggested to the world by the overwhelming influence of the Aristotelian logic on the one side, and the impressive triumphs of natural science on the other. They hold that there exist two types of scientific thought in principle commensurable, and that the historical way of thinking is in its importance and in its logical right perfectly coördinate with naturalistic thought. Yet here again a variety of standpoints have been taken.

The simplest presentation of this doubleness of logical method is offered by those who hold that the whole separation is to be deduced from the doubleness of the logical attitude. They say that we can take with reference to everything in the universe either the attitude of interest in the general law or the attitude of interest in the particular thing. The one interest can never be substituted for the other. In the one case the particular object is for us only a sample illustration for a general relation. We seek the law which expresses that relation and inhibits therefore the interest in the special chance case which is before us. That is the attitude of the naturalist. On the other hand we may give our whole attention to the particular object before us in its uniqueness, and there is no doubt that our practical interests of life force on us just this attitude. Our earth may be astronomically not more important than any other planet, but our practical interest belongs to this planet alone. Our friends may be to the biologist not more instructive than any other group of organisms, but for our friendship those particular men have their unique position and cannot be replaced by other chance copies. To develop systematically this interest in the particular is the function of the historian, and anything which has its particular existence is possible historical material. Yet it is evident that no science can have the task of describing every particular pebble on the beach. There must be a principle of selection, and this is given in the reference to our values. The men who have relation to that which is valuable in the world, to the development of state and law, of art and science and religion, are to be selected for the historian's account. And this ultimate reference to values binds the particular objects together, while it is evident that the law of natural science brings the facts under a point of view under which they have no special value at all, but are indifferent objects of theoretical observation. The antithesis is thus complete. The naturalist seeks the general, the historian seeks the particular. The naturalist refers everything to the law, the historian everything to the value. Both groups of interest create logically independent systems of knowledge. Their difference is thus in no way a difference of material, as there is nothing in the world which cannot be considered from both points of view. The sun which the astronomer studies in relation to the astronomical laws as a chance case of a general relation which holds for myriads of suns, may be at the same time the object of interest for those who ask about the development of this one particular sun which gives us light. And on the other hand, even the Napoleon of the historian may be brought under the laws of biology from the standpoint of the naturalist.

Others who welcome this sharp separation feel doubtful whether it is really the logical attitude which determines the difference and not the content. They claim that it is not true that natural science has to deal with laws only. Natural science may very well give its attention to particular objects too, and the development of our sun or our earth or our mankind is not history but natural science. The true difference, they say, lies rather in the doubleness of the objectifying and the subjectifying attitude.

The sun and earth are for us all objects, but men and their work can be considered in a double way. We can consider our neighbors as objects, as phenomena which we describe and explain, but we can consider them also as subjects of will which we understand and interpret and appreciate, and this doubleness of attitude reaches over the whole of mankind. Wherever there is will, there the object can be taken as a subject and it is claimed that the work of the naturalist is the study of the world in so far as it is conceived as a system of objects, while the study of the historian is the world in so far as it is conceived as a system of will relations. Only subjects of will would thus be able to enter into history at all. And the task of the historian is to understand the systematic relations between the purposive actions. The naturalist starts from the objects of his perception and seeks their causes and their effects. The historian starts from those will demands which reach him as the political, legal, artistic, scientific, economic, religious demands of his social world, and he seeks to interpret them by connecting them with the purposes of the past. The naturalist explains, while the historian interprets intentions and links the will purposes into a connected unity.

1906 Palma, President of Cuba, resigns; United States assumes control.

Hitchcock, hĭch'kŏk, Charles Henry, American geologist: b. Amherst, Mass., 23 Aug. 1836. He was a son of Edward Hitchcock, geologist (q.v.). He was graduated from Amherst College in 1856, was assistant State geologist of Vermont in 1857–61, State geologist of Maine 1861–2, and of New Hampshire 1868–78. In 1868 he was appointed professor of geology in Dartmouth College. In connection with his survey of New Hampshire, he maintained, during the winter of 1870, a meteorological station on Mount Washington, the earliest high-mountain observatory in the United States. He became known as a compiler of geological maps, and for his investigations regarding the geology of the crystalline schists, ichnology, and glacial geology. The location of the terminal glacier in the United States was first suggested by him. He was a founder of the Geological Society of America, and in 1883 president of the American Association for the Advancement of Science. His publications include: 'Elementary Geology' (1861, with E. Hitchcock); 'Mt. Washington in Winter' (1871); and a 'Report on the Geology of New Hampshire' (1873–8), with folio atlas, his most valuable work.

Hitchcock, Edward, American Congregational clergyman and geologist: b. Deerfield, Mass., 24 May 1793; d. Amherst, Mass., 27 Feb. 1864. He was principal of the academy in his native place 1815–18; pastor of the Congregational Church in Conway, Mass., 1821–5; professor of chemistry and natural history in Amherst College 1825–45, and president of Amherst College and professor of natural theology and geology 1845–54. He was appointed State geologist of Massachusetts in 1830, of the First District of New York in 1836, and of Vermont in 1857. In 1850 he was commissioned by the government of his native State to examine the agricultural schools in Europe. His life was in a great measure identified with the history of Amherst College. Connected with it almost from the beginning, in his own presidency he procured for it buildings, apparatus, and funds to the amount of $100,000, doubled the number of students, and established it on a solid pecuniary as well as literary and scientific basis. His earliest scientific publications were the 'Geology of the Connecticut Valley' (1823), and a 'Catalogue of the Plants within Twenty Miles of Amherst' (1829). Later works were: 'Lectures on Diet, Regimen, and Employment' (1831); 'Lectures on the Peculiar Phenomena of the Four Seasons' (1850); 'Reports on the Geology of Massachusetts' (1833–35–38–41); 'Illustrations of Surface Geology' (1857); 'Elementary Geology,' which passed through 25 editions in America, and one third of that number in England; 'Religion of Geology and its Connected Sciences' (1851); and 'Reminiscences of Amherst College' (1863). Dr. Hitchcock suggested as well as executed the geological survey of Massachusetts, the first not only in the long series of scientific surveys in the United States, but the first survey of an entire State under the authority of government in the world. He was the first to give a scientific exposition of the fossil footprints of the Connecticut Valley, and with him ichnology as a science began.

Hitchcock, Ethan Allen, American soldier: b. Vergennes, Vt., 18 May 1798; d. Sparta, Ga., 5 Aug. 1870. He was a grandson of Ethan

Allen (q.v.), and was graduated at West Point in 1817, entering the corps of artillery as a third lieutenant. In 1829 he became the military commandant of the corps of cadets, in which office he continued until 1833. He served in Florida against the Indians, and in the war with Mexico, where he received two brevets, one as colonel and another as brigadier-general. In 1855 he printed for private circulation a pamphlet in support of his opinion that genuine alchemy was not an art for making gold, but that the alchemists were students of man, whose perfection was symbolized by their "philosopher's stone." He subsequently published: 'Remarks upon Alchemy and the Alchemists' (1857); 'Swedenborg a Hermetic Philosopher' (1858); 'Notes on the Vita Nuova of Dante' (1866).

Hitchcock, Ethan Allen, American politician: b. Mobile, Ala., 19 Sept. 1835. He received a secondary education, was in mercantile business at St. Louis, Mo., in 1855–60, then went to China to enter a commission house, of which firm he became a partner in 1866. In 1872 he retired from business, in 1874 returned to the United States, and in 1874–97 was president of several manufacturing, mining, and railway companies. He was appointed envoy extraordinary and minister plenipotentiary to Russia in 1897, and in February 1898 ambassador extraordinary and minister plenipotentiary, the first ambassador accredited from the United States to the court of Russia. In 1898 he was nominated and confirmed as secretary of the interior, and held that position till 4 March 1907.

Hitchcock, James Ripley Wellman, American art critic: b. Fitchburg, Mass., 3 July 1857. He was graduated at Harvard in 1877, and was art critic of the New York *Tribune* 1882–90. He has written: 'The Western Art Movement' (1885); 'A Study of George Inness' (1885); 'Madonnas by Old Masters' (1888), the text to photogravures; 'The Future of Etching'; 'Some American Painters in Water Colors'; 'Etching in America'; 'Notable Etchings by American Artists'; etc.

Hitchcock, Roswell Dwight, American Congregational clergyman: b. East Machias, Maine, 15 Aug. 1817; d. Somerset, Mass., 16 June 1887. Graduated from Amherst College in 1836 and from the Andover Theological Seminary in 1838, he also studied at Halle and Berlin (1847), in 1845–52 was pastor of the First Congregational Church at Exeter, N. H., and in 1852–5 professor of revealed religion in Bowdoin College. In 1855 he became professor of church history at the Union Theological Seminary, of which institution he was elected president in 1880. He became president of the Palestine Exploration Society in 1871, and vice-president of the American Geological Society in 1880. An editor of the 'American Theological Review'; he wrote: 'The Life, Character, and Writings of Edward Robinson' (1863); 'Complete Analysis of the Holy Bible' (1869); and 'Socialism' (1879). With Eddy and Madge, he compiled 'Carmina Sanctorum' (1885); and 'Eternal Atonement,' a volume of sermons, appeared in 1888.

Hittell, Theodore Henry, American historian: b. Marietta, Pa., 5 April 1830. In 1852 he was admitted to the bar at Cincinnati, in 1855 removed to California, in 1855–61 was connected with the *Bulletin and Times* of San Francisco and from 1862 practised law. He was State senator in 1880–2. He wrote a 'History of California,' his chief work; and compiled 'The General Laws of California,' known as 'Hittell's Digest,' and 'Hittell's Codes and Statutes of California.'

Hittites, hit'its, the name of several peoples mentioned in the Old Testament, and in Egyptian and Assyrian inscriptions. In the Old Testament the name is applied to three more or less distinct groups, namely, the "children of Heth" from whom Abraham purchased a burying-place; a people or group of peoples which inhabited Palestine before the Hebrews and resisted their invasion; a kingdom in northeastern Syria, with which Solomon formed marriage alliances. The first group dwelt around Hebron in southern Palestine, and the Hittites mentioned in connection with David, of whom the chief was Uriah, may be their descendants. The second group of Hittites dwelt among the mountains of central Palestine, and the third group, united in some sort of empire, had their seat still farther north. Of this Hittite empire we learn more from the Egyptian and Assyrian records than from the Old Testament. The Heta, according to the hieroglyphic inscriptions, offered a vigorous resistance in northern Syria to the Egyptian king Thutmosis III. (18th dyn.: c. 1560 B.C.), and to his successors of the 19th dynasty, Sethos I., Rameses II. and III., c. 1350–1200 B.C. Carchemish, Kadesh, and Hamath were among their chief cities. The cuneiform inscriptions contain notices of a people called Hatti who frequently fought with the Assyrians from the time of Tiglath-pilesar I. (c. 1100 B.C.) till that of Sargon II. (721–704 B.C.), after which they are no more heard of. The Hittite monuments and inscriptions which have been found in Carchemish, Hamath and neighboring places, as well as throughout Asia Minor, appear to belong to the Assyrian period.

Hittorf, Jacques Ignace, French architect: b. Cologne 1792; d. 1867. He studied his profession in Paris and was employed on many public buildings and places, doing work on the Bois de Boulogne, the Champs-Elysées and the Church of Saint Vincent de Paul. Among his publications may be mentioned 'Architecture Antique de la Sicile'; 'Architecture Moderne de la Sicile' and 'Architecture polychrome chez les Grecs.'

Hitzig, Ferdinand, German theologian: b. Hauingen, Baden, 23 June 1807; d. Heidelberg, 22 Jan. 1875. He was educated at Heidelberg, Halle and Göttingen. He went to Zurich in 1833 as professor of theology, where he remained until 1861, when he returned to Heidelberg. He was quite a voluminous writer on the Old Testament, composing commentaries on the Minor Prophets (1838); Jeremiah (1841); Ezekiel (1847); Ecclesiastes (1847); Daniel (1850); Song of Solomon (1855). He made a translation of the Psalms in 1835.

Hive-bee. See HONEY-BEE; BEE-CULTURE.

Hives. See URTICARIA.

Hoactzin, hō-ākt'zīn or -āk'zīn, a singular South American bird (*Opisthocomus cristatus*) of the size of a pheasant. It is brown streaked with white, and the head has a movable crest. It is interesting principally from the extraordinary way in which the fledglings, as soon as they leave the nest (in a tree), scramble about the branches by aid of their wings used like hands, by reason of the fact that they have a temporary claw on both the index and pollex. The food of these birds is mainly leaves and fruit; and a strong musky odor is given off by the adults, so that in British Guiana they are called "stinking pheasants."

Hoadley, hōd'lĭ, **George**, American lawyer: b. New Haven, Conn., 31 July 1826; d. Watkins, N. Y., 27 Aug. 1902. He was graduated at Hudson College, Ohio, in 1844; studied law at Harvard, was admitted to the bar in 1847 and joined a law firm in Cincinnati of which Salmon P. Chase (q.v.) was the leading member. He was appointed judge of the superior court of Cincinnati in 1859, and re-elected in 1864. He took a leading part among the "Barnburners" (q.v.), was a War Democrat, and during the War joined the Republican party. He defeated Foraker in a contest for the governorship of Ohio in 1883, but failed of re-election in a struggle against the same candidate.

Hoadly, Benjamin, English Anglican prelate: b. Westerham, Kent, 14 Nov. 1676; d. Chelsea 17 April 1761. He was educated at Cambridge; took orders in 1700, and after being settled in London distinguished himself in controversy with Bishop Atterbury and others. A staunch Low-Churchman, he was appointed bishop of Bangor in 1715. A sermon preached before the king of 1717 gave rise to the "Bangorian Controversy" regarding the divine authority of the king and the church. He was translated to the see of Hereford in 1721, to Salisbury in 1723, and Winchester in 1734.

Hoang-ho. See HWANG OR HOANG-HO.

Hoar, Ebenezer Rockwood, American jurist: b. Concord, Mass., 21 Feb. 1816; d. there 31 Jan. 1895. He was the son of Samuel Hoar (q.v.), was graduated at Harvard (1835), and subsequently admitted to the bar. He rose to be judge of the court of common pleas (1849), judge of the State supreme court (1859), and attorney-general of the United States (1869), and was a member of the Joint High Commission that framed the Treaty of Washington (1873–5).

Hoar, George Frisbie, American statesman: b. Concord, Mass., 29 Aug. 1826; d. Worcester, Mass., 30 Sept. 1904. Senator Hoar's paternal and maternal inheritance was very remarkable. His grandfather was an officer in the Revolutionary army and his father, Samuel Hoar, was one of the ablest lawyers and statesmen of his time, a member of Congress from Massachusetts, and a man of great learning and force of character. Senator Hoar's mother was a daughter of Roger Sherman, a signer of the Declaration of Independence. He was graduated from Harvard in 1846, studied law there, and began his law practice in Worcester, Mass. The young man was early attracted to politics and identified himself with the Free Soil party, and his purpose in 1895 — so characteristic of his whole career — is thus stated by himself: "All of us Free Soilers were drawn into politics by a great issue. It

GEORGE F. HOAR.

was to prevent slavery being extended into the new territory between the Mississippi and the Pacific. We were all ardent advocates of freedom. The party and the movement were new, and we were stirred by high ideals. Among the young men who went into the new movement at that time were my brother, Ebenezer Hoar, Erastus Hopkins, Anson Burlingame, Whittier, Lowell, Longfellow, and many others that became well known. There were no offices to gain. There was simply a cause to work for. In the campaign of 1850 the Free Soilers did not carry a single State, only a few Congressional districts." He was a member of the Republican party from the first, and in 1852 was elected to the Massachusetts house of representatives; in 1857 to the State senate. In the intervals of service he practised law. In 1860 he was city solicitor. He presided over the Republican conventions in Massachusetts in 1871, 1877, 1882 and 1885; was a delegate to his party's national conventions in 1876, 1880 (the chairman in that year), 1884, 1888, 1892 and 1896. He served in the national House of Representatives for four successive Congresses, 1869-77, elected as a representative of the Worcester district; in 1877 he was elected to the Senate, and was reelected in 1883, 1889, 1895, and 1901, serving his country continuously as a national legislator since 1869, having represented Massachusetts for a longer period in the national Congress than any other representative from that State. In 1876, he was one of the managers on behalf of the House in the Belknap impeachment trial, and was also a member of the Electoral Commission (q.v.), which decided the Hayes-Tilden contest for the Presidency, the other Republican members of that famous body being Senators George T. Edmunds, O. P. Morton and Frederick T. Frelinghuysen, and Representative James A. Garfield. In the Senate he was chairman of the judiciary committee, and of the committee on privileges and elections, and a member of other important committees. He was known as the old man eloquent of the Senate, having served in that body for 37 years and taken part in all the great questions that have been before the country during that time. He was a determined opponent of the retention of the Philippines, and independent enough to state his views fearlessly in the support of his own theory that the United States should leave the islands to the control of the Filipinos and prevent interference from foreign nations, but his honesty and sincerity were unquestioned and he always retained the confidence of his party and the respect of all. He was a thorough American and believed in the future of his country and placed its welfare above all personal considerations. "The lesson which I have learned in life, which has been impressed upon me daily and more deeply as I grow old," he said in his autobiography, "is the lesson of Good Will and Good Hope. I believe that to-day is better than yesterday, and that to-morrow will be better than to-day. I believe that, in spite of many errors and wrongs, and even crimes, my countrymen of all classes desire what is good, and not what is evil."

Senator Hoar was an idealist, and was not to be turned aside, even by his loyal love of party, from following his sincere convictions. He demanded justice for the negroes and the Indians, openly declared his sympathy for Cuban and Filipino, and as firmly opposed religious intolerance in Massachusetts because his actions were controlled by reasons which he considered were founded in righteousness and truth, and therefore not subject to change.

Senator Hoar was a man of considerable scholarship and took great delight in literary and historical studies. He was a member of several historical and scientific societies, and took much interest in their work. He was president of the American Historical Society, president of the American Antiquarian Society, regent of the Smithsonian Institution in 1880, and trustee of the Peabody Museum of Archæology. He received the degree of LL.D. from the College of William and Mary, Amherst, Yale and Harvard. In 1903 he published 'Autobiography of Seventy Years,' which first appeared in 'Scribner's Magazine' as a serial. The same year, in a speech in his home city of Worcester, Senator Hoar, as if in anticipation of his approaching dissolution, thus summed up the creed of his career:

"If my life has been worth anything, it has been because I have insisted, to the best of my ability, that these three things — love of God, love of country, and manhood — are the essential and fundamental things, and that race, color, and creed are unessential and accidental."

Although 78 years of age, he was in good health until the death of his beloved wife in 1903; their devotion had led many to predict that neither would long survive the other. Senator Hoar was taken seriously ill in June 1904, but lingered until 30 September, when he died at Worcester, Mass.

His death was the occasion of a remarkable display of panegyric in the press of both Republican and Democratic parties. It possessed the peculiar quality of reconciliation, one party regretting what the other considered his noblest quality. The only flaws in his judgment, said the Republican press, were his disagreements with the party leaders on the Philippine and Panama issues; but to the Democratic press his noble loyalty to the right on these occasions was convincing proof of his lofty statesmanship. The Democratic press regretted his inability to see any good in their party, while to Republican journals this virtue redeemed his errors of judgment on the matters of party policy.

One journal said: "As long as the confidence and affection of all the people are given to such a man, it is foolish and false to assume that the old standards are departing and the old ideals becoming broken. The people still know a man when they see him. Still they respect and honor the statesman who loves the republic better than he does himself, who never falters in his service, to whose fingers gold does not cling, and whose never-forgotten ideal is the people's welfare. While they honor such qualities above all others, pure and able statesmen will continue to come to their service," sentiments which were summarized in Ex-President Cleveland's statement that "Senator Hoar's ability, his high-mindedness, and his freedom from political trickery, furnish an example of a useful life which may well be imitated by all those entrusted by their countrymen with public duties."

Editorial Staff 'Encyclopedia Americana.'

Hoar, Samuel, American lawyer and legislator: b. Lincoln, Mass., 1778; d. 1856. He was graduated at Harvard in 1802 and three years later entered upon a highly successful career as a lawyer. He served two terms as a State senator and was chosen by the Massachusetts legislature to challenge the constitutionality of certain laws in South Carolina relating to the imprisonment of free negroes. He was subsequently excluded from South Carolina courts by the State legislature.

Hoarhound. See HOREHOUND.

Hobart, Garret Augustus, American lawyer and politician: b. Long Branch, N. J., 1844; d. Paterson, N. J., 2 Nov. 1899. He was graduated at Rutgers College, New Jersey, in 1863, and admitted to the bar in 1866. At Paterson, where he made his home till his death, he enjoyed a successful law practice. He became successively city attorney, prosecuting attorney for Passaic County, a member of the State Assembly 1873–8, and of the State Senate 1879–85. During his several terms he was speaker of the Assembly and president of the Senate. In 1896 he was nominated at St. Louis for vice-president on the ticket with William McKinley, whose intimate friend he was, and was elected to that office.

Hobart, George Vere, American journalist, playwright, and author: b. Cape Breton, N. S., 16 Jan. 1867. He was educated in Nova Scotia, later coming to the United States as a telegraph operator for the United Press. He became editor of the Cumberland Sunday 'Scimitar,' later writing for the 'Herald,' *Evening News* and 'American' of Baltimore. Since then he has been writing for the Hearst newspapers the humorous sketches, 'John Henry' and 'Dinkelspiel.' He has written 'Many Moods and Many Meters' (1899), and 'Li'l Verses for Li'l Fellers' (1903), both poems; the 'Dinkelspiel' series (1900); the 'John Henry' books (1901–4), and the plays, 'After Office Hours,' 'Miss Print,' 'Hodge, Podge & Co.,' 'Sally in Our Alley,' etc.

Hobart, John Henry, American Protestant Episcopal bishop: b. Philadelphia 14 Sept. 1775; d. Auburn, N. Y., 10 Sept. 1830. He was educated at the College of Philadelphia (now the University of Pennsylvania), and the College of New Jersey (now Princeton), and after trying commercial life in his brother-in-law's counting house, went back to Princeton as a tutor for two years, and was ordained deacon in 1798 and priest in 1801. After brief periods of pastoral service in Pennsylvania, New Jersey, and Long Island, he became assistant in Trinity Parish, New York, where he remained until his elevation to the episcopate, combining with his other duties a prominent share in the legislative councils of the church, as deputy to the General Conventions of 1801 and 1804, and secretary to the House of Deputies in the latter year. In 1811 he was consecrated as bishop-coadjutor in the diocese of New York, and upon the death of Bishop Moore in 1816, succeeded him both in the full charge of the diocese and in the rectorship of Trinity Church. He also gave provisional episcopal care at different times to New Jersey and Connecticut. He was very active in promoting the establishment of the General Theological Seminary, and upon its location in New York became professor of pastoral theology. Hobart College also owed much to him, a debt recognized by the taking of his name, when, in 1852, the original title of Geneva College was changed to Hobart Free College. He wrote or edited a number of theological works, some of which, especially his 'Companion for the Festivals and Fasts' (1805), reached several editions. His 'Apology for Apostolic Order' (1802) is still used as a text-book.

Hobart, the capital of Tasmania, and up to 1881 called HOBART TOWN, is situated at the foot of Mount Wellington (4,166 feet high), on the Derwent River, 12 miles from its outlet in Storm Bay on the south coast. It has handsome public buildings, including government house, the government offices, parliament houses, Episcopal and Catholic cathedrals. There are important domestic manufactures, and in connection with its considerable shipping interests, a fine harbor with modern accommodations. Hobart is connected by rail with Launceston. Pop. (1903) 31,400.

Hobart College, a Protestant Episcopal institution, located at Geneva, N. Y. In 1825 it was chartered as Geneva College; but in 1852 the name was changed to Hobart Free College, and in 1860 to Hobart College. Bishop Hobart (q.v.) had aided the school by advice and by money. An endowment from Trinity Church, New York, had greatly assisted the institution. The college offers scholarships and prizes to worthy students, and the departments are all well sustained. The courses lead to the degrees of A.B., B.S., and Ph.B. There are about 44,000 volumes in the library. In 1904–5 the school had 17 professors and instructors and 105 students. The graduates number nearly 1,500.

LANGDON C. STEWARDSON,
Registrar.

Hobart Pasha, AUGUSTUS CHARLES HOBART-HAMPDEN, third son of the Earl of Buckinghamshire, English sailor: b. Waltham-on-the-Wolds, Leicestershire, 1 April 1822; d. Milan, Italy, 19 June 1886. He entered the English navy as midshipman 1836 and retired as captain at the conclusion of the Crimean War in 1863. During the American Civil War he took the name of 'CAPTAIN ROBERTS' and was given command of a blockade runner, an account of which is to be found in his 'Sketches of My Life' published posthumously. In 1867 he entered the Sultan's service, reorganized the Turkish navy, and fought the Russians on the Black Sea in the War of 1877–8. He was made Pasha (1869) and marshal of the Turkish Empire (1881).

Hobbema, Meindert, mīn'dĕrt hŏb'ē-mā, Dutch landscape painter: b. Amsterdam, 1638; d. there 7 Dec. 1700. He was considered, next to J. Ruysdaal, the best of the Dutch landscape-painters, and as a colorist reckoned even superior to Ruysdaal. The figures in his landscapes are painted mostly by Berchem, Van de Velde, Lingelbach, and J. Van Loo. His paintings consist chiefly of forest scenes, ruins, villages, etc. Some of the most celebrated works of this master are to be found in public or private galleries in France, Germany, and Holland. His greatest painting is 'A View in Holland,' with figures painted by Adrien van de Velde.

Hobbes, John Oliver. See CRAIGIE, PEARL MARY TERESA.

Hobbes, Thomas, English moralist, philosopher, and political scientist: b. within the borough of Malmsbury, Wiltshire, 5 April 1588; d. Hardwicke, Derbyshire, 4 Dec. 1679. Thomas Hobbes is eminent as writer on the theory of government, on psychology, and on metaphysics, and as master of a vigorous and picturesque English style. He was born in the year of the Spanish Armada, 1588, and lived to be 91 years old, active to the end in mind and in body. He was the son of a poor English vicar, was educated by his uncle, a prosperous glover, and spent the last five of his student years at Magdalen College, Oxford. The Oxford of that period was given over to a restricted and arid scholasticism, barring out mathematics, for example, as a black art; and Hobbes retained through life a vivid memory of the pedantry and narrowness of the Oxford of his youth. At the end of these student years, in 1608, he was employed by Cavendish, afterwards Earl of Devonshire, as tutor to his son; and he remained for the next 20 years in the service of this same great family and throughout his life, in close and friendly connection with it. For two years he traveled with his pupil on the continent, and then followed 18 years in England—a service terminated only by the death of his former pupil and constant friend, the second Earl. During these years, Hobbes devoted himself to classical study, which bore fruit in his vigorous translation of Thucydides, published in 1628. The three succeeding years were spent on the Continent, at first in travel with another English youth, later in the eager study, mainly at Paris, of mathematics and natural science. Hobbes himself tells us with what astonishment and delight he first, in 1628, when he was 40 years old, saw and read Euclid's 'Elements.' In 1631 he became tutor to the third Earl of Devonshire, son of his late patron and first pupil. With him he made, in 1634, a third continental journey, learned to know Galileo during his sojourn in Italy, and was admitted, in Paris, to the fellowship of a group of mathematicians and scientists. He must have been pondering on problems of politics and of psychology in the intervals of his study of physics and geometry, for his next book, which circulated in manuscript as early as 1640, set forth his theory of human nature and of the body politic. The publication even privately of this doctrine brought its author into prominence and strongly influenced the course of his life.

The psychology of Hobbes forms the basis both of his political and of his metaphysical doctrine. He distinguishes the 'cognitive (or conceptive)' faculty from the 'motive' faculty of the mind, and recognizes five senses, to which he adds 'a sixth sense, but internal, * * * commonly called remembrance.' He defines the affective consciousness as 'motion about the heart,' which "when it helpeth is called pleasure * * * but when it hindereth the vital motion is called pain." And he ends with a discussion of the passions which reduces will to desire and conceives each emotion from a narrowly individualistic standpoint. "To endeavour" he says, "is appetite"; and, in the race of life, "continually to out go the next before is felicity."

The foundation of the political system of Hobbes is the teaching that men "are by nature equal," and self-seeking; that "many men at the same time have an appetite to the same thing; which yet very often they can neither enjoy in common, nor yet divide"; that consequently "every man is enemy to every other" and that "during the time men live without a common power to keep them all in awe, they seek such a Common Power, as may be able to defend them from invasion of foreigners and are in that condition which is called War." "The only way," Hobbes continues, "to erect such a Common Power, as may be able to defend them from invasion of Foreigners and the injuries of one another * * * is to confer all their power and strength upon one man or upon one Assembly of men, that may reduce all their Wills, by plurality of voices, unto one Will." Hobbes accordingly conceives of a government as formed by a mutual contract of individuals, of whom each seeks simply his own preservation, happiness, and security. The contract, he insists, is between each individual "subject" and every other—not at all, between subject and sovereign. It is made, he says, "by covenant of every man with every man * * * as if every man should say, *I authorize* and give up my Right of Governing myself to this Man, or to this Assembly of men, on this condition, that thou give up thy Right to him." Upon this theory, that the covenant of every citizen with every other underlies government, Hobbes bases his well-known doctrine of the absolute right of the sovereign. For, he argues, all the governed "are bound, every man to every man to Own and be reputed Author of all, that he that already is their Sovereign, shall do, and judge fit to be done." In other words "every Subject is Author of every Act the Sovereign doth."

Hobbes asserts unambiguously the subordination of church to state. "The Kingdom of Christ," he declares, "is not of this world; therefore neither can his ministers (unless they be Kings) require obedience in His name." It follows, he teaches, "that every Christian Sovereign [is] the supreme Pastor of his own Subjects"; and that every subject is bound to obey the command of his sovereign with regard not only to the forms of religious worship but to the nature of the doctrines openly professed. Such conformity to the will of even an "infidel sovereign" does not conflict, Hobbes insists, with our duty to God. For God requires of us only faith and obedience to his laws. "And when the Civil Sovereign is an Infidel, every one of his own Subjects that resisteth him sinneth against the Laws of God (for such are the Laws of Nature) and rejecteth the counsel of the Apostles that admonisheth all Christians to obey their Princes. * * * And for their *Faith* it is internal and invisible; they have the license that *Naaman* had, and need not put themselves into danger for it. But if they do, they ought to expect their reward in Heaven, and not complain of their

Lawful Sovereign, much less make war upon him."

It is not possible, within the limits of this article, to outline the ingenious argument by which Hobbes seeks to foist upon a present generation, the responsibilities of a social contract which a past generation made. Still less is it possible to present an adequate criticism of the conception of Hobbes. Psychologists and sociologists have long since agreed that his psychology and his political theory are alike defective: that societies and governments grew, and are not manufactured: and that sympathy no less than selfishness is a basal instinct. Yet Hobbes's theory of society is still worth studying, not only because it is expressed in such vigorous English, nor even mainly because of the influence it exerted on Rousseau and Spinoza (qq.v.), but primarily because it so ruthlessly depicts society as it would be if men were no more than self-seeking and egoistic.

It is evident that the brilliant attempt of Hobbes to justify the absolute supremacy of the monarch could find little favor in England in the years of the Parliamentary struggle with Charles I. Hobbes, who was morbidly timid, believed that he stood in personal danger and betook himself, a voluntary exile, to Paris where he spent 11 years in the society, on the one hand, of French men of science and letters, and on the other hand, of the English royalists. In 1646 Hobbes became the tutor of the young prince, later Charles II. He published in the meantime an epitome in Latin, 'De Cive,' of his doctrine of government, and afterward the earlier work already referred to. In 1651 he brought out the work by which he is best known, 'Leviathan, Or, The Matter, Form and Power, of a Commonwealth.' This book is the most popular, forcible, and detailed discussion of the political theory of Hobbes. It is prefixed by several chapters which are properly psychological, and which embody an egoistic and sensationalistic psychology full of acute introspection and of keen discrimination. The later chapters of 'Leviathan' include suggestions of materialistic doctrine. In spite of its monarchical tendency, 'Leviathan' was violently opposed by the influential clerical party among the English royalists in Paris. Hobbes concluded that he would be safer even in Puritan England, returned accordingly, and lived unmolested under the Cromwells. At the Restoration, in 1660, he regained the royal favor and he never afterward lost the protection of his old pupil, Charles II.

The metaphysical doctrine of Hobbes is expounded in two books published a few years after his return to England: 'De Corpore,' which appeared in 1655, and a translation, 'Concerning Body,' published a year later. This teaching is succinctly stated in these words: "The world (I mean * * * the whole mass of things that are), is corporeal, that is body; * * * and that which is not body is no part of the universe." The doctrine of Hobbes is, in other words, frankly materialistic; he teaches that the innumerable realities which go to make up the universe are, one and all, non-spiritual, or material. So-called spirits are, he holds, merely subtle and intangible bodies; and even God, the First Cause of the universe, is body. The philosophy of Hobbes becomes in its detail a system of mechanics or of physics; for, since all reality is physical, laws of space or of motion must be ultimate laws.

The metaphysical doctrine of Hobbes deserves more attention than it often receives, because it is so thoroughgoing and internally consistent a system of materialism. The arguments, implicit rather than explicit, on which Hobbes bases it are none the less, in the view of the writer of this notice, unsound. In brief, Hobbes argues for materialism partly because of the untrustworthiness of consciousness, and partly on the ground that physical motions are admitted to be cause of consciousness. 'It is evident,' he says, while describing the phenomenon of vision, in the second chapter of 'Human Nature,' "that from all lucid * bodies, there is a motion produced to the eye, and through the eye to the optic nerve, and so into the brain * * * and thus all vision hath its original from * motion." From similar observations he concludes that ideas (or in his own words, apparitions or phantasms) "are nothing really but motion * ." The reasoning that consciousness because *conditioned by* motion is, therefore, *identical with* motion is evidently illicit; and it is observable that Hobbes, when he tries to define body, motion, and space, really conceives them in terms of ideal reality.

Just before the appearance of the metaphysical works, in 1654, an essay 'Of Liberty and Necessity,' written by Hobbes eight years before in the course of a private discussion with Bishop Bramhall, was published without the knowledge and consent of the author. It was followed in 1656 by a longer and more polemical work, 'The Questions Concerning Liberty, Necessity, and Chance, clearly Stated and Debated between Dr. Bramhall * * and Thomas Hobbes.' The unambiguous teaching of these works is a determinism grounded in psychology, the doctrine "that voluntary actions have all of them necessary causes and are therefore necessitated."

Most of the works which Hobbes published from this time onward are, indeed, controversial in character. Most bitter of them are the books and essays on mathematical subjects, maintaining against Wallis and Ward, Savilian professors in Oxford, the possibility of squaring the circle. The titles of two of these works are an indication of the spirit in which Hobbes wrote them: 'Six Lessons to the Professors of the Mathematics * * * in the chairs set up by * * * Sir Henry Savile in the University of Oxford'; and 'Στιγμαι or Marks of the Absurd Geometry, Rural Language, Scottish Church Politics and Barbarisms of John Wallis.' Hobbes, who was, after all, no trained mathematician, was always worsted in these mathematical contests, but never acknowledged himself defeated.

More serious than the justified criticisms of Ward and Wallis on the mathematics of Hobbes were the attacks upon the orthodoxy and the morality of his teaching. These attacks, and especially the abortive attempt to suppress 'Leviathan' by act of Parliament, caused Hobbes great uneasiness. In the Appendix which he added to his translation of 'Leviathan' into Latin (published 1668) he argued that the teaching of 'Leviathan' is not heretical, and that there remains no English court of heresy; and he wrote at the same time a very vigorous 'Answer to a Book Published by Dr. Bramhall * * * called Catching of the Leviathan,' a book in which the Bishop of Derry had maintained "that the Hobbian principles are destructive to Christianity and to all religion." Nobody doubts today that these charges are unfounded. Hobbes, it is true, inculcated a materialistic philosophy and an egoistic and necessitarian ethics; but upon these doctrines he himself based both the philosophical conclusion that God exists, and an ethical system which exhorts to justice and social virtues, even while it derives these virtues from purely selfish instincts. It is necessary to suppose that many of the men who decried Hobbes had never read him; and that the epithets 'free-liver,' and 'atheist,' which writers of his own and the following century heaped upon him were due, in part at least, to the fact that Hobbes remained throughout his life in some sense under the protection of his former pupil, Charles II. Very unjustly, therefore, he was held responsible for the lax morals of the court. It should be added that from this time onward Hobbes failed to gain from the censor license to publish any work on a political or on an ethical subject. The chief of the works, written at this period but published after the death of Hobbes, is 'Behemoth: The History of the Causes of the Civil Wars of England * * * from the Year 1640 to the year 1660.'

Hobbes spent the last four years of his life with the family he had so long served, that of the Earl of Devonshire. In these later years he returned to the classical studies of his youth, publishing when he was 87 years old, 'The Iliads and Odysses of Homer, translated out of Greek into English, with a large preface concerning the Virtues of an Heroic Poem.' In his very last year he wrote a sketch, in Latin metre, of his own life. He had feared many things, and death most of all, but he died quietly after a short illness, in 1679.

Bibliography.— The authoritative edition of Hobbes is that of Sir William Molesworth: 'English Works' (in eleven volumes); 'Opera Latina' (in five volumes)— London, 1839–1845. A recent reprint of the 'Leviathan' is that of Thornton (Oxford, 1881). Selections, mainly from the ethical and political writings, are those of E. H. Sneath (1898), and F. J. E. Woodbridge (1903). 'The Metaphysical System of Hobbes' edited by M. W. Calkins (Chicago 1905) contains the important chapters of 'Concerning Body.' For biography and criticism the reader is referred to G. C. Robertson, 'Hobbes' (1886); Leslie Stephen, 'Hobbes' (1884); and Tönnies, 'Hobbes, Leben und Lehre' (1896). For complete list of the writings of Hobbes and for further references to his critics, one should consult the works just cited, and the Bibliography of Benjamin Rand, published as Vol. III., Pt. I. of Baldwin's 'Dictionary of Philosophy and Psychology.'

Mary Whiton Calkins,
Professor of Philosophy and Psychology, Wellesley College.

Hob'ble-Bush, a viburnum (*V. alnifolium*) of the southern interior of the United States, whose branches often stretch along the ground and root at the other end, tripping up the unwary; hence it has such other names as warfaring-tree, tanglefoot, and devil's-shoestrings. The branches are long, flexuous, and reddish in color, and the leaves are nearly orbicular and turn to a deep red in the autumn. See Viburnum.

Hobkirk's (hŏb'kerks) **Hill, Battle of**, in the Revolution, 25 April 1781. After Guilford Court-house (q.v.), Greene marched toward the British position at Camden under Rawdon, and encamped at Hobkirk's Hill, about 1½ miles north. He had 940 men in line, prudently encamping in order of battle; and some militia just arrived who took no part in the battle. His trains and artillery had not come up, and a renegade drummer boy informing Rawdon of this, the latter took 960 men, and making a detour to the right through the woods in front of Greene, drove in Greene's pickets with so sudden an onslaught that the Americans had barely time to form. Greene ordered the First Maryland to charge bayonets and William Washington to take the British in the rear with his cavalry, while Ford and Campbell executed flanking movements on Rawdon's wings. But Ford was killed, one of the First Maryland's captains was shot, the men fell into disorder, and Col. Gunby ordered the regiment to form on the rear companies instead of moving the latter forward; the retiring men were seized with a panic, the famous veterans broke, and though soon re-formed, the position was dangerous and Greene had to retreat. Gunby was court-martialed, but acquitted of anything but grave misjudgment. Greene's loss was 135, besides missing militia; Rawdon's 220 (his own figure) or 258 (Tarleton's). Consult Dawson, 'Battles of the United States' (New York 1858); Carrington, 'Battles of the American Revolution' (New York 1877).

Hoboken, hō'bō-kĕn, N. J., city in Hudson County; on the Hudson River. It is the terminus of the Delaware, L. & W. R.R. It is opposite New York city, north of and adjoining Jersey City, and has on the north and west the Palisades. Its area is about one square mile. It has electric railway connections with a number of the cities and towns of the State, and by direct ferries with the business district of New York. The principal streets run north and south, nearly parallel with the river. Its long waterfront gives it excellent shipping facilities; and here are located the docks of the ocean steamship lines; the North German Lloyd, the Thingvalla, the Netherlands-American, and the Hamburg-American. The land upon which Hoboken is located as well as much of that adjoining, once formed a part of the territory of New Netherlands. It was early known as Hobocan Hacking, which means "the land of the tobacco-pipe." The tobacco-pipes which were made by the Indians from the stone found in the vicinity gave rise to the name. In 1630 Michael Pauw, of Holland, purchased from the New Netherlands Company a tract of land a part of which is the site of the present city of Hoboken. The land around was soon cultivated and as New Amsterdam grew in numbers and importance, the gardens across the river became more valuable. John Stevens (q.v.), in 1804, purchased the land upon which the city now stands, and began the town. At this time and for some years after the Elysian Fields of Hoboken were much used as pleasure grounds by New Yorkers. At first Hoboken was a part of the town of North Bergen, but on 28 March 1855 it was incorporated as a city. The disastrous fire at the wharves of the North German Lloyd Steamship Company, which occurred in 1900, destroyed considerable of the city property and three steamers. The estimated number of lives lost was 200. The chief manufactures of Hoboken are iron products, leather, silk, lead-pencils, caskets, wall-paper, beer, shipbuilding and repairing, and chemicals. It has extensive coal yards, and large lumber and brick yards. The drainage of the lowlands is now (1903) under consideration, and by this means a large tract of land will be reclaimed and the sanitary conditions of the city improved. The city is the seat of the Stevens Institute of Technology (q.v.), and of the Sacred Heart Academy. It has Saint Mary's hospital, public and parish schools, and several fine church buildings. The government is vested in a mayor, who holds office two years, and a city council. The mayor appoints the school, library, fire, and health commissioners, also the assessors. The police commissioners are appointed by the mayor and approved by the council. The council elects the inspectors, the city clerk and his assistants. Pop. (1890) 43,648; (1900) 59,364; (1905) about 65,000.

Hob'son, John Atkinson, English social economist: b. Derby, England, 6 July 1858. He was graduated at Oxford University, and from 1887 to 1897 taught English literature and economics for the University Extension Delegacy, and the London Society for the Extension of University teaching. He is one of the foremost of economic writers in England and, as a socialist, advocates the monopolistic control of industries by government, whether municipal, or national. Among his works are 'The Physiology of Industry: Being an Exposure of Certain Fallacies in Existing Theories of Economics' (with A. F. Mummery, 1889); 'The Evolution of Modern Capitalism' (1894); 'The Social Problem: Life and Work' (1901); and 'Imperialism' (1902).

Hobson, Richmond Pearson, American naval constructor: b. Greensboro, Ala., 17 Aug. 1870. He was graduated at Annapolis Naval Academy in 1889 and took a post-graduate course at the Ecole Nationale Supérieure des Mines, and the Ecole d'Application du Génie Maritime in Paris. During the war with Spain he was present at the bombardment of Matanzas and distinguished himself by his heroism in sinking a collier across the entrance to Santiago Harbor, on the night of 3 July 1898, for the purpose of preventing the exit of Cervera's fleet. He resigned from the navy in 1903.

Hobson's Choice, a proverbial expression, denoting "without an alternative." It is said to have had its origin in the practice of Hobson, a carrier at Cambridge, England, in Milton's time, who let horses to the students, and obliged his customers to take the horses in rotation, that they might be worked equally. Milton wrote two epitaphs upon him.

Hoche, Lazare, lä-zär ōsh, French soldier: b. Montreuil 25 June 1768; d. Wetzler 19 Sept. 1797. He took service in the French guards when 16 years old, and at the revolution joined the popular party. He greatly distinguished himself at the siege of Thionville and the defence of Dunkirk, and shortly afterwards, when scarcely 25 years of age, received the command of the army on the Moselle. In 1793 he drove the Austrians out of Alsace, and soon after was arrested by the Jacobins and imprisoned at Paris. In 1794 he was released, and appointed commander of the army destined to quell the rising in the west, and afterwards to that in La Vendée. In 1796 he conceived the plan of attacking Britain, and making a descent on Ireland, but expired suddenly while in camp with his army of invasion.

Hockey, a game of ball known as hurley in Ireland and shinty in Scotland, dating in its present form from about 1883, when a definite code of rules was drawn up by the Wimbledon Club. According to standard rules the game is played between two teams of 11 players each, on a ground 100 yards long by 50 to 60 yards wide. A goal is erected at each end of the field, and consists of two uprights 12 feet apart supporting a horizontal bar 7 feet from the ground. In front of each goal a line 12 feet long is drawn parallel to the goal-line and 15 yards from it; and from each end of this line, with the corresponding goal-post as centre, a segment of a circle is drawn outwards to meet the goal-line. Thus, a kind of semicircle flattened at the top is drawn in front of each goal, and no goal is scored unless the ball is hit from within this line or striking-circle. The ball used is an ordinary cricket ball painted white; and each player is provided with a stick, curved at the end, without any metal fittings, and not too thick to be passed through a ring two inches in diameter. The players are arranged on the field as in Association football, namely, goal-keeper, two backs, three half-backs, five forwards. The game is started by one player of each side bullying the ball in the centre of the ground, that is, by first striking the ground with his stick and then striking his opponent's stick three times, after which either may strike the ball. When the ball is driven between the goal-posts under the bar by a stroke from within the striking-circle, a goal is scored, and the game is won by the side with a majority of goals scored. The ball may be caught or stopped with any port of the body, but it must not be carried, kicked, or knocked on except with the stick; it must be played from right to left only. The goal-keeper is allowed to kick the ball away in defending his goal. Ends are changed at half-time.

Hock'ing, Joseph, English nonconformist clergyman and novelist: b. St. Stephens, Cornwall, 1859. He was educated at Owens College, Manchester, and entered the nonconformist ministry in 1884. Among his many published books are: 'Story of Andrew Fairfax' (1903); 'The Scarlet Woman' (1899); 'The Purple Robe' (1900); 'The Madness of David Baring' (1900); 'Greater Love' (1901); 'Lest We Forget' (1901). He is a brother of S. K. Hocking (q.v.).

Hocking, Silas Kitto, English Methodist clergyman and novelist: b. St. Stephen's, Cornwall, 24 March 1850. He was ordained a minister in the Methodist Free Church in 1870, and after holding pastorates in Liverpool, Manchester, and elsewhere, resigned from the ministry in 1896. He is a prolific writer and several of his books have been much read in America. Among them may be named 'Alec Green' (1878); 'For Light and Liberty' (1890); 'One in Charity' (1893); 'A Son of Reuben' (1894); 'God's Outcast' (1898); 'The Awakening of Anthony Weir' (1901) 'Gripped' (1902).

Hocking River, a stream which has its rise in Fairfield County, Ohio, and flows southeast into the Ohio River. The whole length is about 80 miles; it is navigable for about 70 miles. Along the shore, in the upper part of the course, is the Hocking Canal.

Hocking Valley Railway Company, The. The Mineral Railroad Company was incorporated 14th April 1864, to build a railroad from Columbus to Athens, Ohio, but beyond making preliminary surveys and securing some rights of way, nothing was done toward the construction of the line. Mr. M. M. Greene, who was operating salt works at Salina (now Beaumont), Ohio, in the Hocking Valley, seven miles north of Athens, in 1867, took up the project, and on 26 June of that year, by decree of the Franklin County Common Pleas Court, the name was changed from Mineral Railroad Company to Columbus & Hocking Valley Railroad Company. In 1868 the line was opened for traffic from Columbus to Lancaster, and in 1869 was completed as far as Nelsonville, where it reached the coal field.

Construction was finished 25 July 1870, to Athens with a branch from Logan to Straitsville, in the coal district. The annual report of the president for the year 1870 stated: "That the company owned 12 locomotives, eight passenger cars, three baggage cars, 279 coal, 60 box, and 26 flat cars, in addition to which, private parties furnished 403 coal cars, and that with all this equipment, together with 150 other cars furnished by connecting lines, the company was unable to supply the demand for coal and would have to provide more coal cars." The gross earnings of the line for 1870 amounted to $372,229.

In the year 1871, the gross earnings increased to $548,942 and the president's report for that year stated that a valuable trade for coal had been commenced through Cleveland to points on the Lakes. The report further stated that the heavy traffic made it necessary to renew some of the rails, and that, in order to have a test between iron and steel, 50 tons of steel rails were purchased as an experiment and laid in sidings in Columbus yard under the heaviest wear of any part of the road.

The coal business of the line developed rapidly, the gross earnings for the year 1872 being $854,892. The company trebled its number of coal cars and began to feel the need of proper outlets for traffic to points beyond Columbus, connecting lines being either unable or unwilling to furnish cars for the business offered their lines. It was thereupon determined to undertake the construction of a line to supply the great demand of the Lakes and the Northwest for Hocking Valley coal, and Toledo was selected as the most appropriate port. Accordingly on 28 May 1872, the Columbus & Toledo Railroad Company was incorporated by M. M. Greene, P. W. Huntington, B. E. Smith, W. G. Deshler, James A. Wilcox, and John L. Gill, and a preliminary survey was at once made.

The line was permanently located from Columbus to Toledo on 15 Oct. 1873. The financial panic of 1874, however, made it necessary to defer for nearly a year the construction, which was commenced 17 Aug. 1875; on 15 Oct. 1876, the line from Columbus to Marion was opened for traffic, and on 10 Jan. 1877, the first regular train ran through to Toledo, where the company had acquired valuable frontage on the Maumee river for the construction of docks.

The Columbus & Hocking Valley and Columbus & Toledo Railroad companies entered into a contract 22 Feb. 1877, providing for the joint management of the two lines and for the joint use of terminal property and facilities in Columbus.

During the year 1877, extensive docks were constructed at Toledo, and connecting lines at Toledo furnished an outlet to points in Michigan and Canada. In the meantime, the Columbus & Hocking Valley Railroad had continued to prosper. In 1877, the Monday Creek and Snow Fork branches in the coal field were partially constructed and opened and seven iron furnaces were in blast in the coal region.

The Ohio & West Virginia Railway was incorporated 21 May 1878, to build from Logan, in the Hocking Valley, to Gallipolis, on the Ohio river, and some little grading was done upon this line, but no further progress was made until one year later, 21 May 1879, when Hocking Valley interests took up the project, amended the charter to extend from Gallipolis to Pomeroy, and commenced construction. The line was opened for traffic 15 Oct. 1880, from Logan to Gallipolis, and 1 Jan. 1881, to Pomeroy.

The Columbus & Hocking Valley, and Columbus & Toledo Railroad companies, and The Ohio & West Virginia Railway Company were consolidated 20 Aug. 1881, under the name of the Columbus, Hocking Valley & Toledo Railway Company.

In 1895, the Wellston & Jackson Belt Railway was built by the Hocking Valley Company from McArthur Junction to Jackson, through the Jackson County coal field, affording a valuable feeder to the line, and was opened for traffic to Wellston 1 Dec. 1895, and to Jackson 10 Feb. 1896.

During the past few years radical improvements have been made in the capacity of the line for handling traffic; 40 ton coal cars to the number of nearly 6,000 have been added to the equipment, mogul freight engines have been superseded by consolidation engines of greater capacity, making a large increase in the loading of freight trains; improved machinery for handling coal and iron ore has been placed on the company's docks at Toledo, and the yards, sidings, and station facilities of the line have been increased to take care of the constantly growing traffic.

Of the five seams of bituminous coal mined in the State of Ohio, four are to be found on the line of the Hocking Valley Railway, and through its connection with the Kanawha & Michigan Railway at Athens it also receives shipments of coal and coke from the Kanawha

& New River districts of West Virginia. Through its control of dock facilities at various points on the Great Lakes it has been enabled to transport coal for shipment by lake to the amount of nearly 2,000,000 tons during the navigation season of the year 1904.

The Hocking Valley is the longest line of railway entirely within the limits of the State of Ohio, and occupies a central position from the Ohio river to Lake Erie, passing through the capital, with branches in the populous regions of the coal fields. In 1905 the total mileage of the Hocking Valley Railway was 344.7, made up as follows: Toledo to Pomeroy, 250.8 miles; Athens branch, 20.9 miles; Jackson branch, 17.3 miles; other branches, 43.7 miles. For the year ending 30 June 1905, the gross earnings were $6,013,214. The operating expenses were $4,067,901, thus showing net earnings of $1,945,313, which with other income of $382,230 shows the total net income of the company for that year, $2,327,543.

F. B. SHELDON,
Assistant to President.

Hodder, Alfred, American author: b. Celina, Ohio, 18 Sept. 1866; d. New York 3 March 1907. In 1886–9 he read law in the office of Senator Teller, in 1889 was admitted to the bar at Denver, Col., studied in the Harvard graduate school in 1890–1, and was Morgan fellow there 1891–2. He was for a time lecturer in English literature and drama at Bryn Mawr College, contributed extensively to the New York 'Nation,' and published 'The Powers that Prey' (with Josiah Flynt, 1900), a collection of stories of the criminal classes, and 'The Specious Present' (1901), a metaphysical treatise.

Hodge, Archibald Alexander, American Presbyterian divine: b. Princeton, N. J., 18 July 1823; d. Princeton 11 Nov. 1886. He was the son of Charles Hodge (q.v.) and was graduated at Princeton College 1841, where he became assistant professor. In 1847 after graduation in the Theological Seminary of the same place he went to Allahabad, India, as a missionary. He stayed in Asia for three years and returning home held pastoral charges in Maryland, Virginia, and Pennsylvania until 1877, when he became his father's assistant at Princeton Seminary, succeeding in 1878 to the chair of didactic and exegetical theology made vacant by his father's death. Among his works the most important are 'Outlines of Theology' (1870); 'The Atonement' (1886).

Hodge, Charles, American Presbyterian theologian: b. Philadelphia 28 Dec. 1797; d. Princeton, N. J., 19 June 1878. He was educated in Princeton College, graduating in 1815. In 1816–19 he studied in the theological seminary at Princeton, in 1820 was appointed instructor there, and two years later made professor of Oriental and biblical literature. In 1840 he was transferred to the chair of didactic and exegetical theology in the seminary, and 12 years afterwards appointed to the additional chair of polemical theology. In 1825 he founded the 'Biblical Repertory,' afterwards was renamed 'Biblical Repertory and Princeton Review,' and merged in 1872 in the 'Presbyterian Quarterly and American Theological Review.' From the foundation till 1872 he was editor of and chief contributor to the 'Review,' and two of his works, 'Princeton Theological Essays' (1846–7); and 'Essays and Reviews' (1857), were compiled from his numerous articles in that periodical. Other works are: 'Commentary on the Epistle to the Romans' (1835; enlarged, 1866); 'Constitutional History of the Presbyterian Church in the United States' (1840–41); 'The Way of Life' (1842); 'Systematic Theology' (1871–2), a comprehensive treatise giving an exposition of Calvinistic theology; and 'What is Darwinism?' (1874).

Hodge, Frederick Webb, American ethnologist: b. Plymouth, England, 28 Oct. 1864. He was brought to this country at the age of seven years, and was educated at Washington, D. C. In 1884 he received appointment to the United States Geological Survey, in 1886 became secretary of the Southern Archæological Expedition, and in 1889, was appointed to the Bureau of Ethnology, Smithsonian Institution. He has written various papers on the Indians of the southwest.

Hodge, John Aspinwall, American Presbyterian theologian: b. Philadelphia, Pa., 12 Aug. 1831. He was graduated from the University of Pennsylvania (1851) and from Princeton Theological Seminary (1856). After 35 years of pastoral work he was appointed in 1893 professor of biblical instruction and church polity in Lincoln University. Among his works are 'What is Presbyterian Law?' (1882); 'Theology of the Shorter Catechism' (1888); 'The Ruling Elder at Work' (1897).

Hodges, George, American Episcopal clergyman: b. Rome, N. Y., 6 Oct. 1856. He was graduated from Hamilton College, Clinton, N. Y., in 1877, and from the Berkeley Divinity School, Middletown, Conn., in 1881. He was assistant rector of Calvary Church, Pittsburg, Pa., 1881–9, and rector 1889–94, in the year last named becoming dean of the Episcopal Theological School in Cambridge, Mass. He has published among other works: 'Christianity Between Sundays' (1892); 'The Heresy of Cain' (1894); 'In the Present World' (1896); 'Faith and Social Service' (1896); 'The Battles of Peace' (1897); 'The Path of Life' (1897); 'William Penn' (1900). He is one of the most prominent members of the Low Broad Church School in the Episcopal Church.

Hodgetts, hŏj'ĕts, **Edward Arthur Brayley**, English journalist: b. Berlin, Germany, 12 June 1859. He has been connected with several influential London journals in the capacity of correspondent and was foreign editor of the New York *World* in 1894. Among his published books are 'Liquid Fuel' (1890); 'Round About Armenia' (1896); 'A Russian Wild Flower' (1897); and a translation of 'The Swiss Family Robinson' (1897).

Hodgkin, hŏj'kĭn, **Thomas**, English historian and banker: b. Tottenham, Middlesex, 29 July 1831. He has been for many years the senior partner in a banking firm at Newcastle-on-Tyne, but since 1874 has given his time to historical writing. He has published 'Italy and her Invaders,' a work of much importance, of which eight volumes have already appeared (1880–99); 'Dynasty of Theodosius' (1889); 'Life of George Fox' (1896); 'Life of Charles the Great' (1897); etc.

Hodgkin's Disease. See PSEUDOLEUCÆMIA.

Hodgkinson, hŏj'kĭn-sŏn, **Eaton,** English engineer: b. Anderton, Cheshire, 1789; d. 1861. After a somewhat desultory education, and the pursuit of independent investigations in mechanics he was appointed in 1847 professor of the mechanical principles of engineering at University College, London. He was one of the royal commission appointed in 1847 to inquire into the application of iron in railroad building. His principal experiments led him to the determination of the "neutral line" in the section of fracture, an important step in the progress of engineering science. Among his many writings is 'Researches on the Strength and Other Properties of Cast Iron' (1846).

Hodgson, hŏj'sŏn, **Shadworth Hollway,** English metaphysician: b. Boston, Lincolnshire, 25 Dec. 1832. He was educated at Rugby and Oxford and is the author of 'Time and Space' (1865); 'Principles of Reform in the Suffrage' (1866); 'The Theory of Practice' (1870); 'The Philosophy of Reflection' (1878); 'The Metaphysic of Experience' (1898); etc.

Hodograph, hŏd'ō-grăf, the term for a velocity diagram which facilitates the study of kinematics. It signifies the curve along which the extremities of lines drawn from a fixed point pass and exhibit in direction and magnitude the velocities of a moving object at the different points of its orbit or path.

Hoe, Richard Marsh, American inventor: b. New York 12 Sept. 1812; d. Florence, Italy, 7 June 1886. He was the son of Robert Hoe (q.v.). In 1846 with his brother Peter S. he perfected a rotary printing-press which was called "Hoe's lightning press." Subsequently the two brothers invented the Hoe web-perfecting press. These were especially adapted to newspaper printing and made a revolution in that art. The sons of Richard M. Hoe and of Peter S. Hoe conducted the business after the death of the brothers, and added various improvements to the original Hoe printing-press. The factory in New York in 1903 was said to be the largest printing-press works in the world.

Hoe, Robert, American inventor: b. Leicestershire, England, 1784; d. 1833. He came to the United States in 1803, was for a time a joiner, and later entered partnership with his brothers-in-law, Matthew and Peter Smith, for the sale of a hand printing-press, the invention of the latter. He took over the business in 1823. The original Hoe printing-press was designed and built by him.

Hoe, Robert, American manufacturer: b. 1839. He is a nephew of Richard M. Hoe (q.v.). He became the head of the Hoe firm, and maintained its high position among establishments of its class. A founder of the Grolier Club of New York, he was also its first president. He published an edition (1880) of Maberley's 'Print Collector.'

Hoe'ber, Arthur, American artist: b. New York 23 July 1854. He studied under Beckwith in New York and under Gérôme at the Ecole des Beaux Arts, exhibited for the first time at the Salon in 1882, and is a contributor to most American exhibitions. He is art critic to the *Commercial Advertiser.* Among his writings are 'Treasures of the Metropolitan Museum of Art'; and 'Painting in the 19th Century in France, Belgium, Spain and Italy.'

Hoey, Frances Sarah Johnston, Irish novelist: b. near Dublin 1830. She was married to A. M. Stewart in 1846, and to John Cashel Hoey in 1858. Among her books, which have circulated in America as well as in England, are: 'A House of Cards'; 'A Golden Sorrow'; 'No Sign'; 'A Stern Chase'; 'His Match and More.'

Hofer, hō'fĕr, **Andreas,** Tyrolese patriot: b. Sankt Leonhard 22 Nov. 1767; d. Mantua 20 Feb. 1810. He was landlord of the inn "Am Sand" at Sankt Leonhard, and hence often known as "Sandwirt." In 1796 he led a rifle company against the French on Lake Garda, and after the Peace of Lunéville was prominent in the organization of the Tyrol militia. In 1809 he led in an insurrection of the Tyrolese for shaking off the yoke of Bavaria, to which their country had been transferred by the Treaty of Presburg. In a short time, with intermittent assistance from the Austrians, he defeated the French and Bavarian troops, and nearly the whole country was liberated. Hofer then carried on the military and civil administration, till the Peace of Vienna was proclaimed. Misled by false reports he commenced hostilities anew, and thus forfeited the protection of the amnesty. He remained concealed for some time, but was at last betrayed to the French, and carried to Mantua, where he was tried by a court-martial and shot. His family was indemnified for the loss of their property by the Emperor of Austria in 1819, and his son ennobled. The career of Hofer furnished material for tragedies by Immermann and Auerbach. Consult the studies by Heigel (1874) and Stampfer (1891).

Hoff, hŏf, **William Bainbridge,** American naval officer: b. Philadelphia, 1846; d. Washington, D. C., 23 May 1903. He entered the naval service in 1860, and in 1863 was graduated from the Naval Academy. He took part in several naval campaigns during the Civil War, and at the torpedo school and on the United States steamship Dale he gave his attention to the instruction of seamen in gunnery. In 1893 he was marine commissioner to Great Britain for the World's Fair at Chicago, and was retired in 1897. He was the author of 'Elementary Naval Tactics'; and 'Avoidance of Collisions at Sea.'

Hoffman, hŏf'man, **Charles Fenno,** American poet and novelist: b. New York 1806; d. Harrisburg, Pa., 7 June 1884. He entered Columbia College, and studied law at Albany, being called to the bar in 1827. In 1830 he became joint-editor of a New York journal, and three years later started the 'Knickerbocker Magazine.' For many years he edited the 'American Monthly Magazine,' also. In 1840 his mind began to give way, and from that time till his death he was an inmate of Harrisburg lunatic asylum. His first separate publication was 'A Winter in the West' (1835), followed in 1837 by 'Wild Scenes in Forest and Prairie,' and in 1840 by the novel 'Greyslaer: a Romance of the Mohawk,' which met with immediate and remarkable success. An earlier novel, 'Vanderlyn,' appeared in the 'American Monthly Magazine' during 1837. Several of his songs have gained great popularity. His published volumes of verse include: 'The Vigil of Faith' (1842); 'The Echo' (1844); 'Lays of the Hudson, and other Poems' (1846); 'Love's Calendar, and other Poems' (1848).

Hoffman, Eugene Augustus, American Episcopal clergyman: b. New York 21 March 1829; d. near Plattsburg, N. Y., 17 June 1902. He was educated at Rutgers and Harvard colleges and at the General Theological Seminary. He held successive rectorships at Elizabeth, N. J., Burlington, N. J., Brooklyn, N. Y., and Philadelphia, and in 1879 was appointed dean of the General Theological Seminary, New York, and with others of his family, heavily endowed that institution. Dean Hoffman built Christ Church and rectory at Elizabeth, N. J., and also churches at Woodbridge and Milburn, N. J. He was the author of 'Free Churches' (1858); and 'The Eucharistic Week' (1859 and 1893).

Hoffman, Murray, American jurist: b. New York 29 Sept. 1791; d. Flushing, L. I., 7 May 1878. He graduated from Columbia College in 1809; was admitted to the bar, became assistant vice-chancellor of the superior court of New York in 1839, serving till 1843, and was elected judge in 1853, holding that position for eight years. He wrote: 'Office and Duties of Masters in Chancery and Practice in the Master's Office' (1824); 'A Treatise on the Practice in the Court of Chancery,' in three volumes (1834-40); 'Reports of Cases, Court of Chancery' (1839-40); several treatises on Church Law and numerous other works.

Hoffman, Richard, American pianist and composer: b. Manchester, England, 24 May 1831. He came to New York in his 16th year. He received early instruction from Rubinstein, Liszt, Thalberg, Döbler and Meyer. After his arrival in America he made a tour of the country as a soloist, and later accompanied Jenny Lind on her tours; he also played with Gottschalk and Von Bulow in New York in 1875. Later he became an important figure in American musical life. He has composed music for the piano, songs, anthems, ballads and church music.

Hoffman, William M., American inventor: b. Buffalo, N. Y., 1853. He received only a limited education and began to earn his living when nine years of age. He prospered until he was 20, when misfortune overtook him and he became a fireman on the Erie Railroad. The clumsiness in the action of the piston rod which runs to the driving-wheels of an engine, involving such a waste of power, attracted his attention and decided him to build an engine in which there should be no such starting and stopping, but in which the power should create a direct rotary movement. He studied for eight years the technical branches of engineering, and at the end of this period became chief engineer of a large tannery in Buffalo. He there invented a new set of "fleshing" and "putting out" machinery for use in a tannery, and sold the invention to obtain funds with which to experiment on his engine. He went to Detroit in 1886 and organized a company to produce his engines. He spent the first funds in experiments, and built five models, all of which refused to stir when connected up, nor were they in any way operative. In the winter of 1898-9 he went to Buffalo, there producing No. 6, which was a partial success. It was of a type in which the piston revolved in the cylinder, and showed a great advance over his previous models in control and speed and in sustaining varying loads. The internal friction made in this "annular cylinder" type was too great, and he set out to lessen it or do away with it altogether. Hoffman worked day and night, and when exhausted would ride on a trolley car all over the city till his brain became clear again, then would go back to work. It was on one of these rides that he thought out the principle which, with a few perfections, achieved the long-sought end. Hoffman thought that if the piston would not revolve inside the cylinder, the cylinder might revolve around the piston, and he immediately designed an engine in which the cylinder revolved around the eccentric abutment by introducing radial wings extending from the shell toward and against the stationary eccentric core. This engine, though proved by actual test of 18 months to be a success, was such a disappointment to Hoffman that he mortgaged all his property and returned the money which he had borrowed from financiers in August 1902 to further his investigations. Hoffman's son Bertram and Randl Riehl then joined him, and together, in July 1904 they brought out a 28 h.p. engine which was put into operation in the basement of the Ellicott Square Building in Buffalo and which has proved a success. He then made a twelfth and last design in a 300 h.p. compound engine, which is the largest of its type ever built and which, it is claimed, shows an economy of 33 per cent and a saving in floor space of 80 per cent as compared with the highest type of reciprocating engine, while the friction load has been reduced to 1.1 per cent. All of Hoffman's patents have now been merged into one company, of which he is president.

Hoffmann, August Heinrich, ow'goost hin'-rih hŏf'män, usually known as HOFFMANN VON FALLERSLEBEN, German poet and philologist: b. Fallersleben, Hanover, 2 April 1798; d. Corvei 19 Jan. 1874. He studied at Göttingen and Bonn, was appointed in 1823 custodian of the university library at Breslau, and in 1830 became extraordinary, in 1835 ordinary professor of the German language and literature in the university of that city. He resigned his librarianship at Breslau in 1838, and in 1842 was removed from his chair without a pension because of the liberal political views represented in his 'Unpolitsche Lieder' (1840-1). He led a wandering life till 1845, when he obtained the right of domicile in Mecklenburg. In 1848 he was granted a pension by the Prussian government, and from 1860 he was librarian to the Duke of Ratibor. Of his original writings the best known are his songs, not a few of which, especially that beginning 'Deutschland, Deutschland über Alles' (1841), have long received emphatic popular approval. For several of them he composed tunes. They were published in several volumes, among these being: 'Gedichte' (1827); 'Alemannische Lieder' (1827); 'Hundert Schullieder' (1848); 'Deutsches Volksgesangbuch' (1848); 'Soldatenlieder' (1851); 'Kinderwelt in Liedern,' and 'Alte und Neue Kinderlieder' (1873). A complete edition of his 'Kinderlieder' was prepared by von Donop in

1877. 'Mein Leben' (1868; abridged edition continued to his death, by Gerstenberg, 1892-4), is autobiographical. Consult also the 'Life' by Wagner (1869).

Hoffmann, Heinrich, German painter: b. Frankfort-on-the-Main, 18 Oct. 1814. Beginning life as a room decorator, in 1843, he adopted landscape painting as his profession and studied under Jacob Becker with that end. Long wanderings and careful studies of nature in the Taunus Mountains, in Obenwald, and the Black Forest, as well as in the valleys of the Rhine and Mosel, were followed by extensive travels in Switzerland and the Tyrol. The results of this preparatory training appeared in his first large canvas in which the old romantic spirit was blent with an independent and realistic presentation of nature which at once attracted public attention. He has produced numberless Alpine and forest landscapes, moonlight and street scenes, most of which are in private collections at Frankfort.

Hofmann, August Wilhelm, von, German chemist: b. Giessen 8 April 1818; d. Berlin 5 May 1892. He studied law, obtained the degree of doctor of philosophy, became assistant under Liebig in the Giessen Laboratory, and in 1845 became professor of chemistry in the University of Bonn. The same year he was appointed superintendent of the new Royal College of Chemistry in London, and in 1853 became professor of chemistry in the Royal School of Mines, though still remaining at the head of the College of Chemistry. In 1861 he was elected president of the London Chemical Society, and in 1863 was appointed to the chair of chemistry in the University of Berlin, where he remained till his death. In 1864 he built a laboratory at Bonn and became its director, and in 1868 founded the German Chemical Society. He was judge of several industrial expositions and was a member of many scientific societies, and for his valuable services was ennobled in 1888. A statue of him is in the National Gallery of Berlin. He wrote: 'A Handbook of Organic Analysis' (1853); 'Introduction to Modern Chemistry' (1865); 'Zur Errinnerung an vorangegangene Freunde' (1889); etc.

Hofmann, Heinrich, German painter: b. Darmstadt 19 March 1824. In his native town he began his studies as a copper-plate engraver, but subsequently under Schadow and Hildebrande turned his attention to painting, to which henceforth he devoted his life. After extensive travels in Europe, which included a residence of four years in Italy, he settled at Dresden as professor of painting in the Academy there. The most famous of his pictures are: 'The Burial of Christ'; 'King Enzio in Prison'; 'The Betrayal of Christ,' in the Darmstadt Gallery; 'The Finding of Christ in the Temple,' in the Dresden Gallery; 'Christ Preaching on the Lake,' in the Berlin National Gallery; 'Venus and Cupid'; 'Romeo and Juliet'; 'Othello and Desdemona'; and 'Christ in Gethsemane.' All the creations of Hofmann testify to his sense of refined beauty and are rather remarkable for harmonious coloring and delicacy than for originality of design or composition, as he clings to the tradition of the classic period in the ideal character of his conceptions. His works are popular and have been engraved and photographed more extensively perhaps than those of any contemporary German painter of his order.

Hofmann, Josef, yō'sef, Polish pianist: b. Cracow 20 Jan. 1877. He studied with his father, a professor in the Warsaw Conservatory and director of the Warsaw opera, appeared as a pianist in public at the age of six, became known as one of the most notable of musical prodigies, visited the United States in 1887-8, and was there prevented from playing through the action of the Society for the Prevention of Cruelty to Children. After a period of study, two years of which were spent as a pupil of Rubinstein, he made his début as a virtuoso at Dresden in 1894. His recitals in New York in 1901 showed him to be one of the leading modern pianists. His compositions include some interesting works for the pianoforte.

Hog-feeding. See NUTRITION OF FARM ANIMALS.

Ho'gan, John Joseph, American Roman Catholic bishop: b. Bruff, County Limerick, Ireland, 10 May 1829. He came to St. Louis, Mo., in 1848, studied at the Roman Catholic theological seminary there, was ordained priest in 1852, and built and became pastor of St. Michael's Church of St. Louis. In 1868 he was consecrated bishop of St. Joseph, Mo., and in 1880 was transferred to the see of Kansas City.

Hogarth, hō'gärth, **David George,** English archæologist: b. Barton-on-Humber, Lincolnshire, 23 May 1862. He was educated at Oxford and has since conducted excavations at Paphos, Alexandria, Fayum and elsewhere in the East. He was director of the British School at Athens 1897-1900 and has published: 'Devia Cypria' (1890); 'Modern and Ancient Roads in Asia Minor' (1892); 'A Wandering Scholar in the Levant' (1896); 'Philip and Alexander of Macedon' (1897); 'The Nearer East' (1902).

Hogarth, William, English painter and engraver: b. London 10 Nov. 1697; d. there 25 Oct. 1764. He studied art at Sir James Thornhill's school, James Street, Covent Garden. About 1720 he set up for himself, and designed plates for booksellers, the chief of which are the illustrations to Gray's edition of 'Hudibras' (1726). He had ample employment for what are called "conversation pieces," that is, groups of family portraits, united by some common occupation or interest, but never cared greatly for this branch of art. In March 1729 he married clandestinely the daughter of Sir James Thornhill, and shortly afterward began to display his extraordinary faculty for depicting the vices and follies of his time. In 1730-1 he painted 'A Harlot's Progress,' a series of six pictures, like many of his other works, engraved by himself. It was published in April 1732. The 'Harlot's Progress' was followed by other satiric delineations, such as 'A Midnight Modern Conversation' (1734), 'Southwark Fair' (1735), 'A Rake's Progress' (1735), 'The Distressed Poet' (1736), 'The Four Times of the Day,' and the 'Strolling Actresses Dressing in a Barn' (1738). With less success he also produced the large canvases still in St. Bartholomew's Hospital — the 'Pool of Bethesda' and the 'Good Samaritan,' both executed in 1736; and also painted several portraits. The series of graphic satires was, however, continued by the 'Enraged Musician' (1741) and the famous 'Marriage à la Mode' (his masterpiece), six pictures now in the National Gallery, and engraved by various hands in 1745. 'Industry and Idleness,' 12 plates, followed these in 1747; 'Calais Gate' (1749) came next, and in 1750 the fine plate known familiarly as the 'March to Finchley.' The minor plates of 'Beer Street' and 'Gin Lane' and the set called 'The Progress of Cruelty' belong to 1751. In 1752 Hogarth published his 'Analysis of Beauty,' a treatise containing many shrewd remarks, but confused and illiterate in its style, and the cause of much ridicule. After this he produced (with the aid of Grignion and others) the four prints of the 'Election Series' (1755–8), the 'Cockpit' (1759), etc. In 1762–3 he became involved in a miserable quarrel with Wilkes and Churchill, the result of which, on his side, was the well-known portraits of Wilkes, and of Churchill as a bear ('The Bruiser').

Most of Hogarth's pictures, which now enjoy a much higher repute for technique than formerly, are preserved in public or private collections in Britain. He was entirely uninfluenced by foreign art. His powers of invention and combination were extraordinary; and as a humorist and social satirist with the pencil he has never been surpassed. There can be no doubt also that he genuinely desired to assist by his work in the reformation of manners. Consult the biographies by Sala (1866) and Dobson (1879).

Hoge, hōg, **Moses Drury,** American Presbyterian clergyman: b. Hampden-Sidney, Va., 17 Sept. 1819; d. Richmond, Va., 1899. He was graduated at Hampden-Sidney College and Seminary and was pastor of the Second Presbyterian Church in Richmond, Va. (1845–85). He ran the blockade in a ship from Charleston during the Civil War and secured from England a large number of copies of the Holy Scriptures for distribution among the Confederate soldiers, the British and Foreign Bible Society making a special grant at his request. After the war he was instrumental, especially during the session in 1874 of the Southern Presbyterian Church, in reconciling differences with the Northern Presbyterian Church.

Hogg, James, Scottish poet, familiarly known as "The Ettrick Shepherd": b. Ettrick, Selkirkshire, 25 Jan. 1770; d. Altrive, on the Yarrow, 21 Nov. 1835. After receiving a very scanty education, he began to earn his bread by daily labor as a shepherd. His early rhymings brought him under the notice of Sir Walter Scott, by whose advice he published a volume of ballads called 'The Mountain Bard.' He then went to Edinburgh, where he published the 'Forest Minstrel' (1810), and started a weekly periodical entitled 'The Spy.' The appearance of the 'Queen's Wake' in 1813, with its charming ballad of Kilmeny, established Hogg's reputation as a poet. In 1815 he published 'Pilgrims of the Sun,' followed by 'Mador of the Moor'; the 'Poetic Mirror' (a collection of imitations of living poets); 'Queen Hynde,' and 'Dramatic Tales,' as well as by 'The Brownie of Bodsbeck,' etc. From 1817 he held the farm of Altrive from the Duke of Buccleuch at a merely nominal rent; but his farming schemes never throve, and he was generally in narrow circumstances.

Hogg, James Stephens, American politician and lawyer: b. near Rusk, Tex., 24 March 1851; d. Houston, Tex., 3 March 1906. He took up the practice of law, and was justice of the peace in Wood County 1873–5, and county attorney 1878–80. In 1880 he was district attorney in the 7th judicial district of Texas; in 1886 became attorney-general of the State and from 1890 to 1895 was governor. He was one of the Democratic governors who objected to the use of United States troops by President Cleveland at the time of the Pullman strike in 1894. After serving as governor he returned to the practice of law, and remained active in politics, being prominent as a public speaker.

Hog'nose, a North American colubrine serpent (*Heterodon platyrhinus*), so-called because of its upturned pig-like snout. It is usually about two feet long, gray marked with brown bars, but sometimes is so dark that the whole surface appears blackish; and dwells and seeks its prey mainly in the woods and thickets. When alarmed — and it is extremely timid — it hisses violently (whence other rustic names such as "blowing-adder"), and expands and flattens the head and neck by inhaling air and stretching out the ribs, giving itself a most ugly aspect. If these tactics do not succeed in terrifying the enemy sufficiently, the snake begins a series of astonishing contortions and twistings which end in the animal throwing itself upon its back and seeming dead until a chance of escape offers. Two or three other species are known in the South and West, all of which are regarded as poisonous by most country people, but are really quite harmless.

Hogs, or Swine, hoofed quadrupeds of the family *Suidæ*, including several genera and many species and domesticated races. The males are called "boars," the females "sows," the young "pigs," and the flesh "pork." The hogs proper, both wild and tame, belong to the genus *Sus*, represented in the wilderness of the Old World by the wild boar (*S. scrofa*), which is, or was, known throughout southern and central Europe, Algeria, Asia Minor, and southwestern Asia; and by the Indian boar (*S. cristatus*) of India and Indo-China. The wild boar stands from 30 to 40 inches high at the shoulder and will weigh on the average about 250 pounds. His snout is longer, his ears shorter than those of the domestic hog. He roots up the ground in a different manner, ploughing it in furrows; his tusks are larger, some of them being 10 inches in length, bent circularly, and exceedingly sharp at the points. The young wild boar, for the first three years of his life, follows the sow, the whole litter living in a herd together, and although the adults are plain iron gray (the male exceedingly large and shaggy) the young are striped and spotted. Old boars range the forest alone and unsupported, dreading no single creature, not even man himself. Hunting this animal has always been a favorite amusement, and in Europe is usually pursued on foot by the aid of large dogs, the hunters armed with strong pikes termed *boarspears*. A chase seldom terminates without the maiming or destruction of some of the dogs, and tests the courage of the men, for a charge from an enraged or wounded boar is a formidable thing. In India the chase is pursued on horseback, the rider using a long spear. Hence the sport is known as "pig-sticking," and it involves much risk and danger, and the death of many horses ripped open by the boar's tusks. In addition to these, a small wild pig inhabits western equatorial Africa; there are two lesser species in India, one not much bigger than a hare; and several in the islands stretching from Sumatra to Japan.

Domestic Races.— Swine everywhere have seemed easily tamable and susceptible to domestication, breeding fertilely in confinement and easily adapting themselves to new environments. Since prehistoric times, therefore, the animal has been raised by man in many parts of the world to supply food. The process of domestication seems to have gone farther toward producing a good pork-making animal in the Orient than in Europe until the revival of agriculture there following the decay of the feudal system. In Great Britain there was early introduced eastern blood called Chinese stock, and it is from the union of these two strains — one derived from the European wild boar and the other from some or many Oriental species — that European and American farmyard swine are descended. The foremost breed, in general popularity, is the Berkshire, which originated in the English County of Berks, but is now universal. The Berkshire hog is of large size, yields pork of great fatness and excellent flavor, grows rapidly and is hardy. It is usually black in color. An American breed, developed first in Ohio, and known as Poland-China, is very similar to the Berkshire, and has been perfected until it has become the principal pork-producing hog of the Mississippi Valley. The English white breeds are led by the Yorkshire, which reaches a larger size than any other kind; and from which has been developed an American strain, called Chester Whites, after the county in eastern Pennsylvania where it originated. New Jersey has a local breed called Durocs, or Jersey red hogs, which have the advantage of great hardiness. For these breeds regular stock-registers have long been maintained. Various other well-known strains of swine in Great Britain and America are the Tamworth, Victoria, Essex, etc. The domestic hog has run wild in various parts of the world. In many of the South Sea islands, and in parts of South America, they have practically returned to a feral condition, and are public game. In the southern part of the United States large numbers of pigs, nominally under ownership, range the woods, picking up their own food of herbage, roots and mast; these become gaunt, thin, high-backed, bristly and develop great running powers, cunning (the intelligence of the whole race is comparatively high), and savagery of disposition; they are locally known as "razor backs."

For the proper care and treatment of hogs raised for their pork see NUTRITION OF FARM ANIMALS.

Domestication has changed the form and proportions of the body, the color, etc.; thus the skull is higher and broader in proportion to its length, and it is more upright in the occipital region. The sow brings forth from the 16th to the 20th week after conception, and has usually two litters in a year. Her offspring are very numerous, a litter consisting of from 10 to even 20; but she can bring up no more than she has teats, which are 12 in number. The natural term of the life of these animals is from 15 to 30 years, and they continue to increase in size and strength until they are from four to five years of age. As might be supposed from their habits, they are much infested by vermin of different kinds, and are also liable to many disorders, particularly those arising from gluttony. Notwithstanding repugnant qualities the hog is of incalculable benefit to mankind. Its flesh is pleasant, substantial and nutritious. Pork takes salt better than almost any other meat, and may be cured and preserved in many ways. The fat (lard) is one of the most important culinary articles; the bristles are used in large quantities in the manufacture of brushes, while the skin is in demand among saddlers, trunk-makers, and manufacturers of small articles of leather, calling for great durability with flexibility and a handsome appearance.

The family includes various wild species more or less closely related to the typical swine, such as the babirussa, peccaries, river-hogs, wart-hogs, etc., elsewhere described.

The principal English works on swine are Long's 'The Book of the Pig' (1889), and Spencer's 'Pigs, Breed and Management' (1897). American works of note are Coburn's 'Swine Husbandry' (1889); Harris' 'On the Pig' (1896), and pamphlets issued by the Department of Agriculture. See NUTRITION OF FARM ANIMALS; PORK; PACKING INDUSTRY.

Hogs'head, a liquid measure formerly in use in England. Its capacity varied in different cases. For beer it was 54 gallons, for rum 45 to 50 gallons, for brandy 45 to 60 gallons, and for different kinds of wine it varied from 46 to 93 gallons. In the United States the measure is still in use, being equivalent to 63 American gallons or 52.485 imperial gallons; for tobacco it varies from 750 pounds in some States to 1,200 pounds in others.

Hohenlinden, ho-ĕn-lĭn'dĕn, Germany, a village of Bavaria, 20 miles east of Munich, celebrated for the victory gained by the French under Moreau over the Austrians under the Archduke John, 3 Dec. 1800. The French took nearly 80 pieces of cannon, 200 caissons, and more than 10,000 prisoners, with three general officers.

Hohenlohe-Schillingsfürst, hō-ĕn-lō'ė shĭl'lĭngs-fürst, **Chlodwig Karl Victor**, PRINCE VON, German chancellor: b. Rotenburg-an-der-Fulda March 1819; d. Ragatz, Switzerland, 6 July 1901. He took courses in law and political science at Heidelberg, Göttingen and Bonn. He entered public life and became in 1866 prime minister of Bavaria. In 1874 he was German ambassador at France and in 1885 became governor-general of Alsace-Lorraine. In 1894 he was appointed chancellor and resigned in 1900.

Hohenstaufen, hō'ĕn-stow-fĕn, **House of**, a German dynasty reigning from 1138 to 1254. After the death of the Emperor Henry V. (1125), his two nephews, Frederick II., duke of Swabia, and Conrad, duke of Franconia, aspired to the German crown; but were opposed by the directors of the election, the Archbishop of Mayence and the papal legate; and Lothaire of Saxony was elected. This circumstance, with the demand made by the new emperor of the restitution of all the possessions acquired by the lords of Hohenstaufen during the preceding reign, produced a fierce war between the emperor and the two brothers. Lothaire preserved himself by a union with Henry the Proud, duke of Bavaria, to whom he gave his daughter and the Duchy of Saxony. The Peace of Mühlhausen (1135), between Lothaire and Conrad, put an end to this Ten Years' war. Conrad renounced his title of King of Italy which he had taken, but received the first rank among the dukes, and both he and his brother regained all their lands. After Lothaire's death (1137) Conrad, duke of Franconia, of the house of Hohenstaufen, was raised to the throne of Germany, with the title of Conrad III.

After the death of Conrad III. (1152) the confidence which was felt in the Hohenstaufen family caused the choice to fall on his nephew, Frederick III. of Swabia, called Barbarossa (the Red-beard), who was followed by Henry VI. (1190), and he again by Otto IV. (1197) and Frederick II. (1215–50), all belonging to the same house. After the death of Frederick II. his son Conrad was acknowledged as his successor, with the title of Conrad IV., by most of the states of the empire: but Innocent IV. laid him under an interdict, and declared him to be deprived of all his lands. The conflict between Conrad and the Pope lasted until the latter's death in 1254. The fame of the house of Hohenstaufen is based upon the political greatness to which the Fredericks in particular attained; their success in reducing to order all the states of the empire; the encouragement which they gave to commerce and trade, and their efforts to promote the sciences and arts.

Hohenzollern, hō'ĕn-tsōl-lĕrn, Germany, a province of Prussia, formed in 1849 by the union of the two principalities of Hohenzollern-Hechingen and Hohenzollern-Sigmaringen. It consists of a narrow irregular strip of country encircled by Würtemberg and Baden. Area 441 square miles; pop. (1900) 66,783. The princely family of Hohenzollern dates from Thassilo, Count of Zollern, who died about 800 A.D., after having founded a castle near Hechingen, on the Zollern hill in the Swabian Alb. The fine Hohenzollern castle of 14th century architecture, built in the latter half of the 19th century, occupies the site of the ancient family-seat. There have been several lines and branches of the Hohenzollerns, the first separation taking place about 1165, when Frederick IV. founded the elder or Swabian and Conrad III. the younger or Franconian line. The elder line was subdivided, in 1576, into the branches of Hechingen and Sigmaringen. Frederick VI., the representative of the younger line, in 1415 received from the Emperor Sigismund the investiture of the electorate of Brandenburg, thus founding the reigning dynasty of Prussia. The two branches of the elder line continued unbroken till 1849, when the reigning princes ceded their respective rights and principalities to the king of Prussia, who in 1871 became emperor of Germany. The main branch of the Hohenzollerns is now represented by the imperial family of Germany. See GERMANY.

Hoisting Apparatus, mechanical devices for lifting and moving laterally heavy weights. They are known under various names and include cranes, derricks, overhead trolleys, crane-derricks, etc. The smaller are operated by hand power, the larger by steam or electric power. By their aid the heaviest weights may be readily lifted to any desired height and "slewed" into any desired position. Their use dates from the most ancient times, and they are now in constant and general use all over the world.

Derrick.— This is the simplest form of a machine for hoisting. The name is derived from a family by that title who adapted its form from the early English style of gallows, and the name has now come into common use. In form the derrick is like the letter V, one side being fixed immovably by guy ropes, the other hinged to the bottom of this fixed upright, so that it can be raised or lowered at will. This movable jib is somewhat shorter than the upright and the whole apparatus is on a platform which can turn laterally in a circle. Through the top of the jib is run a pulley block, a rope passing through this and down to the base of the upright, where it is wound about a cylinder, or winch. This, when revolved by hand or other power, winds up the rope or cable, thus raising the weight attached to the other end of the rope. The jib is lowered or raised to get the proper angle for picking up the article to be lifted. This simple form of hoister is in constant use by builders in constructing modern high buildings. By its use, heavy or light weights can be quickly lifted from the ground to the top of even 30-story structures. Derricks are commonly made of wooden spars, unless the work to be done is very heavy or the jib exceedingly long. In such case, a tubular iron spar is used. Hoisting engines of such power and facility of control are now made that they enable the operator to move the jib up or down or sideways easily and quickly. The "stiff-leg" derrick has its upright firmly braced by timbers running from the top to the ground, but this form is not common except in stone quarries or in some work where the derrick is stationary. The more common form is the guy-rope derrick, where strong wire cables extend from the top of the upright to the ground. With this arrangement, the hoisting machine can be moved and located in a fresh position easily. Derricks that will lift and swing to position weights of from 5 to 50 tons are now made in this country. In the contemplated work on the Panama Canal, derricks capable of moving 100-ton loads of stone and rock are to be built, with a radius of over 100 feet for the jib.

Crane.— Thus named because the arm or boom resembles the neck of the crane, which raises and lowers its neck to lift objects from the ground. It differs from the derrick in not having any mast or upright, usually. In the common form of crane the whole apparatus is centered upon a heavy platform which is itself on wheels. The engine which operates the winch also slews the boom in a circle, and, in some cases, moves the whole outfit along the rails upon which the wheeled platform rests. At the base of the boom, on the platform, is an inverted "V" horse, to which are attached the pulley blocks through which run the ropes for raising and lowering objects to be lifted. In large foundries, ship-yards and like places, the locomotive crane runs upon a track which usu-

FORTY TON LOCOMOTIVE CRANE.

IN USE BY THE U. S. GOVERNMENT AT PORT ROYAL, S. C.

ally extends the length of the yard or shop, or perhaps clear around it. Under its own steam, the ponderous machine runs along this track to the object it is desired to move. Steam power then slews the machine laterally so that the end of the jib or boom is over the object, when the latter is attached to the rope running over the end of the jib, the winch turned by the engine and the object lifted into the air. A second rope over another winch then raises the jib to the desired height and the machine runs back over the track to the point desired, where the object is deposited. The utmost expertness and delicacy of handling is acquired by the operator of this steam locomotive crane, which will thus grasp and carry where desired objects weighing often 50 tons or more. The common size is the one capable of lifting five tons only, though there are at Port Royal, in the United States navy yards, several large cranes which just as easily lift 50 tons. This latter machine has a boom 85 feet long and will travel under its own steam along the track 50 feet per minute. It will hoist a 40-ton load seven feet per minute and slew, or turn, a complete revolution in two minutes. The smaller cranes are much used on flat cars as wrecking apparatus for railroads, in excavating and dredging and in heavy construction work. Scores were used in digging the subway for New York city. A small 5-ton locomotive crane costs about $7,500. This style of hoisting apparatus is peculiarly the product of American genius and machines made in America are found in all large contracts for bridge building, railroad construction and like work in every corner of the world. A new machine for placer mining installed in New Mexico in the summer of 1903 adopts this form of crane, using the water over and over for sluicing the sand. It also operates a clam-shell shovel. In more difficult digging the "orange peel" form of shovel is used, the crane raising a ton or more of earth in the shovel and depositing it where desired.

Overhead Trolleys.—In the yard of a shipbuilding company at New London, Conn., has been installed a system of overhead hoisters which combine the advantages of both the derrick and the crane advantageously. The two enormous steamships, Minnesota and Dakota, were constructed by its aid solely. The two ships were built side by side and one trolley system served for both. By this method there are three steel spars, each 120 feet long, each supporting a steel cross-yard 174 feet long. These masts are braced by immense steel guy ropes or cables. The distance between the masts is 300 feet and the tops of the yards, or jibs, are 84 feet from the ground. The working field of the trolleys is a rectangle 600 feet long and 174 feet wide. Along the jibs a track made of wire rope is laid, on which a carriage is swung, suitably centred and controlled. On the main mast, just below the yard, is the house containing the operator and engine. This one man controls the trolley carriages on all the jibs, the raising or lowering and slewing of the jibs and masts and the return of the trolley carriages to the point desired. All is done swiftly and accurately, each carriage being capable of carrying 5,000 pounds. This system can operate four of these trolleys when desired.

Crane-derrick.— This is a combination of the crane and the derrick, as its name indicates. It resembles a figure 4 in construction. The mast can be slewed, but the yard or jib is a fixture and cannot be raised or lowered. Near the juncture of the jib and mast is the house in which sits the operator and where the engine is located. Along the under side of the jib is suspended a wire cable track on which runs a grappler carriage. The jib is usually very long, at least 60 feet, and the grappler runs to the end of this or to such point as is desired to be attached to the object to be lifted. This form of hoister is much used in bridge building and in places where a long reach of jib is desired.

At least 25,000 hoisting machines of these various types are made annually in the United States, one fifth of which are exported. About $25,000,000 is the annual expenditure for this class of machines, aside from the cost of hoisting engines, ropes, wire cable and the other appurtenances of the trade. The largest locomotive cranes cost $50,000 and the small wooden derrick $300 to $1,000. The industry has grown to enormous proportions and new improvements in methods of hoisting are constantly being made for special purposes.

Holbach, Paul Heinrich Dietrich, powl hīn'rĭн dēt'rĭн hōl'bäн (Fr. ōl-bäk), BARON VON, German philosophical writer: b. Heidelsheim, in the Palatinate, 1723; d. Paris 21 June 1789. He was educated in Paris, where he passed the greater part of his life. He was the centre of a circle of men of wit, but of free thinking principles, using his great fortune, says Rousseau, generously, and appearing to advantage in the learned society which he gathered round his table. He was the author of a great number of works, most of which were anonymous or pseudonymous. The principal work attributed to him, which appeared in 1770 under the name of M. Mirabaud, and excited much attention in the learned world, is the 'Système de la Nature ou les Lois du Monde physique et moral.' He afterward published 'Système social, or Principes naturels de la Morale et de la Politique'— a development of the previous work, showing the application of the principles promulgated in it to morals and politics; 'Bons Sens, or Idées naturelles opposées aux Idées surnaturelles'; 'Eléments de la Morale universelle'; etc. According to Holbach matter is the only form of existence, and everything is the effect of a blind necessity.

Holbein, Hans, hänts hōl'- or hōl'bīn, the Elder, German painter: b. Augsburg 1460; d. Alsace 1524. His art training began under the influence of Martin Schongauer, but he quickly launched out into a new style, which left ancient precedents behind. He developed a dramatic energy, a clear and lifelike coloring and pre-eminent distinction of expression which rendered him the acknowledged head of a new school. His figures took the attitude of life. The pictures over the altar in the Cathedral at Augsburg, painted in 1493, are good specimens of his best work; in them are portrayed incidents in the life of Virgin Mary. To the same class belong the remains of an altarpiece in the Dominican Church at Frankfort-on-Main, representing scenes of the Passion (1501); 16 paintings of the Passion in the Munich Gallery; the portrait of the artist with his two sons, in the gallery at Augsburg. His later pictures show traces of the influence exercised by the Italian renaissance, and those painted about 1512 and later are vastly superior to his early work. Among them is his 'Fount of Life' (1519), now in the royal gallery at Lisbon; the altarpiece 'St. Sebastian' (1515), at Augsburg; the altarpiece 'St. Katharine,' in the same gallery; etc. In such works the bold and devotional conception, delicacy and directness of expression, ease of drawing and splendor of coloring, are beyond praise. Excellent also are some of his preliminary sketches and outlines, and in Basle, Berlin, and Copenhagen are collections of his pencil sketches, the most remarkable of which is that at Berlin. Consult: Woltmann, 'Holbein und seine Zeit' (1866).

Holbein, Hans, the Younger, German painter: b. Augsburg 1497; d. London Nov. 1543. He probably received instruction in painting from his father, and about 1515 went to Basle, where he engaged in illustrating books. At Basle he also painted his earliest portraits, and in 1517 went to Lucerne. Here he painted the house of Jacob von Hertenstein, designed windows, and executed other works. Returning to Basle in 1519, he became a burgher in the following year, and during a seven years' residence in that city he executed many works of great importance. In 1526 he went to England. Letters from his friend Erasmus, whose famous 'Praise of Folly' he had illustrated, procured him the patronage of the chancellor, Sir Thomas More, who employed him to delineate the portraits of most of his own personal friends about the court, and introduced him to the notice of Henry VIII., who was a liberal encourager of the fine arts. Among the portraits produced by him during this period are those of More, Archbishop Warham, Bishop Fisher, and several other distinguished persons. From 1528 till 1532 he was again in Basle, but in the latter year he returned to England, where he was destined to spend nearly all the remainder of his life. Holbein painted most of the principal English nobility, whose portraits place him among the world's greatest portrait-painters. Some of his earlier productions, especially his 'Dance of Death,' are also celebrated. In 1538 he completed and published this series. Among the pictures of Holbein's last period are 'The Ambassadors' (1533), and portraits of Hans of Antwerp (1532), English Lady and Gentlemen (1534), Sir Richard Southwell (1538), Duke of Norfolk (1539), Thomas Cromwell, Lady Jane Seymour, Henry VIII. (1542, unfinished), and others. Comparatively few of Holbein's pictures are still extant in England, great numbers of them having been destroyed by Puritan fanatics, or sold and dispersed over Europe. Many of them also perished in the great fire in London in 1666. Holbein also excelled in wood-engraving, and before his visit to England had produced a large number of wood-cuts. He was one of the earliest to paint portraits in miniature. See Woltmann, 'Holbein und seine Zeit' (1874); Wornum, 'Life and Works of Holbein' (1867); Knackfuss, 'Holbein der Jüngere' (1896).

Holberg, Ludwig, lood'vĭg hŏl'bĕrg, Baron, Danish author: b. Bergen, Norway, 3 Dec. 1684; d. Copenhagen, 28 Jan. 1754. He studied at Copenhagen, Oxford and Paris, and after paying a six months' visit to Rome returned to Copenhagen in the end of 1716. In 1718 he was appointed to an ordinary professorship in the university of that city, where after this date he chiefly resided till his death. In 1735 he was unanimously elected rector, and in 1737 treasurer of the university, and in 1747 was raised to the rank of baron. Holberg's numerous productions in various departments of literature as well as the important and salutary influence which he exercised upon his countrymen, place him in the front rank of the literary men of his age. He was extremely versatile — now devoted to history, now to poetry, and now to the drama; but during his whole life he was a sworn enemy to pedantry, theological disputatiousness, and scholastic metaphysics. His works may be divided into four classes — poems, stage pieces, philosophical treatises, and historical works. His poems are chiefly of a satirical nature. The most celebrated among them is 'Peder Paars,' a comic heroic poem in 14 cantos, still regarded throughout the Scandinavian countries as a masterpiece, and the hero of which has become the national comic impersonation in Denmark. It has been translated into several languages. Almost equally famous is his 'Nicholas Klimm's Subterraneous Travels,' a satirical romance in prose, originally written in Latin, but translated into seven modern European languages shortly after it appeared, into Danish first by Baggesen (1789). His numerous stage pieces are either comedies or farces, and nearly all characterized by true comic power. Among his philosophical writings the most important is his 'Moral Reflections' (1744). His historical works include: 'The Political, Ecclesiastical, and Geographical Condition of the Danish Monarchy,' a work of great value as a source of reference; 'A General History of the Jews,' and 'A History of Famous Men and Famous Women' (1739–45).

Hol'brook, John Edwards, American naturalist: b. Beaufort, S. C., 30 Dec. 1794; d. Norfolk, Mass., 8 Sept. 1871. He was graduated from Brown in 1815, from the medical school of the University of Pennsylvania in 1818, began practice at Charleston, S. C., in 1822, and in 1824 was appointed to the chair of anatomy in the Medical College of South Carolina, a post he held for over 30 years. In the Civil War he was head of the South Carolina examining board of surgeons. His 'American Herpetology, or a Description of Reptiles Inhabiting the United States' (1842), won for him recognition among European scientists. He published but 10 numbers of his 'Ichthyology of South Carolina' (1854 *et seq.*), when the Civil War compelled its discontinuance.

Hol'comb, Silas Alexander, American jurist: b. in Gibson County, Indiana, 25 Aug. 1858. He received a common school training, studied law in Nebraska, and in 1891 was made judge of the 12th judicial district. He was governor of Nebraska from 1894 to 1898, having been elected by fusion of the Populist and Democratic voters. He has been justice of the supreme court of Nebraska from 1900.

Hol'combe, Chester, American diplomatist and author: b. Winfield, N. Y., 16 Oct. 1844. He was graduated at Union College in 1861; and served as interpreter and secretary to the United States Legation in China, 1871–85. Becoming an authority on the Chinese and Chinese affairs, in 1896 he acted for the Chinese government in its financial embarrassments. He has published: 'Travels in Western China' (1875); 'The Practical Effect of Confucianism upon the Chinese Nation' (1882); 'The Real Chinaman' (1895); 'The Real Chinese Question' (1899).

Holden, hōl'dĕn, **Albert J.,** American musician: b. Boston 1841. He studied music in New York, and since 1855 has been organist at the Church of the Divine Paternity and at the Church of the Puritans. He has composed more than 300 anthems, hymns and other church music, but his compositions are not confined to sacred music; they include songs, ballads, and choruses; he has also edited and compiled numerous collections.

Holden, Albert W., English painter: b. London 6 July 1848. He studied drawing and antiquities at the British Museum, and gained a studentship at the Royal Academy of Arts, where he afterward exhibited. He has painted historical and humorous genre pictures, and has a high reputation as a portrait painter. Since 1887 he has been professor of fine arts, King's College, London. Among the well known works he has exhibited are: 'A Bank Holiday' (1883); 'Naughty Polly' (1898); 'The Annunciation' (1896); etc.

Holden, Edward Singleton, American astronomer: b. St. Louis, Mo., 5 Nov. 1846. He was graduated at Washington University in 1866, and at the United States Military Academy in 1870; was professor of mathematics at the Naval Academy in 1873–81; and director of the Washburn Observatory (Madison, Wis.) in 1881–5. In 1885–7 he was president of the University of California, and in 1888–98 director of the Lick Observatory, on Mount Hamilton, San José, Cal. It was in connection with the Lick Observatory that his most important work was done, and his services to astronomy found recognition in America and from European states. Among his publications are: 'Index Catalogue of Nebulæ' (1877); 'Life of Sir William Herschel' (1881); 'Astronomy' (with S. Newcomb, 1892); 'Mountain Observatories' (1896); 'Essays in Astronomy' (1900).

Holden, Sir Isaac, English inventor: b. Hurlet, near Paisley, 7 May 1807; d. Reighley, Yorkshire, 13 Aug. 1897. While a worker in a cotton mill in Paisley he fitted himself for the post of a teacher. While conducting an experiment he discovered the lucifer match, but he secured no patent on the invention, the financial benefit of which fell to others. Subsequently he was manager, then owner of a wool-combing establishment, and by his mechanical improvements made significant changes in that industry. His shops at Bradford, with branches at Croix and Rheims, eventually became the largest of the kind in the world. He was several times elected to Parliament in the Liberal interest.

Holder, hōl'dėr, **Charles Frederick,** American naturalist: b. Lynn, Mass., 5 Aug. 1851. He studied at the United States Naval Academy, but resigned in 1871; in 1871–5 was assistant curator of the American Museum of Natural History, from that time turned his attention to lecturing and literary work, and became known as a leading writer on popular science. At Pasadena, Cal., whither he removed in 1885, he became president of the board of education, professor of zoology in Throop University, and honorary curator of the university museum. Among his publications are: 'Elements of Zoology' (1885); 'Living Lights' (1887); 'Louis Agassiz, his Life' (1892); 'Along the Florida Reef' (1892); 'Stories of Animal Life' (1900); 'Half-Hours with Nature' (1901).

Holds'worth, Annie E., English novelist: b. Jamaica. She was married to Eugene Lee-Hamilton, the poet, in 1898. She has been coeditor of 'The Woman's Signal,' with Lady Henry Somerset, and is the author of the popular novels: 'Joanna Traill, Spinster'; 'The Years that the Locust Hath Eaten'; 'Spindles and Oars'; 'The Gods Arrive' (1897); etc.

Hole, Samuel Reynolds, English Anglican clergyman: b. 5 Dec. 1819; d. Rochester, Eng., 27 Aug. 1904. He was educated at Oxford, took orders, was ordained in 1845 and was vicar of Caunton, 1845–87. From 1887 he was dean of Rochester Cathedral. He visited the United States on a lecture tour in 1896, where his humorous, anecdotical lectures were very popular. He was a recognized authority on rose culture and wrote: 'A Book about Roses,' which has reached its 15th edition; 'The Memories of Dean Hole'; 'More Memories'; 'Addresses to Working Men'; 'A Little Tour in America'; 'Our Gardens' (1899); 'Then and Now' (1901); etc.

Hole, William, English painter: b. Salisbury 7 Nov. 1846. He was destined for the profession of engineering but after a journey to Italy turned his attention to art. He studied at the Edinburgh school of art, and in 1889 was elected member of the Royal Scottish Academy. His versatility is shown by the excellence of his work in portrait, genre and fresco, while as an engraver he has made many famous plates after such masters as Millet, Constable and Millais. Among his best known paintings are: 'The End of Forty-Five' (1879); and 'News of Flodden' (1886).

Holguin, ōl-gēn', Cuba, city in the province of Santiago de Cuba; about 25 miles by rail south by west of Gibara, its port; and 70 miles northwest of the city of Santiago de Cuba. Fertile agricultural lands are in the vicinity, also on the southwest is a hilly section bordering on the interior mountain range. A noted cave is in the vicinity. The trade is chiefly in sugar-cane and tobacco. Pop. 6,500.

Hol'ibut. See Halibut.

Hol'iday, any day set apart as a religious or national festival. (See Festivals.) Certain days are fixed by law as bank-holidays for England and Scotland, and it is enacted that all business transactions which would have been valid on any such holiday shall be held as valid if performed on the day following. Thus, when a bill of exchange becomes due, or notice of dishonor falls to be given, on a bank-holiday, the bill is payable, or the notice stands good on the following day. The days fixed for England are Easter Monday, the Monday in Whitsun Week, the first Monday in August, and the 26th of December if a week-day. These are in addition to Christmas Day, Good Friday, and other holidays previously established. The days fixed as bank-holidays for Scotland are New Year's

Day, Good Friday, the first Monday of May, the first Monday of August, and Christmas Day; and if either New Year's Day or Christmas Day falls on a Sunday, the Monday after is held as a holiday. The same act empowers the sovereign to appoint by proclamation a special day to be observed as a bank-holiday, and to alter by order in council any of the days settled by the act.

In the United States there is no national holiday, not even 4 July. The 53d Congress passed an act making Labor Day a public holiday in the District of Columbia, and various States have followed with a similar act. The proclamation of the President designating a day of Thanksgiving only makes it a legal holiday in the District of Columbia and in the Territories. New Year's Day is a legal holiday in all the States except Massachusetts, Mississippi, and New Hampshire. Lincoln's Birthday (12 Feb.) is a legal holiday in Connecticut, Illinois, Minnesota, New Jersey, New York, North Dakota, Pennsylvania, Washington, and Wyoming. Washington's Birthday (22 Feb.) is a legal holiday in all the States except Mississippi. Decoration Day (30 May) in all the States except Alabama, Florida, Georgia, Idaho, Louisiana, Mississippi, North Carolina, South Carolina, and Texas. Independence Day (4 July) in all the States and Territories. Labor Day (in general, the first Monday in September) in all the States except Arizona, Mississippi, Nevada, and North Dakota. Election Day and Christmas Day are generally observed as legal holidays in all the States and Territories. There are various States holidays, such as Patriot's Day (19 April) in Massachusetts, Pioneer's Day (16 Aug.) in Utah, All Saints' Day (1 Nov.) in Louisiana, Admission Day (9 Sept.) in California, and Confederate Memorial Day (10 May) in North and South Carolina. Every Saturday after 12 o'clock noon is a legal holiday in New York, New Jersey, Pennsylvania, Maryland, Tennessee, Virginia, in the city of New Orleans and in Newcastle County, Delaware.

Holinshed, hŏl'inz-hĕd, **Raphael** or **Ralph**, an English chronicler: d. about 1580. He is only known by his 'Chronicles of Englande, Scotlande, and Irelande,' the first edition of which, known as the "Shakespeare edition," because it is the one the poet is supposed to have used in collecting material for his historical plays, was published in London in 1577. In the preparation of this work Holinshed was assisted by several of the most learned men of the day.

Holl, Frank, English portrait and genre painter: son of Francis Holl, an eminent engraver: b. London 4 July 1845; d. there 31 July 1888. He was a very successful student at the Royal Academy, and exhibited constantly from his student days. Among his best-known pictures are: 'Faces in the Fire'; 'Fern-Gatherers'; 'No Tidings from the Sea'; 'Leaving Home'; and the 'Gifts of the Fairies.' In the later portion of his career he devoted himself to portraiture, in which he greatly excelled, and painted many of the celebrities of the day.

Holland, Edmund Milton, American actor: b. New York 7 Sept. 1848. He began his professional career at Barnum's Museum in 1866, was later for 13 years a member of Lester Wallack's company, and as a member of the Madison Square company from 1882 created the parts of Captain Redwood in 'Jim the Penman,' Colonel Moberley in 'Alabama,' and the title-role in 'Colonel Carter of Cartersville.' In 1895-7 he starred with his brother Joseph, and later (1901) appeared as Eben Holden in the dramatization of Irving Bacheller's book of that name.

Holland, Frederic May, American author: b. Boston 2 May 1836. He was graduated from Harvard in 1859, entered the ministry of the Unitarian Church in 1862, but resigned in 1874. His publications include: 'The Reign of the Stoics' (1879); 'Frederick Douglass, the Colored Orator' (1895); and 'Liberty in the Nineteenth Century' (1899).

Holland, Henry Richard Vassall Fox, 3D Lord, English statesman: b. Wiltshire 21 Nov. 1773; d. 22 Oct. 1840. He succeeded to the peerage by the death of his father when less than one year old. In 1798 he took his place in the House of Lords, and as the nephew of Charles James Fox was at once acknowledged as a Whig leader. In 1806 he was commissioner for settling disputes with the United States; was lord privy seal in 1806-7; and chancellor of the duchy of Lancaster. He made Holland House the resort of the wit, talent, and beauty of his day. He was the author of: 'Life of Lope de Vega' (1806); 'Three Comedies from the Spanish' (1807); 'Foreign Reminiscences' (1850); 'Memoirs of the Whig Party' (1852).

Holland, John P., American inventor: b. 1841. As one of the most successful designers in the interesting field of submarine navigation, Holland is well known. His first boat was built in 1875; a second was launched in 1877, and a third in 1881. After a series of severe tests, the Holland boat was ordered by the United States government for the navy in 1900. In 1903 eight of the submarines were put in commission. These have a speed varying from 8.87 to 8 knots, a horse-power of 160 (with one exception), and a displacement in general of 122.55 tons. For some time the inventor was interested in the Holland Submarine Boat Company, but from this he has now retired to devote his time independently to submarines and flying devices. His more recent designs call for smaller and more compact vessels, with much less complicated mechanism, power of remaining longer submerged, and increased safety in operation. See Submarine Navigation, History of.

Holland, Josiah Gilbert, American editor and author: b. Belchertown, Mass., 24 July 1819; d. New York 12 Oct. 1881. He began the study of medicine in 1840, in 1844 was graduated from the Berkshire Medical College, and entered practice at Springfield, Mass. The years that followed were discouraging, for patients did not come to the young doctor. With true Yankee versatility he turned his hand to anything,—taught district school, was a traveling writing-master, and a daguerreotypist. Of his boyish mortification at being a mill hand he has written in 'Arthur Bonnicastle.' He tried editorial work, and started 'The Bay State Weekly Courier,' which ran for six months. Subsequently he taught at Richmond, Va., and for 16 months was superintendent of public schools at Vicksburg, Miss. All these varied experiences gave him the knowledge of American life and appreciation of workaday struggles which later made the value of his poems, essays, and novels. In 1849–66 he was assistant editor of the Springfield *Republican*, and from 1851 also part owner of that journal. It was largely due to his influence that the *Republican* became so widely known and popular a journal. In it his 'Letters to Young People Married and Single: By Timothy Titcomb' first attracted readers by their vivacious style, moral sincerity, and good common sense. Later, in book form (1858) they had a great and immediate success.

In 1870 Dr. Holland was one of the founders and became editor of 'Scribner's Monthly,' later the 'Century Magazine,' and the editorship of this periodical he retained till his death in 1881. Holland's novels: 'Arthur Bonnicastle' (1873); 'Sevenoaks' (1876); and 'Nicholas Minturn' (1877), although showing his quick and sympathetic observation and containing fine passages, have been less popular than his poems. The latter, in their constant appeal to the moral sense, and in their accurate portrayal of the homely and picturesque in New York life, found many admirers. Several of the short lyrics, with 'Bittersweet' (1858); 'Kathrina' (1868), and 'The Mistress of the Manse' (1871), came as messages of an American poet who understood and honored his own people. Consult the 'Life' by Plunkett (1894).

Holland, Thomas Erskine, English jurist: b. Brighton 17 July 1835. He studied at Oxford, was called to the bar in 1863, in 1874 became a reader in English law at Oxford, and shortly afterward professor of international law. The University of Perugia appointed him to an honorary professorship in recognition of his attainments. His best-known work is his 'Elements of Jurisprudence' (1880; 9th ed. 1900), to which was awarded the Swinney prize (1894), decennially bestowed for the best book published on jurisprudence, and which is now a standard text-book in England and the United States. He wrote further: 'An Essay on Composition Deeds' (1864); 'Essays on the Form of the Law' (1870); 'The European Concert in the Eastern Question' (1885); 'Studies in International Law' (1898), and other works.

Holland, William J., American Presbyterian clergyman and educator: b. Jamaica, W. I., 16 Aug. 1848. He was graduated from Amherst College in 1869, from the Princeton Theological Seminary in 1874, entered the ministry of the Presbyterian Church, and was a pastor at Pittsburg, Pa., in 1874–91. In 1891–1901 he was chancellor of the Western University of Pennsylvania (Allegheny), and in 1897 was appointed director of the Carnegie Museum at Pittsburg. In 1887 and 1889 he was naturalist of the United States eclipse expeditions to Japan and West Africa respectively. A recognized authority on museum administration and zoology, he wrote numerous scientific papers in learned publications, and 'The Butterfly Book' (1898).

Holland, a popular designation for the Kingdom of the Netherlands, derived from the provinces of North and South Holland, formerly constituting a feudal countship allied to the Holy Roman-German Empire, and from 1806–10 with other parts of the Netherlands, Hanover, and Oldenburg, ruled by Louis Bonaparte as the Kingdom of Holland. The region is the seat of the hardy and industrious Dutch race and of the Dutch language called by the natives *Nederduitsch*, a dialect of Low German phonology, with evolutionary periods of Old, Middle, and Modern, and an interesting historical and varied literature. See NETHERLANDS.

Holland, Mich., city, in Ottawa County, at the head of Black Lake, which is really an arm of Lake Michigan, and on the Père Marquette railroad; about 80 miles west of Lansing and 25 miles southwest of Grand Rapids. It has direct communication by steamers with Chicago, Milwaukee, and other lake ports. Holland was settled in 1847 by a Dutch colony, and many of its inhabitants are of Dutch descent. In 1867 it was chartered as a city. It is located in an agricultural region, once a lumber section. The manufactures are largely articles made of wood, but the beet-sugar industry is growing in importance. The chief manufacturing establishments are planing-mills, furniture, tub, and basket factories, flour-mills, tanneries, wood-working machinery shops, pickling-plants, beet-sugar factory, grain elevators, and creameries. The manufacture of launches is also an important industry of Holland. The trade is chiefly in the manufactures, and in grain and vegetables. The city owns and operates the electric-light plant and the waterworks. Holland is the seat of the Western Theological Seminary and of Hope College, both under the auspices of the Reformed Church in America. It has a number of fine public buildings, and a free public library. The summer resorts on Black Lake add to the industrial wealth of the city. Pop. (1890) 3,945; (1900) 7,790.

Holland-linen, a fine and close fabric, so called from its first being manufactured in Holland; also a coarser linen fabric, unbleached or dyed brown, used for covering furniture, carpets, etc.

Hol'lander, Jacob H., American economist: b. Baltimore, Md., 23 July 1871. He was educated in the Baltimore schools and graduated from Johns Hopkins University in 1891, receiving his Ph. D. degree in 1894. His ability as economist and financier was soon recognized, and he became associate professor of finance at Johns Hopkins. In 1897 he was appointed secretary of the Bimetallic Commission abroad and was chosen chairman of the Baltimore municipal lighting commission in 1900. In the same year the secretary of war appointed him special commissioner to revise the laws relating to taxation in Puerto Rico, and while engaged in this service he was made treasurer of Puerto Rico by President McKinley.

Hollar, Wenzel or **Wenceslaus**, vĕnt'zĕl or wĕn'sĕs-lâs hŏl'lär, Bohemian engraver: b. Prague 13 July 1607; d. London 28 March 1677. He accompanied the Earl of Arundel, English ambassador to Germany, to London, who employed him to engrave some of the pictures of his collection. Among his numerous works, which are greatly esteemed for their delicate, firm and spirited execution, and which include some 2,740 plates, are the set of 28 plates, entitled, 'Ornatus Muliebris Anglicanus,' representing the dresses of Englishwomen of all ranks and conditions in full-length figures; Holbein's 'Dance of Death,' etc.

Holleben, hōl'lā-bĕn, **Theodore von**, German diplomat: b. Stettin, Pomerania, 10 Sept. 1838. He was educated at the universities of Heidelberg, Berlin, and Göttingen; became an officer in the Body-Guard Hussar Regiment; and took a distinguished part in the Franco-Prussian War. He entered the diplomatic service in 1872; was *chargé d'affaires* at Peking, China, 1873-4, and at Tokio, Japan, in 1875; minister at Buenos Ayres in 1876-84; at Tokio 1885-9; and at Washington, D. C., 1892-3. In 1897 he became ambassador extraordinary and plenipotentiary to the United States. At the command of Emperor William he, together with Secretary Hay, of the State Department, had charge of the arrangements for the official reception of the emperor's brother, Admiral Prince Henry, in February 1902. Failing health caused his resignation, and in 1903 he was succeeded by Baron Speck von Sternberg.

Hol'ley, Alexander Lyman, American engineer: b. Lakeville, Conn., 20 July 1832; d. Brooklyn, N. Y., 29 Jan. 1882. He was graduated at Brown University in 1853, and became editor of 'The Railroad Advocate' in 1850, changing its name to 'The American Engineer.' He introduced into the United States in 1865 the Bessemer steel process, erecting the first Bessemer works in the country at Troy, N. Y. He was lecturer on the manufacture of iron and steel at Columbia University 1879-82. Holley secured many patents, the most important probably being that for the detached converter-shell, an improvement in the Bessemer process. He published with Z. Colburn: 'Railway Economy: a Report on European Railways' (1858); 'American and European Railway Practice' (1860); 'A Treatise on Ordnance and Armor' (1865); etc. In 1890 a bronze bust of Holley was placed in Washington Square, New York, by the mechanical engineers of the United States and Europe.

Holley, Marietta, American author, known by her pseudonym, 'JOSIAH ALLEN'S WIFE': b. near Adams, Jefferson County, N. Y., 1844. She began her literary career as a contributor to the 'Christian Union,' the 'Independent,' 'Peterson's Magazine,' and other periodicals; and in 1873 published her first book, 'My Opinions and Betsy Bobbet's,' which in a measure recalled the 'Widow Bedott Papers' of F. M. Whitcher. This was followed by a series of works containing many touches of distinctive and genuine humor: 'Samantha at the Centennial' (1876); 'My Wayward Pardner' (1880); 'Miss Richard's Boy' (1882); 'Sweet Cicely' (1885); 'Miss Jones's Quilting' (1887); 'Samantha at Saratoga' (1887); 'Poems' (1887); 'Samantha Among the Brethren' (1891), considered by many her best volume; 'Samantha at the World's Fair' (1893), and others. Her writings have had large sale, and been translated into several foreign tongues.

Hollidaysburg, hŏl'ĭ-dāz-bĕrg, Pa., borough, county-seat of Blair County; on the Juniata River, and the Pennsylvania railroad; about 82 miles east of Pittsburg and five miles south of Altoona. Rich coal-fields, iron-ore beds, and limestone quarries are in the vicinity. The chief manufactures are foundry products, agricultural and mining implements, nails, and furniture. Hollidaysburg Female Seminary is a prosperous institution. Pop. 3,000.

Hol'lins, Alfred, English musician: b. Hull 1865. He was born blind, and was educated at an institution for the blind in York, and at the Royal Normal College for the Blind in Upper Norwood, where he specialized in music (piano and organ); he also studied music in Germany. He was popular at the English and German courts, where he gave recitals; and was for a time organist at the United Free Saint George's Church in Edinburgh. He visited America in 1886 and 1888, and his organ compositions are widely known and liked throughout the United States.

Hollins, George Nichols, American naval officer: b. Baltimore, Md., 20 Sept. 1799; d. there 18 Jan. 1878. He entered the navy as midshipman in 1814, and while assigned to the President, Stephen Decatur, was captured by the English and held prisoner at Bermuda until the conclusion of peace. He served also in the Algerine war of 1815, later assumed command of an East Indiaman, and in 1844 attained commander's rank. In 1855, on complaint of American residents who claimed they had been injured by the local officials, he bombarded Greytown, Nicaragua. At that time Nicaragua was under English protection, and the property and lives of English residents having been imperiled, international complications with Great Britain arose. Hollins was commissioned commodore in the Confederate navy at the outbreak of the Civil War, attacked the Federal blockading squadron at the passes of the Mississippi River, and was appointed flag-captain of the New Orleans station. He was superseded in 1862.

Hol'lister, Cal., town, county-seat of San Benito County; on the Southern Pacific railroad; about 80 miles southeast of San Francisco, and 35 miles east by south of Santa Cruz. It is situated in a rich agricultural region, noted for its fruit. The chief industrial interests of the town are connected with dairying, fruit-growing, and the shipment of grain and live-stock. Pop. (1900) 1,315.

Holloway, hŏl'ō-wā, **Laura Carter**, American author: b. Nashville, Tenn., 22 Aug. 1848. She was at one time editor of the 'Home Library Magazine' of Chicago, Ill., was for 12 years associate editor of the Brooklyn *Daily Eagle*, and collaborated with Anton Seidl in the preparation of musical terms for the 'Standard Dictionary.' She wrote: 'Ladies of the White House' (1870); 'The Mothers of Great Men and Women' (1884); 'The Home in Poetry' (1884); 'Chinese Gordon' (1885); 'The Buddhist Diet Book' (1887); and other volumes.

Holloway, Thomas, English patent medicine proprietor and philanthropist: b. Devonport 22 Sept. 1800; d. Tittenhurst 26 Dec. 1883. About 1837 he began to sell his well-known ointment, and soon afterwards brought his pills to the notice of the public. He ultimately succeeded in amassing a very large fortune which he partly devoted to benevolent objects. The Royal Holloway College for Women, on the equipment and endowment of which he expended about $4,000,000 was opened on 30 June 1886. It contains a collection of pictures valued at $500,000. Near it is a sanitorium founded by him for the mentally afflicted of the lower middle class.

Holls, hōlz, **George Frederick William**, American lawyer and statesman: b. Zelienople, Pa., 1 July 1857; d. Yonkers, N. Y., 23 July 1903. He was graduated from Columbia in 1878, and from the law school there two years later. He was admitted to the bar and established a large law practice in New York city, becoming senior member of the firm of Hollis, Wagner & Burghard; in his later life he visited Europe frequently and became widely known there, especially in Germany where he established a branch of his law firm. He was prominent in philanthropic work, being for years an officer of the Legal Aid Society and a director of the Charity Organization Society. He was also an active member of the Republican party, and much in demand as a campaign speaker, especially as he could address the Germans in their own language. In 1893 he was a delegate-at-large to the New York Constitutional Convention, where he was chairman of the committee on education, a member of the committee on cities, and author of several amendments. His frequent visits abroad gave him a wide and intelligent interest in international questions, and at the time of the Hague Conference he was very influential in arousing interest and obtaining a large delegation from the United States. He was secretary of the American delegation at the Conference (1899), was the American member of the committee which drafted the arbitration treaty, and author of the clause on «Special Mediation.» He was afterward appointed a member of the permanent international court of arbitration. A few months before his death President Roosevelt asked him to umpire the adjustment of claims between Germany and England and Venezuela, but he declined. He has written: 'Sancta Sophia and Troitza' (1888); 'Compulsory Voting' (1891); and 'The Peace Conference at the Hague and Its Bearings on International Law and Policy' (1900).

Hol'ly, James Theodore, American Protestant Episcopal bishop: b. Washington, D. C., 3 Oct. 1829. He was of African Roman Catholic parentage, but withdrawing from the Roman Catholic Church, entered the Episcopal Church in 1851, studied for the ministry and in 1856 became rector of St. Luke's, New Haven, Conn. In 1874 he became missionary bishop of Haiti.

Holly. See AQUIFOLIACEÆ.

Holly Springs, Miss., a point on the Mississippi Central Railroad, about 40 miles southeast of Memphis and about 25 miles south of Grand Junction, on the Memphis & Charleston Railroad, and an important strategical point. After the battle of Iuka, 19 Sept. 1862, and the Confederate defeat at Corinth, 3-4 Oct. 1862, the Confederates fell back to Holly Springs. Early in November Gen. Grant had concentrated an army of 30,000 men in the vicinity of Grand Junction to make a movement along the line of the Mississippi Central Railroad in the direction of the rear of Vicksburg. On 8 November Gen. McPherson, with 10,000 infantry and 1,500 cavalry, advanced from Grand Junction southward and pushed the Confederates under Gen. Pemberton back to Holly Springs. The main body of Grant's army moved forward, and Pemberton, abandoning Holly Springs, fell back to Grenada, Grant following to Oxford, 30 miles beyond Holly Springs. There he arrived 5 December, and arranged with Gen. Sherman a combined movement on Vicksburg. Grant was to move directly south on the line of the railroad and take the place in rear; Sherman to move a force from Memphis, accompanied by a gunboat fleet, to descend the Mississippi and attack in front. A depot of supplies was established at Holly Springs, guarded by Col. Murphy, with two regiments of Wisconsin infantry and a regiment of Illinois cavalry, and Grant was about to move forward from Oxford, when Gen. Earl Van Dorn, at the head of 3,500 cavalry, dashed into Holly Springs at daylight, 20 December, and attacked Murphy, who had been warned of the impending danger on the 19th, but neglected to take the necessary precautions and was surprised. He made a feeble resistance and surrendered his infantry; the cavalry cut its way out and escaped with the loss of only seven men. Van Dorn took about 1,500 prisoners, destroyed stores to the value of $1,500,000, and left town in the afternoon. This disaster, in connection with Forrest's raid into West Tennessee, which destroyed Grant's communication, forced him to abandon his movement on Vicksburg and fall back to Grand Junction, leaving Pemberton at liberty to concentrate his forces at Vicksburg against Sherman. Sherman was informed of Grant's failure, but the information reached him after his bloody repulse at Chickasaw Bluff, 27-28 Dec. 1862. Consult: 'Official Records,' Vol. XVII.; Greene, 'The Mississippi.'

E. A. CARMAN.

Hol'lyhock, a tall and rather coarse flowering plant (*Althæa rosea*) of the mallow family, said to be a native of China, but now cultivated all over the world as an ornament of old-fashioned gardens. It rises in a single leafy stalk, sometimes to the height of six or eight feet, studded with large single or double flowers, in varieties from white to yellow, scarlet and purple. Although rather difficult to start and slow of growth, it remains a hardy and easily nurtured perennial of highly effective beauty when suitably placed.

Holm, Saxe, a pseudonym affixed to a collection of 'Stories' (1st series 1874; 2d 1878), originally published in 'Scribner's Monthly' and generally believed to be by Helen Hunt Jackson (q.v.).

Holman, hōl'man, **William Steele**, American politician: b. Veraestau, Dearborn County, Ind., 6 Sept. 1822; d. Washington, D. C., 22 April 1897. He studied at Franklin College (Ind.), was admitted to the bar, and began practice at Aurora, Ind. In 1847-9 he was prosecuting attorney, in 1850 a member of the State Constitutional convention, in 1851-2 of the State legislature. He was a judge of the court of common pleas in 1852-6, in 1856 was elected as a Democratic representative to Congress, where with the exception of eight years, he served until his death. His vigilance in opposing unnecessary appropriations and doubtful measures obtained for him the sobriquets of "The Watchdog of the Treasury," and "The Great Objector."

Holman-Hunt, William. See HUNT, WILLIAM HOLMAN.

Holmes, hōmz, **Abiel,** American Unitarian clergyman and annalist: b. Woodstock, Conn., 24 Dec. 1763; d. Cambridge, Mass., 4 June 1837. He was graduated at Yale College in 1783, and became subsequently a tutor in the college, pursuing at the same time his theological studies. In 1785 he was settled over a parish at Midway, Ga., where he remained till 1791. Returning north he became pastor of the first parish in Cambridge, and continued to fill the office till 26 Sept. 1832. Besides publishing a 'Life of President Stiles' in 1798, he was the author also of 'Annals of America' (1805), which gave him a high reputation for care and accuracy. It was republished in England in 1813. He contributed frequently to the collections of the Massachusetts Historical Society, in Vol. XXVII. of which will be found a complete list of his publications.

Holmès, ō-mĕs', **Augusta Mary Anne,** French composer: b. Paris 1847; d. there Jan. 1903. She studied composition with Lambert, Klose, and César Franck, and began her career as a pianist. Her first work of magnitude was a setting of the psalm 'In Exitu,' sung for the first time in 1873. She later wrote considerable music, including 100 songs, characterized by much grace of expression. In the larger forms her compositions include the well-known symphony 'Hero et Léandre'; three other symphonies, 'Lutèce,' which in 1879 won third prize in an open competition directed by the Paris municipality, 'Les Argonautes' and 'Irlande'; the symphonic poems, 'Les Sept Ivresses,' 'Roland,' 'Pologne,' 'Au Pays Bleu'; an ode of triumph, 'Patrie'; a four-act lyric opera, 'Le Montagne Noire' (Grand Opera 1895), and an allegorical cantata, 'La Vision de la Reine.'

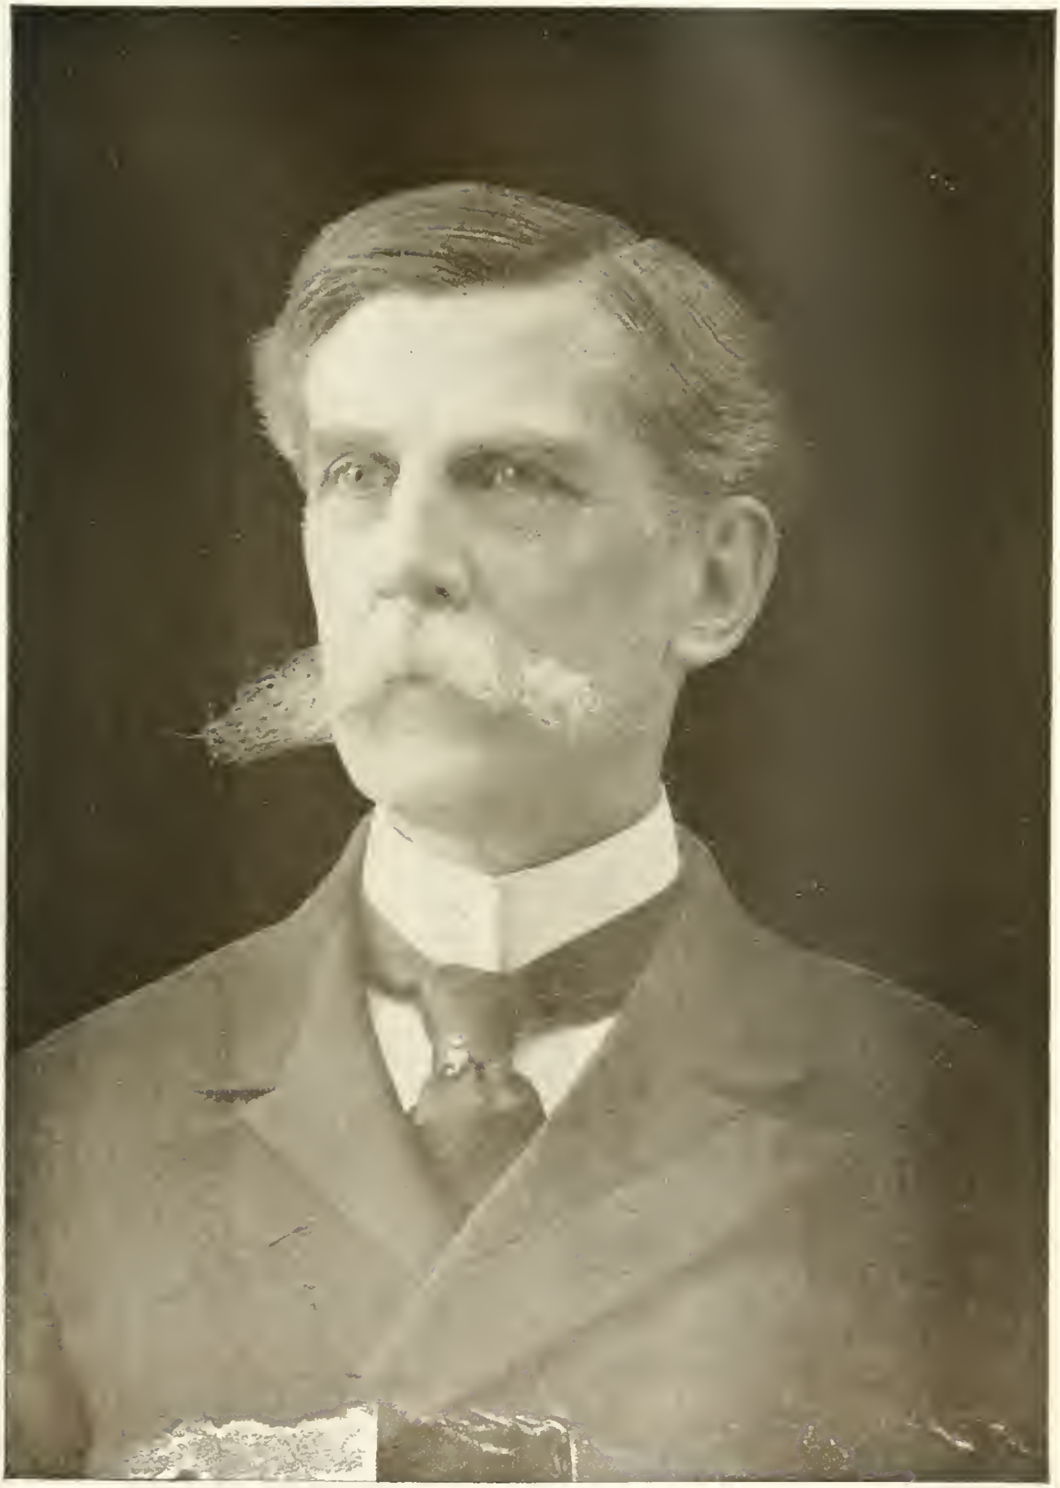
Holmes, Burton, American traveler and lecturer: b. Chicago 8 Jan. 1870. After a secondary education at Chicago he traveled in all the countries of continental Europe, as well as in Japan, Algeria, Tunis, Morocco, Corsica, Greece, and Thessaly, Hawaiian Islands, the Yellowstone Park, the Grand Cañon of the Colorado, the Philippines, and China. About 1890 he became known as a platform lecturer, giving in popular form the results of his observations.

Holmes, Mary Jane Hawes, American novelist: b. Brookfield, Mass. She was married to Daniel Holmes, a lawyer of Brockport, N. Y., where she has since resided. She has published many volumes of domestic fiction which have had an extraordinarily wide circulation but in which the literary element is slight. Among her novels are: 'Tempest and Sunshine' (1854) (perhaps the best known of them all); 'Lena Rivers' (1856); 'Marian Gray' (1863); 'Milbank' (1871); 'Queenie Hetherton' (1883).

Holmes, Nathaniel, American jurist and Shakespearian scholar: b. Peterboro, N. H., 2 Jan. 1815; d. Cambridge, Mass., 26 Feb. 1901. He was graduated from Harvard in 1837 and after admission to the bar in 1839 began to practise in St. Louis. He was judge of the supreme court of Missouri 1865–9, and Royall professor of law at Harvard 1868–72. He retired from his profession in 1883 and henceforth devoted himself to study and authorship. He was a strong believer in the Baconian theory of the origin of Shakespeare's plays, which he defends in his work, 'The Authorship of Shakespeare' (1866). In 1888 he published 'Realistic Idealism in Philosophy Itself.'

Holmes, Oliver Wendell, American poet, essayist and physician: b. Cambridge, Mass., 29 Aug. 1809; d. Boston, Mass., 8 Oct. 1894. He was the son of Rev. Abiel Holmes (q.v.), minister of the first parish in Cambridge, and on the maternal side was a descendant of Anne Bradstreet (q.v.) and related to the orator Wendell Phillips, the poet Richard Henry Dana, and the theologian, Dr. Channing. He was educated at Phillips Academy, Andover, and at Harvard, and was graduated from the latter in 1829 in a class which contained several who afterward became famous. In the next year he became well known through his poem 'Old Ironsides,' first published in the Boston *Advertiser*, and which prevented the breaking up of the famous frigate Constitution. He spent a year in the Harvard Law School but soon turned his attention to medicine and after studying in Paris three years returned to America where he received his degree of M.D. in 1836, the same year in which his first volume of poems appeared. He was professor of anatomy and physiology at Dartmouth College 1839–40. He married in the last named year and established a practice in Boston, becoming in 1847 professor of anatomy and physiology in the Harvard Medical School, a post which he resigned in 1882, when he was at once made professor emeritus. In 1849, and for several succeeding years, he made his summer home at Pittsfield, Mass., the scene of his novel 'Elsie Venner.' He was one of the first contributors to the 'Atlantic Monthly' when it was established in 1857, the opening chapter of his 'Autocrat of the Breakfast Table' appearing in the first issue. It is this work, which has found innumerable readers both at home and abroad, by which he will be longest remembered. These brilliant, conversational papers were followed in 1859 by a similar series, 'The Professor at the Breakfast Table,' and these in 1872, by 'The Poet at the Breakfast Table.' Many of his best poems were scattered through these volumes. In 1861 appeared his novel 'Elsie Venner: a Romance of Destiny,' and in 1868 'The Guardian Angel,' a less striking fiction than its predecessor, but like that exhibiting a remarkable series of studies of character. 'A Mortal Antipathy' (1885) was his only other essay in fiction. His volumes of verse 'Urania' (1846), and 'Astrea' (1850), had made him well known as a poet ere he appeared before the public as the kindly breakfast table autocrat, and he continued to write poetry at frequent intervals for the rest of his life. He was especially happy as the poet of occasions, but much of his verse, witty and sparkling as it is, is ephemeral from its very nature and not destined to endure. In such serious poems,

OLIVER WENDELL HOLMES.



Photographed by Notman.

OLIVER WENDELL HOLMES,

ASSOCIATE JUSTICE OF THE UNITED STATES.

however, as: 'The Chambered Nautilus'; 'The Voiceless'; 'The Last Leaf'; 'The Iron Gate'; and one or two hymns, he takes high rank among the poets of his time, while such poems as 'The One Hoss Shay'; 'Evening, By a Tailor,' and 'Parson Turell's Legacy,' to name no others, are inimitable examples of humorous verse. His later collections of poems comprise: 'Songs in Many Keys' (1861); 'Songs of Many Seasons' (1875); 'The Iron Gate' (1880); and 'Before the Curfew' (1887). As a physician and medical lecturer he was very successful, and among his purely professional works may be named: 'Lectures on Homeopathy and Its Kindred Delusions' (1842); 'Currents and Counter Currents in Medical Science' (1861); 'Border Lines in some Provinces of Medical Science' (1862); 'Medical Essays,' a reissue of some of his earlier work (1883). Still other volumes by Dr. Holmes are: 'Soundings from the Atlantic' (1864), a series of essays originally contributed to the 'Atlantic Monthy,' where the bulk of his writing first appeared; 'Mechanism in Thought and Morals' (1871); lives of 'John Lothrop Motley' (1879); and 'Ralph Waldo Emerson' (1884); 'Our Hundred Days in Europe' (1888); a sprightly record of a short visit to England in 1886, on which occasion honorary degrees were conferred upon him by the universities of Cambridge, Oxford and Edinburgh; and 'Over the Teacups' (1891). His 70th birthday was celebrated by a breakfast given in his honor by the publishers of the 'Atlantic Monthly,' and on this occasion the poet read his poem 'The Iron Gate,' which many persons have considered even finer than 'The Chambered Nautilus' which Holmes himself preferred to any other verses of his. At its best Holmes's prose style is thoroughly admirable, characterized as it is by an unerring sense of the value of words and their fitness for conveying a desired impression, and illumined by the interfused play of a delicate fancy and the most sparkling humor. Next to 'The Autocrat' must be ranked 'The Guardian Angel' among his prose works, the same kindly tolerant spirit being dominant in both, and the same shrewd, wholesome perception of character. In much of his earlier poetry, excepting in his lyrics, Holmes uses the formal ten-syllabled iambic pentameter of the 18th century, but in his hands the measure seems at times more flexible than when used by Pope and his school, and it is at all events relieved from solemnity by his ever present humor. 'Urania' is the best-known of his earlier efforts in this manner, and 'The Schoolboy' (1878) his most notable later one, this latter having been written for the centennial anniversary of Phillips Academy at Andover. Holmes's special characteristic was kindliness, which found its expression as well in his verse as in his prose, and in his ordinary living. He could be keenly satirical on occasion but he never became in the least cynical. Perhaps no American writer, not even Longfellow or Lowell, ever won the English heart so completely as Holmes. Longfellow found a wide hearing in England for his poetry, it is true, and Lowell was thoroughly appreciated by the upper class Englishman of his time, but Holmes was the most generally beloved of the three. In his own country Holmes's gentle, tolerant writing did not a little toward softening the asperities of controversy and liberalizing unconsciously the heart of Puritan New England. Consult: Morse, 'Life and Letters of Oliver Wendell Holmes' (1896); and lives by Kennedy (1883); E. E. Brown (1884).

Holmes, Oliver Wendell, Jr., American jurist: b. Boston 8 March 1841. He was graduated from Harvard in 1861, and in the same year entered the army as lieutenant of the 20th Massachusetts regiment. He was wounded at the battles of Ball's Bluff, Antietam, and the second battle of Fredericksburg, and was mustered out of the army in 1864, with the rank of brevet lieutenant-colonel. He then studied at the Harvard Law School, and was admitted to the bar in 1866, beginning his practice in Boston. He was editor of the 'American Law Review' (1870–3); became professor at the Harvard Law School in 1882, and in the same year justice in the Massachusetts supreme court; in 1899 he was appointed chief justice of the same court. His decisions in this position gave him wide fame among lawyers, and were characterized by originality and literary finish. In several cases his decisions were in favor of organized labor; his position being that workingmen had a right to combine and to "support their interests by arguments, persuasion, and the bestowal or refusal of those advantages which they otherwise lawfully control, so long as they do no violence or threaten no violence." In August 1902, he was appointed a member of the United States Supreme Court. He has published: 'The Common Law' (1881), lectures delivered before the Lowell Institute; and a collection of speeches (1900); he also edited the 12th edition of Kent's 'Commentaries' (1873).

Holmes, Theophilus Hunter, American soldier: b. Sampson County, N. C., 1804; d. near Fayetteville, N. C., 21 June 1880. He was graduated from the United States Military Academy in 1829, served in the Florida war, the occupation of Texas, and the Mexican War, and at the beginning of the Civil War was major and superintendent of the general recruiting service. On 22 April 1861, he resigned his commission in the United States army, forthwith was appointed brigadier-general in the Confederate forces, and organized several North Carolina regiments. He was in command at Aquia Creek, and, promoted major-general, was in command of the trans-Mississippi department from September 1862 to March 1863, was commissioned lieutenant-general, and 3 July 1863 lost heavily in an unsuccessful attack on Helena, Ark.

Holmes, William Henry, American geologist: b. Harrison County, Ohio, 1 Dec. 1846. He was graduated at the McNeely Normal College in 1870, in 1872 was made an assistant on the United States geological survey, and in 1880–9 was a geologist on the survey. In 1889–98 he was archæologist to the United States bureau of ethnology, directing explorations, and in 1894–8 also curator of anthropology in the Field Columbian Museum of Chicago, and professor of anthropic geology in Chicago University. In 1898 he was appointed head curator in the department of anthropology in the United States National Museum. His chief works are: 'Archæological Studies among the Cities of Mexico'

(1895): and 'Stone Implements of the Potomac-Chesapeake Tidewater Province' (1897).

Holocaine. See COCAINE.

Holocephali, hŏl-ō-sĕf'a-lī. or **Chimæroidea**, a group of small shark-like fishes of bizarre appearance occurring in the deeper portions of all colder seas, including in all about seven species, five in American waters. They have a cartilaginous skeleton, are of no value as food, and are known to fishermen as rat-fish and elephant-fish (q.v.). The name Chimæra, given to one genus, emphasizes the strange appearance of these fishes. See ICHTHYOLOGY.

Holophytes, hō'lō-fīts. See FUNGI.

Holostei, hō-lŏs'tẹ-ī, a group of fishes, the bony ganoids, largely fossil, represented by the garpikes. See ICHTHYOLOGY.

Holothuria, hŏl-ō thū'rĭ a, echinoderms of the class *Holothuroidea*, popularly called "sea-cucumbers," from their resemblance in shape and rough skin to that vegetable, in which the body is long, cylindrical, somewhat worm-like, less radiated than other echinoderms with a thick muscular body-wall of longitudinal and transverse muscles. The skin is usually thick, tough, and imbedded in it are in certain forms calcareous plates, wheels and anchors. The mouth is surrounded with a circle of ten branched tentacles, adapted both for respiration and for seizing the food, which consists mainly of foraminifera. The intestine is very long and slender, thus in *Thyone briareus*, which lives in mud and sand on the coast south of Cape Cod, the intestine in an individual three or four inches long is nearly seven feet in length; it opens at the end of the body, and connects with the "respiratory tree," by which the water is introduced into the interior of the body. Unlike other echinoderms the so-called madreporic body is internal. Holothurians move by tubes or ambulacra feet which are filled with water, and when distended act as suckers to drag the animal over the bottom. These suckers are either arranged in five rows or with three rows on the ventral surface, and two above, the latter in some form obsolete, or they are scattered irregularly over the surface of the body, while in *Caudina arenata* of the New England coast there are no suckers. A tendency to bilateral symmetry is seen in a form like *Psolus*, which has a creeping disk and three rows of suckers on the flattened disk-like under side.

The holothurians undergo a metamorphosis, somewhat like that of the starfish; but the transparent larva called "auricularia," is barrel-shaped; what corresponds to the hoops of the barrel being bands of cilia, while the ear-like projections in certain forms give it the name auricularia. Before the larva is fully grown, the body of the young holothurian begins to bud out from near the side of the larval stomach, the calcareous cross-like plates are deposited, and the tentacles begin to grow out. Finally after the larval body is absorbed the young holothurian sinks to the bottom. The degree of metamorphosis is less marked than in other echinoderms, while in two forms development is direct, the young growing in a marsupium or brood-pouch. A form (*Cladodactyla crocea*) living in the south seas at the Falkland Islands, carries its young in a sort of nursery where they are densely packed in two continuous fringes adhering to the dorsal tubes. Holothurians are remarkable from the fact that when captured they eject their intestine, a new one in time being regenerated. The large forms lying about on the coral reefs are known to harbor a small slender fish (*Fierasfer*) which lodges in their cloaca or in the branchial tree. Many of the species are very large, being nearly two feet in length. A common species on the Florida keys and reefs is *Holothuria floridana;* it lives in water only a few inches deep and can be picked up in large numbers; it is fully 15 inches in length, and lives on foraminifera. It has been collected, dried and a shipload exported to China, but the trepang or beche-de-mer of commerce is either of two species (*H. edulis*, and *H. tremula*) inhabiting the Pacific Ocean (see TREPANG). A California species is also dried and exported by the local Chinese.

The class of *Holothuroidea* is divided into two orders: (1) *Actinopoda* represented by *Holothuria, Cucumaria, Thyone, Psolus*, etc.: and (2) *Paractinopoda*, of which *Synapta* is an example, the common form living in sand at low water on the New England coast being *Leptosynapta girardii*. A few forms inhabit great depths. Remains of holothurians have been found fossil: certain calcareous plates attributed to them occurring in the Carboniferous, Lias, Jura, and Cretaceous strata. Minute calcareous bodies referable to *Synapta*, etc., have been detected in the Paris Eocene limestones.

Holst, hōlst, **Hermann Eduard von,** German-American historian: b. Fellin, Livonia, Russia, 19 June 1841: d. Freiburg, Germany, 20 Jan. 1904. He studied history in Dorpat and Heidelberg and in 1865 traveled through France, Italy, etc. His writings were looked upon with suspicion by the Russian authorities and his further stay in that country becoming unsafe, he removed to the United States in 1866. Here he became American correspondent of the 'Kölnische Zeitung,' and sub-editor of the 'Deutsch-amerikanischer Conversations-Lexicon.' In 1872 he was appointed extraordinary professor of history in the University of Strasburg and in 1874 ordinary professor at Freiburg-im-Breisgau. In 1876 he undertook, with means furnished by the Baden government, a journey to London for the purpose of study and in 1878–9 a similar journey to North America at the expense of the Prussian Academy of Science. In 1892 he accepted an appointment in the University of Chicago. He has published: 'Constitutional and Political History of the United States' (1873); 'The French Revolution Tested by Mirabeau's Career' (1894), etc.

Holstein, hŏl'stīn, Germany, a former duchy of Denmark, and member of the Germanic Confederation, since 1866 united to Schleswig-Holstein (q.v.), Prussia.

Holstein Cattle. See DAIRY CATTLE.

Holston, hōl'stŏn, a river which rises in the southwestern part of Virginia, flows south and southwest into Tennessee and unites with the French Broad River about five miles east of Knoxville. The Holston and the French Broad are the head-streams of the Tennessee River. The course of the Holston is through a mountainous country, noted for its beautiful scenery.

It has as tributaries many small mountain streams. Its length is about 200 miles.

Holt, Joseph, American jurist: b. Breckinridge County, Ky., 6 Jan. 1807; d. Washington, D. C., 1 Aug. 1894. He began legal practice at Elizabethtown in 1828, and in 1857 was appointed commissioner of patents. In 1859 he became postmaster-general and in 1860 secretary of war. He was made by Lincoln a judge-advocate general of the army, with colonel's rank, was promoted brigadier, brevetted major-general for distinguished service in the bureau of military justice, and was retired in 1875. With the exception of Cass, he was the only member of Buchanan's cabinet that was not a Confederate sympathizer. Among the courts over which he presided were those before which Fitz-John Porter and Lincoln's assassins were tried.

Hol'ton, Kan., city, county-seat of Jackson County; on the Missouri P., the Chicago, R. I. & P., and the Union P. R.R.'s; about 28 miles north of Topeka and 30 miles west of Atchison. It was settled in 1859 and received its charter in 1870. It is situated in a section noted for good farms. The chief manufactures are flour, wagons, cigars, creamery products, and planed lumber. Its trade is chiefly in wheat, corn, hay, live-stock, and local manufactured products. The government is vested in a mayor, who holds office two years, and a common council. Pop. (1900) 3,082.

Hölty, Ludwig Heinrich Christoph, lood'vĭg hīn'rĭн krēs'tŏf hėl'tĭ, German lyric poet: b. Mariensee, near Hanover, 21 Dec. 1748; d. Hanover 1 Sept. 1776. In 1769 he went to Göttingen to study theology. Here, falling in with Bürger, Voss, the Stolbergs, and other poets of kindred tastes, he became one of the founders of the Göttingen "Hainbund." This league of young enthusiasts was aflame for Klopstock, then considered the greatest German poet for patriotism and for friendship, detested Wieland's sensual poems and his Frenchified manner, read the classics together, and wrote poetry in friendly emulation. Hölty's poems reveal a lovable personality. The strain of sentimentality that runs through all his work is not affectation, as it was with so many of the younger poets of that age in which Rousseau had made sentimentality fashionable, but the true expression of his nature. His range was small; but within its limits his work was excellent, and many of his songs have become the common property of the people. Consult: Voigts, 'Hölty, ein Roman' (1844); Reute, 'Hölty, Sein Leben und Dichten' (1883).

Holub, ho'loob, **Emil,** Austrian explorer: b. Holics, Bohemia, 7 Oct. 1847; d. Vienna 21 Feb. 1902. At 25 he went to South Africa, where he practised in Kimberley and elsewhere as a physician. Later he became engaged in African exploration and in recognition of his services as an explorer received from the Austrian emperor the Order of the Iron Crown. He published 'Beiträge zur Ornithologie Südafrikas'; 'Sieben Jahre in Südafrika' (1881); 'The Colonization of Africa'; and 'From Cape Town to the Maskukulumbe.'

Holy Alliance, an international league proposed by Alexander I., emperor of Russia, 26 Sept. 1815, after the defeat of Napoleon at Waterloo had cleared the way for the execution of his desire of establishing a settled peace in Europe. Alexander, Francis of Austria, and Frederick William III. of Prussia, signed with their own hands, and without the countersign of a minister, the act establishing this alliance, which is said to have been sent to the two latter in the handwriting of the first. It was not wholly published till 2 Feb. 1816, when the text was given in full in the Frankfort *Journal*. It consisted of a declaration, that, in accordance with the precepts of the gospel of Jesus Christ, the principles of justice, charity, and peace should be the basis of their internal administration, and of their international relations, and that the happiness and religious welfare of their subjects should be their great object. Its real aim, however, was to maintain the power and influence of the existing dynasties. It was also stipulated that the three sovereigns should invite others to become members of the Holy Alliance. In Russia and Germany its principles were not discussed except in a spirit of eulogy, but they were uncompromisingly condemned in Britain by many of her foremost statesmen. On 4 Feb. 1823 both Lansdowne and Brougham openly condemned its doctrines in their places in Parliament. Sir James Mackintosh said of the doctrine of legitimacy, in the sense in which it was used by the Holy Alliance, "Sophistry lent her colors to the most extravagant pretensions of tyranny." The events of 1848 broke up the Holy Alliance. It had previously lost much of its authority from the death of Alexander, and the French revolution of 1830. By a special article of the treaty the members of the Bonaparte family were declared incapable of occupying any European throne.

Holy Cross, College of the, an institution in charge of the Fathers of the Society of Jesus, situated at Worcester, Mass. The school was founded in 1843. It has a preparatory department; and the college grants the usual degrees given by classical and scientific institutions. It is self-supporting; up to 1903 it had received no State aid nor any endowments. It has established six fellowships. In 1903 there were connected with the school 28 professors and instructors, and nearly 400 students. The library contained about 25,000 volumes.

Holy Cross, Mount of the, a peak of the Rocky Mountains, in Eagle County, in the State of Colorado. The peak is about 75 miles southwest of Denver, and 20 miles north by west of Leadville. It is 14,006 feet high.

Holy Day, a day set apart in the Catholic Church for the commemoration of some saint or mystery. It is called "of obligation" when attendance at Mass and abstention from servile works are prescribed.

Holy Ghost, or **Holy Spirit,** the third person in the Holy Trinity. The Roman Catholic Church declares the Son to be begotten by the Father, and the Holy Ghost to have proceeded from both. The Orthodox Greek Church maintains that the Holy Ghost proceeds from the Father only; and this is one of the main points of doctrine on which Roman and Greek Catholics differ. The history of the controversy is shortly this: Tertullian and Origen, two distinguished Fathers of the Church in the 3d century, maintained that the Holy Ghost was begotten by the Father through the Son.

Macedonius, bishop of Constantinople in the middle of the 4th century, denied that the Holy Ghost was equal in essence and dignity to God the Father. The Council of Alexandria in 362 declared this bishop and his adherents, the Pneumatomachists, teachers of heresy; and the general council at Constantinople in 381 declared expressly to the whole Christian Church, that the Holy Ghost was the third person of the Trinity, proceeding from the Father, and to be worshipped equally with the Father and the Son. Augustine taught that the Holy Ghost proceeds from the Father and the Son; and the Council of Toledo, in 589, condemned all who believed otherwise. This new formulation of the dogma occasioned a controversy which lasted from the 8th to the 11th century, between the Western or Latin, and the Eastern or Greek Churches, and finally led to their complete separation. The Anglican Church and the Protestant Episcopal Church in the United States use the Greek form of the Nicene Creed. The worship of the Holy Ghost as the third person in the Godhead is common to both Roman and Greek churches, and to the Protestant Trinitarians, being essential to the faith in the divine Trinity. See CREED; TRINITY.

Holy Ghost Flower, or Holy Spirit Plant. See DOVE PLANT.

Holy Ghost, Order of, a former order of Hospitalers, founded by Guy, son of William, Count of Montpellier, in the 12th century, for the relief of the poor, the infirm and foundlings. In the 18th century it was united with the order of St. Lazarus by Clement XIII. Also the name of the principal military order in France instituted in 1578, abolished in 1789, revived at the Restoration, and finally abolished in 1830.

Holy Land, a name given by Mohammedans to Arabia because it was the birthplace of Mohammed; also by Buddhists to India because it was the country of Sakya Muni. It is a common name of Palestine, because the place where Christ lived when upon earth. See PALESTINE.

Holy Orders, the several ranks of the ministry of a church; also the power or authority to exercise that ministry.

In the Roman Catholic Church Holy Orders is one of the sacraments and there are seven orders of the ministry, viz.: priesthood, deaconate, and sub-deaconate: these are the greater or sacred orders; and the four minor orders of lector, acolyte, exorcist, and doorkeeper. Usually the episcopate is classed, not as a separate order, but as the completion and extension of the priesthood. Though every candidate for the priesthood is inducted into the four minor orders and the sub-deaconate and deaconate before he receives priestly ordination, it happens very seldom that a man enters any of those inferior orders intending to remain therein: they are simply steps to the priesthood.

In the Oriental churches, both those in communion with the Roman See — as the Greek Uniate, the Maronite, the United Armenian, etc., and those which are separated from Rome by schism or by heresy, the number of orders is less than in the Latin Church: in all the foregoing churches only four orders, or, counting the episcopate as a distinct order, five orders are recognized; those of bishop, priest, deacon, and lector: and of these the first three, at least, are held to be of divine institution and sacramental.

By the Anglican Church and the Protestant Episcopal Church of the United States three orders are recognized; those of bishops, priests and deacons: but in the 25th of the Articles of Religion those orders are expressly declared to be no sacrament.

The orders of the Oriental churches are generally recognized as valid by the Church of Rome; and when a priest of any of those churches is received into the Roman Catholic Church he is still regarded as a priest: but an Anglican or a Protestant Episcopal minister enters the Latin Church as a simple layman even though he were in Anglicanism a bishop; for Anglican orders have ever been held by Rome to be invalid.

Other Protestan churches, whether episcopal (as the Lutheran) or presbyterial or congregational, do not regard holy orders (or clerical order) as of divine institution or as setting up any essential difference between minister and layman. See CLERGY.

Holy Roman or German-Roman Empire, a title conferred on the German empire in 962 by Pope John XII, at the coronation in Rome of Otho I., who considered himself the lineal representative of the rulers of the ancient Roman Empire which practically had ceased to exist in 476. The designation ended in 1804 with the accession of Francis II. as hereditary emperor of Austria. See HAPSBURG.

Holy Water, in the Greek and Roman Catholic Churches, water which has been consecrated by prayers, exorcism, and other ceremonies to sprinkle the faithful and things used for the church. Some antiquaries think that the use of holy or lustral water was borrowed from the Jews. The Roman Catholic Church considers holy water not only symbolical of the purity of the soul, but in certain cases as effectual in exorcism. At the entrance of all churches is kept a font of holy water, in which those going in and out dip the fingers and bless themselves. The consecration of holy water takes place on Holy Saturday before Easter Sunday.

Holy Week, or Passion Week, is that which immediately precedes Easter. The name Passion Week rather refers to the days following and exclusive of Palm Sunday, since this day, strictly speaking, does not commemorate any incident of Christ's passion, but his triumphant entry into Jerusalem. The three chief days of the week are Maundy Thursday (or Holy Thursday), Good Friday, and Holy Saturday, the most sacred of all being Good Friday. The observance of Holy Week is of very early origin, and it was known as Great Week, Silent Week, Penitential Week, etc. In the ancient Church of Rome, when any of the ordinary Church festivals falls on this week, it is not observed till after Easter. In Rome it used to be observed with much greater solemnity and penitential rigor than now; for the shops are kept open, concerts and other amusements are given, though the theatres are closed. The washing of the feet of poor men is still practised in Roman Catholic churches; and the pope washes the feet of 13 poor persons, all of whom are priests. In Austria the emperor keeps up the old rite of feet-washing with much ceremony.

Holyoake, hōl'ĭ-ōk, **George Jacob**, English political reformer: b. Birmingham 13 April 1817; d. Brighton 22 Jan. 1906. He early became connected with various advance movements in Birmingham. In 1841 he was one of the lecturers chosen to explain Robert Owen's social theories, and next year was imprisoned on a charge of atheism. He supported the Chartist demands, but did not sympathize with their hostility to the Whigs. He took an important part in the agitation for the repeal of the corn laws, and for the repeal of the so-called «taxes upon knowledge.» He was the founder of a purely ethical religion, without theistic element (secularism); and was active as a lecturer and writer in the co-operative movement. His works include: 'The Logic of Death'; 'The Logic of Life'; 'The Trial of Theism'; 'Nature and the Origin of Secularism'; 'Thirty-three Years of Co-operation' (1872); 'History of Co-operation in England, Its Literature and Its Advocates' (1875); 'Among the Americans' (1881); 'Self Help One Hundred Years Ago' (1888); 'The Co-operative Movement of To-day' (1891), a short, useful account of the history of co-operation; 'Sixty Years of an Agitator's Life' (1892), an autobiography; and 'Jubilee History of the Leeds Co-operative Society' (1897).

Holyoke, hōl'yōk, Mass., city in Hampden County; on the Connecticut River, and the New York, N. H. & H. and the Boston & M. R.R.'s; about 75 miles southwest of Boston and 8 miles north of Springfield. Holyoke was settled in the last part of the 17th century by people from Ireland, and for some time it was called Ireland Parish. It was incorporated as a part of West Springfield in 1786; but in 1850 it became a distinct town, with its own government, and it was chartered as a city in 1873. Like the other settlements along the shore of the Connecticut, the inhabitants saw the advantages to be derived from the water-power. At first only the small streams flowing into the Connecticut were dammed, and used for turning machinery; the main stream itself was the great route whereby trade intercourse was established with settlements along its shores. In 1847 the Hadley Falls Company began to devise ways and means of using the water-power of the Connecticut River, which at Holyoke had a fall of about 60 feet. In a few years the dam, 1,000 feet in length, was placed across the river, and the water-power thus obtained gave Holyoke great opportunities for the establishment of manufacturing industries, and they have been well utilized. For some years it was noted for the number and magnitude of its paper-mills; but other industries now enrich the city. Its chief manufactures are paper, paper-products, thread, cotton and woolen goods, knit goods, alpaca, silk, automobiles, machinery, bicycles, wire, belting, screws, bricks, furniture, and school supplies. Some of the public institutions are the College of Music, public library, House of Providence hospital, city hospital, two orphanages located outside the city limits, St. Vincent's for girls and Holy Family for boys. A large percentage of the people are of foreign birth or foreign descent. The school census of 1902 shows the following: Public schools, 3,500 Irish, 3,200 French, 800 German, and 900 American. In the parish schools there were enrolled that same year 3,500 pupils. The law which declares: "No minor who cannot read and write the English language can be employed in any factory or commercial enterprise" is rigidly enforced. Evening schools are provided for those who cannot attend school in the day time. The Holyoke Scientific Society has done special and excellent work in American archæology. It owns a valuable collection of Indian relics. Some of the places of interest near the city, and which may be reached by the electric railway, are Mount Holyoke (q.v.), Mount Tom (q.v.), and Springfield. In 1896 the city charter was revised, and the government is now vested in a mayor, who is elected annually, and a city council. Pop. (1890) 35,637; (1900) 45,712.

Holyoke College, Mount. See MOUNT HOLYOKE COLLEGE.

Holyoke, Mount, a narrow ridge of greenstone, the highest point of which is about 1,120 feet above the sea. It is in Hampshire County, Mass., about one mile east of the Connecticut River, five miles southeast of Northampton, and eight miles northeast of Holyoke. On the summit is a hotel, built in 1821. The hotel can be reached by a carriage road which winds to the top, or by a railway which runs up a steep incline.

Holyrood, hō'lĭ-rood, **Palace and Abbey of**, Scotland, the ancient royal residence at Edinburgh (q.v.).

Homatropin, hō-măt'rō-pĭn. See ATROPINE.

Home, Henry, LORD KAMES, Scottish lawyer and author: b. Kames, Berwickshire, 1696; d. Edinburgh 27 Dec. 1782. He studied law at Edinburgh, and, called to the bar in 1724, soon acquired reputation by a number of publications on the civil and Scottish law. In 1752 he became a judge of session, and assumed the title of Lord Kames. In addition to legal works he published 'Essays on British Antiquities'; 'Essays on the Principles of Morality and Natural Religion,' in which he advocates the doctrine of philosophical necessity; 'Introduction to the Art of Thinking'; and his best-known work, 'Elements of Criticism,' in which, discarding all arbitrary rules of literary composition, he endeavors to establish a new theory on the principles of human nature. In 1776 he published the 'Gentleman Farmer'; and in 1781 'Loose Thoughts on Education.'

Home Education. From the earliest recorded school the conception of education has steadily broadened, till now careful thinkers recognize that education should be for adults as well as for the young, carried on at home as well as in school and through life instead of for a limited course. The agencies for this broader education are in five distinct groups, and workers in this special field after mature deliberation have given to it the name «Home education» because it differs from school education in being carried on at home while the students are engaged in their regular callings, instead of in schools as a chief occupation. The five groups of schools (elementary schools, high schools and academies, colleges, professional and technical schools, universities) might be called the five majors of education, while libraries, museums, study clubs, extension teaching, tests and credentials might be called the five minors.

1. *Libraries.*— This includes reference and lending libraries, magazine and news rooms and all reading of the conventional symbols called print. Reading courses, circles, clubs, and home study from books without instructors belong to this library group, which is the cornerstone of all home education. See LIBRARIES; TRAVELING LIBRARIES.

2. *Museums.*— This includes museums and laboratories of science, art, history, etc. As the library group includes education through the eye by means of conventional symbols, so in its broadest sense the museum group represents education also through the eye from reading the interesting and beautiful language of nature and art; and as reading may often have no direct connection with the public library, so also the museum group may include detached monuments, statues, busts, pictures, and other works of art. See MUSEUMS.

3. *Extension Teaching.*—This includes all agencies which extend personal help or teaching to those who cannot attend regular schools: for example, summer, vacation, Saturday, night schools or classes, extension lectures, correspondence teaching, home study under direction, classes in libraries, Y. M. C. A. or Y. W. C. A. and other organizations. Mere lectures or addresses not accompanied by class or paper work, or instruction in the more limited sense, should be sharply distinguished from extension teaching. They represent the platform and perhaps should be counted as an independent group. Some so-called extension teaching is really little more than lectures, while under the name lecture some excellent instruction is given. The group should perhaps be called "extension teaching and lectures," to keep prominent the difference between the two, while it recognizes as their common distinguishing quality the personal aid and inspiration given by the teacher or lecturer to his class or audience. Lecturers give the inspiration and magnetism of personal contact which cannot be transmitted in print. This personal element, however, is chiefly on the side of the lecturer: the audience is a mass. In extension teaching where the lecturers are to stimulate to personal study and are supplemented by class and written work, the personal element is reciprocal; for the teacher, dealing with each student as an individual, answers his questions, solves his difficulties and is his personal teacher, guide and friend. The lecture is chiefly for inspiration; the teaching, for instruction.

The chief factors in extension teaching are:

Summer Schools.—In the last decade skepticism as to the practical value of summer schools has given way to official recognition by the leading American universities of the demand for such instruction and of the duty to supply it of institutions with buildings, libraries, laboratories, reputation and faculty. Fortunately, many weak institutions, some of them started or maintained from commercial motives and others lacking funds for proper work, have been discontinued as one by one the strongest institutions have offered the needed instruction and thrown open to the public during the summer months their great facilities. See SUMMER SCHOOLS.

Correspondence Teaching.— Commercial experiments have proved that there is a large demand for instruction in many subjects, especially those which add most directly to wage-earning capacity, from those wholly unable to leave their positions to attend any of the established schools. The growth of this demand is evidenced by the great number of advertisements of such instruction and by the marked success of some of the more prominent schools. One of these schools in 1903 had 650,000 students and 114 professors, and upward of 2,000,000 persons were taking correspondence courses in this country. The method having been proved efficient is beginning to be adopted by the endowed institutions; and inevitably as they offer better instruction at less cost and with it their established reputation, correspondence teaching with full recognition of its limitations but also of its possibilities, will become an established and creditable educational factor.

Extension Courses.— In America for the few years near the end of the 19th century hundreds of university extension centres were established, most of them with insufficient knowledge of what a real extension course was and with inadequate facilities and teachers inexperienced in this peculiar but important work. The result predicted naturally followed and most of the organizations which sprung into existence died out. The University of Chicago won first place by the excellence of the work it offered and still carries on. The American Society for the Extension of University Teaching in Philadelphia has been most active and successful of all the voluntary organizations. The New York State extension work was from the first announced to be wholly subsidiary to the more important function of the public library and study clubs. Experience has proved the great merit of the extension method in the hands of skilful teachers with a gift for this difficult kind of teaching, where inspiration is more important than instruction. See UNIVERSITY EXTENSION.

Lectures.—In most cases lecturers have been desultory and have been intellectual entertainments rather than entitled to rank as educational factors. Students of home education, however, recognize the inspirational lecture as a strong lever in their work and are using it more carefully and effectively, and organizing into courses which give better results. The Brooklyn Institute has maintained for many years a remarkable system, giving each year hundreds of lectures from recognized authorities, and in connection with its library and museum affords the best existing example of a great metropolitan home education centre. In New York the free lectures for the people have grown steadily from year to year and exert a great influence for good on the hundreds of thousands who hear them annually. Progressive librarians are more and more feeling the responsibility of guiding the local demand so that the lectures shall become a still more efficient ally of the library in its broad work of giving information, inspiration and intellectual recreation. See also ADULT EDUCATION.

4. *Associations or Clubs.* — This includes all forms of mutual help through associated effort, from the club of two friends in a single house to the great summer schools like Chautauqua, where each July and August thousands gather

from all parts of the country. This work with one's fellows supplies something of the element of residence, which is as valuable a part of the usual college course as are the studies. A certain subtle mental chemistry of the greatest practical value results from contact with other minds pursuing the same studies. If this gives a few weeks actual residence away from home, with daily student life, and a course in such company and surroundings as our best summer schools now offer, the student gets an invaluable taste of real college residence. This mutual help element in home education is chiefly supplied by the numerous literary and study clubs, many of which are coming to give their annual programs, a definite educational value by limiting them to a single worthy subject and supplying members with books, pictures and, if needed, specimens or other aids.

5. *Tests and Credentials.*— The great problem in popularizing education is to secure continuous and systematic study from those lacking the stimulus of the schools. Experience shows that a goal is needed by most people to hold them to completion of what they begin, by giving tests and official recognition, with suitable credentials for work well done. Differing from the other groups their field is to stimulate, test, record, and certify, rather than to give instruction. In spite of the criticisms and abuses of examinations, no satisfactory substitute for the good they accomplish when properly used has yet been found. They are last and least of the minors, but necessary to a complete system.

Educational Factors.— Most well equipped schools have all the factors of home education in active operation, but it is the use of these factors by those who cannot attend schools that constitutes home education. Schools imply residence and are attended consecutively, students advancing stage by stage from kindergarten to university. In home education the student will often use all five minors at once, and in well organized extension courses with lectures, syllabus, class, paper work, directed reading, student club and final examination we have four of the five minors, and in many subjects the museum or laboratory element is also added. A town that aims to provide educational facilities for both old and young at home, through life must make all five groups available. For most places the ideal would be to combine in a single building suitably arranged, the public library, museum, extension, examination, and association or club rooms, thus massing in a single institution, for which the best name is institute, all the essential educational agencies outside regular schools.

While there should be constant co-operation and the utmost harmony between the agencies for home and school education, experience constantly proves that the best results cannot be obtained by putting home education work in charge of school authorities. The obvious reason is that school trustees naturally and properly feel that the school system is the vital part, while libraries, museums, clubs, and extension teaching are only incidentals. The best results are always reached with independent trustees, who regard home education as quite as important as school education, and who devote all their energies to promoting their own work. While two governing boards are thus a necessity, a larger number is more costly and less efficient in administration, so that most close students of this problem advise in all ordinary circumstances the massing of the five minors together under a single board with headquarters in a single building. While in theory the library is one of the five home education factors, in fact the rapidly growing practice is wisely making home education a part of the library. This is because the country is being rapidly dotted with library buildings supported by taxation and endowments and receiving private gifts and public appropriations and support to a degree never equaled in educational history. The public library is already one of the most popular of American institutions and is rapidly gaining ground in all civilized countries. With buildings, endowments, trustees and public sympathy and support, it is the most economical, natural and best centre for the other elements of home education. In New York the official title now used is "New York State Library and Home Education," but it is frankly stated that the words "home education" will be dropped when the public learns that library means not a mere collection of books, but the home of all this closely allied work.

At the national meeting of American librarians in 1898 the entire program was given to impressing as strongly as possible the fact that small as well as large public libraries had the privilege and duty of giving stimulus and aid not alone to readers of books, but to all citizens, young or old, who were seeking intellectual advancement. Libraries are rapidly introducing the museum element in collecting and lending pictures as they do books. Many have started collections in art, science, or history. Laboratories are sure to follow, where persons without such facilities at home may pursue investigations and supplement their reading with experimental work. Even small towns now consider a library building inadequate which does not provide rooms for literary, scientific and similar societies for mutual improvement, and lecture halls, large and small, for the various phases of extension teaching. In the last few years this development has become less a matter of discussion than the rapidity with which individual libraries may take on their new and broader functions.

MELVIL DEWEY,
Formerly Director New York State Library.

Home Rule, the domestic control of local affairs in a province, colony, or dependency of an empire. The term has been employed in recent history most especially with regard to Ireland, which has been a dependency of England ever since Pope Hadrian, as is averred, handed it over to Henry II. of England in 1155, on condition that a certain portion of its revenue should flow into the treasury of the Holy See. Since that time Ireland has been more or less subject to the government of England. English viceroys have ruled at Dublin, and English troops kept the peace. The Irish are a high-spirited and proud nation, and the history of their subjugation has been a bloody one. For many years, however, they had their own parliament, and managed their own domestic affairs. Then came what was called the Union. The Irish parliament was abolished, and Irish boroughs elected representatives to seats at Westminster. This was in 1801, when it is said that the Irish parliament which passed the bill for its own destruction was bribed or cajoled into what Irishmen of to-day consider a fatal and suicidal act. The first Irishman of note to attempt a remedy for Irish grievances was Daniel O'Connell. Catholic emancipation had been won largely through his agitation, seconded by the strong and clear-headed statesmanship of Wellington. In 1834 O'Connell brought forward in the House of Commons his motion for a repeal of the Union. By recent act of Parliament the municipal councils of Ireland had been thrown open to Roman Catholics. O'Connell was elected lord mayor of Dublin, and while his motion for appeal was supported with but 40 votes in parliament, he carried it by 45 to 15 votes in the municipal chamber at Dublin. This was undoubtedly the earliest step in the movement toward home rule, which from that time to the present moment has convulsed Ireland. In the town council at Dublin one of the 15 who had voted against O'Connell's motion for the repeal of the union was a brilliant young lawyer named Isaac Butt. In 1871 he was elected member of Parliament for Limerick and with him the Home Rule party in the English Parliament was born. The party struggled along for many years striving by obstruction and agitation in several quarters to maintain the rights of Ireland, and obtain for her better terms in her relations with the mother country. Mr. Butt, who was a true home ruler, though a conservative, was at length incensed by the obstructionist tactics of Parnell and Biggar, which he thought beneath "the dignity of Parliament," and practically surrendered the leadership of his party, in which he was succeeded by Parnell. In 1877 Parnell was elected president of the Home Rule Confederation of Great Britain. Parnell very quickly showed that he not only had very definite views, but possessed also the courage of his convictions. He became an advocate of peasant proprietorship. For the realization of this idea the Land League was constituted. At a meeting held in London 21 Oct. 1879 it was declared that the objects of the league were, first to bring about a reduction of rack-rents; second to facilitate the obtaining of the ownership of the soil by the occupiers. It was very remarkable to see how English opinion was gradually molded by the great Land League and Home Rule Party. In the elections of 1885 many Conservative candidates almost echoed the words of Parnell in declaring for a "liberal measure of home rule for Ireland." In the elections of 1885 the Liberals came in for a majority and Mr. Gladstone was premier for the third time. He was not long in bringing in a bill providing for "the constitution of an Irish parliament sitting in Dublin with the Queen as its head." He urged the passing of the bill with one of the most powerful, the most effective, and most touching speeches which he ever delivered. But his eloquence was in vain, the measure was defeated by a majority of 30. This was not the last time that Gladstone was to attempt the liberation of Ireland. But bold as had been his change of opinion in putting forth a measure he had in earlier life condemned, his conception of Home Rule for Ireland was quite inadequate compared with what O'Connell contemplated in his agitation for repeal. Such as it was, Gladstone again staked the existence of his ministry on its realization in 1893. The bill passed the House of Commons, but was rejected in the House of Lords, and since that time Home Rule for Ireland has been a dead issue in English politics.

Home Rule, Municipal. See MUNICIPAL GOVERNMENT.

Homer, hō'mėr, a poet to whom was attributed in ancient Greece the authorship of the two epic poems, the 'Iliad' and the 'Odyssey,' which form the foundation of Greek, and consequently of European literature. Of Homer's personality, birth, place, and time, we have no certain knowledge. His very existence has been brought into doubt, and in accordance with the etymology of his name Homer, which means the same as Vyasa, to whom the Mahabharata has been attributed, he is sometimes taken merely for the "arranger" or "compiler" of the works that go by his name. Seven cities, however, contended for the honor of being his birthplace; their names form the hexameter line

Symrna, Rhodos, Colophon, Salamis, Chios, Argos, Athenæ.

These names cover almost the whole geographical area of Greece and at least point to the extent of the poet's fame and influence. Although the dates of his birth and death are equally doubtful, critics have placed him anywhere in the 9th and 10th centuries before Christ, though some have thought these dates 500 years too early. He is traditionally said to have been blind, like Demodocus, the minstrel of the Odyssey. Some in ancient times attributed to him also the Batrachyomachia, and the so-called Homeric hymns, but it is at least doubtful whether these were written by the author of the 'Iliad,' as the Batrachyomachia seems a century later than the epics, and the hymns to Apollo, Demeter, Hermes, Aphrodite, and minor divinities were probably preludes or introductions which the rhapsodes or minstrels sang or chanted before beginning the serious business of the epic recitation.

The 'Iliad' and 'Odyssey' deal with the war waged by European Greece against Asiatic Troy.

The Iliad.— This 'Poem of Ilium' or Troy describes some phases of the war waged by Agamemnon and his brother Menelaus against Priam, whose son Paris had carried off Helen, the beautiful wife of Menelaus. The subject of this epic is called the wrath of Achilles, the representative Greek hero, a romantic and dazzling figure. He remains in his tent without helping in the war because Agamemnon has taken from him the captive slave girl Briseis. At length Hector, the champion of the Trojans, slays in fight Patroclus, the bosom friend of Achilles, who is roused by this from his sullen inactivity, and rushes forth to the battlefield, where he meets and slays Hector, whose funeral rites form the closing incidents of the poem.

The Odyssey.— The 'Odyssey' describes the return of Odysseus from the siege of Troy to his island kingdom, Ithaca, where he is restored to his faithful wife, Penelope, and takes vengeance on the suitors who have sought her hand and wasted her husband's substance in revelry and debauchery during his absence. The first four books describe Odysseus detained in the magic isle of Calypso, and the despatch of his son Telemachus to bring him home. The following eight are taken up with the hero's homeward voyage with his various adventures. In books 13-19, Odysseus in the attire of a beggar is found unrecognized at the door of his home; books 20-24 describe his vengeance on the suitors.

There were some critics of Greece, notably Xenon and Hellanicus, who held that the so-called Homeric epics were written by different men. This school of grammarians were called chorizontes, or separators. There is much indeed to give color to such a view. As has been said, the 'Iliad' was written for men, the 'Odyssey' for women. But what principally distinguishes the 'Odyssey' from the 'Iliad' is the fuller and more complete individualization of the Greek divinities, the higher tone of religious and social life. The knowledge of foreign lands and their products and the means of travel by sea seem also to have reached a more advanced stage.

It remained for F. A. Wolf in his famous 'Prolegomena ad Homerum' (1795) to make the keenest and most searching analysis of these epics, as regards their unity of composition and identity of origin. He relies upon the statement in Greek history that Pisistratus in 540 collected and arranged the Homeric poems in something like their present form. The epics are thus made up of separate ballads, sung by rhapsodes, probably written by different poets, and Wolf has shown much acuteness in pointing out that long epic poems could not have been transmitted from such early antiquity without handwriting, which did not then exist, and in indicating what portion of each epic originally formed individual and distinct songs or lays. Consult: Jebb, 'Introduction to Homer' (1887); Monro, 'Homeric Grammar' (1891); Ebeling, 'Lexicon Homericum' (1885); Leaf, 'The Iliad' (1888); Hayman, 'The Odyssey' (1882).

Homer, Winslow, American painter: b. Boston 24 Feb. 1836. He studied in the National Academy of Design and was also a pupil of Frederic Rondel. He was sent to the front during the Civil War as special artist to 'Harper's Weekly' and on his return to New York exhibited his first important work, 'Prisoners from the Front' (1864), which won him recognition. In 1865 he was elected Academician. Taking up his residence in Scarboro, Maine, he painted for many years a series of pictures which indicated a marked development in style, sentiment, and power. There was a trace of conventionality at least in the subjects of such pictures as 'Home, Sweet Home,' which he painted between 1864 and 1884. From the latter date he began his portrayal of the fisher population of New England. Dramatic and realistic in the highest degree is the series of seven canvases from the 'Life Line' (1884) to the 'Lookout' (1897). But this artist has reached his finest vein in his pure marines, of which by far the greatest is 'The Maine Coast.'

Homestead, hōm'stĕd, **Pa.,** borough, in Allegheny County, on the Monongahela River and on the Pittsburg & L. E. and the Pennsylvania R.R.'s; about seven miles south of Pittsburg. It was settled in 1871 and incorporated and chartered in 1880. The chief manufactures are foundry-products, glass, machinery, and steel products. It is noted for its large steel plants, which employ over 6,000 men. The borough owns and operates the waterworks. At one time Andrew Carnegie (q.v.) was the principal owner of the Homestead steel works. Pop. (1890) 7,911; (1900) 12,554.

There occurred in Homestead a serious strike which began 6 July 1892. Reductions in wages, change in time of signing the schedule, and refusal to recognize the Amalgamated Iron and Steel Association, or to hold any conferences with the men, had brought on a general strike to date from a certain time, and enraged the men into burning H. C. Frick, the manager, in effigy; whereupon the works were at once shut down, 1 July, two days ahead of the agreed time, and the men armed themselves and prepared to resist by violence any attempt to supply their places with non-union men. The advisory committee of the union took charge of the town with regular armed companies, and allowed no one to enter the mills without their permission. On 5 July the company announced an intention to make repairs, and appealed to the sheriff for protection; he sent a small squad, who were at once driven from town by the strikers, the latter denying that any damage was intended and offering to be sworn in as deputies themselves. The company then hired a body of 300 Pinkerton detectives, who came up the river in barges; but the strikers broke through the fence surrounding the mill, intrenched themselves behind a barricade of steel rails and billets, and whenever the Pinkerton men attempted to climb the steep bank (which they began at 4 A.M. of 6 July), shot them down. Next day they procured a 10-pounder brass cannon and bombarded the boat, splintering her wooden sides, but failing to pierce the steel plates within. They then sprayed the boats with oil from a hose, and emptied barrels of it on the river, setting it on fire to float down and fire the boats. The detectives repeatedly ran up flags of truce, which were at once shot down. At length the advisory committee sent delegates to offer a safe-conduct to the detectives, if they would leave their arms and ammunition and quit the town under guard; they were forced to submit, but when leaving under escort, the mob stoned, shot, and clubbed them shockingly, one having an eye struck out by a woman in the mob. Seven were killed first and last, and 20 to 30 wounded; and 11 strikers and spectators were killed by their return fire from the boats. The governor (Pattison) refused to use the State power to quell the riot till the 10th, insisting that the local authorities must do their utmost first, and the sheriff must summon the citizens; and the troops did not arrive till the 12th, when the town was put under martial law. A committee of Congress was appointed to investigate the case; and later, a Senate committee in the interest of the strikers was appointed to inquire into the hiring of private armed parties to maintain public order. On 21 July Mr. Frick was shot and stabbed in his office, but recovered. On the 18th a number of the strikers were arrested for murder: and retorted by indicting the Carnegie Company, the Pinkerton brothers, and five of their men, for murder. The advisory committee was also charged with treason and usurpation, in taking military possession of the town. The mills were soon supplied with new men, but the strike was not officially declared "off" till 20 Nov. 1892.

Homestead and Land Laws. Under the United States laws any citizen or person who declares intentions to become a citizen, male or female, 21 years old, or head of a family, may become the possessor of a homestead of 80 or 160 acres, by occupation and cultivation, to be taken from unreserved public lands, surveyed or unsurveyed. A fee of $5 or $10 is required to be paid for filing affidavit of settlement, citizenship, age or family status. Total fee is from $26 to $34, according to the land district. Five years' residence and cultivation are required, but only three are demanded where 5 or 10 acres of forest trees have been cultivated. Ex-Union veterans or their heirs obtain patent one year after residence. Benefits are limited to one claim, except that veterans who have made one land settlement may also take a homestead claim. Under timber-culture provisions homestead locators may secure another 160 acres, including timber area, by cultivating 40 acres of trees. A homestead is free from debt liability before patent issues. Locator may, on proof of settlement six months after occupancy, buy said land at pre-emption price.

Homestead discussion began in 1852 by the Free-Soil party demanding reservation for settlers. It was presented first in Congress by Galusha Grow, 1854. A bill was first offered in 1859, and passed the House; an act passed in 1860, granting homestead on payment of 25 cents an acre, was vetoed by President Buchanan. The present law was signed by President Lincoln, 20 May 1862. Homestead law initiated the national land policy. It marks the third step in definite change from purchase to settlement. Pre-emption policy, granting preference to occupancy over speculating purchases, was the second step. First was sale or grants *en bloc*. It began in 1801 when an act was passed granting pre-emption to Miami Valley settlers on Ohio-Symmes tract. Sixteen acts were passed before that of 1832, which fixed the price at $1.25 and $2.50, and divisions at 40, 80, 120, and 160 acres. Under Pre-emption Laws, a locator having civic rights and also able to testify that he or she does not possess 320 acres of land in the United States, or has not abandoned any to settle on public lands, can hold for cultivation and residence up to 160 acres. After a limited period a locator may on satisfactorily proving settlement, purchase and obtain patent at minimum or maximum rate, the latter, $2.50, being paid for government land within railway grant. No restriction is placed on pre-emptor's acquirement of private lands. Under timber-culture acts entry additional to pre-emption or homestead may be made of legal subdivision, one fourth of which must be devoted for eight years to timber culture. On proof, a patent will issue for tracts; the total fee is $18.

Timber acts are in the nature of a land bounty for forest culture in sub-humid areas. Desert land acts are designed to encourage reclamation by irrigation of arid lands. Entry is of 640 acres permitted on "dry lands" within California, Nevada, Oregon, Arizona, New Mexico, North and South Dakota, Wyoming, Utah, Idaho, Montana, and Washington. Three years are allowed to bring water thereon. On proof of this, same may be purchased at 25 cents an acre. Under present laws mineral lands are held for industrial development, miners' customs being recognized by Congress and upheld by the federal judiciary. Locators form district, lode, or placer, adopt regulations, and elect recorder. Quartz or lode claims permitted of 1,500 lineal by 600 lateral feet, 300 on each side of lode. Boundaries must be marked plainly, entry recorded, and work to the value of $100 or more be performed each 12 months in order to hold claim. Qualifications as to persons or associations are the same as in other land entries. No alien is permitted to hold, occupy, work, or possess public lands. Placer claims of 20 acres to the individual, or not over 160 to associations, are similarly permitted. Patents issue on proving up and payment of fees.

The mineral land policy of the United States fluctuated till the act of 1866 was passed. Lands were sold or leased at different periods, and the procedure was wasteful both to miners and people. Mill sites and right of way for ditches are provided for. Coal lands are pre-emptible on civic and occupancy requirements by payment of from $10 to $20 per acre. First priced land is not within 15 miles of a railway; the other is within such distance. The individual limit is 160 acres; association 320 acres. An association on proof of $5,000 expenditure may enter one section. Only one entry is permitted. Saline lands being exempt from settlement, are offered for sale at $1.25 an acre, and then become subject to private entry. Public land for town site purposes is arranged for (1) by Interior Department setting aside suitable area and selling lots of definite size; (2) by town associations, filing plats of 640 acres or less therein. Town associations failing to file plats, lots may be sold publicly after 12 months at increase of 50 per cent. on minimum price. The actual occupant of a town lot may prove up and preempt by time of sale, paying minimum price for same. Stone and timber lands designated as unfit for cultivation, within California, Oregon, Nevada, and Washington, may be purchased by persons having required civic qualifications as follows: Affidavit and proof of non-mineral character and non-speculative purpose required, and they must be sworn to as for personal use and benefit. Notice of application to be published for 60 days in land-office and nearest newspaper. Penalties are provided for perjury or for trespass on timber lands.

The domain is also subject to various land-grant and bounty laws. These include State grants for internal improvements, institutions, common schools, seminaries, and agricultural colleges; land bounties, naval and military; canal, wagon, and railway grants; military and Indian reservations. Under graduation act, land unentered privately can be sold at public sale at minimum figures. The public domain area was acquired by cessions from original States, 259,171,787 acres; by purchase from Spain, France, Mexico, Texas, and Russia 1,580,900,-800 acres; total, 1,840,072,587 acres.

Public lands are surveyed into "hundreds," 10 miles square: then into "sections," of 1 mile square, again subdivided into quarters, and down to eighths. This is known as the rectangular system. A general land-office, forming a bureau of the Interior Department, is in charge of land administration. Each State and Territory has a surveyor-general, and each congressional district a land-office. In the Territories these are provided as required. A large portion of the domain acquired from Mexico still remains subject to private grants. The land laws of Hawaii were drawn up to protect small holders. See PUBLIC DOMAIN. GORHAM D. GILMAN,

Ex-U. S. Consul to Hawaii.

Homicide, hŏm'ĭ-sīd, is either justifiable, excusable, or felonious. Of the first sort are such cases as arise from unavoidable necessity or accident, without any imputation of blame or negligence in the party killing. So where a crime is punishable capitally according to the laws, the judge is bound to condemn the criminal to death, and the sheriff or other executive officer to carry the sentence into effect in the manner prescribed by the sentence of condemnation. But the judge must have jurisdiction of the offense, and be duly commissioned; and the executive officer must be empowered to carry the sentence into effect, and must perform the execution in the manner prescribed by law, otherwise the execution of the criminal will make the judge or the officer, as the case may be, guilty of criminal homicide. So, too, where an officer of justice is resisted in the execution of his office, in his attempt to arrest a person in a criminal, or, as is maintained, even in a civil case, he is not obliged to give back, but may repel force with force; and if the person resisting is unavoidably killed, the homicide is justifiable, for few men would quietly submit to arrest if, in case of resistance, the officer was obliged to give back. It is, however, laid down as law that if a felony be committed, and the felon attempts to flee from justice, it is the duty of every private citizen to use his best endeavors to prevent an escape, and if in the fresh pursuit the party be killed where he cannot be taken alive, it will be deemed a justifiable homicide. The same rule applies to cases of an attempt on the part of a felon to break away and escape after he has been arrested, and is on the way to jail. So if a party has been indicted for felony, and will not permit himself to be arrested, the officer having a warrant for his arrest may lawfully kill him if he cannot be taken alive. But this is to be understood only of officers, and not of private persons. Magistrates and officers authorized to suppress and disperse mobs are justified by the common law in taking the requisite measures and using the requisite force for this purpose, though it extend to the killing of some of the rioters. The law arms every private citizen in the community with the power of life and death for the prevention of atrocious felonies accompanied with violence and personal danger to others, as in case of an attempt to murder or rob, or commit burglary or arson, the person making the attempt may, by the common law, if he cannot be otherwise prevented, be killed on the spot, and the law will not recognize the act as a crime. In cases of this sort, in order to justify the homicide, it must appear that there were good grounds for a suspicion that the person killed had a felonious intent. A woman is justifiable in killing one who attempts to ravish her, and the husband or father may be justified in killing a man who attempts a rape on his wife or daughter.

The cases already mentioned of justifiable homicide are those in which the public authority and laws are directly concerned. The laws of society, however, leave every individual a portion of that right of personal defense with which he is invested by those of nature. If one may interpose to prevent an atrocious crime against society, where he is not himself in any personal danger, the laws will, *a fortiori*, permit him to defend himself against attacks upon his own person. Murder is the killing of a person who is under the protection of the laws, with malice prepense, either express or implied. Malice is the distinguishing characteristic of murder, and may be either aforethought, or expressed, or implied. It is not necessary in order to constitute the crime of murder that the slayer should have the direct intention of killing. If the act be done with a wicked, depraved, malignant spirit, a heart regardless of social duty, and deliberately bent upon mischief, it is characterized by what the law denominates malice, though it may not result from any enmity or grudge against the particular victim. So if a man wantonly discharges a gun among a multitude of people, whereby any one is killed, the act will be done with that depravity of disposition which the law considers malice. Murder can be committed only by a free agent, for the crime presupposes a will, motive, or disposition on the part of the perpetrator. An idiot or insane person cannot commit this crime. But drunkenness is in general no excuse for homicide, though the act be done under its immediate influence.

The manner of killing is not material. Whether it be by sword, poison, beating, imprisonment, starvation, or exposure to the inclemency of the atmosphere, it will be equally murder. This crime may be committed by mere advice and encouragement. An infant unborn is within the protection of the law, and it is laid down that if, in consequence of poison given or wounds inflicted before the birth of a child which is afterward born alive, it dies soon after its birth, the act is murder. The act of suicide is considered by the law to be murder, and the person making away with himself is accordingly styled a "self-felon."

The lines of distinction between felonious and excusable or justifiable homicide, and between manslaughter and murder, are in many cases difficult to define with precision. But in general the accused has the advantage of any uncertainty or obscurity that may hang over his case, since the presumptions of law are usually in his favor. The characteristic distinction laid down in the books between murder and manslaughter is the absence of malice in the latter. Sudden provocation may be an excuse for striking another without the intention to give a deadly blow; and though death ensue, the party may not be guilty of murder. One circumstance, showing the degree of malice, or rather showing its presence or absence, is the kind of weapon used in giving a wound on a sudden provocation; and another circumstance of importance is the fact of the weapon's being already in the hand or not, for going to seek a weapon gives time for deliberation. The ground of excuse of homicide, in case of provocation merely, is the supposed sudden passion, some influence of which the law concedes to the frailty of human nature. But the excuse of self-defense goes still further; and where a man is attacked, so that his own life is endangered, or in such way that he may reasonably suppose it to be so, he may repel the attack with mortal weapons. One of the most frequent cases of manslaughter was that occasioned by single combat, and on account of the firm hold which the point of honor had taken of European nations, was long among the most difficult subjects of legislation. (See DUEL.) The crime of murder in its most aggravated degree is punished with death in most parts of the civilized world.

Hom'ily (Greek, *homilia*, intercourse), as an ecclesiastical term, a discourse addressed to an audience on some subject of religion. The homily was so called to distinguish it from the speeches of profane orators. The ancient homily was sometimes simply a conversation, the prelate talking to the people and interrogating them, and they in turn talking to and interrogating him. The difference between the homily and the sermon was the entire absence of oratorical display from the former, and the elucidation of the Scriptural text in natural order, without throwing the exposition into the form of an essay.

The earliest existing examples of the homily proper are those of Origen in the 3d century. In the schools of Alexandria and Antioch this form of discourse was sedulously cultivated, and Clement of Alexandria, Dionysius, and Gregory Thaumaturgus are among the names most eminent in this department. Augustine and Gregory the Great were among the western composers of homilies. Later still Bede, several of the popes, and foreign ecclesiastics still adhered to the homiletic form of exposition as the most suitable to impress the truths of Scripture with efficacy on the popular mind.

In the Church of England there were two books of homilies that were long authoritative, and are still sometimes appealed to to settle disputes as to what the Anglican doctrine is in points on which they bear.

Homing-pigeon, a variety of the common pigeon in which the love of home and power of flight have been developed to make the bird useful and reliable as a bearer of messages; also a fancy variety characterized by the possession of certain definite points, but not necessarily useful as a homer. The show carrier-pigeon is a large, long-necked variety, with abnormally developed wattles about the base of the beak and round the eyes, but the true homer is of smaller size, and lacks the enormous tuberculated growth.

The training and breeding of homing-pigeons were long almost confined to Belgium, and two main types of the Belgian homer have been distinguished as the Antwerp and the Liège varieties, the former being larger but less graceful in form than the latter. American pigeon fanciers breed mainly from the Antwerp type, and the birds are commonly designated Antwerps.

The training of a homing-pigeon begins when it is about three months old. It may then be taken to a distance of about a mile from its loft in a suitable direction and liberated in order that it may fly back. After an interval of a day or two it should be carried three miles from home in the same direction and set free, and on the third occasion, a few days later still, the distance is usually increased to six miles. This mode of training is continued steadily during the season, the successive distances above those already mentioned being 12, 25, 50, 75, 96, 125, 155, and 200 miles. The intervals of rest must be carefully preserved, especially in times when the weather is unfavorable. During the bird's second season it is made to repeat something of its first year's performances and to extend its flight to 250 miles or possibly to a greater distance. During the following three seasons good birds will be at their best, and even for some few years later they may do good work. During the training period and also at other times the housing and feeding of the birds must be carefully attended to.

Velocities of over 30 yards per second have been recorded for various pigeons, but the average velocity is rather less than half that amount. One bird, in 1896, actually covered the distance from Thurso to London, just over 500 miles, within one day, its average velocity being about 24 yards per second. In unfavorable weather the height attained varies from about 320 to rather over 400 feet, but in good weather some birds will reach a height of about 1,000 feet. The distance from Algiers to Paris, fully 1,100 miles, is one of the longest on record as having been traveled by a pigeon.

There has been much discussion regarding the means by which pigeons return to their homes over such long distances. Untrained birds often fail to return, and during training young birds are often lost.

Many instances are recorded of the employment of pigeon messengers by ancient peoples. During the first half of the 19th century pigeons were widely used in Great Britain for the rapid communication of intelligence, and in particular many stockbrokers obtained early information of the state of the markets by this means. The introduction of the electric telegraph, however, soon led to the complete disuse of the pigeon post. The siege of Paris during the Franco-German war of 1870–1 first brought the carrier-pigeon into prominent notice as a valuable means of communication in time of war. During that siege more than 350 birds were sent out of the city in balloons, and of these some 300 were liberated with messages. Only some 70 returns were made, and these were effected by 57 birds. By the adoption of microphotography the space occupied by a message was so reduced that a single pigeon could carry a very large number of messages without having its movements hampered in the least. One of the pigeons that succeeded in returning to Paris carried no less than 40,000 messages on eighteen collodion films which were enclosed in a goose-quill attached to the tail. Since that time the leading Continental powers have established elaborate pigeon systems for use in time of war. During the war with Spain, in 1898, the fleet of vessels that patrolled the Atlantic coast was supplied with a number of carrier-pigeons' cotes, but happily there was no occasion for testing their effectiveness, though in times of peace messages are frequently successfully carried from war vessels to points on the shore. Consult books mentioned under PIGEONS.

Hominidæ, hō-mĭn'ĭ-dē, the family to which man was assigned in the earlier systems of animal classification; but many modern zoologists refuse him so great a distinction, making man, zoologically considered, only a species (*Homo sapiens*) of a genus of the family *Simiidæ*, which also includes the genera of the anthropoid apes. See MAN.

Homœopathy (Greek ὅμοιος, like, and παθος, suffering or disease). The term signifies similar affection, passion, suffering or disease. As employed in Medicine, and as understood by Hahnemann and physicians of the homœopathic school, it is properly defined as follows: (1) The treatment of disease by means of its similimum; (2) treatment of disease by a medicine capable of causing, in a healthy person, symptoms similar to those manifested by the patient. This definition can refer only to the symptoms producible by the drug, and the symptoms exhibited by the patient. It makes no direct reference to the name or type of the disease, nor to the type or class of the drug administered, nor to the size or strength of the dose. Nevertheless, homœopathy does hold important incidental relationship to the classification of drugs, to the facts and principles of dosage, and to diagnosis and all other departments of pathology. Under this definition, the experimental application of homœopathy requires that the drug shall cover the *tout ensemble* — or, as Hahnemann expresses it, the "totality" of the symptoms as exhibited by the patient; and not merely one, or a few, of the dominant or diagnostic symptoms or conditions. Neither does it imply that the homœopathic remedy can overcome any and all the adverse conditions and circumstances under which it may be administered.

As a system of medical practice, Homœopathy recognizes this principle of similarity as between the symptoms of the curative drug and the symptoms appearing in the patient. In this form of practice, the symptoms exhibited by the patient are carefully ascertained and studied with reference to their significance and relations, and these furnish the indications upon which the selection of the "similar remedy" is then made with equal care. Whether the object of the prescriber be immediate and complete restoration to health in a curable case, or mere alleviation of suffering in a case not curable, the same course is pursued; since, in the experience of the profession, the similimum possesses peculiar efficacy in either class of cases.

In homœopathic practice, the finding of the curative remedy is of *first* importance, as a matter of course. But, the diagnosis of the case is a most urgent consideration, because it materially aids the physician in his quest for the "totality" of the symptoms, suggests his general management of the case, prompts the sanitary precautions to be taken, guides him in his prognosis, etc. Moreover, it sometimes calls to his mind a group of medicines among which the curative similimum will probably be discovered, and in this indirect way may assist in the medical treatment. Yet is must be distinctly understood that in homœopathic prescribing, the final choice of the remedy is always made, not by the name of the disease, nor even by the symptoms usually present in the disease, but only by those occurring in the individual patient. Pathology, both structural and functional, is also a subject of careful research in connection with homœopathic practice, as under other systems; but never for the purpose of formulating "theories" of the nature of the disease, on which to base treatment.

In common with all other modern "schools" of physicians, homœopathists hold that whenever the originating or "exciting" cause of the disease can be discovered, it should be removed if possible; and they claim that when this is done the disease will often disappear spontaneously. When the disease does not so disappear after removal of the cause which had apparently produced it, homœopathic physicians are convinced that some other ("maintaining") cause has been developed. In most cases this perpetuating cause is occult and its nature altogether undiscoverable. They also hold the view that if this latter cause be removed, the continuance of the malady is inconceivable. Equally incredible is it that the disease can be actually "cured" so long as the cause remains operative; if it could be, it would be immediately reproduced; unless meantime the bodily susceptibility to the disease were also removed. Hence, the homœopathic profession does not concede a "cure" in any case in which the operative cause remains active, and therefore, in the view of these practitioners, the word "cure" has a much narrower meaning, and actual cures are accomplished much less frequently than is generally supposed; the majority of such so-called cures being merely recoveries — recoveries facilitated, or perhaps made possible, by the skilful efforts of the medical practitioner — but recoveries nevertheless.

Under this view, that the disease has a central morbific cause, it is impossible that homœopathists can accept the opinion that the malady can be cured by the mere lopping off of one or a few of its principal symptoms, or of its prominent pathological processes or conditions. How, then, do homœopathists explain their ability to reach with their remedies the perpetuating or "maintaining" cause of disease, conceding, as they do, their inability to determine its nature, or even its location?

Starting out with the accepted principle that "like causes operating under like conditions produce like effects," the homœopathist assumes the converse of the proposition to be likewise true; namely, that like results appearing under like conditions and circumstances, indicate the operation of like causes. When two patients in similar conditions of health manifest similar morbid symptoms, the phenomenon is, by all pathologists, considered as indicating the operation of causes in corresponding portions of the two organisms, and acting in a similar manner. This view is not peculiar to any medical school, but is held by all physicians alike. To this doctrine, the homœopathist adds the belief that it also applies to the effects of drugs, as well as to those of natural (?) diseases; and that when similar morbid manifestations result, in one case from disease and in the other from the effects of a drug, the phenomenon still indicates a physiological or (pathological) cause operating in a similar part or parts of the organisms involved, and operating in a similar manner in both. So much as to the *locality* of the cause — the "seat of the disease," upon which the "similar" drug acts. What of the *manner* in which it acts?

It was long ago shown by Hahnemann and others that the effects of almost any drug upon the human body are of two kinds, primary and secondary, direct action and reaction; and that these two actions are, in a measure, the opposite, one of the other. This view has been advocated by numerous physicians, not always of the homœopathic school. Of late years the phenomenon has attracted more attention from medical writers than formerly, and is generally spoken of as "the dual action of drugs." To illustrate: a drug may first stimulate, and afterward depress, a certain organ of function. Another may first depress and then stimulate; and the symptoms will, of course, take their character from the action or reaction of the drug. Some homœopathists are of opinion that this dual quality of drug action is the proper explanation of the curative potency of the similimum. Others, Hahnemann included, explain it on other grounds. Others consider it likely that the different effects of large and small doses — a fact observed by many practitioners — may account for the cures made by the similar remedy. All homœopathists agree, however, that the question turns upon the curative *fact*, and not upon its explanation; and hold that one and all of these explanations may yet prove to be erroneous; yet firmly convinced that the main fact will remain unaffected through all changes in theory and doctrine.

Homœopathy, like any other principle or art, has its own particular field of application and operation. Thus it does not cure *directly*, a mechanical injury to the tissues, or any impairment wrought by chemical means; though it does cure the functional diseases and disorders caused by the irritation of such injuries. The homœopathic remedy acts *directly* only upon function. It never alters a structure except by first modifying a function. Nor does a drug ever act homœopathically upon a function unless that function be disordered. When a drug acts on a healthy function, or when it causes disorder in a function, such action is never homœopathic, whatever may be the mode of its selection and whatever the form or quantity in which it is administered. *The homœopathic medicine is a specific-restorative-stimulant, only and always.* Such, in brief, is an exposition of homœopathic belief and practice, and of its underlying principles and doctrines as taught by Hahnemann and held by the profession as a body. The small dose used by homœopathic prescribers is considered in another part of this article.

Homœopathy as a mode of medical practice is usually said to have originated in 1796, when Dr. Christian Friedrich Samuel Hahnemann published in 'Hufeland's Journal,' at Jena, an 'Essay on a New Principle for Ascertaining the Curative Powers of Drugs.' In this essay he criticizes the state of the medical art, and especially urges that the chemical properties and powers of drugs are not adapted to the work of curing disease, but that cures must be accomplished by an entirely different property resident in medicinal substances. Having read of cures in medical literature and observed, in his own patients, recoveries occurring under the evident influence of the "similar" remedy, he offers the following theory of the phenomenon: "Every powerful medicinal substance produces in the human body a kind of peculiar disease; the more powerful the medicine, the more peculiar, marked, and violent the disease. We should imitate nature, which sometimes cures a chronic disease by superadding another, and employ, in the (especially chronic) disease we wish to cure, that medicine which is able to produce another very similar artificial disease, and the former will be cured; *similia similibus*." Hahnemann further explains his conception of a homœopathic cure in his 'Organon,' section 26, in the following language: "A weaker dynamic affection is permanently extinguished in the living organism by a stronger one, if the latter (while differing in kind) is very similar to the former in its manifestations." This language he designates the "homœopathic law of nature." The term "homœopathy" or "similar disease," as representing the new medical practice, may have been suggested not alone by the fact of cures produced by the similar drug, but also by Hahnemann's theoretical explanation of the phenomenon.

A correct and adequate conception of homœopathy, of the difficulties necessarily encountered in its propagation and establishment, and of the place it holds and the influence it exerts in the development of therapeutics can be obtained only through knowledge of the conditions of general medicine down to the close of the 18th century. It is essential, therefore, that reference be made to certain points in the progress of medical history from its beginnings to and including the period of the investigations that resulted in the discovery of homœopathy as a general therapeutic principle. This reference does not need to embrace all the departments of medical science — anatomy, physiology, pathology, etc.— but the department relating to treatment, or therapeutics only. It is requisite for us to know and appreciate the mental conception — the basis of reason — upon which the "art of healing" was established prior to the advent of homœopathy as a system of medical practice.

The earliest efforts of men to alleviate the sufferings caused by illness and mechanical injury were chiefly instinctive. Water, moist earth, the fleshy portions of plants, and other cooling substances, were employed by men, as well as by the lower animals, to mitigate the pain, heat, and discomfort of local inflammation; and other simple expedients were instinctively resorted to for various disordered conditions. In time the number and variety of known remedial agents, as well as of the diseases for which they were used, must have been rapidly extended by experience. And thus began the "empirical method" of treatment — the natural second step in the progress of medicine.

Inefficient as were these modes of treatment, they were far more rational than most of those that occupy the pages of medical history for many succeeding centuries. These later methods were based, not on observation and experience, but upon pure assumptions having, as John Stuart Mill expresses it, "no limitations other than those of the imagination." (The construction of medical theories, or philosophical explanations of observed facts, was a still later development.)

Among the large number of these hypotheses are the following: (1) That disease is a punishment sent by some malevolent deity; (2) that it is due to the influence of a comet, a planetary conjunction, an earthquake, or some other celestial or terrestrial phenomenon; (3) that it is caused by abnormal preponderance of some one of the four elements (fire, air, earth, and water) of which the human body was said to be composed; (4) that it originates in a disturbance of the bodily states of heat, coldness, moisture, and dryness; (5) that it arises from disproportion in the four humors which supply the organism — blood, mucus, black bile, and yellow bile; (6) that it is produced by a *materia peccans,* or offending matter, which must needs be expelled; (7) that the body contains multitudes of "invisible pores" through which circulate infinitesimally minute atoms or corpuscles, and that disease has its cause in obstruction or relaxation of these pores; (8) that disease is based upon three possible states of the organism — "strictum," "laxum," or "mixtum" — which must be treated with laxatives, astringents, or a combination of both, as might be needed; etc., etc. All these hypotheses, and many others, arose prior to the close of the 2d century A.D. Their absurdity is not more grotesque than that other hypothesis which underlies each and all of them; namely, that a knowledge of the cause or nature of disease can indicate the means and method of its cure; a view not held at present by any homœopathic or other scientific physician.

The period between the 2d century and the 15th presents little record of therapeutic art; but with the invention of the printing-press came a stronger impetus to all forms of research, medical included. Since that time increasing knowledge of anatomy, chemistry, and physiology has led to the elaboration of therapeutic theories based upon certain facts relating to these natural sciences. The advances in anatomy had suggested a mechanical basis for therapeutics; pneumatics, friction of fluids in vessels, the diameters, curvatures, and angles of blood-vessels were brought forward to explain the phenomena of disease and to suggest measures for its cure. Physiology and chemistry brought out a renewal of the ancient doctrine of "four elements" and the substitution of the three "alchymistic symbols" represented by mercury, salt and sulphur, whose union is health, and their separation disease. The author of this doctrine, Paracelsus, also ascribed to the "vital force" not only the power, but also the intelligence, to resist disease and to provide for its cure. About the middle of the 18th century, or near the time at which the discovery of the general principle of similars was made, physiological hypotheses became largely identified with therapeutics; and the same might be said of chemical theories. Health and disease were the results of a contention between the acids and the alkalies. Haller held to the view that disease was due to change in the "irritability" of the tissues. Cullen revived an old doctrine that disease was caused by "spasm" and "atony," and required to be treated in accordance with that view. Brown, the rival of Cullen, concluded that diseases were either "sthenic" or "asthenic," and required asthenic, or sthenic medication, as the case might be.

Before the close of the 18th century the medical profession had acquired knowledge of a number of drugs possessed of "specific" properties for the cure of particular diseased conditions; among them Peruvian bark for intermittent and other malarial fevers, mercury for syphilitic diseases, sulphur for itch, etc. These specifics exerted their curative effects by virtue of properties not at all understood at that time, and but imperfectly known a century later. These specific cures were limited to comparatively few diseases. For the treatment of the conditions with which the medical practitioner is contending daily, which constitutes almost his entire duty, he had nothing but fallacious assumptions and hypotheses to depend on. Such was the condition of the medical art at the time when Hahnemann began his independent researches in therapeutics.

Hahnemann possessed unusual linguistic attainments, which gave him access to the publications not only of Germany, but of England, France, Spain, Italy, Austria, Greece, and Arabia. He was not only a literary scholar. He was also a practical expert in the fields of chemistry, pharmacy, and industrial technology. He made many discoveries in industrial chemistry, and introduced scores of improvements in the details of manufacturing chemical products. At the period of his earliest responsible connection with medicine, "there was," says Rapou, "complete anarchy in the domain of therapeutics." Hahnemann, unwilling to trust the lives of his patients to the tender mercies of this conglomeration of assumptions, adopted the use of the class of remedies known as specifics, whose effects were easily ascertainable, though their *modus operandi* was altogether unknown.

Homœopathy was not an invention, like some of the "systems" of medicine that preceded it; neither was it a sudden discovery. It was an evolution extending from 1790 to 1835, a period of 45 years. The earlier portion of the process is described by Bradford, who in speaking of its beginning says: "We now come to the translation of a very important book (Cullen's 'Materia Medica'), from which must be dated the discovery of the Law of Similars. It has been asked why Hahnemann at this time happened to translate this particular book, and it has been asserted that he used it as a blind to foist on the world his peculiar theories. It is not probable that when he commenced upon Cullen Hahnemann had any particular medical theories, but only a growing disgust for the medical fallacies of the day. This is clearly evidenced by his writings at that time. It is not to be wondered at that he should translate the work at that particular time. He was translating for money, for the booksellers and publishers of Leipsic, and it is not likely that he selected the books which he was to translate. Dr. Cullen was an authority on the subject of the materia medica of his day, an experienced lecturer, a talented chemist, and a brilliant and popular teacher in Edinburgh. Naturally the Germans wished to learn of his new and peculiar theories regarding disease, as well as to obtain the use of his 'Materia Medica,' which at this time was a standard work.

"Hahnemann was the most accomplished translator of medical works of the time, and what more natural than that the task should be given to him. Cullen published the first edition of this book, in London, in 1773. Another edition was issued in 1789, in two volumes, and it was this edition that Hahnemann used in his translation. In this book, Volume II., Cullen devotes about 20 pages to *Cortex Peruvianis* (Peruvian Bark), gives its therapeutical uses in the treatment of intermittent and remittent fevers, advises its use to prevent the chill, and gives minute directions for the safest period of the disease in which to use it. Hahnemann was impressed with the use of this drug, with which he as a physician had before been familiar. Something in the manner in which Cullen wrote decided Hahnemann to experiment with it upon himself and to see what effect it would have upon a person in perfect health. The result of this experiment will be given in Hahnemann's own words. In the translation of William Cullen's 'Materia Medica,' Leipsic, Schweikert, 1790, page 108 of Volume II., appears the following foot-note by Hahnemann: 'By combining the strongest bitters and the strongest astringents, one can obtain a compound which, in small doses, possesses much more of both these properties than the bark, and yet no specific for fever will ever come of such a compound. This the author (Cullen) ought to have accounted for. This perhaps will not be so easily discovered for explaining to us their action in the absence of the Cinchona principle.

" 'I took, by way of experiment, twice a day, four drachms of good *China*. My feet, finger ends, etc., at first became cold: I grew languid and drowsy; then my heart began to palpitate and my pulse grew hard and small; intolerable anxiety; trembling (but without cold rigor); prostration throughout all my limbs; then pulsation in my head, redness of my cheeks, thirst, and, in short, all those symptoms which are characteristic of intermittent fever, made their appearance, one after the other, yet without the peculiar, chilly, shivering rigor.

" 'Briefly, even those symptoms which are of regular occurrence and especially characteristic — the stupidity of mind, the kind of rigidity in all the limbs, but above all, the numb, disagreeable sensation which seems to have its seat in the periosteum, over every bone in the body — all these made their appearance. This paroxysm lasted two or three hours each time, and recurred *if I repeated this dose, not otherwise;* I discontinued it, and was in health.'

"The next note in the German translation is as follows: 'Had he (Cullen) found in bark traces of a power to excite an artificial antagonistic fever, he certainly would not have persisted so obstinately in his mode of explanation.' " ('Life and Letters of Dr. Samuel Hahnemann,' by T. L. Bradford, M.D., pp. 35–7.)

These experiments seemed to show that Peruvian bark is capable of producing in the healthy human organism a series of symptoms quite closely resembling those of that peculiar form of fever which it is known to cure. Instead, however, of solving any questions in the mind of Hahnemann, it only served to suggest several others. Does Peruvian bark then produce the same symptoms that it specifically cures? Is its specific curing property dependent on its power to cause the symptoms which it cures? If so, is this power peculiar to *Peruvian bark*, or is it to be discovered in other drugs? And do all drugs possess the power to cause symptoms similar to those they cure?

To obtain light upon these questions occupied his efforts during the six years between the translation of Cullen's 'Materia Medica' and the publication of the 'Essay' above mentioned. To quote from a writer in the British 'Homœopathic World,' 1875, p. 234: "Drug after drug, specific after specific, was tested on himself and on healthy friends with one unvarying result — each remedy of recognized specific power excited a spurious disease resembling that for which it was considered specific. But many more symptoms than those diagnostic of any one disease resulted from almost every medicine, and aroused a hope in the experimenter's mind of specifically treating a greater number of diseases than had ever been so treated before. Besides discovering many valuable phenomena undreamt of, he verified his discoveries and observations by ransacking the volumes of recorded experiments in materia medica and the whole history of poisoning." The members of his family and his personal and professional friends aided in the work of experimentation, and tests of each medicine were made with different doses, and on many different persons, all the work being conducted under his own supervision.

Dr. Bradford tells us that at the time of Hahnemann's translation of Cullen's 'Materia Medica,' that is, at the beginning of his independent investigations in 1790, he had no preconceived theories or opinions to sustain. This view of his biographer is corroborated by the absence from Hahnemann's writings of even remote reference to any *a priori* conception or suspicion of a general curative relation between drugs and diseases. Nor does it appear that he then possessed the faintest conception of the magnitude, or of the quality, of the task he was gradually assuming. His original object evidently was to ascertain why Peruvian bark cures intermittent fever, and to learn if the view held by Cullen — that its curative property resides in a combination of bitter (tonic) and astringent qualities — was indeed true. There is no historic evidence that before 1790 the general therapeutic principle of similars had even dawned upon his mind. But we may be quite sure that the logical and philosophical principles that must necessarily govern his researches had been well thought out before the work had very far advanced.

Hahnemann and his disciples claim that in the discovery of homœopathy as a general principle of organic science, and in its conception and development as a system of medicine, assumption, speculation and hypothesis have had no place; but that observation, experimentation, and inductive classification constitute the scientific and solid foundation of fact upon which it rests. They assert that all its essential doctrines are susceptible of demonstration, that they have been verified and reverified times without number, and that for the first time in the history of intellectual development the establishment of the homœopathic principle showed that the Baconian method of research is as applicable in the realm of therapeutics as in any other department of scientific investigation. If we look over the records of the processes leading to its discovery, it appears that these processes were under the guidance of the following principles of scientific philosophy, all of which are distinctly set forth by Hahnemann in his 'Organon':

1. That in the study of disease with a view to its cure, the only safe dependence is upon the manifestations (symptoms) perceptible to the senses, and that no safe conclusions can be drawn from mere theories erected upon these signs and symptoms. The signs and symptoms constitute the only side of the disease that is turned toward the physician, and the totality of these signs furnishes the only true expression or portrait of the disease.

2. That the specifically curative power of a drug resides not in its physical, nor yet in its chemical properties, but in its capacity to produce changes in the functions of the organism.

3. That the dynamic properties of a drug — in other words, its power to specifically cure disease — can be ascertained only by observing the signs and symptoms which it can produce in the organism, and that these specifically curative properties cannot be inferred from the physical or chemical properties of the drug substance.

4. That experiments for the purpose of ascertaining the pathogenetic properties (signs and symptoms) of drugs must be conducted under the precautions necessary in other researches; and the tests must be repeated and varied with a view to eliminate every influence and agency that can vitiate the experiment. The drug experimented with, and the person experimented upon, must both be "standard." That is, the drug must be pure and unmixed with any other substance capable of disguising, modifying, or otherwise affecting its own specific activity, and the person experimented upon (prover) must be possessed of good health, and free from any unhealthful occupation or habit, and from any mental, moral, or other influence or agent that can modify the pure effects of the drug upon his organism. Also, that the experimentation with the drug must be continued until its whole pathogenetic effect has been elicited.

5. That the observations made from such experiments as those here indicated constitute the only source of a pure and "standard" materia medica, and supply the only material from which general therapeutic principles can be discovered or deduced.

6. That effects observed from the action of a drug upon diseased persons (clinical effects) or those obtained from a combination of drugs (polypharmacy) are not "standard" effects and cannot serve as reliable guides in a search for therapeutic principles.

In the opening sections of the 'Organon,' Hahnemann mentions as among the physician's essential acquirements:

(1) Knowledge of diseases; (2) knowledge of the dynamic properties of drugs; (3) knowledge of the curative relations between the two. This knowledge he holds essential both to the development of therapeutic science and to enable the physician to prescribe the curative remedy.

In order to qualify the physician for his work his knowledge of disease must be composed of facts perceptible to the senses. Our physiological and pathological deductions in reference to a case of disease are more or less uncertain and theoretical. Absolute knowledge of disease is limited to its signs and symptoms, besides which there can be no certain and assured foundation for a science of therapeutics.

The knowledge of drug-properties must be equally certain and substantial. All drugs possess three classes of properties — physical, chemical, and specific or "dynamic." The physical and chemical properties can be ascertained by physical and chemical methods. The specific or dynamic properties, that is, the properties which alone impart the power to accomplish specific cures of disease, can be learned only by observing their power to cause changes in the health of the organism as shown by their capacity to produce signs and symptoms. Here again the signs and symptoms constitute the only sure basis of classification and induction in the construction of a science of therapeutics.

Having possessed himself of so much of such knowledge as was within his reach, Hahnemann then began the investigation of the great and dominating question: Given a knowledge of diseases as expressed by signs and symptoms, and a knowledge of drug properties as expressed by signs and symptoms, can we discover between them any general relation that will guide the physician in his search for the curative drug? In this work of "interrogating nature" he had already been led to infer what her reply might be. His experiment with Peruvian bark had given him a somewhat emphatic hint. Then followed the six years of experimentation upon himself, his family, and friends; with what result we have already seen. Accompanying and following these experiments came the "ransacking of the libraries"— a work for which few men were so well fitted. This literary search resulted in two important discoveries. First, that when two diseases manifesting quite similar symptoms appear in the same organism, they antagonize or annihilate each other. This subject is carefully outlined in the 'Organon,' sec. 42–45, and in sec. 46 the writer cites a score of illustrative instances obtained from the pages of contemporaneous literature, the authority being carefully mentioned in every citation.

The second result of this literary search is that it corroborates the view with which Hahenemann set out; namely, that even under the modes of treatment in vogue before his day, undoubted cures frequently resulted from the action of drugs possessed of the power to cause symptoms similar to those of the cases cured. Some of these cases are well worthy of study by those interested in medical subjects. In the earlier editions of the 'Organon' and in the 'Essay on a New Principle for Ascertaining the Curative Powers of Drugs,' these published cures are reported *in extenso*, the literary source being given, together with the name of the physician in each case. In the Dudgeon translation of the 5th German edition the same list occupies 31 pages of the appendix. In practically all of the cases reported, the mere name of the disease is sufficient to suggest the fact of similarity between the symptoms of the malady cured and the symptoms of the drug prescribed. In other cases the symptoms themselves are given with more attention to detail than was customary at that period of medical history. If we sum up the remedies named in the 'Essay,' together with those mentioned in the 'Organon,' we have a total of 63 drugs to which Hahnemann was able to ascribe homœopathic cures occurring in the practice of physicians who had no knowledge of the homœopathic principle.

In presenting this list of cases successfully treated with the similar remedy, Hahnemann has made nearly 500 citations of writers who had no suspicion that any general law of therapeutics was involved in the operation of their prescriptions. The degree of similarity shown between the pathogenetic properties of the drugs administered and the symptoms manifested by the patients seemed, in most cases, to be positive and emphatic, and in some instances striking. In what he has to say regarding the curative effects of opium this fact is graphically shown. He says:

"A condition of convulsions without consciousness, resembling the death-agony, alternating with attacks of spasmodic and jerky, sometimes also sobbing and stertorous, respiration, with icy coldness of the face and body, lividity of the feet and hands and feebleness of the pulse (precisely resembling the symptoms of opium observed by Schweikert and others), was at first treated unsuccessfully by Stütz with potash, but afterward cured in a speedy, perfect, and permanent manner by opium. According to Vicat, J. C. Grimm, and others, opium produces an extreme and almost irresistible tendency to sleep, accompanied by profuse perspiration and delirium. This is the reason why Osthoff was afraid to administer it in an epidemic fever which exhibited similar symptoms, for the system he pursued prohibited the use of it under such circumstances. It was only after having employed in vain all the known remedies and seeing that death was imminent that he resolved to try it at all hazards, and behold, it was always efficacious. J. Lind also avowed that opium removes the head troubles, and the burning sensation in the skin and the difficulty of perspiring during the pyrexia; under opium the head becomes free, the burning febrile heat disappears, the skin becomes soft, and its surface is bathed in a profuse perspiration. But Lind was not aware of the circumstance that opium produces very similar morbid symptoms in the healthy. Alston says that opium is a remedy that excites heat, notwithstanding which it certainly diminishes heat where it already exists. De la Guérène administered opium in a case of fever attended with violent headache, tension and hardness of the pulse, dryness of the skin, burning heat, and hence difficult and debilitating perspirations, constantly interrupted by the extreme restlessness of the patient. He was successful with this case because opium possesses the faculty of creating an exactly similar feverish condition in healthy persons, of which he knew nothing, though it is stated by many observers. In a fever where the patients were speechless, eyes open, limbs stiff, pulse small and intermittent, respiration labored, snoring, and stertorous, and deep somnolence (all of which are symptoms perfectly similar to those which opium excites), this was the only substance which C. L. Hoffmann saw produce any good effects. Wirthenson, Sydenham, and Marcus have in like manner cured lethargic fevers with opium. C. C. Mathai, in an obstinate case of nervous disease, where the principal symptoms were insensibility and numbness of the arms and legs, after having for a long time treated it with inappropriate remedies, at length effected a cure by opium, which, according to Stütz, Young, and others, causes similar states in an intense degree. Hufeland performed, by the use of opium, the cure of a case of lethargy of several days' duration. How is it that opium, which, as everyone knows, of all vegetable substances is the one which in its primary action (in small doses) produces the most severe and obstinate constipation, should be one of the most efficient remedies in constipation of the most dangerous character, if not by virtue of the homœopathic therapeutic law, so long unrecognized? The honest Bohn was convinced by experience that opiates were the only remedies in the colic called 'miserere': and the celebrated F. Hoffmann, in the most dangerous cases of this nature, placed his sole reliance on opium combined in the anodyne liquor called after his name. Can all the 'theories' contained in the 200,000 medical books which cumber the earth furnish us with a rational explanation of this and so many other similar facts?"

The great German physician and philosopher was careful to credit other medical men with having obtained foregleams of his great discovery. "How near," he says, "was the great truth sometimes of being apprehended!" And again: "There have been physicians here and there across whose minds this truth passed like a flash of lightning without ever giving birth to a suspicion of the homœopathic law of nature."

From Hahnemann's literary and experimental investigations alone, both he and his disciples have unhesitatingly justified their belief in a general curative relation between drugs, as represented by their symptoms, and diseases as represented by their symptoms, and their belief that this curative relation is properly set forth by the word "similarity." The proofs herein presented are considered conclusive, although similar evidence has been constantly accumulating in the writings of medical men of all schools, and in the practice of hundreds and thousands of homœopathic physicians for more than a century.

In Hahnemann's foot-note (see Dudgeon's Appendix to the 'Organon,' p. 207) it is shown that he early became aware of the "danger which is to be anticipated from large doses of homœopathic remedies." He says, however, that "it often happens, from various causes which cannot always be discovered, that even very large doses of homœopathic medicines effect a cure, without doing any particular harm." In most instances homœopathic physicians came to regard the small dose as a necessity to homœopathic practice. Thus, a full dose of belladonna, or of opium, administered to a patient already suffering with symptoms like those producible by one of these drugs, might be perilous. Experience also taught them that the curative action of the homœopathic drug could be secured as well or even better through the small dose. The results claimed for these small or minute doses naturally aroused the skepticism of physicians and laymen alike, and became a serious hindrance to the spread of the homœopathic system. The very nature of the homœopathic principle, however, carries with it the necessity for the use of the diminished dose.

Homœopathic physicians, when prescribing minute doses of their remedies, are under the necessity of employing great care in securing absolute purity and simplicity in the preparation of their medicines; and this has led to the need of a special pharmacy for homœopathic prescribers. Another corollary of the homœopathic law of cure is the "single remedy," without which no prescription can be strictly homœopathic. Still another principle follows from the application of this law: namely, that a homœopathic prescription can never be made from the *name* of the disease. The similarity must be traced between the symptoms of the drug and those of the individual patient. This fact is fortunate in that it at once brands the advertised "homœopathic" proprietary medicine as a fraud and a pretense, no matter in what form it may be put upon the market.

The spread of homœopathy in the country of its birth, and in other countries of Europe, has been slow. The delay in securing its establishment has been due partly to the cause already mentioned — an unwillingness on the part of both physicians and laymen to accredit the little dose with curative potency. But the chief obstacle to its advancement is to be sought in inimical legislation and the lack of facilities and authority to educate young men and women for homœopathic professional life, and the consequent inability to supply the public need of homœopathic physicians.

Homœopathy was introduced into the United States in 1825 by a physician named Hans B. Gram, who at that time settled in New York. In this country, with its free institutions and its asserted freedom of opinion, the new medical thought found less antagonism to overcome, although there were many obstacles to be encountered, chiefly of a social and legislative character. The physicians of America, less conservative, perhaps, than those of Europe, were more disposed to inquire into the scientific and practical aspects of homœopathy, with the result that in less than 20 years more than 300 of them were engaged in its practice. These physicians speedily conceived the necessity for having their own students educated under teachers of their own faith and practice, and in 1848 organized and equipped a medical college for this purpose. This school was almost immediately succeeded by others; and these institutions have very largely contributed to the rapid spread of homœopathic practice in all parts of the United States.

When Dr. H. B. Gram arrived in New York in 1825, the only homœopathic literature in the English language was Hahnemann's 'Geist der homöopathischen Heilkunst,' a pamphlet of 24 pages, translated by himself and published by J. & J. Harper, of New York. The remaining homœopathic literature was all in the German language, and it is recorded that such was the interest felt in the subject that numerous converts to Hahnemann's system, some of them past middle life, pursued the study of German in order to facilitate their investigations in homœopathy. At the close of the first quarter-century of the new practice, more than 25,000 pages in the English language had been published by the homœopathic press, and at the end of 50 years the aggregate reached more than 150,000 pages. (See 'Transactions of the World's Homœopathic Convention of 1876, Vol. II., pp. 1020–65.)

The progress that homœopathy has made in the United States can be best shown by the records of its organizations and institutions. The American Institute of Homœopathy, the national society of homœopathic physicians, organized in 1844, now has a membership of over 2,000. There are six other national organizations, formed to promote various departments of medical and surgical interest. State societies are organized in 36 of the commonwealths, and at the present rate of increase these bodies will in a few years exist in every State. To these may be added 150 local societies of various kinds. In the United States homœopathic physicians are in charge of 220 hospitals, general and special, 66 other institutions — asylums, homes, etc., and 65 dispensaries, 20 medical colleges, and 32 medical journals.

The exact number of physicians practising homœopathy in this country cannot be ascertained with accuracy, but it is known to be not less than 12,000, and has been estimated as high as 18,000. The number of people employing these physicians, regularly or irregularly, cannot be less than 15,000,000. Thus has the influence of homœopathy extended during its American career of 75 years.

The influence of homœopathy upon public and professional sentiment has been beneficent and pronounced. Laymen and physicians have alike learned from the practice, that large quantities of potent and dangerous drugs are not often necessary to determine recovery from disease, and physicians have reached the wise conclusion that cures sometimes occur under the influence of small doses, as well as quantities with larger.

Bibliography.— Ameke, 'History of Homœopathy'; Boericke, 'A Compend of the Principles of Homœopathy'; Bradford, 'Homœopathic Bibliography of the United States from the Year 1825 to 1891 inclusive'; 'Life and Letters of Dr. Samuel Hahnemann'; 'The Pioneers of Homœopathy'; Dake, 'Therapeutic Methods'; Dudgeon, 'The Lesser Writings of Hahnemann'; 'Lectures on Homœopathy'; Dunham, 'Homœopathy the Science of Therapeutics'; Hahnemann, 'Organon of the Art of Healing'; 'Materia Medica Pura'; 'The Chronic Diseases: Their Peculiar Nature and Their Homœopathic Cure'; Mack, 'The Philosophy of Homœopathy'; 'Transactions of the American Institute of Homœopathy' (1844–1903); 'Transactions of the World's Homœopathic Convention' (1876).

PEMBERTON DUDLEY, M.D., LL.D.,
Professor of Institutes of Medicine, Hahnemann Medical College, Philadelphia.

Homol'ogy, a principle first enunciated by E. Geoffrey St. Hilaire. It is the anatomical or morphological identity of parts or organs, which may have entirely different functions. Thus the wing of a bird is homologous with the fore limb of a dog or the arm of man. On the other hand analogy involves the idea of physiological identity, or use. Thus the wing of a bird is analogous to the wing of an insect. Homologous organs are also present in groups of animals which have had a common origin; thus the swimming-bladder of a fish has given origin to the lungs of the higher vertebrates, the physiological differences arising from change of function. See ANATOMY, COMPARATIVE; ANALOGY.

Homoousian, hō-mō-oo'sĭ-an (Greek *homos*, "the same," and *ousia*, "substance") and **Homoiousian** (Greek *homoios*, "like," and *ousia*, "substance"). The Council of Nice adopted the word homoousian to express that the Son was of the same substance with the Father, while the followers of Arius adopted the term homoiousian, as a sort of middle and reconciling theory, to express that the Son, though not of the same, was yet of a similar substance with the Father. The doctrine of Arianism was not only that the Son was subordinate to the Father, but that he was totally unlike him, being a mere created being.

Homoplasy, hō'mō-plăs-ĭ, the effect of the influences of convergence (q.v.), upon homologous structures. The term was proposed by E. Ray Lankester and used at first with a rather broader meaning subsequently restricted and defined by Osborn. See ANALOGY.

Homop'tera. See HEMIPTERA.

Homs, hōms. See HEMS.

Hondo, hōn'dō (signifying "chief island"), the largest island of Japan (q.v.), for a long time erroneously known as Nippon or Niphon, the Japanese name for the whole empire.

Honduras, British, or **Belize,** a colony in Central America, bounded on the north and northwest by Yucatan (Mexico), on the east by the Caribbean Sea and Gulf of Honduras, and on the south and west by Guatemala. Its chief town, Belize, has 9,113 inhabitants. The Cockscomb Mountains in the southern district rise to the height of 3,700 feet. Principal rivers are the Old, the New, and the Sibun. The northern part of the colony contains many lagoons, and a chain of cays stretches along the coast. The forests yield mahogany and logwood in large quantities; cattle raising and the cultivation of coffee and fruits receive some attention. The value of exports since 1897 has been decidedly greater than that of imports. During the year ending 31 March 1902 exports reached $1,427,500 in value; imports for the same period, $1,262,500. In 1901 exports of mahogany amounted to 6,485,952 superficial feet; logwood, 19,682 tons. Registered shipping: 6 steamers and 204 sailing vessels. Vessels entering and clearing in 1901, 414,795 tons. The total number of letters, books, postal cards, parcels, and newspapers transmitted by the post-office in 1901 was 245,694. That is to say, proportionately to the population, from 100 to 350 per cent more than in the neighboring Guatemala and Honduras. The standard of currency since 15 Oct. 1894 has been United States gold. In common use are silver coins and government notes. British Honduras is governed as a crown colony, by a governor, assisted by executive and legislative councils, the former composed of five members and the latter of eight. Expenditures since the close of 1899 have been less than the revenue, the latter being derived from customs duties, excise, land-tax, licenses, and the sale or leasing of lands. Total expenditure in the year ending 31 March 1902, about $256,050; revenue, $300,750; public debt, $173,680. There are [illegible] primary schools, with 3,423 pupils, receiving aid from the government; also a few denominational secondary schools. Population, according to the latest census, 37,479, an increase of about 17 per cent since the previous census. For origin and early history of the settlement, see BELIZE; also CENTRAL AMERICA.

Consult: 'Consolidated Laws of the Colony of British Honduras' (London 1887); Gibbs, 'History of British Honduras'; and Henderson, 'An Account of the British Settlement of Honduras.'

MARRION WILCOX,
Authority on Spanish America.

Honduras, Gulf of, a spacious inlet of the Caribbean Sea, having on the west British Honduras, and on the south Guatemala and Honduras. In it several smaller bays of which the Gulf of Amatique, with its inner recess, the bay of St. Tomas, are spacious and deep. Several large rivers, the Belize, Chamelicon, Dulce, Motagua and Ulua, flow into the gulf. Along the shores are the islands of Turneffe, Manabique, the Bay Islands including Ruatan, Utila, and Bonacca, and numerous islets and reefs called cays.

Honduras, Republic of, a country of Central America, bounded on the north and northeast by the Gulf of Honduras and the Caribbean Sea; on the southeast and south by Nicaragua; and on the southwest and west by Fonseca Bay, Salvador, and Guatemala. Estimated area, 46,250 to 46,400 square miles. The departments of the republic, with the population of each as shown by official statistics of 1901, are as follows: Tegucigalpa, 81,800; Copán, 62,398; Gracias, 48,242; Choluteca, 45,340; Olancho, 44,496; El Paraiso, 39,918; Santa Bárbara, 36,228; Valle, 33,450; Comayagua, 29,023; La Paz, 27,384; Intibucá, 26,348; Cortéz, 21,801; Yoro, 19,988; Colón, 13,791; Atlántida, 8,797; Bay Islands, 4,737. The capital, Tegucigalpa, has 12,000 inhabitants. Mountain ranges, which rise to heights of 5,000 or even 10,000 feet, are massed in the western half of the republic; the Juticalpa, Camasca, and Tompocente ranges, however, are near the frontier of Nicaragua in the east. Rivers emptying into the Caribbean Sea or Gulf of Honduras are the Coco or Wanks, and Patuca, in the east, and the Ulua, Chamelicon, etc., in the west. The Choluteca flows southward from the Misoco Mountains near Tegucigalpa, and empties into Fonseca Bay, on the Pacific coast. Large lakes are the Caratasca, on the Mosquito coast, and Yojoa, among the western mountains. The chief port on the Pacific is Amapala; other ports of entry are Puerto Cortez (on the Gulf of Honduras), La Ceiba, Truxillo, Roatan, and Iriona.

Minerals, Woods, and Agricultural Products. — Gold is found between the south and centre; silver in almost all sections. Lead, copper, saltpeter, iron, coal, platinum, zinc, and antimony are also widely distributed. The value of ores produced in 1902 was approximately $1,000,000 (that is, 23,234 ounces of gold, 1,010,204 ounces of silver, and a considerable quantity of copper). Only about 5 per cent of the mines of the country are being worked. The forests from sea-level to an altitude of 1,000 feet, contain mahogany, ebony, dyewoods, sarsaparilla and other medicinal plants, and cabinet woods, cedar, etc. At an elevation of 1,800 feet are dense and very extensive forests of pine and similar woods. Agriculture receives more attention than formerly, and the leading product is the native maize, of which 500,049 bushels were raised in 1902, chiefly in the departments of Copán, Gracias, and Santa Barbara. Bananas and plan-

tains are grown on 42,840 acres of territory in the departments of Cortéz, Atlántida, the Bay Islands, etc. The wheat crop in 1902 was 15,813 bushels; rice, 3,914,219 pounds. Nearly 20,000 acres are devoted to the cultivation of plantains. Cocoanuts, lemons, and oranges are produced for export on a large scale. The coffee crop in 1902 amounted to 4,494,826 pounds, and tobacco to 1,378,573 pounds. Sugar-cane is cultivated on 13,263 acres; indigo on about 9,000 acres. The total value of agricultural products in 1902 was about $2,482,449.10. The number of cattle is estimated at 571,120; horses, 43,549; mules, about 14,000, etc.

Commerce and Manufactures.— The total value of imports in 1902 was 4,377,161.42 *pesos*, or about $1,750,684.68 in United States currency; of exports, 6,170,353.27 *pesos*. Imports came chiefly from: the United States (60 per cent), Germany, Great Britain, Belize, Central America, and France. Exports were sent to: the United States (two thirds of total), Great Britain, Central America, Cuba, and Germany, with comparatively small amounts to other countries. The articles exported, together with their values (in *pesos*), follow: Metals, 2,319,070.49; fruits, 1,943,168.06; cattle, 560,411; coffee, 275,826.68; hides and skins, 257,598.10; woods, 217,459.70; tobacco and cigars, 200,851; indigo, 105,425; sarsaparilla, 80,602.50; rubber, 77,552.50; wheat and flour, 66,992; salt, 22,716.20; hats, 14,150; miscellaneous, 28,529.04. Exports to the United States were valued at 1,235,624.79 *pesos* more than imports from that country. Native industries include the manufacture of cigars, flour, hats, and candles.

Railways, etc.— A contract for the completion of an interoceanic railway was entered into by an American syndicate in 1897; in 1902 the government's concession to the syndicate lapsed, but a prorogue was requested. The line from Puerto Cortéz runs southward to San Pedro and La Pimienta. Tegucigalpa is to be connected with the Pacific coast, at San Lorenzo, by a line which is now being constructed. Roads in the country, with a few exceptions, are mere mule-paths. A cart-road from the capital to San Lorenzo is completed as far as La Venta. There are 245 post-offices, and the number of letters (both internal and foreign correspondence) is not more than 1,250,000 in a year. The republic has 3,249 miles of telegraph wire; the capital and some other towns telephone services.

Money, Weights, Measures, and Banking.— The standard dollar, or silver *peso*, is worth about 40 cent, United States currency. Gold coins of the value of 20, 10, and 5 dollars, and silver pieces, fractions of one dollar, are also in circulation. While the metric system is authorized by law, the chief measures and weights in commercial use, as in the other countries of Central America, are: Centaro = 4.2631 gallons; fanega (dry) = 1.5745 bushels; libra = 1.043 pounds; and vara = 33.874 inches. Note also, manzana = 1 5-6 acres, and arroba = 2¾-3½ gallons. The capital of the Bank of Honduras, 30 June 1902, was 600,000 *pesos*; bank-bills in circulation, 60,242 *pesos*.

Government, Finances, Army and Navy.— The president and vice-president of the republic, nominated and elected by vote of the people, serve for four years; the former is assisted by the ministers (chiefs of departments) of finance, interior, foreign relations, public works, war, public instruction, and justice. The legislative body is composed of deputies elected by the people, there being one deputy for each 10,000 inhabitants. The budget for the fiscal year 1903-4 gives, as the total of receipts from all sources, 2,637,724.20 *pesos*, the largest items being, customs duties, 1,100,000 *pesos*; tax on aguardiente, 805,000 *pesos*; and lottery and wharfage, 223,500 *pesos*. The estimate of expenditures in the same budget is 2,625,985.45 *pesos*, the largest item being for the war department — 941,853.85 *pesos*. The foreign debt of the republic (that is, the loans of 1867-70, with arrears of interest amounting nearly to two and a half times the principal sum) was determined by calculation to be about $96,124,940 in United States currency; and the internal debt was put at 1,332,400 *pesos* in 1900. But in the annual message of the retiring president, Sr. Sierra, sent to Congress 1 Jan. 1903, the assertion was made that the total "recognized" debt had been only $1,704,124.67 silver in 1899, and that this amount was reduced to $1,221,298.09 silver by 31 Oct. 1901. President Sierra completely ignored the large foreign loans, speaking of the 1,704,124 *pesos* as "the entire amount of the debt existing at the beginning of my term of office," "the public debt," etc. The army on 31 July 1902 comprised, according to a statement in the same message, 480 *jefes*, 2,608 officers, and 47,841 men. The permanent force consisted of 87 *jefes*, 226 officers and 2,481 men. Two small steamers belong to the government, and are used as revenue vessels.

Population, Education, and Religion.— The total number of inhabitants, as shown (by departments) in the first paragraph of this article, is 543,741, exclusive of forest tribes. Very few of this number are of Spanish descent, the great mass of the people being Indians or Mestizos. Between 1899 and 1903, new schools to the number of 136 were founded, making a total of 851; and 30,025 pupils received instruction in 1902. There are 13 national "colleges" and one private school for higher education; professional schools with faculties of jurisprudence and political science, and medicine and surgery, at Tegucigalpa; the Escuela de Derecho at Comayagua; a national library with 6,854 volumes; and an art school. Primary instruction is compulsory, gratuitous, and secular. Freedom of worship is secured by constitutional guaranty; the government does not contribute to the support of any church; the prevailing religion is Roman Catholicism.

History.— The first place of debarkation of Christopher Columbus on the American mainland was near the present Cape Honduras, where he landed on Sunday, 14 Aug. 1502. On the following Wednesday Bartholomew Columbus landed at the mouth of Rio Tinto. They sailed thence along the coast to Cape Gracias á Dios (see Central America). The conquest of the country was effected by Hernan Cortés, who found the natives manageable, but their land "covered with awfully miry swamps," as he wrote to the Spanish emperor 3 Sept. 1526. "I can assure your majesty," he adds, "that even on the tops of the hills our horses, led as they were by hand, and without their riders, sank to their girths in the mire." The most important fact in the history of Honduras — the fact that the Indians remained in possession of so large a portion of the country that their descendants constitute the bulk of the population to-day — is a consequence of the policy observed by Cortés and his successors. The natives were tractable; without their assistance it would have been impossible to move about among the dense forests, swamps, and mountains; therefore the Spaniards realized that more was to be accomplished by diplomacy than by force. Massacres occurred, but extermination was not attempted; on the contrary, Honduras became in time a nation of Spanish-speaking Indians, those of pure or nearly pure blood being more numerous now than before the conquest. For the era of independence, confederation with the neighboring states, etc., see CENTRAL AMERICA.

Bibliography.— American Republics, International Bureau of the, 'Monthly Bulletin' (1902–3); Cortés, 'Fifth Letter of Cortés to the Emperor Charles V.'; Diaz, 'Historia Verdadera de la Conquista de la Nueva España'; Sierra, 'Mensaje,' etc., in 'Pabellon de Honduras,' Tegucigalpa 10 Jan. 1903; Squier, 'Honduras,' and 'Honduras Interoceanic Railway'; Wells, 'Explorations and Adventures in Honduras.'

MARRION WILCOX,
Authority on Spanish America.

Hone, hōn, **Philip**, American merchant: b. New York 1781; d. there 4 May 1851. He was a successful auctioneer in New York, established there the first savings bank (1816), was mayor in 1826, and one of the founders of the Mercantile Library Association. Prominent in national political affairs, he aided in the formation of the Whig party. His diary, a portion of which, edited by Tuckerman, appeared in 1889, contains important side-lights on the early history of the Whigs. Hone was also at one time naval officer of New York port.

Hone, a strop or stone for sharpening knives and razors. See WHETSTONE.

Honesdale, hōnz'dāl, Pa., borough, county-seat of Wayne County; on the Lackawaxen River; the Erie, and the Delaware & H. R.R.'s; about 15 miles northeast of Carbondale and 30 miles northeast of Scranton. The first locomotive used in America, the "Stourbridge Lion," made its trial trip from this city. It is situated in a coal-mining region, with good farming land in the valleys. Its manufactures are silk and woolen goods, boots, and shoes, machine-shop and foundry products, axes, electric elevators, green, cut, engraved, and decorated glassware, men's clothing, and wheels for polishing glass. Large quantities of coal are shipped annually from Honesdale. Pop. (1900) 2,864.

Honesty. A flowering herb. See SATIN-FLOWER.

Honey, a sweet sticky liquid obtained by bees and other insects from flowers (see HONEY-BEE; and FLOWERS AND INSECTS) as food, or taken home to be stored as food for the young. The care with which the honey-bee (q.v.) collects and stores this substance in its hive has led to bee-culture (q.v.). Honey is highly nutritive, especially as a fuel for the energies of the body, as four fifths of its components are carbohydrates, the remainder being water with a trifle of protein. The saccharine elements are mainly grape-sugar and some fruit-sugar, which are so readily affected by yeast that various fermented drinks are made with honey as their basis, of which the best known are the mead and metheglin in great demand among all Teutonic peoples a thousand years ago, and the equivalents of which are still made in Russia, Abyssinia and elsewhere. Before the general manufacture and use of cane-sugar, honey was largely depended upon for purposes of sweetening, and was put into a great number of cakes and confections now rare or only locally manufactured. Of the place which it took among the ancients in the household, in ceremonials, worship, and folk-lore a large amount of curious information may be gathered from such books as Beckman's 'History of Invention' (1846); Dutt's 'Materia Medica of the Hindoos' (1877), and similar works, of which lists may be found in Warring's 'Bibliography of Therapeutics' (1868), and in the 'Catalogue of the United States Army Medical Museum.' The importance of honey was, indeed, much greater to the ancients than to us; as might be inferred from its frequent mention in the Bible as a sign of abundance or the resource of the destitute. It has well-recognized medicinal properties, especially as a demulcent against hoarseness, catarrh, etc., in promoting expectoration in disorders of the breast, and as an ingredient in cooling and detergent gargles. Its effect is usually laxative also. It is used to sweeten certain medicines; and is sometimes mixed with vinegar in the proportion of two pounds of clarified honey to one pint of the acetic acid, boiled down to a proper consistence over a slow fire, and thus forms the oxymel simple of the shops. It enters into the composition of various sweetmeats, especially in the East, such as the genuine Oriental nougat. These properties and the flavor and color of honey vary with the qualities of the flowers from which it is made. Thus in Europe the white Narbonne honey of France, is said to owe its peculiar and delicious flavor to the rosemary and other labiate flowers on which the bees feed. The Grecian honey also stands in high estimation. Mt. Hymettus in Attica has been famous since classic times for this product; but that yielded by the bees who range the thyme-covered hills of Corinth is said to excel it. Another famous ancient source of supply was Sicily, especially about Mt. Hybla; and Corsica is yet celebrated for its honey and wax, which in ancient times were the chief exports of that island. In the eastern United States the early light-colored honey obtained from the blossoms of the white clover, is especially esteemed; also that derived from raspberry plantations, bass-wood flowers and the like; while that made later in the summer from buckwheat is in favor among darker varieties. California is an extensive producer of honey from various flowers.

As the aromatic agreeable flavors and healthful qualities of special flowers (fortunately in the majority) are kept and apparent in ordinary good honey, so certain bad qualities are retained and spoil some honey, which thereby becomes deleterious to the human system, acting as a nauseant, a purgative, affecting the nerve-centres or even seriously poisoning those who eat it. This is the case in the United States with honey made from the flowers of the mountain laurel (*Kalmia*) and some other toxic plants. Some persons are unable to eat any kind of honey, without disarrangement of the digestion or nerves, or both; and all should use it in moderation.

The industry of bee-keeping is for the purpose of supplying the market demand for honey. Modern hives are so constructed that the bees build separate combs each filling a box with glass sides, which are taken out and sent to market as the bees finish them. Another method of marketing is in the form of "strained" honey, the liquid pressed from the comb after warming, through sieves of linen cloth, or by other means. There is no reason why this should not be as good as that left in the comb, if properly prepared and preserved, and it permits of saving the material of the combs for wax (q.v.); but it makes possible adulteration, which is freely taken advantage of. The chief adulterant is commercial glucose, which occasionally is substituted to the extent of three fourths of the volume, leaving only enough real honey to flavor the mass. As glucose (grape-sugar) is a large constituent of this substance in nature no great harm results (when the glucose is good), beyond the deception; and wholly artificial honey has been largely sold in the past as the product of bees.

The United States is probably the greatest honey-producing region of the globe, and exports a vast quantity to Europe annually. The census of 1900 reported 4,149,426 swarms of bees, valued at $10,186,513; and the annual production of honey at 61,196,160 pounds, which, together with 1,765,315 pounds of wax was worth $6,664,904.

Honey Ant, a true ant of the family *Formicidæ*, fifth sub-family *Camponotinæ*, and allied to the typical ants (*Formica*). The honey ant (*Myrmecocystus melliger*), is so called from certain of the wingless individuals being so many honey-pots, their abdomens being distended with honey fed to them by the normal workers, including both dwarfs and majors. It occurs from central Colorado (Garden of the Gods) to New Mexico and as far south as the city of Mexico. It erects mounds six or seven inches across and two or three inches in height, of the shape of a truncated cone. In the interior is the "honey chamber" or a rough dome-roofed vault or fissure, the honey-bearers (600 in a large colony) clinging by their feet to the roof. Their yellow bodies are stretched along the ceiling, their swollen, round, amber-colored abdomens of the size of currants hanging down. The "honey" is obtained in the night time by the workers which go in long processions to some distant scrub-oak bearing nectar-producing galls. The workers return with distended abdomens, and feed the honey-bearers with the nectar. C. McCook thinks the honey-bearers are not a distinct caste, but simply workers "with an overgrown abdomen." The honey is thus stored, as bees store their honey, for food in winter or times of famine. Consult McCook, 'The Honey Ants of the Garden of the Gods,' etc. (Philadelphia 1882).

Honey-badger, a small mustiline burrowing animal (*Mellivora indica*) of India, which eats insects, frogs, birds' eggs, and small animals generally, and is fond of honey. The natives believe it robs graves, but destruction of poultry is its worst sin. It is nearly related to the South African ratel.

Honey-ball, or **Globe-flower**, the flower of an American shrub (*Cephalanthus occidentalis*) of the madder family, which grows in wet places, where it is called button or river bush, and bears extremely fragrant flowers whose small florets are folded or packed into balls, while "the long styles and capitate stigmas remind us of pins stuck in a cushion."

Honey Bear, the sun-bear (q.v.).

Honey-bee. Bees in general are *Hymenoptera*, of the family *Apidæ*. Bees are distinguished from wasps and other hymenoptera in the first place by the long, broad, flattened basal joint of the hind tarsus, which is adapted for carrying pollen to the nest. Bees are also more hairy than others of their order, and some of the hairs are plumose or feathery. The mouth-appendages are long and highly specialized, especially the long flexible proboscis or tongue (hypopharynx). There are no wingless adult forms. While the more primitive genera are solitary, in the more specialized or social kinds, besides the males and females, there are workers, which are, as a rule, sterile females in which the ovaries are undeveloped. Of the bee family there are now known to be about 150 genera and 1,500 species.

Original Home of the Honey-bee.— Although the honey-bee (*Apis mellifica*) has followed the white man in his migrations from the Old World to the New, and to Australia, New Zealand, etc., its original birthplace is in southern Asia, probably including the eastern shores of the Mediterranean Sea. Besides *A. mellifica* there are seven or eight other species, all except one southern and eastern Asiatic, including the islands of Timor and Celebes; the exceptional one (*A. adamsoni*) inhabiting tropical Africa and Madagascar. We know little of the honey-bees of China and Japan.

Like other domestic animals (and the honey-bee is the only domestic insect we possess), this bee is divided into races of which the Ligurian bee (variety *ligustica*), originally inhabiting Italy and adjoining regions, is a well-marked one, and another is the Egyptian honey-bee (variety *fasciata*). There are several sub-varieties of the northern form of *A. mellifica* in Germany. The English naturalist Ray, who published before Linné gave the name *A. domestica* to the northern dark form, our common honey-bee. This dark, northern form is the one which has been carried by the European race to various parts of the world, in some of which it is now wild. It occurs in the West Indies, in North America, including Mexico, in central and southern Africa, and in Australia and New Zealand. The variety *ligustica* has also been found at the Cape of Good Hope.

Besides the honey-bee there are other social forms in Central and South America, as well as other tropical countries, including Australia, which store up honey; these are small bees, exceedingly numerous in individuals, which belong to the genera *Melipona* and *Trigona*, and are stingless, though the sting exists in a rudimentary state. *Trigona mosquito* is known to send off swarms and to have but a single queen in a colony. The nests are built in hollow trunks of trees, in banks of clay or earth, and they gather pollen, nectar, and resin. On the whose, the honey-bee stands at the head of the hymenopterous series, and, in fact, at the head of the class of insects, though the house-fly is in some respects more extremely specialized.

Structure of the Honey-bee.— Besides the males or drones, and the female or queen, the colony consists of workers; these carry on the work of the society, gathering nectar, pollen, building the cells and feeding the young. The colony is permanent, differing in this respect from that of bumblebees, which come to an end each autumn. We will first describe the chief points in the external anatomy of the insect. The body is divided into three regions, the head, thorax, and abdomen. The eyes are of two kinds, simple and compound, the male differing from the queen and the workers in the large compound eye meeting in the middle of the top of the head. The mouth-appendages consist of three pairs,— first the jaws or mandibles: these in the queen and drone are notched, but in the worker the edge is entire and serves for biting, and in comb-building for thinning out wax shreds, also for scooping and molding the wax, while the next pair of appendages, or accessory jaws, are called maxillæ, and are used as a trowel. In the bumblebee the maxillæ are also used for piercing the corolla of flowers like the wistaria and honeysuckle, but those of the honey-bee appear to be too weak for this purpose. They also ensheathe the proboscis. The so-called tongue (ligula, lingua or hypopharynx) is the long, slender, hairy appendage adapted for gathering the nectar of flowers. It is an outgrowth of the under lips (labium or fused second maxillæ), is situated in a tube formed by the maxillæ and labial palpi, and can be partially withdrawn into the memtum, or base of the under lip. It can move up and down in the tube thus formed. It is covered by a hairy sheath, and is very elastic, this being due to a rod extending through its centre, enabling it to be used as a lapping tongue. Cheshire states that the rod on the under side has a gutter or trough-like hollow, which forms a false tube by the intercrossing of black hairs. There are also two side-ducts, which extend along to the end of the tongue, where the "spoon" or "bouton" is situated. This is provided with very delicate split hairs, "capable of brushing up the most minute quantity of nectar, which by capillarity is at once transferred by the gathering hairs to two side groove-like furrows at the back of the bouton." The central duct, because of its smaller size and consequent greater capillary attraction, receives the nectar, if it sufficient in quantity to fill the side ducts. "But," says Cheshire, "good honey-yielding plants would bring both centre and side into requisition. The nectar is sucked up until it reaches the paraglossæ, which are plate-like in front, but membranous extensions, like small aprons, behind; and by these the nectar reaches the front of the tongue, to be swallowed as before described. The process of gathering the nectar is not exactly either a sucking or a licking process; but, as Cheshire shows, the action is primarily due to capillary attraction.

Organs of Smell and Taste.— Bees are guided to flowers chiefly by smell, rather than by the color of the flowers they visit. (See FLOWERS AND INSECTS.) The olfactory organs are multitudes of microscopic pits in the antennæ — the organs of smell. The sense of taste is lodged in a minute soft baggy fold on the under side of the upper lip, which is rich in taste-cups; and, besides, there are a few taste-papillæ or cups found by Packard at the base of the paraglossæ and on the base of the labial palpi. These sites of the gustatory organs are situated where the food or nectar will come in contact in passing down the throat into the stomach.

Formation of Honey and the Honey-Stomach.— In insects there is the fore stomach (proventriculus) and the true or chyle-stomach. The former is called by apiarians the "honey-sac" or "honey-stomach." "If," says Cheshire, "it be carefully removed from a freshly killed bee, its calyx-like 'stomach-mouth' may be seen to gape open and shut with a rapid snapping movement." The entrance to the stomach is guarded by four valves, which open to allow the passage of food from the honey-sac to the chyle-stomach. It is closed at will by circular muscles. Thus the bee can carry food for a week's necessities, either using it rapidly in the production of wax, or eking it out if the weather is unfavorable for the gathering of a new store. By means of a complicated mechanism a bee in sucking up from composite and other flowers nectar together with much pollen (1) can either eat or drink from the mixed diet she carries, gulping down the pollen in pellets, or swallowing the nectar as her necessities demand; (2) when the collected pollen is driven into the chyle-stomach, the tube-extension prevents the pellets forming into plug-like masses just below, for by its action these pellets are delivered into the midst of the fluids of the stomach to be at once broken up and digested; (3) "while the little gatherer," says Cheshire, "is flying from flower to flower, her stomach-mouth is busy in separating pollen from nectar, so that the latter may be less liable to fermentation and better suited to winter consumption. She, in fact, carries with her, and at once puts into operation, the most ancient, and yet the most perfect and beautiful, of all honey-strainers.' "

How the Honey is Made.— Honey is made of nectar, and is due to a chemical change in the honey-sac. The bee gathers the nectar with its "tongue," swallows it; it then passes into the honey-sac, and is regurgitated as honey. The nectar when gathered is almost entirely pure saccharose, and, according to Bertrand, when regurgitated it is found to consist of dextrose and levulose; this change appears to be practically the conversion of cane-sugar into grape-sugar. A little salivary fluid is poured out into the mouth as the bee sucks the nectar, and this effects the chemical change. Cheshire thinks that the salivary fluid is added while the nectar is being sucked, and is passing over the middle parts of the under lip, so that the nectar may be honey when swallowed by the bee.

Many and probably all bees eat the pollen while gathering it. The plumose hairs of bees are of use in collecting the pollen grains which adhere to them, but the exact method of accumulation of the pollen and the mechanism of its conveyance from hair to hair till it reaches the part of the body it must attain in order to be removed for packing in the cells, is not fully understood, but the head and front legs scratch up the pollen-grains, and the honey-bee has a pollen-basket on each hind leg, the basal joint of the tarsus being broad and slightly hollow, with nine rows of short hairs to which the pollen-grains adhere.

Life History and Social Life.— In founding a new colony the young swarms consist of a queen-bee and a number of workers, a surplus population of the old colony. The swarming is not a nuptial flight, but an act of emigration. After the new swarm has been housed, the workers begin their labors by secreting wax. This is formed in glands on the inside of the ventral plates of the abdominal segments, appearing outside as thin projecting plates, which are removed by the wax-pincers on the hind legs; after being molded by the jaws they form the hexagonal cells in which the young or larvæ live and the food is stored, and thus the comb is gradually built up. The queen then lays an egg in each cell, and the larvæ (grubs) on hatching are fed by the workers. This they do by eating honey and pollen, which is formed in the digestive organs, into a kind of pap. This pap looks like arrowroot made with water, and the very young grubs partly float in it, besides absorbing it by the mouth. The young grubs, as they increase in size, are weaned from this glandular secretion or pap, pollen, honey and water being added, while the pap or glandular secretion is gradually withdrawn. The queen larvæ, according to Cheshire, is not weaned, but the secretion or pap (the so-called "royal jelly"), which is a rich, highly nitrogenous food, is added unstintingly to the end, and owing to this the queen becomes larger and fertile. When the colony is progressing well and young bees emerge, these act as nurses, the old ones going out of the hive to forage. When the grub is full-sized the worker bees seal up the cell with a cover made of pollen and wax, but pervious to the air. In this cell the grub spins a cocoon in which it pupates, finally biting its way out; the bee developing in three weeks from the time the egg is laid.

The new queen arises from an egg laid in the royal cell, which is large and slipper-shaped. She develops in 16 days. Only one queen is allowed in the hive at one time. The males (drones) arise from unfertilized eggs. The drone cells are a little larger than the ordinary worker cells. A drone is developed in about 24 days. When a swarm leaves the hive the old queen quits with it, but when a second swarm goes off from a hive it is accompanied by a young queen, who is frequently and perhaps usually, unfertilized.

The young queens will usually mate when five to seven days old, flying from the hive for this purpose. In a day or two after mating the queen generally begins to deposit eggs, and is then ready for use in the hive or to be sent away as an "untested queen."

Bee-Culture.— Spring is the best season to start a hive or apiary. In April a good colony situated in the Central States ought to have brood in five or six combs. The Langstroth hive with its modern improvements is the best, and the novice should select those holding 10 to 12 frames in each story.

Swarming is the result of an abundant secretion of honey, and combs crowded with bees and brood, that is, overpopulation. Just before swarming there is a partial cessation of field-work, the workers clustering or loitering about the entrance to the hives. Suddenly those which happen to be in the hive at this time rush forth, accompanied by the old queen, and cluster on some tree or shrub near by. Hiving the new swarm can be done after a little experience and the use of smoke. Swarming may be prevented by giving abundant room for the storage of honey early in the season, before, as Benton says, the bees get fairly into the swarming notion. The honey also should be frequently removed. Also the hives should be well ventilated and shaded in hot weather. To successfully winter bees the colony must have a good queen, and young workers, also good and abundant food. Those colonies having the most honey compactly stored in the brood department and close about the very centre when the last brood of young bees should emerge, are the ones which will winter best. A good substitute for honey is a syrup made of granulated sugar, to be fed early in autumn. The bees should be kept dry and warm, and there should be no manipulation out of season. (Benton.)

Diseases and Enemies.— Diarrhœa is due to sour or fermented honey, dampness, and chilling of the bees. Foul-brood is a germ-disease, occasioned by *Bacillus alvei;* it affects both the brood and the adult bees. Of insect enemies the caterpillar of the wax or bee-moth is the most destructive, but with care it can be kept out of well-regulated hives.

Agency of Bees in Cross-Fertilization of Plants.— A hive is an essential thing in an orchard, and were it not for the visits of bees the fruit in many cases would not set. Also in hothouses where cucumbers are raised, a small hive of bees is indispensable for fertilizing the flowers. See BEE-KEEPING; FLOWERS AND INSECTS.

Consult: Cheshire, 'Bees and Bee-Keeping' (2 vols., London 1886); Benton, 'The Honey Bee'; Bulletin No. 1, new series, U. S. Department of Agriculture, Division of Entomology, Washington, 1896, contains a list of the best books on bee-keeping.

ALPHEUS S. PACKARD,
Late Professor of Zoology, Brown University.

Honey-bird, or Honey-guide. See GUIDE-BIRDS.

Honey Bloom, one of the American species (*Apocynum androsæmifolium*), the "spreading dogbane" of the family *Apocyanaceæ* (q.v.). It grows in fields and thickets all over temperate North America, and has the medicinal qualities characteristic of the family.

Honey-buzzards, a genus (*Pernis*) of Old World hawks, formerly called "perns," which subsist mainly on insects, especially burrowing wasps, and bees, with their young and food-stores, which they dig out of the ground.

Honey-creepers, a group of small warbler-like birds (the family *Cœrebidæ*) of gay plumage, numerous in the West Indies and neighboring lands, where they are known about gardens and plantations and admired for their agility in searching flowers for small insects, and their cheery notes. Among them are the "banana-birds" (q.v.).

Honey-dew, the sweet secretion of certain plants and insects. (1) Some trees in warm climates yield from their leaves in very warm moist weather a saccharine liquid which may fall in drops, or may form a sticky film over each leaf. This exudation, dried, is one form of manna. (2) Certain minute insects, chiefly plant-lice, leaf-hoppers, and related bugs, yield a sweetish secretion, sometimes so copiously as to bedew a whole tree, and even fall in drops, giving the phenomena called weeping trees. The usual cause in this case is the presence of a tree-hopper (*Proconia undata*). Honey-dew in both cases attracts insects in large numbers, who feed upon it or upon the lesser insects gathered to the feast: and these, in turn, attract larger predatory animals, as birds, lizards, etc. Moreover dust sticks to it, closing the pores of the leaves to the injury of the tree; and, still worse, the honey-dew forms a highly favorable culture-ground for the spores of smuts and other pernicious fungi.

Honey-eater, or **Honey-sucker,** any of various small and somewhat thrush-like long-billed birds of the family *Meliphagidæ,* which inhabit the Australian regions, and seem to feed upon the nectar of flowers. They do so to some extent, but mainly are in search of insects within the corolla, collecting them easily by means of a peculiar tongue, which is divided near the end into a sort of fringe. They also eat soft fruit, and spend much of their time hunting insects on the ground. Well-known examples are the soldier-bird, parson-bird, pimlico, friar-bird (qq.v.) and others familiar in Australia and New Zealand.

Honey-guides. See GUIDE-BIRDS.

Honey Hill, Battle of. On the night of 28 Nov. 1864 Gen. Foster, commanding the Federal troops in the Department of the South, left Hilton Head, S. C., with 5,000 infantry, cavalry, and artillery, and about 500 sailors and marines, for Boyd's Neck on the south side of Broad River, the object of the movement being to cut the railroad connecting Savannah and Charleston, and otherwise co-operate with Sherman, who was marching to the coast. Owing to a thick fog many of the boats lost their way, and it was late in the afternoon of the 29th before the troops got ashore. Gen. Hatch was put in command, with orders to push forward and cut the railroad. Hatch marched immediately; the guides and maps proved worthless, and, after marching and countermarching the greater part of the night, he went into bivouac about 2 o'clock on the morning of the 30th. Information of Foster's appearance at Boyd's Neck was carried to Gen. Hardee at Savannah on the evening of the 29th, and next morning at 2 o'clock, the advance of G. W. Smith's Georgia militia arriving at Savannah, Hardee directed Smith to hasten it to Grahamsville Station on the Charleston & S. railroad. The station was reached at 8 A.M., and the men marched out on the road leading to Broad River landing, about three miles where, on the crest of the north bank of a small stream, a work for light guns had been thrown up and trenches for infantry prepared. These works were about 100 yards from the little stream, and upon Honey Hill, 10 or 12 feet above the water level. On the right of the battery of five guns was a dense forest, on the left an open pine wood. The ground in front was open. Preparations were completed by 10 o'clock, at which hour about 1,000 militia filled the trenches on the right and left of the battery. Early in his march Hatch encountered the Confederate outposts, drove them in, and, soon after 10 o'clock, came under fire of the guns. Hatch attempted a flanking movement, but failed, and made several direct assaults during the day, all of which were repulsed, and at dusk he began his retreat to Boyd's Neck. His loss was 711 killed and wounded, and 43 missing. During the action Smith was reinforced by the 47th Georgia, but at no time did he have more than 1,400 men. He lost 8 killed and 42 wounded. Consult 'Official Records,' Vol. XLIV.

E. A. CARMAN.

Honey-locust, or **Honey-shucks.** See LOCUST TREE.

Honeysuckle, a genus of plants, *Lonicera,* belonging to the natural order *Caprifoliaceæ.* Upward of 100 species are native to the northern hemisphere. The honeysuckle family is represented in the North American flora by different species, among which are *L. sempervirens,* the trumpet honeysuckle; *L. grata,* American woodbine; *L. flava,* yellow honeysuckle, etc. "Coral honeysuckle" is another name in the United States for *L. sempervirens.* It is much valued in the South, where it is native, for its flowers of beautiful color and grateful perfume. In the eastern United States the Japanese honeysuckle has escaped from cultivation. The common honeysuckle, *L. periclymenum,* with distinct leaves and red berries, is indigenous in Great Britain: but two others have been naturalized, *L. caprifolium,* distinguished by its upper leaves being united (connate) and perfoliate, and by its smooth orange-colored berries: and *L. xylosteum,* an erect shrub, with small, yellowish, scentless flowers and scarlet berries. There are many other species in America, Europe, and Asia, and the name honeysuckle is often given to shrubs with sweet flowers of quite different genera.

Honey-sweet. See MEADOW-SWEET.

Hongkong, hŏng'-kŏng', or **Hian-Kiang,** hē'än-kē'äng (signifying "the place of sweet streams"), an island off the southeast coast of China, forming with Kau-lung on the mainland, a British crown colony and naval station. The island is on the east side of the estuary of the Chu-Kiang or Canton River, 90 miles south of Canton, and is separated from the mainland by the narrow Lyemun strait. About 10 miles long and about 7½ miles broad, the island is of rocky formation, attaining in Victoria Peak a maximum altitude of 1,809 feet. While almost treeless it is noted for its profuse flora. Good water is abundant. Hongkong is a great entrepôt for the foreign commerce of China, and Victoria (q.v.) the chief town and centre of its commerce is a free port. The foreign commerce is carried on mainly with Great Britain and Germany, whence considerable quantities of goods are imported, cottons being the principal item,— and to which tea, silks, hemp, etc., are exported.

In 1902 Hongkong exported, in vessels of European construction, goods to the value of $3,963,463, besides $2,372,397 worth of goods in transit, making a total of $6,335,860, and showing an increase of $720,288 over the previous year.

Comparing 1902 with 1901 the number of steamships which entered the port of Hongkong and their classification by the flags they carried, is as follows:

Courtesy of the Philadelphia Commercial Museums.

QUEEN STREET, HONGKONG.

Flag	Ships 1901	Ships 1902	Total Tonnage 1901	Total Tonnage 1902
British	321	324	2,894,519	2,965,030
German	122	123	1,242,499	1,360,524
Japanese	65	56	692,981	865,400
Norwegian	3	3	78,004	263,379
French	22	27	209,094	219,111
Chinese	4	17	3,349	163,396
Austrian	20	20	128,483	125,929
American	19	23	130,476	121,939
Others	33	37	119,498	131,518
Totals.........	609	630	5,498,903	6,216,226

In 1901 the vessels entered the port 3,510 times, and in 1902 4,000 times.

The currency is chiefly in silver dollars. The revenue of the government is derived from land rents, licenses to sell opium, spirits, etc., taxes, postage, office fees, fines, etc. The colony's prosperity is due chiefly to the presence of large numbers of Chinese engaged in trade or in working building stone, one of the island's principal products. Exclusive of the naval and military establishments which numbered 5,597 and 7,640 respectively, the population in 1901 was 283,905 of which 274,543 were Chinese and one third of these by birth, British subjects. Hongkong was ceded to Great Britain in 1842; some 376 square miles on the mainland, with 100,000 Chinese inhabitants, were leased in 1898.

Honolulu, Hawaii, capital and principal city of the Hawaiian Islands (now a United States Territory), and commercial metropolis of Polynesia; the business heart of the central Pacific. It is 2,089 miles southwest of San Francisco, in lat. 21° 17′ 56″ N., lon. 157° 51′ 48″ W. It lies on the southwest side of Oahu (the third island of the group in size, and northwest of Hawaii, with a safe harbor formed by a natural breakwater of coral reef, pierced by a broad opening. A fine lighthouse here throws a light visible for 25 miles. With its natural advantages, and the absence of rivals, the city occupies a unique position. From its central location it is a common point of touch for the three great trans-Pacific steamship routes — from the United States and British Columbia to New Zealand and Australia, from the same to Japan, China, and the Philippines, and from South America to Japan and China. Several independent steamship routes also run from it. It has regular communication with San Francisco, Vancouver, and Seattle, Peru, Auckland, and Sydney, New York and Boston, Yokohama and Hongkong, Liverpool, Glasgow, and Bremen, besides other places. The steamship line to Sydney touches at the Fijis; the line to Auckland, at Apia, Samoa. From Honolulu it is 3,850 miles to Auckland, about 4,000 to Sydney, and 3,445 to Yokohama. It is the port of foreign trade for the archipelago; hundreds of vessels and some $20,000,000 worth of products pass in and out of it annually. There are numerous wharves and warehouses here and a government custom-house. (For the items of the trade, see Hawaii: the great items are sugar and molasses, rice, coffee, hides, and wool.)

Honolulu lies at the mouth of the valley of Nuuanu, which runs back between two high ridges to a pass between two peaks about 3,000 feet high in the great eastern range of mountains; the view from the brink of the *pali* or precipice at this pass, is one of the notable sights of the neighborhood. The climate is mild and equable, and many sufferers from lung troubles in the United States seek it for a sanatorium. The extreme range of temperatures is 52° to 88°, average 70°. The rainfall is very irregular, but never slight; from 40 to 60 inches annually. The island is volcanic, the bordering reefs coral; hence the city streets are macadamized with coral and lava, porous rock making good surface drainage. The city is well laid out in American fashion, being indeed a modern American place; the old one-story wooden huts, mingled with grass huts among the trees, have mostly given place to cottages, unpretentious indeed, but neat and comfortable, and making parts of a beautiful and picturesque whole of luxuriant gardens and surroundings of tropical trees, with which also some of the streets are abundantly shaded — the great Norfolk pine, papaya, bread-fruit, mango, and monkey-pod, umbrella-tree, tamarind tree, algaroba, bamboo and koa, date and cocoa palms, candle-nut, royal-palm and poinciana regia, alligator-pear, china-rose bush, blooming all the year round, etc., many with rich and fantastic blossoms, others with great parasitic ferns, besides peach, oleander, banana, guava, orange, citron, and others. The flowers are also of great beauty and luxuriance.

The city has nearly 200 acres of public parks. There are all modern appliances and services for civilized work and comfort; several first-class hotels, physicians, lawyers, daily and weekly newspapers, four banks and two theatres, insurance offices, several hospitals, a public library, etc. There are 22 public schools, including a high school and normal school, with a total attendance of over 4,000 pupils, besides 37 private schools, with an attendance of 2,700 pupils. There are a number of churches, Protestant and Catholic; the city is the seat of a Roman Catholic and an Anglican bishop. It is also the residence of the government officials, and the consular agents of many European powers. It has waterworks owned and operated by the Territorial government, and furnishing excellent water, pumped from artesian wells, supplemented by water from the adjoining valleys. Ice is made by machinery. There is an electric street lighting system operated by the government, and an electric street railway system, built and conducted by a chartered company; a telephone system; and there is a submarine cable to San Francisco and wireless telegraph to the neighboring islands. Of manufactures the number of different lines is upward of 30, of course chiefly for local needs; the largest branch is foundry and machine-shop manufacture, which is carried on in large works, and turns out some $650,000 a year of product. Next to this is rice-milling, with some $150,000 a year. Minor industries are ice, harness, leather, jewelry, soap, and shipbuilding. The total number of all employees in 1900 was 1,854, and the total annual wages paid $1,201,648.

The chief building is the former royal palace, now the executive building, in the Italian style, finished in 1882. The judiciary and other government buildings are near it. The most interesting place is the museum, with many curious relics of early Hawaiian history, corals, and shells and other native curiosities, land and marine. The chief in interest and value is the great feather war-cloak of Kamehameha I., the founder of the monarchy, valued at $150.000. This was the chief treasure of the former sovereignty, and was used as a mantle of state by the sovereigns. It was made of yellow feathers from the *mamo* bird, found only in the mountains, each bird furnishing only two small tufts of feathers for it, one from under each wing. It is four feet long, and has a spread at the bottom of 11½ feet. Nine generations were employed in making it.

Honolulu harbor was discovered by Capt. Brown in November 1794. The city as a modern foundation dates only from 1816, when John Young, an Englishman, and a faithful counsellor of the king, Kamehameha, advised its fortification. Previously it had been only a native village of huts, of little commercial importance. In 1820 it was made the capital of the archipelago, and afterward became the seat of government. Population (1870) 14.852; (1890) 22.907; (1900) 39.306. Since the annexation of Hawaii to the United States, it is rapidly increasing. Of the population in 1900, 24.746 were males and 14.560 females: the total being divided as follows: 11.090 Hawaiians, 9.061 Chinese, 7.229 whites, 6.179 Japanese, 5.000 Portuguese, and 147 negro. Of these, 21.871 were born in Hawaii and 17.435 born in foreign countries. (This classification is based upon a census taken by the plague inspectors during the spring of 1900, and is believed to be approximately correct. Of the 7.229 whites about 2.000 are classed as foreigners.)

W. D. Alexander.

Former Surveyor-General Hawaiian Islands.

Honor, Knights of, a secret, beneficiary order founded in 1873. In 1902, there were in the United States 36 grand lodges, 1.960 sub-lodges and 54.029 members. Since its organization the order has disbursed over $79.000.000 in benefits, and in 1902 the amount was $3.074.649. The order is incorporated under the laws of Missouri, with headquarters in St. Louis.

Honor, Knights and Ladies of, a fraternal, benevolent society founded in 1877 at Louisville, Ky. In 1902 there were 16 grand lodges, 1.100 sub-lodges, and 63.000 members. Since its organization over $10.000.000 has been disbursed in benefits, and during 1902, the amount was $1.173.000.

Honorius I., hō-nō'rĭ-ŭs, Pope: d. 12 Oct. 638. He was elected pope in 625. In the hope of allaying a controversy he temporized with the leaders of the Monothelite heresy, which, while recognizing the twofold nature of Christ, declared he had but one will, a doctrine condemned by the sixth council of Constantinople. He was anathematized by the council that condemned the heresy. Pope Leo II., in confirming the acts of this council, says that Honorius was condemned for "not extinguishing the flames of incipient heresy." For a full account of the case of Honorius, consult Parson, 'Studies in Church History,' Vol I.

Honorius II., Pope: d. 14 Feb. 1130. He was elected pope in 1124, and was at the time of his election bishop of Velletri. A part of the bishops and cardinals had previously invested Cardinal Thibaut with the papal dignity; but both candidates having resigned Honorius was re-elected.

Honorius III., Pope: d. 18 March 1227. He became pope in 1216, on the death of Innocent III. He at once wrote to the King of Jerusalem to assure him of his support; to the bishops of France, to encourage pilgrims, and to the Emperor of Constantinople to promise him assistance. John, king of England, had left to his successor, Henry III., the burden of a war with the French Prince Louis, who laid claim to the English throne, and had been encouraged in his pretensions by Innocent. Honorius reconciled the barons with Henry, and obliged Louis to renounce his pretensions. He then turned his attention to the crusades, and crowned Frederick II. emperor of Germany, on condition that he would go to Palestine within two years. In France he instigated Philip Augustus and Louis VIII. to support the war against the Albigenses. He was succeeded by Gregory IX.

Honorius IV., Pope: d. 3 April 1287. He was elected pope in 1285, and supported the French king, Philip the Bold, in the war against Peter of Aragon.

Honorius, Flavius, Roman emperor, son of Theodosius the Great, b. Constantinople 9 Sept. 384 A.D.: d. Ravenna, Italy, 26 Aug. 423 A.D. On the death of his father in 395 the empire was divided into two parts, Honorius receiving the western half, with Rome as his capital. The principal events of his reign are the adoption of rigorous measures against paganism in 399; the devastation of Northern Italy by Alaric in 400–403; another irruption of barbarians under Rhadagasius 405–6. Both invasions were repelled by his able minister Stilicho, who, however fell under the displeasure of his weak and indolent master, and was assassinated at Ravenna in 408. Taking advantage of the death of the defender of Rome, Alaric marched upon the city and plundered it in 410.

Hooch, or Hoogh, Pieter de, pē'tėr dė hooн, or hōg, Dutch painter: b. Utrecht 1630; d. Amsterdam soon after 1677. His early art training was much influenced by Rembrandt. In 1655, he was enrolled in the Painters' Guild of Delft, where he resided, but later removed to Amsterdam. He was the chief representative of Dutch genre painting, and his specialty was the delineation of Dutch interiors, with their semi-darkness, suffused by the witchery of sunlight. Sometimes he set out two or more rooms in perspective, the vista of which was drawn and lit up with extraordinary skill.

Hood, John Bell, American soldier: b Owingsville, Ky., 29 June 1831; d. New Orleans, La., 30 Aug. 1879. He was graduated at West Point in 1853, and bore a commission in the United States Army till 1861 when he joined the army of secession. The part he took in the Virginia campaign gained for him the rank of major-general, and at Gettysburg his division made a gallant record in its position at the extreme right of the Confederate line. He took part in the battle of Chickamauga on 19–20 Sept. 1863, having come to Tennessee to the support of General Bragg. When General Johnston was endeavoring in the spring of 1864 to impede Sherman's advance on Atlanta, Hood was a lieutenant-general in his army and his corps on

THE HARBOR OF HONOLULU.

25 May 1864, was attacked by Hooker at New Hope Church. He succeeded Johnston the following July in the command of the Army of Tennessee, fought the battle of Peach Creek with Sherman 20 July 1864, but was compelled to retire behind the fortifications of Atlanta. After the battle of Jonesboro he retired from Atlanta, which was entered by Sherman. His attack on the forces under Schofield at Franklin being repulsed, he proceeded to Nashville, where he met General Thomas. Thomas advanced from his entrenchments on 15 December, and a two-days' battle ensued. Federal preparation had been carefully and deliberately made. A general attack on the afternoon of 16 December caused the entire Confederate line to give way. Soon Hood's army was in full retreat toward Franklin, the larger part of it "in great confusion," according to Hood's official report. After a nine-days' pursuit by the Federals, the remnant of the Confederates, now largely disintegrated, crossed the Tennessee. Hood, at his request, was relieved of his command. Subsequent to the war he was a commission merchant at New Orleans. He wrote 'Advance and Retreat: Personal Experiences in the United States and Confederate States Armies' (1880), and articles for 'Battles and Leaders of the Civil War' (1887). Consult these works; see also NASHVILLE, CAMPAIGN AND BATTLE OF.

Hood, Robin, English outlaw: said to have been b. 1160 and d. 1247. According to the popular account, with his followers, he inhabited Sherwood Forest, in Nottinghamshire, and also the woodlands of Barnsdale in the adjoining West Riding. They supported themselves by levying toll on the wealthy, and more especially on ecclesiastics, and by hunting the deer. The principal members of his band were his lieutenant Little John, his chaplain Friar Tuck, William Scadlock, George-a-Greene, Much the miller's son, and Maid Marian. His skill with the long-bow and quarter-staff was celebrated in tradition. What basis of fact there is for the story of Robin Hood is doubtful. Grimm maintained that he was one with the Teutonic god Woden. Other theories suppose him to have been a rebel yeoman in Lancaster's rebellion under Edward II.: a Saxon chief who defied the Normans; and a fugitive follower of Sir Simon de Montfort after the battle of Evesham. He figures prominently in Scott's novel 'Ivanhoe,' and in 'The Foresters,' a drama by Tennyson. The earliest known mention of him is in 'The Vision of Piers Plowman,' version B. (about 1377), in which Sloth says he knows "rymes of Robin Hood." 'The Gest of Robin Hood' (assigned to 1400), almost epic in length, consisting of 456 four-line stanzas, is the oldest extant ballad on this theme. Others of the more important ballads are 'Robin Hood and the Monk,' 'Robin Hood and Guy of Gisborne,' and 'Robin Hood's Death.' The remaining ballads are, in general, of inferior merit. It seems probable that there were what may be called a Sherwood cycle and a Barnsdale cycle, respectively. Many proverbs and sayings exist in connection with Robin Hood. Consult: Child, 'English and Scottish Ballads' (1883); Fricke, 'Die Robin Hood Balladen' (1883); and Ritson, 'Robin Hood' (new ed. 1885).

Hood, Samuel, VISCOUNT, British naval officer: b. Thorncombe, Devonshire, 12 Dec. 1724; d. Bath, Somersetshire, 27 Jan. 1816. He entered the navy in 1740, was promoted lieutenant in 1746, commander in 1754, and post-captain in 1756. While commanding the Vestal in 1759 he took the French Bellona after a three-hours' fight. From 1767 to 1771 he was commander-in-chief in North America. Having served as commissioner of the Portsmouth dockyard in 1778–80, he was made admiral of the blue in 1780, and almost immediately was sent in command of a squadron to reinforce Rodney on the North American and West Indian stations. He remained on that duty until the signing of the peace, and distinguished himself in several battles. Despatched in 1781 to blockade Martinique, he was intercepted by De Grasse and the French fleet, against which he fought in April and in July (under Admiral Graves). Again in the West Indies in 1782, after an absence along the North American coast, he outmaneuvered De Grasse in several minor contests, and later, on 12 April, took an important part in the victory of Dominica, when he led the rear of the British line. In 1784 he was elected to Parliament for Westminster, and in 1788 made a lord of the admiralty. He took command of the British fleet in the Mediterranean in 1793, and occupied Toulon. Hood had a great reputation as a tactician, and a high tribute was paid him by Nelson, who had been one of his subordinate officers. Consult James, 'The Naval History of Great Britain' (1822–4; new ed. 1837).

Hood, Thomas, English poet and humorist: b. London 23 May 1799; d. there 3 May 1845. In 1821 he became sub-editor of the 'London Magazine,' and from that time appears to have resolved on devoting himself entirely to a literary life. In 1826 he published 'Whims and Oddities.' This was followed by 'National Tales' in prose, and a volume of serious poetry, which, though favorably received, did not obtain much popularity. In 1830 he started the 'Comic Annual,' which, during the eight years of its existence, was made the vehicle of many of his most remarkable productions. At the same time his pen was diligently employed on other subjects, and he published the powerful poem called 'Eugene Aram's Dream,' 'Tylney Hall,' a novel, which, though defective in its plan and structure, abounds in fine strokes of wit and humor. His health had begun to fail, and in consequence he lived on the Continent 1835–40. He continued his 'Comic Annual' during his residence at Coblentz and Ostend, and in 1838 published 'Hood's Own.' His continental experiences also furnished materials for his 'Up the Rhine' (1839), a series of imaginary letters after the manner of Smollett's 'Humphrey Clinker.' The whimsical cuts inserted in the work, as well as its combination of good sense and humor, made it very popular. Shortly after his return, he undertook the editorship of the 'New Monthly Magazine,' and continued it until 1843. His principal contribution to it was the famous tragi-comic story in verse of 'Miss Kilmansegg.' His last periodical, entitled 'Hood's Magazine,' was commenced in 1844. It contains some of his best productions, though several of them were written after his health had completely given way, and while he was propped up by pillows in bed. Hood is unrivaled as a punster, and seems to have been almost equal master of the comic and the pathetic. In the latter style his 'Song of the Shirt' is universally known, and as a burst of poetry and indignation is not surpassed by anything in the English language.

Hood, Thomas, generally known as TOM HOOD, English miscellaneous writer: son of the preceding: b. at Wanstead, Essex, 19 Jan. 1835; d. Peckham Rye, Surrey, 20 Nov. 1874. He was educated at Oxford in 1853, with a view to a clerical career, but edited the 'Liskeard Gazette' in 1858–9, and from 1860 till 1865 was a clerk in the accountant-general's department at the War Office. In 1865 he became editor of the comic paper called 'Fun.' His first separate publication was 'Pen and Pencil Pictures' (1857), and among his subsequent works are: 'The Daughters of King Daher, and other Poems' (1861); 'Jingles and Jokes for the Little Folks' (1865); 'Captain Masters's Children' (1865), his best novel; 'A Golden Heart' (1867); 'The Rules of Rhyme: A Practical Guide to English Versification (1869), a work which has gone through two later editions; 'From Nowhere to the North Pole' (1874). From 1867 he produced 'Tom Hood's Comic Annual.' A volume of his 'Favourite Poems,' with a memoir by his sister, Mrs. Broderip, was published in the United States in 1877.

Hood of Avalon, Arthur William Acland Hood, BARON, English naval officer: b. Somersetshire 14 July 1824; d. Glastonbury 15 Nov. 1901. After service on the coasts of Spain and of Syria, he was made lieutenant in 1846, and in 1854 commander in recognition of his services with the naval brigade before Sebastopol. Assigned to the China station, he participated in the capture of Canton (December 1857), and in 1858 received the commission of post-captain. In 1862–6 he was in command of the Pylades of the North American station, in 1866–9 of the Excellent and the Royal Naval College at Portsmouth, and in 1869–74 director of naval ordnance. He was promoted rear-admiral in 1876, was first sea lord of the admiralty in 1885–9, and became admiral in 1886. His attitude in connection with the development of the British navy was strongly conservative.

Hood, Mount, a peak of the Cascade Range, in the northern part of Wasco County, in Oregon. The height is usually given as over 11,225 feet, but the latest explorers claim it is nearly 12,000 feet. Mount Hood was at one time an active volcano; the lava is found on the slopes and some distance from its base.

Hood River, a name applied to a valley, town, and river in Wasco County, Oregon. The town is situated on the Columbia River and on the line of the Oregon Railway & Navigation Company, 66 miles east of Portland and 22 miles below The Dalles, the county-seat. The Hood River strawberry has acquired a reputation almost phenomenal, and is distributed over an immense area of country extending from Denver and Omaha on the south to Winnipeg in the province of Manitoba to the north and east. The output in 1903 was 150 carloads. The apple industry is also rapidly assuming large proportions, grades of superior excellence are produced, and the highest priced Spitzenburgs and Yellow Newtown Pippins found in the markets of New York and London were grown in Hood River. The valley proper extends south from the Columbia River to Mount Hood, some 20 miles, and is protected and cradled by the Cascade range of mountains on the west and a high divide putting out from Mount Hood on the east. The amount of land adapted for fruit culture in this unique valley exceeds 50,000 acres. The river itself drains all of the north side of Mount Hood, has a large and constant flow of water, and for the last 10 miles of its course before entering the Columbia has an average fall of over 60 feet per mile, affording 10,000 measured horse-power per mile. There are immense forests of fir and cedar about the head-waters of this stream, and one of the largest saw-mills in the State is conveniently situated near its confluence with the Columbia. The climate is a happy mean between the moist section of western Oregon and the semi-arid plains of the Columbia. The scenery is grand in the extreme and yearly attracts the attention of many visitors. The town is pleasantly situated, overlooking the Columbia River, is supplied with electric lights, while the telephone is universally present in both town and country. It is, however, the superlative excellence of its fruits that has given Hood River a reputation almost world-wide. The population of town and valley (1904) is about 6,000.

E. L. SMITH.

Hooded Crow, a crow native in northern Europe (*Corvus cornix*), so termed in allusion to markings on the head. Head, wings, and fore parts are jet black, the rest of the bird ash-gray; bill and feet are black. It retires to the southward from its more northerly haunts at the time of the crow migration. In England it is known as the gray, dun, or Royston crow. The hooded crow found in India is similar in general appearance, but is a smaller species.

Hooded Seal, a large dark-gray spotted seal of the North Atlantic, closely related to the common harbor seal, and named *Cystophora cristata*. It reaches a length of about 10 feet, and is especially distinguished by a large inflatable sac upon the face, the expansion of which is thought to be a defensive device, calculated to terrify enemies. It is occasionally seen on ice-floes along the Labrador coast.

Hooded Warbler, a fly-catching warbler (*Sylvania mitrata*), common in the southern United States in summer and making its nest in low bushes. It is bright yellow except a solidly black crown, neck and breast, comparable to a hood, leaving the face golden yellow.

Hoodoo. See MASCOT.

Hoof, a toe-nail which is large, envelops the terminal phalange, and is of material assistance in walking, as in the case of horses, cattle and other ruminants, and in the elephant, rhinoceros, etc. It is most highly developed in the horse, where the whole terminal part of the foot is reduced to a single, well-booted toe. In split-hoofed or cloven-hoofed animals there are two toes approximately equal, and booted with hoofs flat on their inner sides and closely appressed. The small non-functional toes hanging behind the hock-joint in most split-hoofed animals are often called "false hoofs." Accidents and diseases affect the hoofs of domestic animals (see FOOT-ROT, etc.), and require careful attention, especially in the case of horses. The soundness of a horse's foot is mainly preserved by permitting it to grow uninjured by the rasp and knife, and kept clean by being washed with cold water; all other aplications are injurious and destroy the toughness of the "horn surface." Softness and brittleness of the hoof, which are fruitful sources of cracks and corns, may be remedied by placing the feet for several hours daily in thick woolen swabs, kept cool and moist by frequent applications of cold water, and by encouraging a more healthy growth of horn by occasional mild blisters round the coronary band. Cracks (or sand-cracks) mostly occur among horses much upon the road, cause lameness, and constitute unsoundness. When serious and recent, poulticing, thinning away of the crust about the crack, and perfect rest are essential. After the earlier heat and tenderness are removed a hot iron should be drawn at right angles to the crack, both above and below, so as to separate the diseased from the sound horn. Waxed thread or fine wire should be wound round the hoof, and a sound growth of horn stimulated by a blister round the coronet.

Hooft, Pieter Corneliszoon, pē-tĕr kor-nā'-lēs-zōn hōft, Dutch poet and historian: b. Amsterdam 26 March 1581; d. The Hague 21 May 1647. He was son of that Cornelius Hooft who did much to procure Elizabeth's recall of the incompetent and tyrannical Leicester in 1587. He traveled through France, Italy, and Germany in 1601, and on his return began with patriotic ardor to improve and purge the speech of his mother country. With this aim in view he translated Tacitus into Dutch, and made that Latin writer the model of his style, as a historian. His historical writings are vivid and comprehensive. His poems are chiefly in the erotic vein. He also produced dramas in the form of pastoral, tragedy, and comedy. In his comedies the domestic life of the Netherlands is admirably portrayed. In the castle of Moritz, Prince of Orange, at Muiden, where he lived as high bailiff, he used to gather round him a coterie of brilliant men and women, and this intellectual circle famous as the "Muiderkring" included the poets Huygens, Vondel, and Baerle. His principal works are 'Hendrik (IV.) de Grote zijn leven en bedrijf' (1671); 'Nederlandsche Historien' (1656); the poems 'Minneliederen'; 'Afbeeldinglien van Minne'; the pastoral drama 'Granida' (1605); the tragedies 'Geraerdt van Velzen' (1813); and 'Baeto' (1616); and the comedy 'Warenar.'

Hook, Theodore Edward, English novelist and journalist: b. London 22 Sept. 1788; d. 24 Aug. 1841. For some years Hook led a life of gaiety in London, and became notorious for practical jokes and similar escapades. In 1812 he was appointed accountant-general and treasurer of the island of Mauritius; but, owing to his gross carelessness, a large deficiency in the military chest was discovered, and in 1818 he was sent home under arrest, but no proceedings were taken against him. From 1820 to 1841 he was editor of the 'John Bull,' and at intervals from 1824 to 1828 published his 'Sayings and Doings,' while in 1836 he became editor of the 'New Monthly Magazine.' His other principal works are a series of novels, among which may be mentioned 'Love and Pride'; 'Jack Brag'; 'Gilbert Gurney'; 'Gurney Married.'

Hooker, hŭk'ĕr, **Edward**, American sailor: b. Farmington, Conn., 1822; d. Brooklyn, N. Y., 1 May 1903. He followed the sea in the merchant service until the outbreak of the Civil War when he joined the United States navy as acting master, and served with distinguished bravery. He was commissioned as lieutenant-commander in the regular naval service in 1884 and full commander two years later, when he retired.

Hooker, Isabella Beecher, American philanthropist: b. Litchfield, Conn., 22 Feb. 1822; d. 25 Jan. 1907. She was a daughter of Dr. Lyman Beecher (q.v.) and in 1841 married Joseph Hooker, a lawyer. She made a special study of the right of women of the United States to vote; was active in various reform movements, and is known as a public speaker. She wrote 'Womanhood, Its Sanctities and Fidelities.'

Hooker, Joseph, American soldier: b. Hadley, Mass., 13 Nov. 1814; d. Garden City, N. Y., 31 Oct. 1879. He was graduated at West Point in 1837 and received a commission in the 1st artillery. He served in Florida and on the northeast frontier 1837–40 and during the Mexican War was aide to Generals Smith, Harmer, Butler and Pillow. He saw much service in both the northern and southern campaigns, and resigned from the army in 1853. From that date to the breaking out of the Civil War he was successively farmer, engineer and militia colonel. In 1861 he went to the front as a brigadier-general of volunteers. In 1862 he was commissioned major-general of volunteers and was present at the battle of Williamsburg, Va., and was subsequently conspicuous in the Peninsular campaign and in the battles of Bristoe Station and Chantilly. He also took part in the Maryland campaign, and in September of 1862 was appointed brigadier-general in the regular army. Two months later he was placed in command of the Fifth corps, and at the battle of Fredericksburg commanded the Third and Fifth corps. In 1863 he was put in command of the Army of the Potomac, but although very successful in refitting and reorganizing his troops, failed to show, as head of an army, those qualities which had characterized him in the field as corps and division commander. At Chancellorsville the defeat of the Federal troops by General Jackson was largely due to Hooker's vacillation and his want of power to cope with the sudden surprise of his right flank by the Confederate general.

In 1863 he was despatched in command of the Army of the Cumberland to reinforce Rosecrans at Chattanooga and distinguished himself on 24 November in the so-called "Battle among the Clouds" on Lookout Mountain. He was brevetted major-general in the regular army in 1865, and a paralytic stroke forced him to retire from active service with that rank in 1868.

An equestrian statue of General Joseph Hooker by the sculptor French, was unveiled on Beacon Hill, Boston, 25 June 1903, with imposing ceremonies. The day was made a State holiday.

Hooker, Sir Joseph Dalton, English botanist; son of Sir William Jackson Hooker (q.v.)

b. Halesworth, Suffolk, 30 June 1817. He was educated at the University of Glasgow, accompanied Sir James Clark Ross's Antarctic expedition of 1839–43 as assistant-surgeon and naturalist, and in 1847 published an account of its botanical results in two volumes, entitled 'The Botany of the Antarctic Voyage of H.M. Discovery Ships Erebus and Terror in the years 1839–43.' He went to India in 1847, in order to investigate the botany of part of the Himalayan region, and in 1854, three years after his return issued his 'Himalayan Journals, or Notes of a Naturalist in Bengal, the Sikkim and Nepal Himalayas, the Khasia Mountains,' etc. In his work on the 'Rhododendrons of the Sikkim Himalaya' (1849), he first introduced to the notice of European gardeners many splendid and now familiar species of these favorite shrubs. In 1871 he set sail for Morocco, and in May of that year he and his companions reached the summits of the Great Atlas, which till then had never been trodden by any European foot. A record of this journey is contained in the work written with John Ball, 'Journal of a Tour in Morocco and the Great Atlas' (1879). He traveled in the Rocky Mountains and California in 1877. In 1855 was appointed assistant to his father in the directorship of Kew Gardens, and on his father's death in 1865, succeeded him as director. He retired in 1885. He was president of the Royal Society during the five years 1873–8. Among his other works are: 'Introductory Essay to the Flora of New Zealand' (1853); 'Introductory Essay to the Flora of Indica' (1855); 'Flora Novæ Zealandæ' (1853–5); 'Flora of Tasmania' (1856–60); 'The Flora of Australia: its Origin, Affinities, Distribution, etc.' (1859); 'Genera Plantarum' (1862–83), with George Bentham, an epoch-making revision of the natural system of classification; 'The Student's Flora of the British Islands' (1870; new ed. 1883), an excellent and popular work; 'The Distribution of the North American Flora' (1878); and the great 'Flora of British India' (1875–97).

Hooker, Richard, English theologian: b. Heavitree, near Exeter, March 1554; d. Bishopsbourne, 2 Nov. 1600. He was educated at Oxford. In 1581 he took orders, and was shortly after made preacher at St. Paul's Cross, in London. In 1584 he became rector of Drayton Beauchamp, Buckinghamshire. The following year he was appointed by Archbishop Whitgift Master of the Temple for life. Here he became engaged in a controversy with his colleague Walter Travers, whose sympathies were strongly puritanical, and to this controversy we owe his celebrated work 'Of the Laws of Ecclesiastical Polity.' The first four books were printed in 1594. The fifth book of his great work appeared in 1597; the last three in 1600. 'The Ecclesiastical Polity' written in defense of the Church of England, is no less remarkable for learning and extent of research than for the richness and purity of its style, which entitles its author to be regarded as one of the classics of the Elizabethan age. See Lives by Walton, and Keble.

Hooker, Thomas, American colonial clergyman: b. Markfield, Leicestershire, England, probably 7 July 1586; d. Hartford, Conn., 7 July 1647. After being graduated at Cambridge he took orders, preached in London, and was chosen lecturer at Chelmsford in 1626. Having been silenced by Laud for nonconformity, he established a grammar school, and about 1630 went to Holland, where he preached at Delft and Rotterdam. In 1633 he came to New England with Cotton and Stone, and was settled with the latter at Newtown, now Cambridge, being ordained by the brethren of the church. In 1636 he removed with about 100 others to what is now Hartford, Conn., where he and Stone were the first ministers of the church. He was a remarkably animated and able preacher, of commanding presence and earnest zeal, and he has been called the Luther of New England. It was his custom to preach without notes. Some 200 of his sermons were sent to England, where about half of them were published. His most celebrated work, 'A Survey of the Summe of Church Discipline,' written with John Cotton, was published in England (1648). Many of his works have gone through repeated editions. See Walker, 'Life of Hooker' (1891).

Hooker, Sir William Jackson, English botanist: b. Norwich 1785; d. 12 Aug. 1865. He applied himself to the study of botany at an early age, and in search of botanical specimens visited Scotland and the Scottish islands, France, Switzerland, and Iceland. His investigations on the British 'Jungermanniæ and Mosses' drew attention to his attainments, and he was elected to the chair of botany in the University of Glasgow, a position he filled for 20 years. In 1836 he was knighted, and in 1841 was appointed director of the Royal Gardens at Kew, a post which he held up to the time of his death. Under his management these gardens increased their area from 11 acres to 270. They are well laid out, and contain hot-houses and conservatories far superior to anything of the kind on the Continent, and include museums filled with objects derived from the vegetable kingdom, botanical libraries, and a most extensive and excellently arranged herbarium. Among his works may be mentioned 'Tour in Iceland' (1811); 'The British Flora'; 'Flora Boreali-Americana'; 'Illustrations of the Genera of Ferns, Icones Plantarum'; 'British Ferns'; etc.

Hooker, Mount, Canada, a peak in the Rocky Mountains; 15,690 feet high; near the eastern boundary of British Columbia.

Hoonoomaun, hoo'noo-män. See Entellus Monkey.

Hoop Ash. The black or water ash (*Fraxinus nigra*). See Ash.

Hooper, hûp'ėr, **John,** English reformer and martyr: b. Somersetshire, about 1495; d. Gloucester 9 Feb. 1555. He embraced the principles of the Reformation and in 1539, to avoid the persecution consequent on refusing to sign the new articles of faith put forth by Henry VIII., withdrew to the Continent. On the accession of Edward VI., in 1547, he went to London, and contributed greatly to the progress of the Reformation. In 1550 he was nominated bishop of Gloucester. On the accession of Mary, in 1553, he was one of the first victims fixed upon, and being imprisoned in the Fleet, was treated with great severity. In 1555 he was required formally to recant his opinions. This he refused to do and was burned at the stake near his own cathedral. His works consist chiefly of a 'Godly Confession and Protestation of the Christian Faith'; 'Lectures on the Creed'; 'Sermons on the Book of Jonah'; 'Annotations on the Thirteenth Chapter of the Romans.'

Hooper, William, American patriot: one of the signers of the Declaration of Independence: b. Boston, Mass., 17 June 1742; d. Hillsboro, N. C., October 1790. He was graduated at Harvard College in 1760, studied law with James Otis in Boston, and removed permanently to Wilmington, N. C., in 1767, where he soon rose to professional eminence and was noted for his social qualities and hospitality. He was delegated to the Continental Congress in 1775, and was till his death a leader in the councils of North Carolina.

Hoopeston, hoops'tŏn, Ill., city in Vermilion County; on the Lake Erie & W. and the Chicago & E. I. R.R's.; about 85 miles south ot Chicago and 48 miles south by east of Kankakee. It is situated in an agricultural region, and its chief industries are connected with agricultural products. It has large sweet-corn canning establishments, and factories for making the cans and the canning machinery. There are manufactured other canned goods, also horsehoe nails and agricultural implements. Grain and hay are shipped to the larger markets. The government, in accordance with the charter of 1877, is vested in a mayor who serves for two years and in a city council. The city owns and operates the waterworks. Pop. (1890) 1,911; (1900) 3,823.

Hooping-cough, a series of coughs ending in a long-drawn breath, during which a shrill whistling sound, the hoop, is produced. Several fits of coughing succeed one another, until some phlegm or mucus is expelled. Vomiting not infrequently follows a fit of coughing. It has recently been discovered that the cause of the complaint is a poison acting as an irritant on the pneumogastric nerve. Hooping-cough is contagious, and most commonly attacks children, generally but once in their lives. The first symptoms are a difficulty of breathing, and other slight febrile affections, which are succeeded by hoarseness, cough, and difficulty of expectoration. After a fortnight or more the cough becomes convulsive, and is attended by the hoop. In four or five weeks the expectoration becomes loose, and the fits of coughing gradually diminish in frequency and duration. Hooping-cough is seldom fatal to adults, but is most fatal in the first year of childhood. Bronchitis and pneumonia are the most serious complications.

Hoopoe, hoo'pō, a peculiar bird of the Old World, which takes both its vernacular and scientific name (*Upupa*) from its whooping cry. It is of the group *Coccygomorphæ* (q.v.) and represents a family (*Upupidæ*), many species of which inhabit southern Asia and Africa, while one (*U. epops*) is a well known migrant in Europe. It is about 12 inches long, is brown above and white beneath, with black, white-barred wings, and a very large cinnamon-red black-tipped crest and a long, sharp, curved bill. It seeks its food on the ground, nests in holes in trees, crannies in walls, etc., and has many curious traits and habits which have caused the bird to take a prominent place in the folk-lore of all countries. The African hoopoes belong to the genus *Irrisor*, and are called wood-hoopoes. They have brilliant plumage, but no crest. They go about in noisy flocks, and have much the appearance and habits of woodpeckers.

Hoorn, hōrn, or **Hoorne,** hōr'nė, or **Horn,** or **Hornes,** ŏrn, Count of (Philip II., De Montmorency-Nivelle): Flemish soldier and statesman: b. about 1520; d. Brussels 5 June 1568. His father was a descendant of the French family of Montmorency, and on the mother's side he was related to Lamoral Egmont, with whose fate his own was linked. His mother becoming a widow when he was about eight, was married again to John, Count van Horn, one of the wealthiest nobles of the Netherlands, who, left his estates to his wife's children on condition that they should assume his name. Philip was thus at the outset of his career one of the most influential of his order, and received from Charles V. and Philip II. important trusts and distinctions. He accompanied Philip II. to Spain, where he is supposed to have received information of the designs of the Spanish court against the Netherlands, and to have communicated them to the Prince of Orange. Returning to the Netherlands he joined Orange and Egmont in resisting the aggressive policy of Philip; yet continued loyal to the crown. He was, however, suspected by the Spanish court, and upon the arrival of Alva in Brussels was enticed with Egmont to that city, and arrested in September 1567, on a charge of high treason. Ceaseless but vain efforts were made to obtain for him a fair trial, and appeals for clemency on his behalf were made by potentates in all parts of the Continent. He was executed with Egmont in June 1568.

Hoosac (hoo'sak) **Mountain,** the name given to a spur of the Green Mountains (q.v.) which is in the northwestern part of Massachusetts, on the east side of the valley of the Hoosac River. The whole length is about 16 miles. The mountain is noted for its beautiful scenery.

Hoosac Tunnel, in the towns of Adams and Florida, in Berkshire County, in Massachusetts, and piercing the Hoosac Mountain. It is on what is now known as the Boston and Maine railroad, the route from Boston to Troy, N. Y., by way of Greenfield. From the west entrance of the tunnel to Troy is 54 miles; from the east entrance to Boston, 137 miles. The tunnel is nearly five miles in length, the longest tunnel in the United States. Before the general introduction of railroads, and, as early as 1825, the project was broached of making a canal across Massachusetts from Boston to the Hudson River. This plan was abandoned when railroads were built across the State. In 1851 the tunnel question had advanced so far that surveys of various routes were made and some experiments were begun. The work of tunneling began in 1856 and was completed in 1873. For so long a tunnel the ventilation is good owing to the shaft, 1028 feet, sunk near the centre. The width is sufficient for two tracks. The total cost, including 39 miles of adjoining railroad, was about $13,000,000.

Hoo'sic Falls, N. Y., village in Rensselaer County; on the Hoosac River and on the Boston & M. railroad; about 28 miles northeast of Albany. The first permanent settlement was made in 1688, and the first charter was received in 1827. The charter has been revised and the last revision was in 1890. The village has excellent water-power. The chief manufactures are agricultural implements, paper and paper-making machinery, shirts, cotton and woolen goods, and flour. The government of the village is vested in a president who holds office three years, and a board of trustees. Pop. (1890) 7,014; (1900) 5,071.

Hoosier (hoo'zhėr) **Schoolmaster, The,** a story by Edward Eggleston (q.v.) published in 1875, and the most popular of its author's works. It is descriptive of the life of the Middle West in the pioneer days of the early 19th century.

Hoosier State, a popular name for Indiana. The word is said to be a corruption of "husher," formerly a colloquial name for a fighter or a bully.

Hop-hornbeam. See IRON-WOOD.

Hopatcong, hō-păt'kŏng, **Lake,** in Sussex County, New Jersey; about 33 miles northwest of Jersey City and 25 miles west of Paterson. The lake is 725 feet above the sea, and eight and one-half miles long and three and one-half miles wide. Its outlet is the Musconetcong River which flows into the Delaware. Lake Hopatcong is a favorite summer resort, its beautiful scenery is one attraction. It is surrounded by hills and low mountains, all well wooded, and many of the trees are evergreens.

Hope, Anthony. See HAWKINS, ANTHONY HOPE.

Hope, Ascott R. See MONCRIEFF.

Hope College, in Holland, Mich., a coeducational institution, founded in 1866, by Dutch settlers, and under the auspices of the Reformed Church in America. At the close of 1902 there were connected with the school 14 instructors and 200 students.

Hope Diamond, a famous blue diamond weighing 44¼ carats, in possession of the family of H. T. Hope, of England, until 1903, when it was sold to an American.

Hope'dale, the name of a community founded by Rev. Adin Ballou, in 1841, at Milford, in Worcester County, Mass. At the beginning there were 28 persons who wished to lead lives in accordance with high ideals of Christianity. They formed themselves into a joint-stock company, purchased a farm of 238 acres, established a settlement, and proceeded to cultivate the soil, and to manufacture their own breadstuffs and clothing. At first a board of trustees were the chief governing power and had entire control of the industries. Later more responsibilities were given to the members, and the industries were, in different ways, apportioned among them. In 1854 there were 200 members; but the community had become a financial failure and dissensions had crept in. In 1856 they were in debt, and as a joint-stock company they disbanded; but continued as a semi-communistic community until about 1862, when they gave up the industries they had established to private individuals, and formed themselves into Hopedale Parish with their founder as pastor. Consult: Adin Ballou, 'Hopedale Community.'

Hop'kins, Alphonso Alvah, American author and lecturer: b. Burlington Flats, N. Y., 27 March 1843. He was for three years professor in the American Temperance University; from 1867–86 was editor of three agricultural papers successively. Since 1868 he has lectured on temperance and other social and political subjects; in 1882 he was the prohibition candidate for governor of New York. He has written 'Geraldine, a Romance in Verse,' a popular poem in the style of Owen Meredith's 'Lucille' (1881); 'His Prison Bars' (1878); 'Sinner and Saint' (1880); 'Wealth and Waste' (1896); 'Ballads of Brotherhood' (1900).

Hopkins, Edward, American colonial governor: b. England 1600; d. London March 1657. He was a prominent merchant of London, and came to Boston in 1637, but soon after removed to Hartford, where he was chosen a magistrate in 1639, and governor of the colony of Connecticut every other year from 1640 to 1654, alternating with Haynes. He afterward went back to England, where he was chosen warden of the English fleet, commissioner of the admiralty and navy, and member of Parliament. But he never lost his interest in the colonies, and at his death bequeathed much of his estate to New England, giving £1,000 for the support of grammar schools in Hartford and New Haven, which are still flourishing, and £500 which went to Harvard College and the grammar school at Cambridge.

Hopkins, Edward Washburn, American philologist: b. Northampton, Mass., 8 Sept. 1857. He was graduated from Columbia in 1878, and going to Germany to study took the degree of Ph.D. at the University of Leipsic. In 1895 he became professor of comparative philology and Sanskrit at Yale. He has written 'Caste in Ancient India' (1881); 'Manu's Lawbook' (1884); 'Religions of India' (1895); 'The Great Epic of India' (1901); and 'India Old and New' (1901).

Hopkins, Esek, first commodore of the American navy: b. Scituate, R. I., 1718; d. North Providence, R. I., 26 Feb. 1802. In November 1775 he received a commission from the Continental Congress as commodore and "commander-in-chief" of the navy, soon after which he put to sea with the first squadron sent out by the colonies. The fleet sailed for the Bahama islands, and captured the forts at New Providence, and with them 80 cannon, and a large quantity of ordnance, stores, and ammunition. On his return, when off Block Island, the commodore took the British schooner Hawke and the bomb brig Bolton. For this act the president of congress complimented Hopkins officially. Commodore, or Admiral Hopkins, as he was generally called (even by Washington, who so addressed him in his official letters), performed other remarkable exploits, though he had great difficulties to contend with. His name became a synonym for heroism, and for American patriotism. In June 1776, Hopkins was ordered by Congress to appear before the naval committee in Philadelphia to reply to charges which had been preferred against him for not annoying the enemy's ships on the southern coast. He was defended by John Adams, and was acquitted. The unavoidable delays at a later period in getting his ships ready for sea gave another chance for his enemies to complain; and neglecting a citation to appear at Philadelphia, because no specific charges were made against him, and on account of his general disgust at the conduct of his opponents, he was dismissed the service, 2 Jan. 1777. He resided near Providence, and exerted during a long life a great political influence in Rhode Island, being often elected to the general assembly of that State. Consult Field, 'Esek Hopkins' (1898).

Hopkins, John Henry, American Protestant Episcopal bishop: b. Dublin, Ireland, 30 Jan. 1792; d. Rock Point near Burlington, Vt., 9 Jan. 1868. At the age of eight, he was brought to America, his father settling in Philadelphia. He became a successful member of the bar in Pittsburg, where his interest in church work was so earnest that the vestry of Trinity Church unanimously elected him rector of the parish though he was not even a candidate for orders. He accepted the call, was ordained in 1823, and remained in Pittsburg until 1831, when he went to Trinity Church, Boston, as assistant, and became at the same time professor of systematic divinity in a theological school. He was consecrated bishop of Vermont in 1832 and combined with the episcopate the rectorship of St. Paul's Church, Burlington. Though at the head of a small diocese, he exerted a widespread influence as a learned theologian and a controversialist of uncompromising bravery and great versatility. He is said to have been the first to suggest the idea out of which grew the important Lambeth Conferences of the entire Anglican Communion, and it is unquestionably to his prudent and charitable efforts that the happy reunion of the northern and southern dioceses after the Civil War was largely due. Besides controversial works, which at the time had great effect, he published 'The Primitive Creed' (1834); 'The Primitive Church' (1835); 'The American Citizen' (1857); and 'The Law of Ritualism' (1866). See 'Life of Bishop Hopkins by One of his Sons' (1873).

Hopkins, Johns, American financier and philanthropist: b. Anne Arundel County, Md., 19 May 1795; d. Baltimore 24 Dec. 1873. His parents, Quakers, gave him a fair education and the training of a farmer. At 17 he went to Baltimore, there became a grocer, and in 1822 founded the house of Hopkins & Brothers. He built up a trade in Maryland, Virginia, and North Carolina, having practically a monopoly in his line. His credit and counsel were highly valued in financial and mercantile affairs. He retired in 1847 with a large fortune, which he employed in banking and railway operations. In 1873 he gave property worth $4,500,000 to found a free hospital; he presented Baltimore with a public park, and also gave over $3,000,000 to found the Johns Hopkins University in Baltimore.

Hopkins, Lemuel, American physician and political writer: b. Waterbury, Conn., 19 June 1750; d. Hartford, Conn., 14 April 1801. He practised medicine at Litchfield 1776–84, when he removed to Hartford, where he sustained a high reputation, and had an extensive practice till his death. He was singular in his appearance, manners, and opinions; a man of talents and learning, and also a poet. He was associated with Trumbull, Barlow, Alsop, Theodore Dwight, and others (called the "Hartford wits"), in the 'Anarchiad,' the 'Echo,' 'Political Greenhouse,' the 'Guillotine,' and similar satirical compositions; and is said to have written for Barlow the beautiful and well known version of the 137th psalm beginning, "Along the Banks where Babel's Current Flows."

Hopkins, Margaret Sutton Briscoe, American author: b. Baltimore 7 Dec. 1864. She married Prof. A. J. Hopkins of Amherst College, and has been engaged in literary work since 1890. She has written under the pen name of "Margaret Sutton Briscoe" 'Perchance to Dream and Other Stories' (1892); 'Links in a Chain' (1893); 'Jimty and Others' (1898); 'The Sixth Sense and Other Stories' (1899).

Hopkins, Mark, American college president: b. Stockbridge, Mass., 4 Feb. 1802; d. Williamstown, Mass., 17 June 1887. He was graduated at Williams College, Mass., in 1824, and having filled a tutorship in the college two years received in 1828 the degree of M. D., and in the same year commenced the practice of medicine in New York. In 1830 he was recalled to Williams College to fill the chair of moral philosophy and rhetoric, and in 1836 became president of the college, a position which he held till 1872. In addition to his labors as an instructor, he lectured before the Lowell Institute of Boston, the Smithsonian Institution, and various scientific and literary associations. Presiding over a college which has been called the cradle of foreign missions, he took an active part in the deliberations of the American board of commissioners for foreign missions, of which he was president from 1857. He published 'Lectures on the Evidences of Christianity' (1846); 'Miscellaneous Essays and Discourses' (1847); 'Lectures on Moral Science' (1862); 'The Law of Love and Love as Law' (1869); 'Outline Study of Man' (1873); 'Scriptural Idea of Man' (1883); 'Teachings and Counsels' (1884). See Carter, 'Life of Mark Hopkins' (1892).

Hopkins, Pauline Bradford Mackie, American novelist: b. Fairfield, Conn., 1874. In 1899 she married H. M. Hopkins; she has been in literary work since 1896. Her works include 'Mademoiselle de Berny, a Story of Valley Forge' (1897); 'Ye Lyttle Salem Maide, a Story of Witchcraft' (1898); 'A Georgian Actress, an Historical Romance' (1900).

Hopkins, Samuel, American Congregational clergyman: b. Waterbury, Conn., 17 Sept. 1721; d. Newport, R. I., 20 Dec. 1803. He was graduated at Yale College in 1741, studied theology under Jonathan Edwards (q.v.), and in 1743 was ordained at Housatonic, now Great Barrington, Mass., where he continued until 1769, when he removed to Newport, R. I., and was pastor there till his death. He possessed almost incredible powers of application, and is said to have been sometimes engaged during 18 hours of the day in his studies. He published 'Dialogue, Showing it to be the Duty and Interest of the American States to Emancipate all their African Slaves' (1776); 'System of Doctrines Contained in Divine Revelation, Explained and Defended' (1793); etc. His theological opinions gave rise to the famous Hopkinsian Controversy. Hopkins differs from orthodox Calvinism in his opposition to the doctrines of original sin and of the atonement; moreover, he put particular stress on the virtue of altruism and unselfishness, even claiming that selfishness, of whatever nature, was inherently and essentially sinful. Consult: West, 'Life of Hopkins' (1805); Park, 'Memoir' (1852). See also Mrs. Stowe's novel, 'The Minister's Wooing,' in which Hopkins is the central figure.

Hopkins, Stephen, American statesman; a signer of the Declaration of Independence: b. Scituate, R. I., 7 March 1707; d. Providence 13 July 1785. In 1733 at Providence he was elected a member of the general assembly, and in 1739 became chief justice of the court of common pleas. In 1755 he was elected governor of the State, and remained in office, with the exception of four years, until 1768. In 1754 he was appointed a member of the board of commissioners assembled at Albany, N. Y., to concert a plan of union for the colonies. In 1765 he was elected chairman of a committee appointed at a special town meeting held in Providence to draft instructions to the general assembly on the stamp act. In August 1774, he was, with Samuel Ward, elected to represent the State in the general Congress held at Philadelphia, and was also chosen in 1775 and 1776. On the naval committee he was placed next after John Hancock, the chairman, and greatly assisted in the formation of a navy. For 50 years he filled some public station; he was for many years chancellor of Brown University. In 1765 he commenced a 'History of the Planting and Growth of Providence,' published in the 'Providence Gazette.' In the same year he published 'The Rights of the Colonies Examined,' which was reprinted in London.

Hopkins, Tighe, English author: b. 8 Dec. 1856. He is a frequent contributor to English and American periodicals and among his numerous works are ''Twixt Love and Duty' (1886); 'For Freedom' (1888); 'Dungeons of Old Paris' (1898); 'An Idler in Old France' (1889); 'The Man in the Iron Mask' (1901).

Hop'kinson, Francis, American jurist; one of the signers of the Declaration of Independence: b. Philadelphia 21 Sept. 1737; d. there 9 May 1791. He was graduated at the College of Philadelphia (now the University of Pennsylvania), having been the first student who entered that institution at its opening, and afterward studied law. In 1776 he was sent from New Jersey as one of her representatives in Congress. During the Revolution he distinguished himself by satirical and political writings, which attained such popularity that it has been said that few pens effected more than Hopkinson's in educating the American people for political independence. He also ridiculed in prose and verse most of the social follies of his time. In 1779 he was made judge of the admiralty of Pennsylvania, which office he held for ten years, until the organization of the federal government, when it expired. As soon, however, as Washington became President of the United States, he addressed to Hopkinson a letter enclosing a commission as United States district judge for Pennsylvania. He was skilled in painting and music, composing highly popular airs for his own songs. Of his political writings the most prominent were: 'The Pretty Story' (1774); 'The Prophecy' (1776); 'The Political Catechism' (1777). The best known of his poems are: 'The Battle of the Kegs,' a humorous ballad, and 'The New Roof, a Song for Federal Mechanics.' The 'Miscellaneous Essays and Occasional Writings of Francis Hopkinson' were published in 1792.

Hopkinson, Joseph, American jurist and poet: b. Philadelphia 12 Nov. 1770; d. there 15 Jan. 1842. He was a son of Francis Hopkinson (q.v.). He was educated at the University of Pennsylvania, studied law, and began to practise at Easton, Pa., in 1791, whence he returned to Philadelphia. From 1815 to 1819 he was a member of the House of Representatives from Philadelphia. He opposed the recharter of the United States bank, and made a noted speech on the Seminole war. At the close of 1819 he retired from Congress, declining a re-election. Having gone to Bordentown to reside, he was elected to the legislature of New Jersey. In 1828 he was appointed judge of the United States court for the eastern district of Pennsylvania, an office which had been filled by his father under Washington. In 1837 he was chairman of the judiciary committee of the convention to revise the constitution of Pennsylvania. He is, however, best known as the author of the national song 'Hail Columbia,' written in 1798 for the benefit of an actor named Fox.

Hop'kinsville, Ky., city and county-seat of Christian County, on the Louisville and Nashville, and the Ohio Valley R.R.'s. Here are Bethel Female and Southern Kentucky colleges, Western Kentucky insane asylum, and manufactures of tobacco, lime, brick, wagons, and carriages, a national bank and the Hopkinsville high school. The city has an assessed property valuation of over $2,000,000. Pop. (1900) 7,280.

Hop'per, De Wolf, American actor: b. New York 1858. He made his first professional appearance in 'Our Boys' (1878), and later appeared in 'Hazel Kirke' and other plays. He studied vocal music for several years and became a star in comic opera and musical comedy.

Hopper, Isaac Tatem, American philanthropist: b. Deptford, N. J., 3 Dec. 1771; d. New York 7 May 1852. He was a member of the Society of Friends, and in the division which took place in 1827–8, joined the anti-orthodox or "Hicksite" branch. In 1829–41 he was director of a New York shop for the sale of Hicksite books, in 1841–5 was treasurer and book-agent of the Anti-Slavery Society, and from 1845 devoted his efforts to the work of the New York Prison Association. He was widely known for his interest in benevolent objects, especially negro emancipation and the assistance of discharged prisoners. At Philadelphia he was a founder and the secretary of a society for the employment of the poor, teacher in a colored school, and otherwise interested in philanthropic measures. He was an eloquent speaker. Consult the 'Life' by Child (1853).

Hop'pin, James Mason, American scholar and author: b. Providence, R. I., 17 Jan. 1820. He was graduated from Yale in 1840, studied law at the Harvard law school (1841–2), theology at the Union and Andover seminaries (1843–5) and the University of Berlin (1847–9), was ordained to the Congregational ministry in 1850, and was pastor at Salem, Mass., in 1850–9. In 1861–79 he was professor of homiletics at Yale, in 1861–3 also pastor of the College church, and from 1879 until his retirement as professor emeritus in 1899 professor of the history of art. His publications include 'Notes of a Theological Student' (1854); 'Old England: Its Art, Scenery, and People' (1867); 'The Office, and Work of the Christian Ministry' (1869); 'Homiletics' (1881); 'Pastoral Theology' (1889); 'The Early Renaissance' (1892); and 'Greek Art on Greek Soil' (1897).

Hoppner, hŏp'nėr, **John**, English portrait painter: b. London 4 April 1758; d. 23 Jan. 1810. He entered the schools of the Royal Academy in 1775; and became a fashionable portrait painter and the rival of Lawrence. He was a member of the Royal Academy in 1795. His paintings have suffered from his use of bad mediums; but his repute has risen, and in 1896 a portrait by him was sold for 1,800 guineas.

Hopps, John Page, English Unitarian clergyman: b. London 6 Nov. 1834. He was educated at the Baptist College in Leicester, and first entered the Baptist minstry. Becoming a Unitarian, he held pastorates in Unitarian churches in Sheffield, Dukinfield, Glasgow, Leicester, and Croydon. He was a member of the first school board of the city of Glasgow. He was proprietor and editor of 'The Truthseeker,' 1863–87, and became editor of 'The Coming Day' in 1891; he has written 'Pilgrim Songs'; 'A Scientific Basis of Belief in a Future Life'; 'The Alleged Prophecies concerning Jesus Christ in the Old Testament'; 'The Plain Truth about the Bible'; 'First Principles of Religion and Morality.'

Hops (*Humulus lupulus*) are a climbing plant, often met with in the wild state in northern Europe and in North America. The hop belongs to the hemp family (*Cannabinaceæ*) and it is the sole representative of its genus, but is cultivated in many varieties. It is a diœcious plant, that is, the pistillate (female) and staminate (male) infloresence is borne by different plants. In American and English hop-gardens it is customary to grow a sprinkling of male plants, but these are rigorously excluded on the Continent. In the former case the pistillate inflorescence becomes impregnated and forms seeds, in the latter they do not. In good hops the seeds are scarce, small, shrunken and sterile, that is incapable of propagating the plant. Many believe that the formation of seed ought to be prevented, as the seeds are useless to the brewer, the main consumer of hops, and besides they only add weight to the hops. Hop-plants are not raised from seeds, but are propagated by cutting off and transplanting portions of the underground stem or root. Only the pistillate plant is cultivated, because its ripe flower is the part of the hop-plant used in brewing. It has been introduced into Brazil, Australia and the Himalayas.

The hop is a perennial herbaceous plant, which produces each year several long twisting, striated stems, 15 to 20 feet in length, which clamber over hedges, brush, etc., with ease. The leaves are stalked, opposite, three to five lobed, and coarsely serrate. They are, like the stem, rough to the touch. The male inflorescence forms a panicle; the flowers enclose five stamens in a small greenish five-parted perianth. At an early stage the female inflorescence is less conspicuous. The strobile or catkin consists of several small acute bracts or leaves at whose base are situated two sessile ovaries, each subtended by a rounded bractlet. These bracts are attached to the extremity of the stem in such a way as to form a cone, and are shaped similar to roofing tiles, being one half to three quarters of an inch long.

The ovary and the base of the bracts are covered with a yellowish powder, the "hop-meal" or lupulin, which is the active principle of the plant.

Only a very slight amount of hops is used in medicine, being chiefly employed as a stomachic in dyspepsia; a pillow stuffed with hops is said to induce sleep. Nevertheless by far the largest portion of the hops produced is used in the manufacture of various beers, so that here this subject is treated with that idea in view.

The pistillate plant alone is cultivated, because hop growers on the Continent, especially Germany and Austria, find that unfertilized pistillate plants produce strobiles richer in aroma, more plenteous in lupulin, and in general better than where the plants were fertilized through the pollen of the staminate plant. In the United States we always find the strobiles containing much seed, while the choice imported Bohemian and Bavarian hops are seedless. The pistillate plant flowers in August, and its strobiles are ready for harvesting during September.

The continental European growers always strive to have early, medium and late hops, so that there the hop-picking begins late in August and lasts through the early part of October. In the United States the picking is usually over in two weeks. The time at which the strobile is fit to pick is indicated by the change of color from a light golden to a somewhat deeper hue, also by the closing up at the tips and making a rustling sound when touched. The seeds should be firm and dark in appearance before the hops are gathered. Much loss can occur by too early picking, while too late harvesting is also detrimental to the value and quality of the product.

For about 1,000 years hops have been added to beer or wort, in former times to prevent its spoiling and also to give it its pleasant and characteristic flavor and aroma; and its cultivation has progressed as the manufacture of beer became more widespread. Germany and England had hop gardens in the 8th and 9th centuries, but the cultivation was not rationalized until the 16th century, and at the present is a very important agricultural product.

Abroad the finest hops are raised in Bohemia, its "Saazer" hops being known throughout the world. Next to this ranks the Bavarian "Spalter hops," and the product of the so-called "Hallertau." As a rule the Bavarian hop is stronger than the Bohemian, but somewhat inferior in quality. Würtemberg, Saxony, Baden, Prussia and Alsace also raise a good quality of hops; and Belgium, northern France and Burgundy cultivate it on a large scale. England's most famous hops are the "Farnhams," the "Golony" and "Grape" varieties. Owing to the high import taxes, Russia has also begun to raise hops. Of all these only the "Saazer" and the "Spalter" are imported to the United States. The following table gives an idea of the size of the world's production during the years 1900 and 1901:

WORLD'S PRODUCTION OF HOPS IN HUNDREDWEIGHTS.

Countries	1901	1900
United States	451,000	528,000
German Empire	283,580	523,600
Austro-Hungary	308,000	214,500
France	49,500	55,000
Belgium and Holland	93,500	55,000
Russia	88,000	88,000
Great Britain	726,000	385,000
Australia	3,300	13,200
	2,002,880	1,862,300

In the United States, the culture of hops was introduced as early as 1625 in New Netherlands, and 23 years later in Virginia, but although encouraged by special legislation in 1657, never assumed its present important agricultural role until 1800. During the first half of the 19th century Vermont produced seven eighths of the entire United States crop; since then New York has held first place. It has always been the tendency of hop cultivation to concentrate in well-defined districts, but in spite of this accumulative tendency, the centre of cultivation has slowly but surely moved westward. At first Massachusetts, Vermont and Maine were the chief hop States, but as the quality of the New York hops was far superior, and the quantity three times as great, the former States soon abandoned hop culture. The result was that during 1850-65 a small portion of New York, lying south of the New York Central Railroad between Rochester and Albany, monopolized the hop raising of the United States. Small patches were planted in Wisconsin and Michigan in 1860 and in 1866, when the New York crop was completely destroyed by vermin, Wisconsin hop-growers obtained exorbitant prices for their excellent product, which induced many to plant hops, expecting to realize a fortune in a few years, but the prices speedily declined owing to an overproduction. During 1870 and 1880 New York again was at the head, but at that time fresh competition began to develop on the Pacific coast. The «Russian River» hops of California were a marvel; their texture was «fine as silk»; their color «bright golden»; they were «clean picked»; their «contents of lupulin» second only to the best German brands, so that it was no wonder that hop-culture there advanced quickly to 40,000 bales, the yield of 1902. The first of the three following tables shows the yield in pounds of the various States from 1849 to 1899. The next table gives a comparison between the acreage, yield and value of the hop crop for 1899, 1889, and 1879; and in the third table this comparison has been calculated to

percentages of the total United States crop, in order to give a clearer idea of the hop industry during these years.

New York hops are almost entirely consumed in the United States, while the greater amount of the Pacific coast hops (especially Oregon) is exported. The English production is scarcely ever sufficient for its needs, so that Great Britain must import some and mostly takes Oregon hops, because they are especially adapted to the English ale brewer's requirements.

The hop plant is subject to many diseases, due mostly to parasites, among which are the hop plant-louse (*Phordon humuli*), the hop-grub (*Gortyna immanis*), the hop-vine snout-moth (*Hypena humuli*), the hop-merchants (*Polygonia interrogationis*), the zebra caterpillar (*Mamestra picta*), the common woolly bear caterpillar (*Spilisonma virginica*), the saddle-back caterpillar (*Empretia stimulea*), hop vine leaf-hopper (*Tettigonia confluenta*); various beetles, the "red spider" or spinning mite, and the needle-nosed hop-bug (*Calocoris fulmomaculatus*), which mostly produce red smut, etc., and even destroy entire crops. Fungus pest, blight and mold (black smut), are extremely rare in the United States, although widespread in England and Europe. It is almost impossible to eradicate these pests, except by extreme measures. The best remedies for the destruction of the animal parasites is the use of bisulphide of lime or a heavy spraying of soap and tobacco emulsion. Sulphur in any form is a good remedy, and a spray of kerosene soap emulsion, to which a small quantity of flowers of sulphur is added, is generally effective. In extreme cases the affected plants are cut down and burned to prevent a spread of the disease.

The elements also play havoc with the development of the tender hop-vine. High winds will tear the vine from its support; drouth will tend to change the color of the light yellow strobile to the objectionable "pole redness"; and too much water will produce a lack of lustre, when the hops are said to be "blind." This is due to the fact that the entire energy of the plant is spent in the formation of leaves, the strobile being scarcely developed.

Hops contain hop-oil, hop-resins, acids, hop-tannin, hop-bitter, hop-wax, nitrogenous bodies, carbohydrates and mineral substances. Diastase (an enzyme) has also been found, which is especially valuable in ale brewing. Hop-oil, the principal constituent of the lupulin, present in 0.2 per cent to 0.8 per cent, is obtained by distilling the hops with water. It is colorless and hardly soluble in water. The characteristic agreeable aromatic flavor of the hops depends on this oil. If exposed to air the oil turns to resin, passing to valerianic acid, to which the cheesy odor of old hops can be traced. According to Hayduck, there are three resins in hops, the α, β, and γ, of which the first two are soft and the latter hard. The preserving, antiseptic effect of hops is due to the two soft resins, as they are distinctly prejudicial to the growth of butyric acid and many other bacteria, but do not have much effect on acetic acid bacteria and sarcina. In old hops valerianic acid, malic acid, citric acid and succinic acid are present. Hop-tannin is chiefly stored in the leaves of the strobile and is a pale brown amorphous powder soluble in dilute alcohol, which through oxidation passes into phlobaphen. The hop-bitter is obtained from the two soft resins, and imparts a pleasant bitter taste to the beer, without which it would be flat and insipid. Hop-wax is present in considerable proportions in hops, but, since it is insoluble in water and even in 90 per cent alcohol, it has no value in beer. Nitrogenous constituents of hops are about 2 per cent to 4 per cent, which calculated to albumen are 12 per cent to 24 per cent, of which 0.75 per cent to 1.6 per cent are soluble. Bungerer maintains that 30 per cent of the nitrogenous substances are asparagin. Behrens says that trimethylamin and free ammonia are also present. Griess and Harrow have discovered cholin in hops. Brown and Morris have shown the presence of an enzyme similar to diastase, which will saccharify starch, that is, change it into sugar. This enzyme is chiefly accumulated in the seeds. The carbohydrates contained are cellulose, sugar, dextrin. According to Brown and Morris there is present 1.55 per cent dextrose and 2.10 per cent levulose, together 3.65 per cent of inverted sugar. According to Thausing hops contain 5.3 per cent to 15.3 per cent of ash and an average of 7.54 per cent, of which over one third is potash, one sixth phosphoric acid, one sixth silica, and some sodium, lime, magnesia, iron oxide, sulphuric acid and chlorine. The presence of an alkaloid in the seed has been ascertained by Dr. Ernst Hantke, but research on this point is still progressing.

Although it is possible to estimate with a fair degree of accuracy the several constituents of hops, it has not been so far found possible to establish any definite relation between the value of the hops and the amounts of hop-oil, resins, tannin, etc., which they contain. Consequently up to the present time, chemistry has not afforded much assistance in this direction. Hence the value of hops is still judged according to its general properties. The color, size and appearance and lustre of the strobile, the quantity and color of the lupulin, the amount of seed, the odor, taste and cleanliness, are the essential points in the valuation of hops.

Fine hops possess a silky lustre which is lacking in inferior grades. The color is greenish yellow, varying with the origin. New York hops have a somewhat paler color of a stronger greenish shade, while the Pacific coast hops have a more pronounced yellowish color. A reddish tint may indicate pole-redness, or, what is worse, that the hops have become overheated in the bale, which implies a darker coloration of the lupulin and deterioration of quality. The form and size of the strobile is also characteristic of the origin. Small strobiles are preferable to big ones, as they contain on an average more lupulin; and the fewer the seeds the better. The bracts ought to lap over one another and hold firmly together, whereby the lupulin is kept in better. The odor and aroma should be strong, fine, free from any off-smell such as odors of fruit, garlic, etc. Only very slight amounts of stems, foliage, or stripped cones should be present, as they impart a coarse taste to the beer. The amount of lupulin present in the strobile is an indicator of the value of the hops, because it contains those resins, volatile oils and bitter substances, which are so essentially valuable to the brewer. In fresh hops, slight pressure will force out the contents of the strobile in a transparent droplet, but in old hops the contents of the lupulin granule will not flow, due to resinification, and the expressed juice is more syrupy, wax-like and opaque. In short, the preparation of the strobiles for the market should be as follows: After the crop has been harvested, it is dried. The largest part of the German crop is merely air-dried or sun-dried, and it is claimed that this "natural cure" preserves far more of the essential oils and other active principles than is possible by the artificial hot-air cure used in the United States and England, and that this at least in part accounts for the peculiarities of Spalt hops that command such extraordinary prices. The kiln in which the hops are dried resembles in some respects the drying kiln of the maltster. This process requires great care, as much of the hops may be easily damaged. When the moisture has been completely removed, sulphur is placed on the fire, which has the effect of brightening the color; the evolved sulphurous acid also acts as an antiseptic, destroying to some extent the germs of mould-fungi and other organisms. After drying, the hops are stored three or four days, whereupon they are baled and are then ready for the market. They are easily affected by warmth, moisture, air and light, and for this reason must be protected in storage against these influences. For brewing purposes it is almost impossible to pass off a substitute for hops, although lupulin and hop-extract are now manufactured. The lupulin is separated from the strobile, and inasmuch as it contains the essential constituents for which hops are used in brewing, it can be better utilized, although it is impracticable and impossible to replace the entire quantity of hops with lupulin alone because it contains very little tannin, which also is essential. The same remark is applicable to hop-extract.

Dr. Ernst Hantke,
President of the Industrial Chemical Institute of Milwaukee.

Horace (Quintus Horatius Flaccus). Roman poet of the Augustan Age: b. Venusia, Italy, 8 Dec. 65 B.C.; d. Rome 27 Nov. 8 B.C. Our information about Horace's life is derived in the main from his own writings, which are supplemented in a few details by a brief biography attributed to Suetonius. He was born at Venusia, a small town in Apulia, near the boundaries of Lucania and Samnium. His father was a freedman, and, according to Horace's own statement, followed the trade of a *coactor* or collector. He seems to have prospered, for he was able to purchase a small farm. He was not satisfied to send the boy to the local school of Flavius, which was patronized by the aristocracy of Venusia, but moved to Rome to give his son the best possible educational advantages. It is to his credit that he did this, not that Horace might better his position in life, but for the sake of the education itself. At the capital he supplied his son with the means of making a creditable appearance, and he himself accompanied him to and from his classes, giving him moral instruction in a shrewd and homely way by pointing out men who offered examples to be followed or shunned. To this training Horace owed both his habit of self-examination and his consequent temperance and self-control, and that keen observation of men and things which is one of his marked characteristics. He nowhere makes mention of his mother, who very likely died while he was an infant.

At Rome Horace pursued the usual grammatical studies under the notorious "flogging Orbilius," and doubtless supplemented them by more advanced work in rhetoric and literature. It is, however, in marked contrast to the fulness of our information about the other details of his life, that we know little or nothing about the masters who influenced him or about the particulars of his education, except that he implies that he attended the classes of several teachers. We may, however, infer something from the results. He certainly acquired a taste for reading, both in the literature of Greece and that of his native land, a habit which he continued to follow throughout his life. Somewhere about 46 B.C., in his 19th year, Horace went to Athens to study philosophy but he does not seem to have been especially attracted by any particular school. In his early life he leaned toward the Epicurean doctrine, but as time went on he turned more and more to that of the Stoics, without, however, committing himself to either sect. The assassination of Cæsar and the arrival of Brutus in Athens in September 44 B.C., put an end to his quiet student life. He joined the army of the liberators, and received a commission as tribune, though he was in no way fitted for the post. At Philippi he fled from the field with the rest of the routed forces, and, as he himself says, "left his shield behind." His humble estate was confiscated, but on his return to Rome in 41, when a general amnesty was granted by Octavian, he in some way secured a position as clerk in the quæstor's office, which furnished him the means of livelihood.

Horace freely admits that it was lack of money which first led him to write verse, and it was to his efforts in this line that he owed his advancement. He soon made the acquaintance of Vergil and of Varius, by whom he was introduced to Mæcenas. After a delay of several months, during which the astute statesman doubtless took the young man's measure, his position was established by his admission to the select circle of Mæcenas' literary friends. This honor, as he says with pardonable pride, was due not to high birth, but to his personal character. In 33 he received from his patron a small estate, the famous Sabine farm, situated in the valley of the Digentia, a small stream flowing into the Anio, about 30 miles northeast of Rome. Through Mæcenas he became intimate with the most eminent men of the day, both in literary and in political life, including Augustus. Toward the emperor his attitude was one of dignified independence. He was quick to recognize the advantages of the peaceful and established order of things which Augustus had brought about, and he celebrates it in many of his odes; but he did not hesitate to decline the position of private secretary which the emperor offered him. This he did without giving offense, for Suetonius quotes extracts from letters of Augustus which indicate a cordial and even an intimate friendship. Horace also preserved his independence in his relations with his benefactor Mæcenas, as appears from several passages in his works, although he showed a proper gratitude for his many favors.

In the year 35 Horace issued his first book of satires, to which he himself gave the title of 'Sermones,' or familiar talks. On this branch of literature, which the Romans claimed as their own creation, see SATIRE. He took as his model Lucilius, and at first seems to have followed him closely, but he soon found himself out of sympathy with the earlier poet's severity in invective and disregard of form. In the fourth and tenth Satires he subjects the work of his predecessor to a thorough criticism, and defines his own ideal of what satire should be. This book was complete in itself, and begins with an essay addressed to Mæcenas. That the reception given to his first effort, which did not lack serious defects, was not wholly favorable, and that Horace had not satisfied himself, is evident from the poet's own words in the introductory essay of the second book, which seems to have appeared in the year 30. This book marks a great advance on the first, from which it differs in its externals in having no formal dedication and in being cast almost wholly in dialogue form, whereas in the first book Horace himself had been the chief speaker. In the following year, urged by Mæcenas, Horace published his first collection of lyrics, some of which doubtless represent his earliest attempts at verse. It was a volume of 17 Epodes, or 'Iambi,' as he himself named them. He chose as his model the Greek iambic poet Archilochus, and followed him closely in form. His work, however, has little of the bitter invective for which the Greek poet was notorious, and Horace shows no little originality both in his choice of themes and in his treatment of them. Six years later Horace, now a man of 42, published the first three books of the Odes, which form a work complete in itself, opening with a dedication to Mæcenus and closing with an epilogue in which he predicts his own immortality. In his choice of metres he followed especially Alcæus and Sappho, from whom he also took many of the subjects of his odes. But he shows the influence of many other Greek poets, as well as considerable independence. Although this work did not wholly escape hostile criticism, it at once placed Horace in the front rank of Roman poets. This position was formally recognized in 17 B.C. through his appointment by Augustus to write the ode, the well-known 'Carmen Sæculare,' which was sung at the celebration of the secular games in that year.

His next work was a return to the field of satire, for the 'Epistles' belong with the 'Sermones' to that branch of literature in the Roman sense of the term. They differ from the 'Sermones' in their greater finish and in their external form. Horace regarded the hexameter as the conventional form for satire, and the poetic epistle represents his third and final choice of form for his essays in that measure. The first book was apparently issued in the year 20. Horace was then a mature man, who had made his mark, and his tone is more assured and his self-appreciation is greater, though without any trace of egotism. The practical philosophy of life seemed to him the thing most worthy of serious consideration, and to teaching this he proposed to devote the rest of his literary work. This book, which consists of 20 letters, of which some are genuine and some fictitious, is also dedicated to Mæcenas. The second book is devoted wholly to literary criticism, a subject which lay within the domain of satire and had already been handled in some of the 'Sermones.' The chronology of the book is somewhat difficult. It was probably published in the year 14. Whether the *Ars Poetica* formed the third letter of the second book or not is uncertain. It has been assigned to various years from 20 to 8 B.C., and if it really belongs to the latter date, it must have been published separately, perhaps after Horace's death, and is the latest of his works. The title which Horace gave it seems to have been 'Epistula ad Pisones,' but it received its present designation at an early period. The second book of epistles begins with a letter addressed to Augustus, who is said by Suetonius to have taken Horace to task for dedicating none of his works to him. In his epistles, Horace had formally renounced lyric poetry. Nevertheless, at the express request of the emperor, he published a fourth book of odes in 13 B.C. This collection, though admirable in form and containing some of Horace's best work, is characterized by a certain perfunctoriness and lack of spontaneity. It was not addressed to Mæcenas, but is without a formal dedication. This was, however, not due to any diminution of his regard for his patron, but to the fact that the book was published by the special request of Augustus.

Of the remaining years of the poet's life we know very little. Suetonius says that he died 27 Nov. 8 B.C., and there seems to be no ground for rejecting this testimony. No authentic portrait of Horace has come down to us. From his own allusions to his personal appearance, and from a letter of Augustus, quoted by Suetonius, we learn that he was stout and short, with dark eyes and hair, but prematurely gray. He further tells us that he was quick to anger, but easily appeased. He never married, and of all the loves of which he sings, Canara alone seems to be other than imaginary.

It is probably safe to say that Horace has been the most widely read of all Roman writers, not excepting Vergil, and that he has appealed to a more varied circle of readers than any of his countrymen. This statement applies especially to his odes, since it is to them that his popularity with the general public is for the most part due. It has been said that the odes are not poetry of the highest type, and that when they are analyzed and their contents subjected to searching criticism, the sum total of poetic material is scanty. This is unquestionably true, yet it is equally true that their influence and popularity have none the less been great. This is due in part to the personality of the man and the sympathetic feeling which he rouses in his readers on account of his broad humanity; and in part to the fact that the very simplicity of the odes and their ease of comprehension appeal to readers of all classes. As Mackail says, he realized that limited as was his own range of emotions, that of mankind at large was still more so. In some cases, notably in the love poems and the convivial odes, we are conscious that he did not always feel even the emotions which he describes. In spite of all criticism, the one undoubted fact remains, that the odes of Horace have pleased readers of all epochs and all sorts and conditions of men.

Horace's claim to originality is greater than is usually admitted. In his day the question of imitation of Greek models had ceased to exist, and the question was, rather, which model to choose. In the Augustan Age we find two schools, those who followed the Alexandrine writers, and those who went back for their inspiration to the Greeks of the classical period. Horace belonged to the latter class. His contempt for the followers of Alexandria is outspoken, and so undiscriminating as to include such really great poets as Calvus and Catullus. He certainly knew how to make what he borrowed his own, and many of his odes are so thoroughly national in character that they can have owed little except their external form to Greek sources. In his Satires, in spite of his avowed imitation of Lucilius in the beginning, his originality is far greater, and these are in reality his greatest works. While less popular with the general reader, they are of great interest for the light which they throw on Horace's life, personality, and habits, as well as for the vivid pictures which they set before us of the complex Roman life. In his daily walks about the city, Horace used his powers of observation, and drew material from all sides and from all classes of society. Above all we can trace in them his own self-improvement and the development of his character, and the gradual growth of that sound judgment and good taste which characterize the work of his mature years. The Satires are further characterized by a genial and good-natured humor. Like Dickens, he chose appropriate names for many of his characters — such as *Novius*, or Newman, for the parvenu, though, like those of Dickens, they were not always of his own coinage. The Satires also abound in the familiar phrases of every-day life, in puns and plays upon words, in proverbs and homely fables and stories.

Horace's works, as he himself humorously predicted, became school text-books at an early period. Juvenal implies that this was the case in his day. This fact and his general popularity led to the numerous commentaries on his works, which began to appear as early as the days of Nero, of which those of Porphyrio, of the early part of the 3d century, and the collection falsely attributed to Helenius Acron, have come down to us. The great number of manuscripts which exists testifies to his popularity in the Middle Ages. His fame at that time was, however, much less than that of Vergil, and, though he also was regarded as a magician, it was only at Palestrina and at Venusia that such legends were current. In modern times his influence on French and English satire has been great, as well as on modern poetry in general.

The date of the first edition is uncertain, but is earlier than 1471. Since then the editions of Horace's works, or of parts of them, have been legion. Of these may be mentioned as epoch-making that of Richard Bentley (Cambridge 1711), which has often been reprinted (the reprint at Berlin in 1869 contains a word-index by C. Zangermeister). The standard critical text is that of O. Keller and A. Holder (Leipsic 1864–70, a second edition of the first volume containing the 'Odes,' 'Epodes,' and 'Carmen Sæculare,' appearing in 1899). A commentary on this edition is furnished by Keller's 'Epilegomena zu Horaz' (Leipsic 1879–80). Of editions with notes may be mentioned: J. G. Orelli, 4th ed. by W. Hirschfelder and W. Mewes (Berlin 1886–92), containing a complete word-index; A. Kiessling (Berlin, 2d ed. 1890–8); H. Schutz (Berlin 1880–3); these two appear in new editions from time to time; L. Müller, 'Odes' (Leipsic 1900), 'Satires and Epistles' (Leipsic 1891–3); E. C. Wickham, 'Odes and Epodes' (3d ed. Oxford 1896), 'Satires and Epistles' (Oxford 1891); Page, Palmer, and Wilkins (London and New York 1896). The edition of the 'Odes and Epodes' by P. Shorey (New York 1896) is of special interest to the general reader on account of its large number of parallel passages from English poetry.

The simplicity and directness of Horace's thought have been a constant temptation to translators, and the number of English versions, particularly of the 'Odes,' is very great. But his care in composition and his inimitable skill in the use of words, his *curiosa felicitas*, as Petronius terms it, make him exceedingly difficult to translate, and, while some brilliant successes have been achieved with single odes, no one has done justice to him as a whole. Many of the attempts which have been made are reviewed in two articles in the 'Quarterly Review' (Vol. CIV., 1858, and Vol. CLXXX., 1895). The following may be mentioned: Lord Lytton, 'Odes and Epodes' (London 1869); Cooper, 'Horace's Odes Englished and Imitated by Various Hands' (London 1880); Martin, 'Works of Horace' (Edinburgh 1888); Conington, 'Odes and Epodes' (3d ed., London 1885), 'Satires and Epistles' (London 1892); Gladstone, 'Odes' (New York 1894); Green, 'Odes and Epodes' (London 1904). An edition of Horace's works, in six volumes, containing both text and translations, has recently been issued by the Bibliophile Society of Boston. To give an adequate literary criticism of Horace is nearly as difficult as to translate him, and is out of the question within the limits of a brief article. Consult: the various histories of Roman literature, especially that of Mackail (New York 1900); Sellar, 'Roman Poets of the Augustan Age — Horace and the Elegiac Poets' (London 1892); Nettleship, 'Lectures and Essays' (Oxford 1885); Patin, 'Etudes sur la poesie latine' (3d ed., Paris 1883); Tyrrell, 'Latin Poetry' (Boston 1895); Boissier, 'The Country of Horace and Virgil' (London 1896); Lang, 'Letters to Dead Authors' (London 1886).

John C. Rolfe,
Professor of Latin Language and Literature, University of Pennsylvania.

Horæ, hō'rē, in Greek mythology, goddesses of the seasons. They were generally regarded as attendants of the gods, and guardians of the Olympian gates. Their characteristics, however, varied, and their number was variously represented as two, three, or four. Hesoid names three — Euxomia (good order), Dike (justice), and Eirene (peace), and thus makes prominent their attributes as also guardians of social and political conditions.

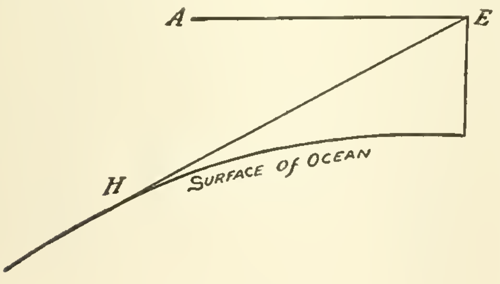
Horatii, hō-rā'shī-ī, three Roman brothers, who, in the reign of Tullus Hostilius, engaged the same number of Alban brothers (the Curiatii), in order to decide the contest between the two nations. A sister of the Horatii was betrothed to one of the Curiatii; but both sides forgot their private relations in the service of their country. Two of the Romans soon fell. The contest was unequal, but Horatius saw his antagonists faint with the loss of blood. In order therefore to separate them from one another, he feigned flight, and, while they pursued him as well as their wounds would permit, at unequal distances, he suddenly turned and slew one after the other. He was conducted back to the city amidst the rejoicings of the Romans, adorned with the spoils of the slain. There he saw, in the crowd, his sister in tears for the death of her betrothed. Angered that her lamentations for her lover should mingle with the rejoicings of the nation on his victory, the brother plunged his dagger into her breast. He was condemned by the duumviri to be scourged to death, but he was later pardoned.

Horeb, hō'rĕb, a mountain in the northern part of Arabia, of the same ridge as Mount Sinai, which lies not far distant from it, memorable in the history of Moses. The monks on Mount Sinai still point out the rock on Horeb from which water issued at the blow of Moses.

Horicon, hŏr'ĭ-kŏn. See George, Lake.

Hori'zon. In its most familiar sense the horizon is the line or circle around which earth and sky seem to meet. On the ocean this circle is smooth and easily visible, and is then called the *sea horizon.*

In astronomy the horizon is defined by a plane at right angles to the direction of gravity, extending out indefinitely on all sides, and called the *plane of the horizon.* The circle in which this plane cuts the celestial sphere is called the *astronomical horizon.* All points of it are apparently on a level with the eye of the observer. Owing to the rotundity of the earth



the sea horizon is lower than this astronomical horizon — a narrow strip of sky separating the two. The angular distance between them is called the *dip of the horizon.* The higher the observer is above the ocean, the greater is the dip. To an eye on the surface of the water, the sea horizon and the astronomical horizon coincide, so that there is no dip. The geometrical principle which determines both the dip and the distance of the visible horizon, are seen in the figure. The circular arc is here the surface of the ocean. The eye of the observer is situated at the point E, a short distance above the surface of the water. A tangent drawn from the eye to the surface meets the latter at the visible horizon, H. Let a horizontal line E A be drawn from the eye, the angle A E H is then the geometric dip of the horizon. The geometer will readily see that this is equal to the angle at the surface of the earth between O and H. Since one minute of arc in the curvature of the earth's surface corresponds to one nautical mile, it follows that, geometrically, the dip of the horizon in minutes is equal to its distance in nautical miles. But, in the actual case, the line of sight is curved in consequence of the refraction of the air. The result of this is that the actual horizon is further than given by the geometric theory, and the dip somewhat smaller. The following table shows the relation between the apparent dip and the height of the eye above the water and the distance of the sea horizon.

Height in Feet	Dip of Horizon	Distance of Horizon Miles
1	1.0	1.3
2	1.4	1.8
3	1.7	2.3
4	2.0	2.6
9	2.9	4.0
16	3.9	5.3
25	4.9	6.6

On board a steamship the eye of an observer on the promenade deck is generally from 15 to 20 feet above the water. It follows that the distance of the horizon is about five miles. A ship farther away than this will have more or less of her hull below the horizon. At double the distance the entire hull will be below the horizon, and only smokepipe and masts visible. As she goes yet further, these also will disappear, as if sinking below the water.

Simon Newcomb.

Horn, a tough, flexible, semi-transparent substance derived from the epidermis, which may be developed morbidly as a corn, or naturally, as in the callosities on the legs of a horse; or in connection with important functions, as when it forms the outer sheath of the outgrowths upon the heads of ungulate animals, called "horns," the "shell" of the tortoise, the nails, claws, and hoofs of animals, the beak of bird and turtle; and the hairs and feathers of mammals and birds, or their modification into spurs, scales, spines, bristles, whalebone, nasal horns, etc. This epidermal tissue consists largely of keratin, an albuminoid composed mainly of carbon (about one half), oxygen, nitrogen, and sulphur.

The horns of mammals are in effect modifications of the hairy integument covering parts liable to great wear, or needing to be hard and sharp, especially the outgrowths of the skull characteristic of male ruminants. Hollow horns are usually unbranched and persistent, but in the pronghorn (q.v.) they are shed annually while the bony cores grow and their vascular coverings persist and give rise to the new horns. Hollow horns are found usually in both sexes, but in some genera of antelopes only in the male. In the pronghorn the horns of the female are almost hidden in the hair of the head, and are small, short, and unbranched. Such horns as these are called hollow or sheath horns, and are very different from antlers (q.v.). Another form of true horn is that on the snout of the rhinoceros (q.v.) where, when more than one appears, the projections stand one behind the other in a median line, and not side by side. This nasal rhinoceros-horn is not a hollow sheath clothing a bony core, but a solid mass of coarse agglutinated hairs, arising from the skin and supported by a thickening of the underlying bone.

Utility of Horn.— In their natural form, the horn-sheaths of oxen, sheep and antelopes have been put to a great variety of use, as weapons, receptacles, handles, and musical instruments — the latter surviving in certain ceremonial usages and in the general term "horn" for a wind instrument. Cleaned and polished it served many additional needs, forming the primitive drinking cups; and it is from this ancient usage that the general name of "horns" has been given to a species of drinking cup, and its spirituous contents. The horns of victims sacrificed to the gods were often gilded by the Romans and suspended in the temples, more especially in those of Apollo and Diana. From the most remote times the altars of the heathen divinities were likewise embellished with horns, and such as fled thither to seek an asylum embraced them. Originally the horns were doubtless symbolical of power and dignity, since they are the principal feature of gracefulness in some animals, and instrument of strength in others. Hence these ornaments were frequently bestowed in imagination and art upon gods, and were actually worn by heroes. In more modern times ox-horns have been used the world over for carrying gunpowder; and museums abound in quaint relics of this kind elaborately ornamented by soldiers and hunters. Small bottles (inkhorns) of this substance were the first receptacles for ink, and are still used in the East, where opium for smoking is usually kept in horn-boxes. Before the general adoption of glass panes in windows thin plates of horn were often used, as they still are in barbarous parts of Asia; lanterns were made of them; and the faces of the mediæval horn-books were so protected. The material now lends itself to manufacturing into many other articles by reason of its toughness, pliability and capability of being softened by heat and then molded. The heat is applied in the form of hot water; and splitting into thin sheets, or welding pieces together, or molding fragments into various forms, may all be accomplished under combined moisture, heat and pressure. Both the natural horn and the molded substance may be carved, or impressed with a die, polished and dyed. Hence an enormous variety of useful and ornamental articles may be made, and the horns of cattle have commercial value.

Horn, a musical instrument, originally formed, as the name denotes, from the horn of an animal. The name includes a large family of wind-instruments, many of which have fallen into disuse. The hunting-horn was long the chief form extant. The French horn consists of a metallic tube of about 10 feet in length, very narrow at top, bent into rings, and gradually widening toward the end whence the sound issues, called the bell, or in French the *pavillon*. It is blown through a cup-shaped mouth-piece of brass or silver, and the sounds are regulated by the player's lips, the pressure of his breath, and by the insertion of the hand in the bell of the instrument. The compass of the instrument is three octaves. Music for the horn is always written on the key of C, an octave higher than it is played, with the key of the composition marked at the beginning of each movement. Great improvements have been made in the instrument by C. J. Sax of Paris, whose saxhorn gives a greater volume of sound than the old instrument. The buglehorn is a tube of 3 feet 10 inches in length bent into small compass. It is usually provided with keys, and has a range of two octaves, and notes commencing with the upper B of the bass clef.

Horn, Cape. See Cape Horn.

Horn-fly, a European fly (*Hæmatobia serrata*), since about 1890 become widespread in North America, which have a curious habit of clustering in masses about the base of the horns of cattle. It is closely related to the house-fly and stable-fly, and although annoying does no serious harm to the cattle or their horns

Horn'aday, William Temple, American naturalist: b. Plainfield, Ind., 1 Dec. 1854. He studied zoology and in 1875–9 visited as a zoological collector South American countries, India, Ceylon, the Malay Peninsula, and islands. In 1882–90 he was chief taxidermist of the United States National Museum, and in 1896 was appointed director of the New York Zoological Park. His publications are: 'Two Years in the Jungle' (1885); 'Free Rum on the Congo' (1887); 'The Extermination of the American Bison' (1887); 'Taxidermy and Zoological Collecting' (1892); 'The Man who Became a Savage' (1895).

Horn'beam (*Carpinus*), a genus of trees of the natural order *Cupuliferæ*, of which the species *C. betulus* is common in Europe, in some places growing to nearly 100 feet in height, although in Great Britain, where it is much planted, it is a small tree. It is also called horn-beech, hardbeam, and yoke-elm. It has barren flowers in a cylindrical catkin; fertile flowers in a lax catkin; nuts in pairs. It grows in woods and hedges, often in a damp tenacious soil, and forms a principal part of the ancient forests on the north and east sides of London. The wood is white, tough, and hard, and burns like a candle. It is used in turnery, for cogs of wheels, etc. The inner bark yields a yellow dye. The American hornbeam (*Caprinus Americana* or *Caroliniana*) is a small tree rarely attaining the height of 30 feet, sparingly diffused over most of the United States. It is also called water-beech, blue beech and ironwood. The wood, fine-grained, tenacious, and very compact, is used for handles, as of carpenter's tools, ets., its serviceability being restricted by reason of its inferior size. See Ironwood.

Horn'bill, a genus (*Buceros*) and of a family (*Bucerotidæ*) of birds now placed in the division *Coraciiformes*, and related to the hoopoes and owls. The species are numerous and are found in Africa, India, and throughout the Malayan region as far as New Guinea, are mostly large birds, the largest being more than four feet long, the smallest rather smaller than a magpie. They are bulky birds of heavy, noisy flight; their large bills are surmounted by bony crests or "helmets" of varied shape and sometimes of great size, but rendered light by the presence of numerous air-cells. Their food is principally fruits, but in certain circumstances they become to a great extent omnivorous. Thus a well-known South African ground-hornbill devours snakes, and is highly regarded by the negroes because of its enmity to them, and ability to overcome the largest and deadliest vipers. Several are mainly terrestrial in their habits. The most curious fact regarding these birds is that during the breeding season the female is imprisoned on her nest in a cavity in a tree-trunk, she herself apparently gradually plastering up the entrance by the use of her excrements, until there is left only a small aperture through which the male supplies her and her offspring with food until the young ones are nearly full grown. In captivity the male bird has been observed to disgorge at intervals the lining of his gizzard in the form of a bag, and it is supposed that the food supplied to the female during her term of captivity in the breeding season is enclosed in this structure. Consult: Newton, 'Dictionary of Birds' (1896).

Hornblende, hōrn'blĕnd, or **Amphibole,** an abundant and widely diffused mineral, remarkable on account of the various forms and chemical compositions that it exhibits, and its diversified colors. Almost numberless varieties of it are recognized, to many of which distinct names have been given. It crystallizes in the monoclinic system, and is brittle, with a hardness of from 5 to 6 and a specific gravity of from 2.9 to 3.4, according to its composition. It has a vitreous or pearly lustre, and its fibrous varieties often have a silky appearance. The variety most commonly known as "hornblende" is usually black or greenish black, and occurs in many rock formations, notably in granites and basalts, and in certain schists and slates. The strongly colored varieties are pleochroic. Common hornblende is a silicate of iron, aluminum, magnesium and calcium. The various hornblende minerals are now collectively known as the "amphibole group." See AMPHIBOLE.

Hornbook, an elementary school book in use in England down to the time of George II. It was made up of a single leaf on which was written the alphabet in large and small letters; the Roman numerals, and the Lord's Prayer. The leaf was sometimes set in a frame and sometimes pasted against a piece of sliced transparent horn; hence the name. There was a handle through which a string was inserted whereby the book might be tied around the waist.

Horne, C. Silvester, English Congregational clergyman: b. Sussex 1865. He was educated at Glasgow University and Mansfield College, Oxford, and after leaving the latter institution was pastor of the Kensington Congregational Church until 1903, when he became pastor of the Whitefield Tabernacle in Tottenham Court Road, London. He has been active in many social and religious enterprises and is one of the most prominent men in his denomination in England. He has published 'History of the Free Churches.'

Horne, Richard Henry, or **Hengist,** English poet and essayist: b. London 1 Jan. 1803; d. Margate 13 March 1884. He was educated at Sandhurst, and entered the Mexican navy as midshipman, serving till the close of the Mexican war of independence. He then returned to London to begin a literary career. To his early period belong two tragedies, 'Cosmo de' Medici' (1837), and 'The Death of Marlowe' (1837), both of which contain fine passages. A poem sent to him for criticism by Elizabeth Barrett opened the way to a cordial friendship and a correspondence of seven years. In 1852 Horne removed to Australia, and remained there until 1866; his book, 'Australian Facts and Principles,' being one outcome of this residence. Again returning to England, he continued literary work until his death. His last publications were tragedies, including 'Judas Iscariot: A Miracle-Play' (1848), and a curious prose tract, 'Sithron the Star-Stricken' (1883), which he pretended to take from the Arabian. His best known work, however, is his epic poem 'Orion' which Poe said might be called "a homily against supineness and apathy in the cause of human progress, and in favor of energetic action for the good of the race."

Horned Dace, Rattlesnake, Screamer, Viper, etc. See DACE, RATTLESNAKE.

Horned Toad, lizards of the family *Iguanidæ,* popularly called toads from a certain general resemblance in form and manner to those animals. The body and head are broad, thick, and flattened, the tail short and the usual attitude a sort of squatting posture with the head elevated. About a dozen species of the genus *Phrynosoma* occur in the arid parts of the southwestern United States and in Mexico. The best known are *P. cornutum* and *P. coronatum,* which, because of the bizarre appearance, quaint ways and tolerance of captivity, are often brought back as souvenirs by visitors to those regions. The scales on the body bear prominent conical spines, and the long horns of the head are supported by bony cores. Their mottled brown and gray colors harmonize well with their natural surroundings. The horned toads love to bask in the sunshine in the hottest weather and to bury themselves in the burning sand. Never very active, they become extremely sluggish in cool or dull weather and hibernate in the winter. They feed on all kinds of insects, for which they search only during the hottest hours of the day, and drink copiously of water when sprinkled in the form of drops. Like many other lizards, but unlike most of the *Iguanidæ,* they are viviparous.

Horned Viper. See VIPER.

Hornellsville, hôr'nĕlz-vĭl, N. Y., city in Steuben County; on the Canisteo River, and on the Erie and the Central N. Y. & W. R.R.'s; about 57 miles south of Rochester and 46 miles northwest of Elmira. The first settlement was made in 1790, but it was a part of Canisteo and was called Upper Canisteo until 1820. The present name was given in honor of George Hornell, who had done much for the early development of the town. It was incorporated as a city in 1890. Hornellsville is situated in a fertile agricultural region, noted for fruit. Its chief manufactures are sash, doors, and blinds, railroad supplies, furniture, leather, carriages and wagons, silk, bricks, tiles, wire-fencings, gloves, and agricultural implements. It has a good public high school, St. Ann's Academy, St. James Mercy Hospital, and a number of fine public and private buildings. The government is vested in a mayor, who holds office two years, and a city council. The subordinate officers are appointed by the mayor subject to confirmation by the council. Pop. (1900) 11,918.

Horner, William George, English algebraist: b. 1786; d. Bath, 22 Sept. 1837. He was educated at a private school near Bristol, and later taught there, becoming head master in 1806. In 1809 he established a school at Bath, which he conducted until the time of his death. His only work of importance was his discovery of a method of solving numerical equations of any degree, which he first announced in a paper read before the Royal Society in 1819, and afterward published in the 'Philosophical Transactions.' The method is still in use, and is known by Horner's name. See ALGEBRA, HISTORY OF THE ELEMENTS OF.

Hor'net. The true hornet is a European wasp (*Vespa crabro*); but in America the term is applied to almost any form of large stinging wasp, especially such as make papery nests. In some portions of the United States this is considered the only "hornet," but in the vicinity of New York the European hornet also occurs; and southward a somewhat smaller species (*V. carolina*) goes by this name.

Hornet, The, the name of two sloops-of-war in the American navy during the War of 1812. The chief was a ship-rigged 18-gun sloop, and did brilliant service. Through December and January 1812–13, under Master-Commandant James Lawrence, she blockaded the 20-gun English sloop Bonne Citoyenne in the harbor of Bahia, Brazil, till overmatched by a 74: Lawrence was surprised and himself had to take refuge in the harbor, but instead of being blockaded, slipped out the next night under the very guns of the man-of-war. After capturing a merchantman, on 24 February he fell in with the English sloop-of-war Peacock, Capt. William Peake, each at this time having 20 guns; they engaged at 5.25 P.M., and in eleven minutes the Peacock was a sinking wreck and surrendered. Her captors made every effort to keep her afloat, but in a few minutes she sank, carrying down 13 of her own crew and three of the Hornet's. Peake and four men were killed and three wounded; the Hornet had one killed and two wounded, besides two more hurt by an exploding cartridge. "A vessel moored for the purposes of experiment could not have been sunk sooner." said an English paper of the time; 'it will not do for our vessels to fight theirs single-handed.' On 22 Jan. 1815, under Capt. James Biddle, she encountered off Tristan d'Acumha, in the South Atlantic, the English brig Penguin, Capt. James Dickinson, with 19 guns of about the same metal as her own 20; in 22 minutes the Penguin surrendered, but on Biddle going forward, two British seamen shot him in the neck (not vitally), and were immediately shot down themselves. The Penguin lost her captain and 9 others killed, and 38 wounded; the Hornet, one killed and 11 wounded. The Penguin was shot to pieces, and could not be taken away, so she was scuttled; the Hornet was almost uninjured. On 28–9 April she had a long chase from the British ship of the line Cornwallis, the rear-admiral's flagship, and only escaped by thoroughly dismantling herself.

Horol'ogy. See CLOCK; CLOCK-WORK.

Hor'oscope. See ASTROLOGY.

Horrocks, hŏr'ŏks, **Jeremiah,** English astronomer: b. Toxteth, near Liverpool, about 1617; d. 3 Jan. 1641. He was educated at Cambridge and was appointed in 1639 to the curacy of Hoole, Lancashire, and in that village made his famous observation (24 Nov. 1639, O. S.) of the transit of Venus, the first on record. Newton, in the 'Principia,' bears honorable testimony to the value of Horrocks' astronomical work. The observation of the transit is by no means regarded as his sole astronomical achievement, as he added to our knowledge of the physical cause of celestial motions, deduced the solar parallax, corrected the solar diameter, and, made tidal observations. Hevelius printed the 'Venus in Sole Visa,' which was first published in Germany (1662); a translation of this work, with memoir by Whatton, appeared in 1859.

Horschelt, Theodor, German painter: b. Munich 1829; d. 1871. He began his early studies in the Munich Academy, and later became a pupil of Albrecht Adam. At first he painted horses, among which is 'The Poacher' (1850), and then turned to military scenes, painting 'The Seizure of Shamyl' and 'Cossacks Returning from a Razzia.'

Horse, in a general sense, a member of the ungulate family *Equidæ* (q.v.); but in ordinary use the word designates the single domestic species (*Equus caballus*), the wild original of which is unknown. It is not decided, in fact, whether a single species, or more than one, was the source, nor where the domestication of the horse was first effected. The evolution of the species, elsewhere sketched, took place in the American continent, and the writings of some of the earliest voyagers to the eastern coast of South America contain allusions which some commentators regard as evidence that horses survived and were known to the people who occupied the La Plata valley at that time, but this is open to doubt. It is probable that at the dawn of civilization the wild ancestors of our modern horses roamed in bands over the whole extent of grassy uplands stretching from northern Africa to eastern Manchuria, on the steppes of Russia, and wherever in Europe open country might be found; and it is also probable that they were among the first animals which men killed for food and afterward captured and tamed in order to keep a supply of food under control. This act must have been one of the earliest steps toward community life and civilization. The oldest paintings and carvings left by the ancient inhabitants of the valley of the Euphrates show that saddle-horses were familiar to them; and it is fair to suppose that the supremacy primitively gained by the people of central Asia over other parts of the world was largely due to their use of horses in war, giving them a great advantage over unmounted tribes; but it was not until much later — probably no earlier than 2000 B.C. — that the animal came into use in Arabia and Egypt, where before had been only camels and asses. So far as can be judged, these early Assyrian war-horses were rather small, robust, large-headed and shaggy beasts, much like Przewalsky's horse or the kiang (q.v.). A very similar animal was domesticated by the men of the Polished Stone Age in Europe, excellent portraits of which were etched by neolithic artists upon pieces of bone, and have come down to us among the contents of graves opened by archæologists in France, Switzerland and elsewhere. Later, but still in the prehistoric period, Europe was repeatedly invaded by Asiatic hosts who brought with them eastern horses. These modified, if they did not supersede, the local stock. When Rome conquered the barbarous inhabitants of Europe its horses, which were of Asiatic stock, with perhaps some African mixture, largely superseded those of the conquered tribes, and from the mingling there sprang the big heavy breeds which characterized the Middle Ages, and were intended for strength and weight-carrying, rather than for nimbleness and speed. It was not until near the end of the 17th century that the introduction into France and England of certain sires of Arabian breed — a clean-limbed, small-headed, agile, hardy race, which arose in Arabia and Palestine about 2,000 years ago — began the improvement of British stock, which has reached its highest development in the modern European racehorse, hunter and hackney. From this stock was derived the American horses which have been perfected in at least one new direction — that of the trotter.

Horse, Care and Diseases of the. *Breeding.*—As *heredity* is the basis of all permanence in breeding, and *variation* the condition of advancement, we can, under intelligent selection, environment, and control, attain to a constant improvement. In selecting horses for breeding, certain leading principles must guide. These may be shortly stated as: (1) adaptability to the use of the breed; (2) quality, style; (3) strength, endurance; (4) good conformation; (5) good constitution; (6) good pedigree; (7) prepotency; (8) no violent crossing of equally prepotent animals; cross the desirable prepotent animal on a non-prepotent cross-bred animal; (9) a speedy amelioration of a large number is most certainly obtained through a prepotent stallion, which leaves a large number of his offspring every year; (10) sound, vigorous health; the prepotent parent must be at his best, and no non-prepotent one should be bred to him, none that is old, feeble, or reduced by disease, overwork, underfeeding, etc; the lack of prepotency will not prevent the transmission of the systemic weakness to the offspring; (11) secure an environment calculated to enhance the qualities we seek in the progeny. Systematic exercise that is not exhausting, generous tissue forming, but not fat forming regimen, and pure, dry, genial but bracing air are especially important.

Contagion Through Sexual Congress.—Many maladies may be transmitted during coition, but some are especially liable to be so. Dourine, glanders, genital eczema, contagious acne, horse-pox, mange, and contagious abortion are to be specially guarded against. Some, like strangles, influenza, and contagious pneumonia, may be transmitted by an animal that has already passed through the disease and acquired immunity. Special care, therefore, or even veterinary supervision of horses devoted to breeding is a desideratum.

Care of the Pregnant Mare.—Exercise is a valuable provision too often neglected. Free range on breeding ranches, or, for valuable mares, separate paddocks, secure this, while working mares are better to continue the work, provided it is not unduly straining nor jarring, nor productive of excessive fatigue, exhaustion, or debility. This maintains appetite, digestion, assimilation, muscular tone, and vigor, favors the development of a stronger, better foal, and keeps the dam fitter for foaling and nursing. Feed well, avoiding what is hard of digestion, or liable to cause impaction, indigestion, fermentation, or, above all else, diarrhœa. On good pasture grain may be omitted, unless in the last month of gestation, or if the mare is visibly running down. Good, clear, sound oats or barley, or bran mash with some boiled flaxseed may be given, and heating agents like maize, buckwheat, or wheat avoided. During gestation violent purgatives and active diuretics are liable to bring on abortion.

Care of the Foal.—To avoid danger to both mare and foal in parturition, provide a roomy box-stall with door opening outward, or a paddock. The foal born indoors is always in danger of infection through the raw surface of the navel. The common or box-stall swarming with microbes is more to be dreaded than exposure to storms outside. When severe weather forbids foaling outdoors, the box should be thoroughly cleansed, disinfected, and whitewashed to obviate this danger. Navel infection may cause simple inflammation, swelling, and abscess, or the germ may propagate itself through the inactive umbilical vein to the liver, causing infective hepatitis with abscesses or necrosis; or, reaching the bowels, it causes infective diarrhœa (white scour); or it may colonize the joints, as infective arthritis (joint ill); or again it may cause pneumonia, or multiple abscesses in different organs. The gravity of the resulting disease varies with the infection, and a deadly germ, located in a stable, is liable to attack all foals that come later in the season. Both stable and navel should be disinfected. The foal should be delivered on clean straw, which may be sprinkled with carbolic acid. The navel-string may be severed with an emasculator previously cleaned and boiled, or tied with a carbolized new cord painted with tincture of iodine, and, when dry, dusted with tannic acid impregnated with iodine and carbolic acid.

The new-born foal may have the back (flexor) tendons contracted so as to stand over at the knee and fetlock, and in the worst cases the extensor pedis tendon, the opponent of these, is found to be divided across and the muscle wasted and degenerated. A succession of such cases in the same stable suggests infection. Slight cases will recover under splints and bandages, while for more severe ones an aseptic surgical operation may be required. The foal should have the first milk (*colostrum*) to clear away tenacious bowel contents and prepare for healthy function. A mild laxative of raw linseed or olive oil may be requisite in the absence of colostrum. In the absence of the dam's milk the foal may be raised on cow's milk reduced by adding one third boiled water and sugar to sweeten. After two or three weeks the undiluted cow's milk may be allowed. The cow should be free from tuberculosis.

For the pure bred racer or trotter the foal should have half a pint of oats daily at a month old, to be increased with his growth. Even draft breeds are benefited by such early grain-feeding.

Exercise is essential to the growing foal. The quality of bone, muscle, brain, and other parts depends largely on physiological use, and rich blood, active digestion, and assimilation, vigorous health, strength and endurance are incompatible with confinement and inactivity. This may at first be secured by freedom to play in pasture, or by careful handling and training by a judicious manager. But to put the two-year-old into a severely contested race, or full training, or to devote the draft colt to regular work, is but to invite disaster. The bones are as yet too soft, they contain too much organic matter and too little mineral, the muscles lack firmness and power of endurance, the whole system is immature and imperfect, and overtaxing exhausts or deranges the functions, and direct injury or impaired development is the natural result.

CARE OF THE FEET.

Overgrown Hoofs.—With unlimited exercise on firm ground, the unshod foot is sufficiently worn down, but when confined for months indoors or in a limited straw yard overgrowth occurs, especially at the toe, and a dangerously increased strain is thrown on the joints, ligaments, and back tendons. Distorted and twisted feet, bruises of the sole by the ingrowing heels and quarters, ringbones, ossified cartilages, sprains of the flexor tendons, and diseases of the fetlock, pastern, and coffin joints are common, and irreparable results. The feet exposed to this should be frequently pared and adjusted. Remove excess of toe, reduce and balance the inner and outer sides of the wall, file or cut to the level the incurving heels and quarters, and round off the sharp outer edge of the hoof. Dry, imprisoned plates of horn pressing up on the sole must be set free and removed. But do not file the surface of the hoof-wall. This removes nature's protective covering and exposes open horn tubes to exhale moisture, and conduces to dryness, brittleness, shrinking, compression, and inflammation of the sensitive parts, atrophy, and lameness.

Defective Growth of Hoof.—Imperfect growth of hoof may arise from shoeing, pinching, filing, paring, etc., to excess, but also from compulsory idleness. The circulation inside the hoof is greatly accelerated by the ascent and descent of the foot within the horny box in action, and a free blood supply in a healthy tissue favors growth. Life at pasture on firm ground tends to abundant, strong, tough, durable hoof, while close confinement in a stall makes for a thin, friable, brittle, and shrunken horny covering. Constant soaking in water softens the hoof, reducing its tenacity, and tending to flattening of both wall and sole. The Belgian and other horses bred on wet, swampy ground generally show large, flat, pliant, and most undesirable hoofs. Such feet are especially liable to thrush, canker, corns, bruises, grease, and laminitis. Feet habitually resting on piles of reeking manure in stalls, sheds, or yards suffer the additional injury of softening and disintegration from the ammonia gas, and attacks by the swarming putrefying microbes which abound in such material.

Good hoofs, beside use and care, depend on generous living. The fuller growth on the spring and summer grass, forming a permanent ring, illustrates this. Daily washing of the hoof is important, and a subsequent smearing with an ointment of tar and vaseline or oil is useful in preserving the natural moisture and preventing the attacks of microbes.

Shoeing.—For good feet, shoes may be dispensed with on soft ground or mud roads, but they become necessary on hard roads and for hard-worked animals. Tips, extending back to the broadest part of the foot only, are the least objectionable. Full sized shoes are too often made to pinch, distort, bruise, or injure the foot beyond repair; and a poor foot is as injurious to a horse as an unstable foundation to a building. The first consideration is the preparation of the foot, giving due balance to heel and toe, inner side and outer, sole and wall, heel and bars. While removing all overgrown wall and bars, and all sole-plates that have become detached from the tough living horn beneath and now act as foreign bodies, the tough horn itself should not be exposed, nor removed except as a thin margin around the outer edge, where it is smoothed to the same level as the wall, to which it acts as a support, and the bearing surface of which for the shoe it slightly extends. The outer surface of the wall must be spared abrasion by the file, with consequent drying and contracting as already noticed. Shoes should be removed and reset every four weeks at the utmost, to avoid pinching, setting in, bruising, and other injuries. Intelligent shoeing, conserving the feet, goes far to obviate diseases of the feet, the most common and harmful of equine diseases. Among these may be specially named corns, bruises, pricks, quittors, sandcracks, thrush, canker, sidebones, laminitis, navicular disease, contracted hoof, cleft hoof, wry hoof, crooked hoof, loose wall, hollow wall and graveling. As the integrity and easy normal function of the foot is further one of the best means of protection against distortions and diseases of the various joints of the limb, it follows that the preservation of sound feet by good shoeing and intelligent care is one of the greatest desiderata in horse management.

FEEDING AND DIGESTIVE DISORDERS.

The natural food of the horse is *grass* and though charged with excess of water, and at first liable to scour, and always to cause flaccid muscles and lack of energy and endurance, yet a run at pasture, with pure air, normal, easy exercise, and stimulation of stomach, liver, bowels, metabolism, and excretion will often improve or arrest infirmities of digestion, assimilation, elimination and even innervation. Heaves (broken wind), chronic bronchitis, various forms of nasal discharges, indigestion, torpid liver, gall stones, and kidney affections are examples of maladies which improve at pasture. Dried grass in the form of hay is the standard food of the domesticated horse. This is best from natural pastures with a mixture of grasses, to be followed by blue grass, timothy, ryegrass, and clover, the latter being the most dangerous as a horse fed. Upland hay is more aromatic and choice than that from low, damp or irrigated meadows, and the first crop is always the best. New hay will sometimes disagree, while the old, though lacking aroma and less palatable, is less likely to cause digestive disorder. At a year old and over it is brittle, dried, more fibrous and less nutritive. Badly cured hay is always innutritious, and often directly poisonous, when altered by bacterial ferments, molds and their products. The results are shown in heaves, gastric disorders, liver troubles, brain affections (staggers), kidney and skin diseases. Second crop hay, clover and alfalfa hay are especially dangerous in this sense, the excess of proteids in the last two, and especially of foliage, delaying curing and favoring the multiplication of ferments. Oats are the standard grain feed for horses. But like hay they must be well matured on good soil, and well cured. Mustiness brings essentially the same evils as in hay, and newly harvested they are liable to disagree. Kiln-dried oats are to be avoided, also those that have sprouted. The composition of oats and hay shows the excess of proteids, carbohydrates and fats in the first, with and a given weight of oats is of more value than an equal amount of similar nutritive elements in wheat or barley.

Good judgment and regularity in feeding and watering are essential to success with any feed. Feeding in irregular amounts at varying intervals, and with uncertain watering will undo the good effects of a generous ration. The small stomach (16 quarts) cannot admit a large feed of oats and saliva without suffering, and, if overdistended, it becomes paretic or torpid, and dangerous fermentation and gaseous distension may ensue. Again, if feeding is delayed the hungry craving and nervous excitement cannot be undone by a generous feed later. Then again, if the perspiring and exhausted animal is allowed to slake his thirst with a bucket of ice-cold water, he may have heart failure, or

	Water	Proteids	Carbohydrates	Fats	Cellulose	Salts
Meadow hay	14.59	10.11	40.90	2.34	25.52	6.54
Oats	14.3	12.0	60.9	6.0	10.3	3.0
Maize	10.6	10.3	70.4	5.0	2.2	1.5

Maize is notorious for the deficiency of proteids relatively to the carbohydrates and fat. With a great excess of heat and energy producing constituents and a deficiency of earthy salts it is less calculated to foster growth and development, and predisposes rather to fat. It tends more to impactions of the bowels and indigestion, with resulting skin eruptions, and above all to the destructive recurrent inflammation of the eyes, which ruins so many young horses. Yet it is fed over large areas as the exclusive grain feed, and such is the adaptability of the living system that the minimum evil results. To obviate the evils it can be fed with cooling, laxative agents as wheat bran, carrots, or turnips, or an ounce of Glauber salts may be given daily.

Barley, rye and wheat have been successfully fed to horses but are not equal to oats in supporting the animal and fitting for hard work.

Beans, peas and other leguminous seeds are fed when a horse is subjected to an extraordinary strain of work or endurance, being especially valuable for the excess of proteids they contain. They should be thoroughly matured and dried as the fully formed and partially ripened seeds of several species contain a narcotic poison.

The relative amount of hay and oats for a horse of 1,000 pounds live weight may be stated as follows: *Cavalry horse:* Oats 12 pounds, hay 14 pounds. *Carriage horse:* Oats 10 pounds, hay 12 pounds. *Draft horse:* Oats 15 pounds, hay 12 pounds. The horse at rest can live on a mere maintenance ration sufficient to keep up bodily temperature and repair waste. A horse in active work will need about one half more. For very severe or rapid work about one third more must be added. For hard work a broad ration-proteids 1, to carbonaceous matter 6, is preferable to a narrow ration-proteids 1, to carbonaceous matter 3. An economical feed can often be made of a number of agents compounded from their known chemical composition, to form such a balanced ration, but mere chemical ingredients are not final, as palatability and adaptability have still to be reckoned colic, or gastric congestion with sympathetic skin eruption or laminitis, or inflammation may attack any organ that has been previously weakened.

An excellent appetizing food is molasses. This has been largely neglected because of the mistaken idea that it contained heat producing elements only. But corn carbohydrates furnish energy to the acting muscles and other tissues as fuel does to an engine, and sugar, having no need of digestion, can supply force with less loss than can starch or fat. Not the least of its good qualities is the relish with which it is taken and that it imparts to other less attractive food taken with it. For the horse otherwise healthy, but debilitated by poor or faulty feeding or overwork, molasses is to be depended on to restore weight and energy alike. For this purpose it may be given in the amount of two pounds per day, and even in double that amount if subjected to severe work.

Overdistension of the Stomach.—Sudden inflation of the stomach with gas, the product of fermentation in unwholesome contents (frosted grass, roots, apples, green potatoes, overripe ryegrass, millet, vetch, etc., irritant plants); from overfeeding (at the cornbin, in ripe grain, etc.), from violent exertion on a full stomach, or from a full feed when debilitated from starvation, disease, or overwork, is liable to cause death in two hours or a little more. The horse can rarely vomit, or belch gas, the stomach does not absorb, and the outlet by the bowels is one hundred feet long, so that the organ is usually ruptured with fatal results. Among the other less rapid disorders are catarrhal inflammation of the stomach, intestinal colic, congestion, inflammation, impaction, twisting, invagination, calculi and worms. Of poisons may be named: lead through water, etc.; molds, fungi, and bacteria in food (causing gastric, intestinal, hepatic, pulmonary, nervous, cutaneous or kidney diseases); ergot, smut (causing gastric disorder, ulcers of the mouth, abortions, etc.); lupines, Senecio Jacobœa (causing cirrhosis of liver); astragalus, oxytropis (loco, brain disease), equisetum (gastric and intestinal catarrh); to which may be added cicuta, conium, œnanthe, aconite, rhus, ranunculus, larkspur, anemone, digitalis, wild cherry, wild onion, camas, helenium, hyacinth, clematis, thorn apple, colchicum, belladonna, hyoscyamus, bitter sweet, euphorbium, hellebore, wild parsnip, laurel, oleander, etc.

Liver Diseases.—These are notoriously prevalent in hot, damp regions in horses kept in close stables on rich, abundant feeding, in such as have dry feeding and scarcity of water in winter, and in such as have a poorly balanced ration with excess either of proteids or of heating carbohydrates. In damp tropical regions special care is needed as to the site, exposure, ventilation and purity of stables, the dietary, exercise and grooming to obviate liver complaints. Transient fevers, nervous digestion, skin and kidney disorders often originate from troubles in the liver.

Grooming is most important in the finer breeds of horses in clearing off oil and dandruff, rendering the skin pliant, and favoring secretion, exhalation, cooling and elimination. On the contrary, animals at pasture and exposed to cold and wet find a measure of protection in the sebaceous and thick hairy covering. When, however, drenched with perspiration or rain, and in a warm air, the relaxing effect on the skin and general system is very debilitating, hence clipping may become a necessity to be followed by special precautions against cold. The active friction (massage) of grooming renders circulation active, especially that of the lymph, relieving fatigue, favoring elimination and improving the tone of the muscles and general system. The heels need particular care. Clipped heels are irritated by the stubby hair in the folds back of the pastern often precipitating chaps and grease which would have been escaped in the unclipped. The heel is normally protected by the abundance of sebaceous secretion, but when this is rubbed off by dust, clay, sand, etc., the part suffers readily from cold, wet, dried gritty mud or other irritants. Washing the heels, above all with caustic soap, and leaving them to dry in cold air or draft is hurtful. Prompt drying of the heels will obviate the danger, and, if there is already any swelling, gentle massage with a little vaseline will improve the condition. In obstinate cases the source of the trouble may be sought in disorder of digestion, liver or kidney.

Many disorders of the nervous system, lungs, skin, eye and kidneys are due to constitutional troubles which cannot be dealt with here in general terms. Such diseases are usually manifested by elevated body temperature and accelerated or modified breathing or pulse. The temperature of the healthy, mature horse, at rest in a cool or moderate environment, is 99° to 100° F., respirations 10 to 12 per minute, and pulse 35 to 45.

Contagious Diseases.—These agree in one fundamental feature that each is due to a microbe, which passes more or less directly from the affected animal to the sound one, thus propagating the disease. The arrest of the epizootic and even its complete and final extinction, is merely a question of preventing such transmission and of destroying every infecting germ. This truth is not yet duly appreciated by stockowners, legislators nor sanitary officers, but when it is fully realized we shall be near the total extinction of most animal plagues to the unspeakable profit of humanity. The *Contagious diseases* may be divided into two classes: (1) Those in which the infection is either confined to solipeds, or mainly propagated by the equidæ, so that its extinction in these would mean the final extinction of the disease, and (2) those which are propagated in other genera as well, so that the extinction of the germ in other species also would be essential to its complete eradication.

To the first class belong strangles (distemper), contagious pneumonia, equine influenza, glanders, tetanus, vesicular exanthema, contagious acne, petechial fever, gastro-enteritis of the new born, South African horse sickness, dourine, surra, Nagana, Mal de Caderas, infectious paraplegia. The first four of these affections are constantly spread in the United States through sales, public stables, stockyards, railroad cars, ships, and sale-stables, and no radical measure is taken to destroy the germs in such infected places, or to prevent the infection of all solipedes that pass through them.

In the second class must be included: Horse-pox, contagious abortion, thrush of the mouth, infectious ophthalmia, tuberculosis, rabies, malignant œdema, anthrax and emphysematous anthrax. The first six of these are propagated more by other genera than the horse, so that the burden of the work for their extinction would have to be expended on these other classes. The last three are caused by germs which can live out of the animal body in the soil, and their extinction would involve the drainage and sanitation of the infected soils as well.

Parasitic Diseases.—A number of parasites that prey upon solipeds can live indiscriminately in other animals as well. Among these may be named the *Tricophyton* of ringworm; *Aspergillus* of pneumomycosis; *Actinomyces:* different species of wood ticks; *Dermanyssus* of poultry acariasis; *Trombidium Americanum* (and *F. Holosericium*): *Linguatula Denticulata; Eustrongylus Gigas; Filaria Medinensis; Distoma Hepaticum* and *D. Lanceolatum*. By reason of their variety of hosts these would be less easily got rid of. But another list includes the obligato parasites which must live in the soliped at some stage or perish. These accordingly can be extinguished on the same principle as can the microbes of exclusively equine plagues. They include the larvæ of four species of botfly (*Œstrus Equi, Œ. Hæmorrhoidalio, Œ. Pecorum* and *Œ. Nasalis*); three lice (*Hæmatopinus Macrocephalus, Trichodectes Pilosus,* and *Tr. Pubescens*); four mange acari (*Sarcoptes Scabei V. Equi, Psoroptes Communis V. Equi, Symbiotes Communis V. Equi,* and *Demodex Folliculorum V. Equi;* three tapeworms (*Tæmia Perfoliata, T. Mamillana,* and *T. Plicata*); two stomach worms (*Spiroptera Microstoma* and *Sp. Megastoma*); five intestinal worms (*Ascaris Megalocephala, Oxquris Curvala* and *O. Mastigodes, Sclerostoma Equinum* and *Sc. Tetracanthum*): one of the serous cavities (*Filaria Papellosa*); one of the lungs (*Strongylus Arnfieldi*); and four of the blood (*Filaria Hæmorrhagica, F. Irritans, F. Sanguinis Equi,* and *F. Reticulata*). For the obligato parasites their extinction on the victim, and his removal from the source of a fresh supply means a final extinction of the parasite, as the worm cannot be perpetuated without its host. In the case of worms, which survive as eggs and embryos in damp earth and water, the exclusion of solipeds for a year or two from infested stables and fields, from waters (ponds, lakes, wells, streams) that receive drainage from infested places, and from food derived from such verminous localities, entails the inevitable destruction of these parasites in such habitat outside the body. An essential condition of complete success is that the infested animals must be themselves cleared of the worms, to prevent their colonizing new places with the parasite, and, in the case of such as are entertained in the blood, or serous cavities or in cysts in the tissues, this takes time to allow of their migrating into the bowels or reaching their limit of life and perishing. The mere use of anthelmintics or vermifuges alone is no radical treatment for these parasites. A veterinary sanitation which is far reaching enough to do away for all time with the class of contagious and parasitic epizootics, is the only one worthy of twentieth century knowledge, or which will fulfill the duties of the age.

James Law,
Director New York State Veterinary College, Cornell University.

Horse, Evolution of the. As a domestic animal the horse is to be found almost everywhere that man can live. He is spread all over the world — from torrid to arctic climates, in all the continents, in remote oceanic islands — he is completely cosmopolitan. But as a wild animal the horse is limited to the Old World, and is found there only in the open arid or desert plains of Central Asia and Africa. There are two species in Asia, the Asiatic wild ass (*Equus hemionus*), and the little known Przewalsky's horse (*E. przewalskii*), while in Africa there are the African wild ass (*E. asinus*) and the several species of zebra (*E. zebra, E. burchelli, E. quagga*). In the Americas and Australia there are no true wild horses, the mustangs and broncos of the Western plains and South America being feral (domesticated animals run wild) and descended from the horses brought over from Europe by the early white settlers. When the Spaniards first explored the New World they found no horses on either continent. The Indians were quite unfamiliar with them and at first regarded the strange animal which the newcomers rode with wonder and terror, like that of the ancient Romans when Pyrrhus and his Greeks brought elephants to fight against them.

The horse is distinguished from all other animals now living by the fact that he has but one toe on each foot. Comparison with other animals shows that thi. toe is the third or middle digit of the foot. The hoof corresponds to the nail of a man or the claw of a dog or cat, and is broadened out to afford a firm, strong support on which the whole weight of the animal rests. Behind the "cannon-bone" of the foot are two slender little bones, one on each side, called *splint-bones.* These represent the second and fourth digits of other animals, but they do not show on the surface, and there is nothing like a separate toe. So that the horse may be said to be an animal that walks on its middle finger-nail, all the other fingers having disappeared.

The teeth of the horse are almost equally peculiar. The molars are long, square prisms which grow up from the gums as fast as they wear off on the crowns. Their grinding surface exhibits a peculiar and complicated pattern of edges of hard enamel between which are softer spaces composed of dentine and of a material called "cement," much like the dentine in quality but formed in a different way. The dentine is formed on the inside surfaces of the enamel while the tooth is still within the jaw-bone; the cement is deposited on the outside surfaces of the enamel after the tooth has broken through the jaw-bone and before it appears above the gums.

Various other peculiarities distinguish the horse from most other animals; some of these are shared by other hoofed animals. The two long bones of the fore-arm (*radius* and *ulna*) are separate in the greater number of animals, but in the horse, and in many other hoofed animals, they are consolidated into a single bone. The same consolidation is seen in the bones of the lower leg (*tibia* and *fibula*). The lengthening of the foot and stepping on the end of the toe raises the heel in the horse, as in many other animals, to a considerable height above the ground, where it forms the hock joint, bending backward, as the knee bends forward. In these as in various other ways the legs of the horse are especially fitted for swift running over hard and level ground, just as its teeth are for grinding the wiry grasses which grow on the open plain.

The zebra and the ass have the same peculiar structure of teeth and feet as the domestic horse, and differ only in the color of the skin, proportions of various parts of the body, etc.

Fossil Horses of the Age of Man.— In the early part of the Age of Man, or Quaternary Period, wild species of horse were to be found on every continent except Australia. Remains of these true native horses have been found buried in strata of this age in all parts of the Unfted States, in Alaska, in Mexico, in Ecuador, Brazil and Argentina, as well as in Europe, Asia and Africa. All these horses were much like the living species, and most of them are included in the genus *Equus.* A complete skeleton of one of them (*Equus scotti*) was found by the American Museum expedition of 1899 in northern Texas. The difference between it and the domestic horse is chiefly in proportions, the skull shorter with deeper jaws, the legs rather short and feet small in proportion to the body. In these characters this fossil horse resembles an overgrown zebra rather than a domestic horse. We know nothing of its coloring. It may have been striped, and in this case would have been very zebra-like; but there are some reasons for believing that it was not prominently striped. The bones are petrified, brittle and heavy, the animal matter of the bone having entirely disappeared and having been partly replaced by mineral matter. They are not much changed in color, however, and are so perfectly preserved that they look almost like recent bone.

All the remains of these native horses which have been found in America have been petrified more or less completely; this means that they have been buried for many thousands of years, for petrifaction is an exceedingly slow process.

It serves as an easy method of distinguishing them from bones of the domestic horse, found buried in the earth. These cannot in any case have been buried for more than four or five centuries, and have not had time to petrify. Remains of these fossil horses are found in various parts of the United States, chiefly on the Niobrara River in Nebraska, and in central Oregon. Many separate teeth and bones have been found in the phosphate mines near Charleston, S. C.; other specimens have come from central Florida, from southern Texas, Arizona, Kansas, Louisiana and even from Alaska. They are, in fact, so often found in deposits of rivers and lakes of the latest geological epoch (the Pleistocene) that the formation in the western United States has received the name of Equus Beds.

In South America, in strata of the Pleistocene Epoch, there occurs, besides several extinct species of the genus *Equus*, the *Hippidium*, a peculiar kind of horse characterized by very short legs and feet, and some peculiarities about the muzzle and the grinding teetch. The legs were hardly as long as those of a cow, while the head was as large as that of a racehorse or other small breed of the domestic horse. All these horses became extinct, both in North and South America. It may have been that they were unable to stand the cold of the winters, probably longer continued and much more severe during the Ice Age than now. It is very probable that man — the early tribes of prehistoric hunters — played a large part in extinguishing the race. The competition with the bison and the antelope, which had recently migrated to America — may have made it more difficult than formerly for the American horse to get a living. Or, finally, some unknown disease or prolonged season of drought may have exterminated the race.

In Central Asia, two wild races persist to the present day; others were domesticated by man in the earliest times, and their use in Chaldæa and Egypt for draught and riding is depicted in the ancient mural paintings. In Africa the larger species became extinct in prehistoric times, as in America, but the smaller zebras still survive in the southern part of the continent (one species, the quagga, abundant 50 years ago, is now probably extinct), and the African wild ass is found in the fauna of the northern part. The wild horse of prehistoric Europe, a small race, short-legged and shaggy-haired, was domesticated by man, a fact that is known from the rude drawings scratched on bone or ivory by men of the Neolithic or Polished Stone Age. But the domestic horse now in use is derived chiefly from the Asiatic race, although it is probable that in some breeds there is a considerable strain of this shaggy, short-legged European race, and it is possible also that African races may have been domesticated and to some extent mixed with the Asiatic species. The domesticated ass is a descendant of the African species.

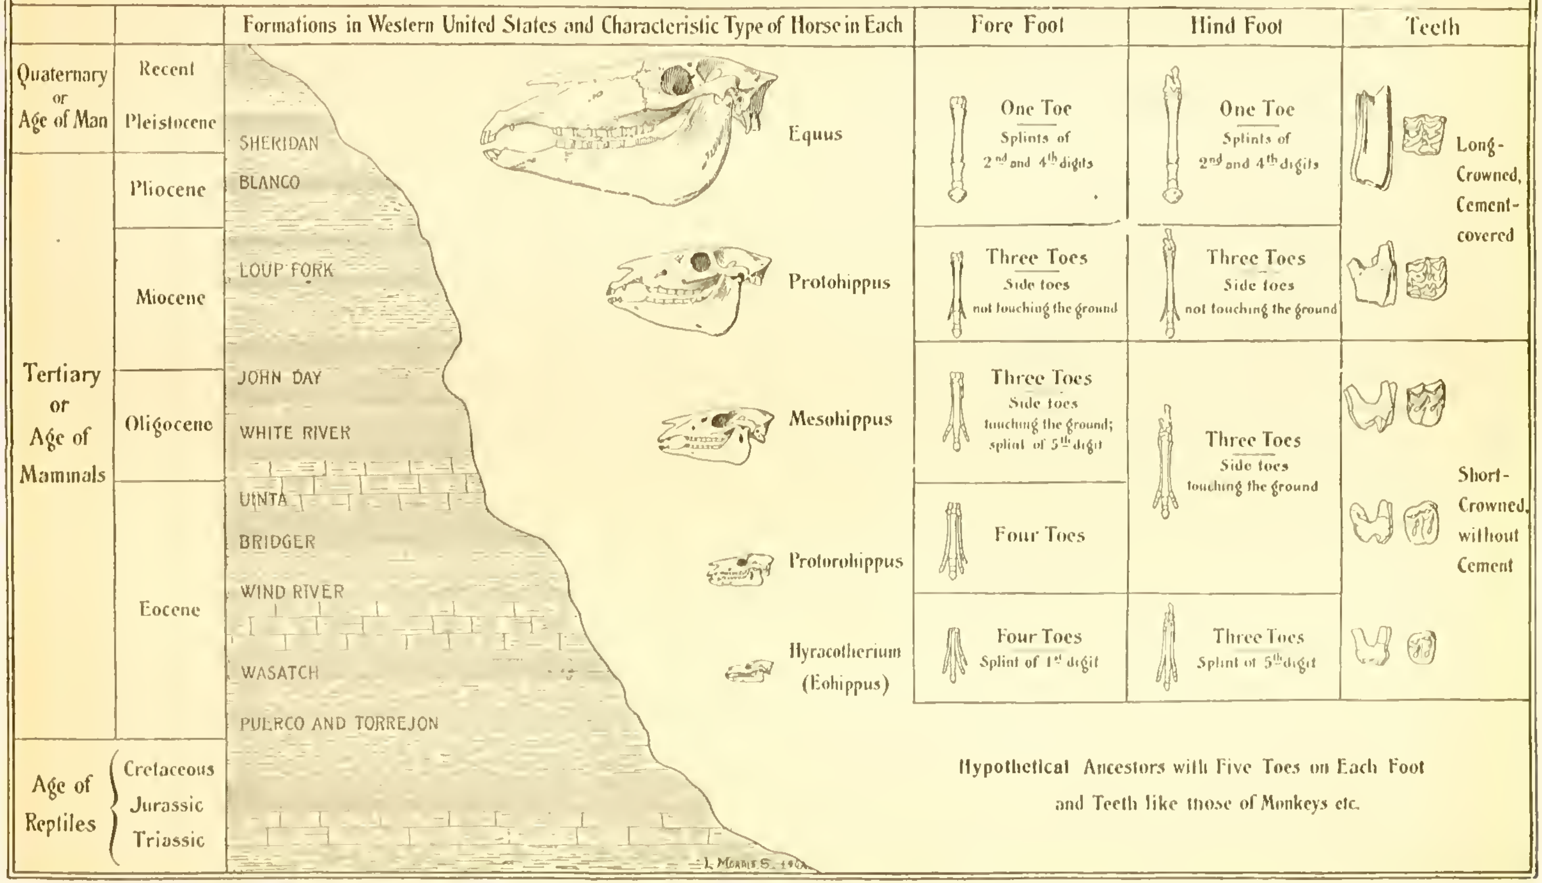
The Evolution of the Horse.— The history of the evolution of the horse through the Tertiary Period or Age of Mammals affords the best known illustration in existence of the doctrine of evolution by means of natural selection and the adaptation of a race of animals to its environment. The ancestry of this family has been traced back to nearly the beginning of the Tertiary without a single important break. During this long period of time, estimated at nearly 3,000,000 of years, these animals passed through important changes in all parts of the body, but especially in the teeth and feet, adapting them more and more perfectly to their particular environment, namely the open plains of a great plateau region with their scanty stunted herbage, which is the natural habitat of the horse. In the series of ancestors of the horse we can trace every step in the evolution of those marked peculiarities of teeth and feet which distinguish the modern horse from an ancestor which so little suggests a horse that, when its remains were first found 40 years ago, the animal was named by the great palæontologist Richard Owen, the *Hyracotherium* or "Coney-like Beast." Its relation to the horse was not at that time suspected by Prof. Owen, and was recognized by scientific men only when several of the intermediate stages between it and its modern descendant had been discovered. On the other hand, this first ancestor of the horse line is very difficult to distinguish from the contemporary ancestors of tapirs and rhinoceroses, and indicates how all the modern quadrupeds have diverged from a single type, each becoming adapted to the needs of its especial mode of life.

The earliest known ancestors of the horse were small animals not larger than the domestic cat, with four complete toes on each forefoot and three on each hindfoot. There is reason to believe that the still more ancient ancestors of this and all other mammals had five toes on each foot. In the forefoot of the earliest known stage we find a splint-bone or small, slender rudiment representing the missing first digit or thumb, which no longer appears on the surface of the foot, while in the hindfoot there is a similar rudiment representing the outer or fifth digit, but no trace is left of the innermost or first digit. The proportions of the skull, the short neck and arched back and the limbs of moderate length, were very little horse-like; recalling, on the contrary, some modern carnivorous animals, especially the civets (*Viverridæ*). The teeth were short-crowned and covered with low rounded knobs of enamel, suggesting those of monkeys and of pigs or other omnivorous animals, but not at all like the long-crowned complicated grinders of the horse.

Commencing with the *Hyracotherium*, 12 stages have been recognized from as many successive formations, showing the gradual evolution of the race into its modern form, and each stage is characteristic of its particular geological horizon. Some of the stages have been found in several parts of the world, but by far the most complete and best known series comes from the Tertiary Bad Lands of the Western States. Besides the main line of descent which led into the modern horses, asses and zebras, there were several collateral branches which have left no descendants. Of some stages all parts of the skeleton have been found, of others, only the jaws, or jaws and feet, are known. We can mention only the more important stages.

1. The *Hyracotherium* is the most primitive stage known, but only the skull has been found, so that it has not been determined exactly what the feet were like. The teeth display six rounded knobs or cusps on the upper molars and four on the lower ones, and these are just be-

THE EVOLUTION OF THE HORSE.



ginning to show signs of fusing into cross-crests. The premolar teeth have only one main cusp, except the third and fourth premolars (next the molars) in each jaw, which have two and three, respectively. The only specimens which have been found were in the London Clay or Lower Eocene of England and are preserved in the British Museum.

2. The *Eohippus* is much better known. It comes from the Lower Eocene of Wyoming and New Mexico, and is very like the *Hyrocotherium* except that the molar teeth have the cusps more clearly fusing into cross-crests, and the last premolar is beginning to look like one of the true molars. The forefoot of this animal has four complete toes and the splint of a fifth. The hindfoot has three complete toes and the splint of another.

3. *Protorohippus.* In these animals the splint of the first digit in the forefoot and the splint of the fifth digit of the hindfoot have disappeared, but there are still four complete toes in the fore- and three in the hindfoot. The crests on the molars are a little clearer and the last premolar has become almost like the molars, while the next to the last premolar is beginning to become so. A skeleton of *Protorohippus* shows an animal of the size of a small dog, and proportioned much like the breed known as the *whippet.* The *Protorohippus* was found by Dr. J. L. Wortman in 1880 in the Wind River Bad Lands of Wyoming, and was described by Prof. Cope and others under the name of the "Four-Toed Horse."

4. Of *Orohippus* we have only parts of jaws and teeth. A specimen of the forefoot is exhibited in the Museum of Yale University.

5. *Epihippus* (*Upper Eocene*).—Of this stage of the evolution of the horse only incomplete specimens have been found. The molar teeth have the once round cusps almost completely converted into crescents and crests, while another tooth of the premolar series has become like the molars. The toes are still four in the forefoot and three in the hindfoot, but the central toe in each foot is becoming much larger than the side toes. (This species happens to be somewhat smaller than those found in the Middle Eocene stage, but no doubt there were others of larger size living at the same time). *Palæotherium* and *Paloplotherium* of the Upper Eocene of Europe form a side branch. They were very abundant in Europe, but have not been found in the New World. On each foot they had three toes of nearly equal size, and the teeth show a rather peculiar pattern. One of these animals was thought by Prof. Huxley to be a direct ancestor of the horse, but it now is considered to be merely a collateral relative. Some species of *Palæotherium* were of large size, equal to a tapir. They were first described in the year 1804 by the celebrated Baron Cuvier from remains found in the gypsum quarries of Montmartre, Paris.

6. *Mesohippus. Oligocene* (*White River Formation*). In this stage there are three toes on each foot, a splint representing the fifth digit of the forefoot of the Eocene ancestors. The middle toe is now much larger than the side toes, which bear very little of the weight of the animal. Three of the premolars have now become entirely like the molar teeth, the crests on the crown are completely formed, and the outside crest in the upper molars has taken the shape of two crescents. In the Middle Oligocene is found *Mesohippus bairdi* about the size of a coyote, while in the Upper Oligocene occurs *Mesohippus intermedius* as large as a sheep. Of both these animals all parts of the skeleton are known.

7. *Anchitherium* (*Lower Miocene*).—This stage has been found both in Europe and in America. It is much like its predecessor, but is larger and has the crests of the teeth somewhat higher and more complete. It probably is not in the direct line of descent of the horses, but is on a side branch.

8. *Parahippus* and *Hypohippus* (*Middle Miocene*).—In *Parahippus* the tooth-crests are much higher, and the transverse ridges on the upper molars are beginning to change shape so as to become a second pair of crescents inside the outer pair. *Hypohippus* is off the direct line of descent; its teeth are like those of *Anchitherium,* by which name it has been generally called, but the animal was much larger, equaling a Shetland pony in size. A complete skeleton of the *Hypohippus* was found near Pawnee Buttes, Colorado, in 1901 by Barnum Brown, of the Whitney expedition. In the forefoot of *Hypohippus* small rudiments still remain representing the first and fifth digits, but there is no splint of the fifth, as in *Mesohippus.* The second and fourth digits still touch the ground, though lightly. The feet of *Parahippus* were much like those of *Hypohippus*, but the side toes were smaller.

9 and 10. *Protohippus* and *Pliohippus* (*Middle* and *Upper Miocene*).— In this stage the crowns of the upper molars have become much longer, the two pairs of crescents on the upper molars are complete, with two half-separated cusps within the inner pair. And the valleys between the crests have become filled with cement, so that with the wear of the teeth the edges of hard enamel are backed inside by dentine and outside by cement. In this way the surface of the tooth has a series of enamel ridges always projecting a little above the grinding surface, because the softer material on each side wears down into hollows, yet never breaking off, because they are braced so thoroughly on each side. This is a very efficient instrument for grinding hard grasses. In *Protohippus* and *Pliohippus*, especially in the former, the crowns of the teeth are by no means as long as in the modern horses; they must therefore wear more slowly or wear out at an earlier age. The feet in these two genera have but one toe touching the ground. The side toes (second and fourth digits) are complete, but much more slender than in the earlier stages, and are apparently useless, as they cannot reach the ground. In some species of *Pliohippus* they have almost disappeared. The forefoot of *Protohippus* still retains tiny nodules of bone at the back of the "wrist" (sometimes improperly called in the horse the "knee-joint"), which are the remains of the first and fifth digits.

11. *Hipparion* (*Pliocene*).—This genus, probably also a side branch of the genealogical tree of the horse family, is much like *Protohippus*, but larger and with more complication about the tooth pattern. It is common in the

European Pliocene beds and has been found in America also. The feet are still three-toed, the side toes as large as those of the older *Protohippus.*

12. *Equus* (*Pleistocene* and *Recent*).— In this stage, that of the modern horse, the side toes have entirely disappeared and are represented by splints on the fore- and hindfoot. No trace remains on the forefoot of the little nodules which in *Protohippus* represented the first and fifth digits. The crowns of the teeth are much longer than in the last stage, and of the two half-separated inner columns on the upper molars, one has disappeared, the other has increased in size and changed in form. The skull has lengthened and the animal is much larger.

13. *Hippidium* (*Pleistocene, South America*).— The feet are like those of *Equus*, except that they were short and stout. The teeth are like those of *Pliohippus*, from which it is supposed to be descended. The skull is large and long, with very long slender nasal bones. Casts of the skull and limbs presented by the Museo Nacional of Buenos Ayres, Argentine Republic, are exhibited here.

The Change in Feet and Teeth.— Along with the disappearance of the side toes in the evolution of the horse there is a considerable increase in the proportionate length of the limbs, and especially of the lower part of the leg and foot. The surfaces of the joints, at first more or less of the ball-and-socket kind, which allows free motion of the limbs in all directions, become keeled and grooved like a pulley-wheel, permitting free motion forward and backward, but limiting the motion in all other directions and increasing considerably the strength of the joint. By this means the foot is made more efficient for locomotion over a smooth regular surface, but less so for traveling over very rough ground, and it becomes of little use for striking or grasping or the varied purposes for which the feet of polydactyl animals are used.

The increased length in the lower leg and foot increases the length of the stride without decreasing its quickness. The heavy muscles of the leg are chiefly in the upper part, and to increase the length of the lower part changes the centre of gravity of the limb very little. Consequently the leg swings to and fro from the socket nearly as fast as before, since in an ordinary step the action of the leg is like that of a pendulum, and the speed of the swing is regulated by the distance of the centre of gravity from the point of attachment, as that of a pendulum is by the height of the bob. To increase the length of lower leg and foot therefore gives the animal greater speed; but it puts an increased strain on the ankles and toe-joints, and these must be strengthened correspondingly by converting them from ball-and-socket joints to "ginglymoid" or pulley joints. Additional strength, likewise at the expense of flexibility, is obtained by the consolidation of the two bones of the fore-arm (*ulna* and *radius*) and of the leg (*tibia* and *fibula*) into one, the shaft of the smaller bone practically disappearing, while its ends become fused solidly to its larger neighbor.

The increase in length of limb renders it necessary for the grazing animal that the head and neck should increase in length in order to enable the mouth to reach the ground. An example of these changes is the modern horse, in which we find the neck and head much elongated when compared with the little *Hyracotherium*, and this elongation has taken place *pari passu* with the elongation of the legs. The reduction and disappearance of the side toes and the concentration of the step on the single central toe serve likewise to increase the speed over smooth ground. The soft yielding surface of the polydactyl foot is able to accommodate itself to a rough irregular surface, but on smooth ground the yielding step entails a certain loss of speed. A somewhat similar case is seen in the pneumatic tire of a bicycle; a "soft" tire accommodates itself to a rough road and makes easier riding, but a "hard" tire is faster, especially on a smooth road. Similarly, the hard, firm step from the single toe allows of more speed over a smooth surface, although it compels the animal to pick its way slowly and with care on rough, irregular ground.

The change in the character of the teeth from "brachydont" or short-crowned to "hypsodont" or long-crowned enables the animal to subsist on the hard, comparatively innutritious grasses of the dry plains, which require much more thorough mastication before they can be of any use as food than do the softer green foods of the swamps and forests.

All these changes in the evolution of the horse are adaptations to a life in a region of the level, smooth and open grassy plains which are now its natural habitat. At first the race was better fitted for a forest life, but it has become more and more completely adapted to live and compete with its enemies or rivals under the conditions which prevail in the high dry plains of the interior of the great continents. The great increase in size, which has occurred in almost all races of animals whose evolution we can trace, is dependent on abundance of food. A large animal, as may be shown on ordinary principles of mechanics, requires more food in proportion to its size than does a small one, in order to keep up a proper amount of activity. On the other hand a large animal is better able than a small one to defend itself against its enemies and rivals. Consequently, as long as food is abundant, the larger animals have the advantage over their smaller brethren, and by the laws of natural selection the race tends to become continually larger until a limit is reached when sufficient food becomes difficult to obtain, the animal being compelled to devote nearly all its time to getting enough to eat.

Cause of the Evolution.— The evolution of the horse, adapting it to live on the dry plains, probably went hand in hand with the evolution of the plains themselves. At the commencement of the Age of Mammals the western part of the North American continent was by no means as high above sea-level as now. Great parts of it had but recently emerged, and the Gulf of Mexico still stretched far up the valley of the Mississippi. The climate at that time was probably very moist, warm and tropical, as is shown by the tropical forest trees, found fossil even as far as Greenland. Such a climate, with the low elevation of the land, would favor the growth of dense forests all over the country, and to such conditions of life the animals of the beginning of the Mammalian period must have been adapted. During the Tertiary the continent was steadily rising above the ocean-level, and at the

same time other influences were at work to make the climate continually colder and drier. The coming on of a cold, dry climate restricted and thinned the forests and caused the appearance and extension of open, grassy plains. The ancient forest inhabitants were forced either to retreat and disappear with the forests, or to adapt themselves to the new conditions of life. The ancestors of the horse, following the latter course, changed with the changing conditions, and the race became finally as we see it to-day, one of the most highly specialized of animals in its adaptation to its peculiar environment. At the end of the Age of Mammals the continents stood at a higher elevation than at present, and there was a broad land connection between Asia and North America, as well as those now existing. At this time the horse became cosmopolitan, and inhabited the plains of all the great continents, excepting Australia.

It is a question whether the direct ancestry of the modern horse is to be searched for in western America or in the little known interior plains of eastern Asia. It is also unknown why the various species which inhabited North and South America and Europe during the early part of the Age of Man should have become extinct, while those of Asia (horse and wild ass) and of Africa (wild ass and zebra) still survive. Man, since his appearance, has played an important part in the extermination of the larger animals; but there is nothing to show how far he is responsible for the disappearance of the native American species of horse.

Parallel Evolution in Other Races.—It is interesting to observe that while the evolution of the horse was progressing during the Tertiary Period in North America another group of hoofed animals, the *Litopterna*, now extinct, in South America evolved a race adapted to the broad plains of Argentina and Patagonia and singularly like the horse in many ways. These animals likewise lost the lateral toes one after another, and concentrated the step on the central toe; they also changed the form of the joint-surfaces from ball-and-socket to pulley-wheel joints; they also lengthened the limbs and the neck; and they also lengthened the teeth, and complicated their pattern. Unlike the true horse, they did not form cement on the tooth, so that it was by no means so efficient a grinder. This group of animals native to South America became totally extinct, and were succeeded by the horses, immigrants from North America, which in their turn became extinct before the appearance of civilized man.

Many of the contemporaries of the horse in the northern hemisphere were likewise lengthening the limbs, lightening and strengthening the feet, elongating the tooth-crowns to adapt themselves to the changing conditions around them, but none paralleled the horse evolution quite so closely as did the pseudo-horses of South America. But the camels in America, the deer, antelope, sheep and cattle in the Old World, progressed on much the same lines of evolution, although their adaptation was not to just the same conditions of life.

WILLIAM D. MATTHEW,
American Museum of Natural History.

Horse, the French Coach. The prevailing characteristic of a Frenchman is his devotion to those things that make life pleasant. From an artistic standpoint he leads the world. Pleasure and horses go together. A Frenchman is instinctively a horseman. The French cavalry is without an equal in the world. Since the time of Napoleon the French government has taken charge of the breeding of horses that are best adapted for cavalry uses, and in accomplishing this purpose the government has contributed to the production of a very high-class coach horse. The cavalry horse of France is usually selected after the committee has finished their work of picking out the very best stallions for breeding purposes. Nearly every French coach stallion that stands for public service in France is owned by the French government. The French have been willing to advertise and sell their other breeds of horses, but they have been loath to part with their coach horses. The instinct of self-preservation causes the French government and the French people to keep their French coach horses at home in order to have better horses than can be found in any other country.

The breed of French coach horses has its origin from the same source as the English thoroughbred. On the one hand, the English thoroughbred surpasses in speed, while the French coach horse is superior in all of those qualities that go to make up a high-class carriage horse. Like the Percheron, the French coacher is developed in its highest state of perfection in Normandy, but he comes from the northern part, while the Perche is in the south of Normandy.

The French coach horse is about 16 hands high; his average weight is between 1,200 and 1,300 pounds. His color is as a rule bay, brown or chestnut. His outline is most pleasing. He is a fast trotter, and under the conditions of horse racing in France under saddle over a turf track a distance of 4,000 metres he holds the record. The French method of developing their trotters cultivates a very high, attractive style of action. Not only is the French coacher seen in every French city hauling the most gorgeous equipages over the boulevards surrounding Paris, but he is to be seen in the best stables throughout all of the capitals of Europe, especially in London.

The French coacher supplies the English royalty with their most useful and most attractive carriage horses.

For more than 20 years French coach stallions have been brought to America very sparingly. Where they have been crossed with the best road mares, trotting bred mares, the result has been most satisfactory. High-grade carriage horses that go into our best markets and sell for the highest prices usually have a strain of French coach blood flowing through their veins.

A perfect type of the French coach horse when standing or in action is impossible to describe in words. To fully realize his superiority, to appreciate and admire his style and magnificent high action, one must actually see him. Words are inadequate to describe him, and the most perfect picture falls far short of the most perfect horse.

JOHN R. MCLAUGHLIN.

Horse, the Percheron. The Percheron horse is the production of the most patient care and the application of the best scientific principles of breeding. From the dawn of history the French breeders of draft horses have been most successful, and the horses they have raised have been renowned the world over.

In the 16th, 17th and 18th centuries the same rules of selection in breeding have been applied that prevail to-day. The good horses were permitted to reproduce themselves and multiply. The inferior and unsound ones were never permitted to breed. The result of this most careful selection, based on scientific principles, has given the French the best draft horse that the world produces.

In a very small portion of Normandy called the "Perche" the highest result has been attained. From this district the Percheron horse has been sent to all parts of the world with such satisfactory results that the word Percheron today means the ideal draft horse the world over. From the very beginning up until the present time the object of the Percheron breeders has been to produce the kind of horse that would move the greatest weight with the greatest speed.

In making their selections for breeding purposes the Frenchmen have not only picked out stallions and mares that would make the best horses, but comely appearance and pleasing outline have also in a measure been their guide, and as a result the Percheron horse to-day is not only the best draft horse in the world, but he is one of the most attractive. He is indeed a handsome horse. The prevailing color of the Percheron horse is from black to white, including all of the various gradations from black, dark gray, dapple gray, gray and white.

About 50 years ago the first Percheron stallions were imported from France to America, and those that became most famous came to Ohio. One, called Louis Napoleon, owned in Union County, Ohio, and afterwards sold to go to Normal, Ill., both here in Ohio and in his new home in Illinois, was admired by all. In a few years, when his colts began to appear, the reputation of the Percheron breed in America was so well established that hundreds and even thousands of them have been imported to America each year.

During the past hundred years the government in France has maintained a system of supervision over the horse-breeding industry. The government does not own every Percheron stallion, but every Percheron stallion must be approved by the government inspectors and must receive a certificate of approval before he can be used for breeding purposes in France. Many of the best stallions belong to the government. Many of those owned by private individuals receive a subsidy from the government if their owner will offer their services to the public.

On account of the very high tariff laws the French breeders supply nearly all of the horses used in France. The ups and downs of prosperity and depression do not affect the horse-breeding industry in that country. During the period of depression that prevailed in the United States ten years ago American breeders became very much discouraged. Most of the stallions were castrated and the best mares were disposed of, but in France these conditions did not prevail.

In '97, '98 and '99, when more prosperous conditions were brought about in this country, the demand for horses was very greatly increased. The French were able to supply the deficiency. Good stallions and mares could be found there in abundance when a surplus could not be found anywhere else in the world. Instinctively the French breeders keep their best stallions and mares, no matter what the foreign demand may be, and as long as they pursue this policy the best Percheron horses will be found in France and the best breed of draft horses in the world will be the Percheron.

JOHN R. MCLAUGHLIN.

Horse Bot-fly, a bot-fly (*Gastrophilus equi*) parasitic in horses. The adult is about .75 inch long; the wings transparent with dark spots forming an irregular band toward the centre; the body brown and very hairy, the head whitish in front, and the abdomen dark-spotted. The females (males are rarely seen) have an elongated tapering abdomen. The oblong light yellow eggs are glued, one by one, to the hairs of the forepart of the body, where they are likely to be licked off by the animal. The moisture of the tongue causes the developed larvæ to break through the shell almost instantly, and to be carried into the mouth and thence to the stomach. Many curious facts have been observed in connection with these eggs and their development, and may be found fully discussed by Osborn in his 'Insects Affecting Domestic Animals,' issued by the United States Department of Agriculture (1896). Reaching the stomach, the larvæ fasten themselves to its walls by hooks in the posterior end of the body, and great masses sometimes accumulate, seriously obstructing the pyloric outlet. They remain there, absorbing nourishment and interfering with digestion through the winter, and on the return of warm weather let go their hold, pass out through the intestines, enter the ground, pupate there for a few days, and then emerge as flies. This pest chiefly affects horses out at pasture, and can be prevented only by removing the eggs, which can easily be seen. The attempt to remove the bots from the stomach by turpentine or other drugs is a dangerous proceeding which should only be attempted under direction of a veterinarian.

Horse-chestnut, or Buckeye, a tree of the small family *Hippocastanaceæ* and genus *Æsculus*, represented in Europe by the horse-chestnut (*Æ. hippocastanum*), now cultivated in all parts of the world, but native to Greece, Turkey, and southwestern Asia; and three indigenous American species known as buckeyes, from the appearance of the fruit. These trees are shapely, have leaflets diverging from the stalk like fingers, and bear white or tinted flowers in large erect panicles, turning the whole tree into the semblance of a big bouquet. The fruit of the horse-chestnut much resembles a huge chestnut, and is prickly when young. In this respect the common or Ohio buckeye (*Æ. glabra*) agrees with it, but has only five leaflets in each leaf and its flowers are small and not showy. The unpleasant odor exhaled by the bark and leaves in all this genus is especially strong in this species. A more southern species, developed into fine trees in the southern Alleghanies, is the sweet or yellow buckeye (*Æ. octandra*) which with the red buckeye (*Æ. pavia*) bears smooth fruit. Though so handsome, rapid in growth and serviceable as ornamental or shade trees, they are otherwise of little value. The wood is light colored, soft, and useful mainly for paper pulp and small articles; it contains a large quantity of saponaceous material, so that country people use the mucilaginous sap as soap. The leaves and roots of the Ohio buckeye are poisonous. The seeds are bitter but are eaten by cattle and sheep, with the preparation of boiling in alkaline water which is necessary in Europe; and from them a flour is made especially adapted to bookbinders' and shoemakers' paste, as, besides having great tenacity, it will not be attacked by insects. In France starch is produced from horse-chestnut seeds on a large scale. The seeds are also used in the southern United States to impart a flavor of age to raw whiskey. The red buckeye has been naturalized in Europe as a park tree. California has a species of its own, Japan another, and a third grows on the Himalaya Mountains.

Horsefield, Thomas, American naturalist and explorer: b. Bethlehem, Pa., 12 May 1773; d. London, England, 1866. He was graduated in medicine at the University of Pennsylvania, and served as "medical apprentice" in the Pennsylvania Hospital from 1794–99, being the fifth interne in the hospital in the order of appointment. In October 1799 he accepted service as surgeon on the "China," about to sail for Java. He returned in the latter part of 1800, but in 1801 went again to Java for the purpose of thoroughly exploring the island, and was commissioned as regimental surgeon by the Dutch Colonial Government. From 1802 he devoted himself to the thorough examination of the flora, fauna, and geology of the island, at first under the auspices of the Dutch government, and, when possession of Java was taken by the English, under the especial patronage of Sir Thomas Stamford Raffles, the lieutenant-governor. A warm friendship, due to kindred tastes, sprang up between Horsefield and his celebrated patron, and, when the English tenure of Java ceased and Sir Stamford Raffles returned to England, Horsefield accompanied him, bringing with him the collections he had made, which were placed in the museum of the East India Company in London, of which he was presently made the curator, a position which he held for nearly fifty years until his death. Horsefield, by his explorations and writings, laid foundations for our knowledge of the natural history of the far East. He contributed while in Java many important papers to the publications of the Batavian Society of Arts and Sciences. In 1824 he gave to the world his great work entitled 'Zoological Researches in Java and the Neighboring Islands,' and from 1838–52 issued in folio parts the 'Plantæ Javanicæ Rariores.' Both works are sumptuously illustrated by colored plates. In 1856–58 he published the 'Catalogue of the Birds in the Museum of the East India Company,' and in 1857–59, with Frederic Moore, the 'Catalogue of the Lepidopterous Insects in the Museum of the East India Company.' Besides these larger works he was the author of a multitude of papers published in the 'Transactions' and 'Proceedings' of societies.

To him perhaps more than to any other single naturalist are we indebted for the first correct account of the botany and zoology of the regions with which he became familiar in his early life.

W. J. Holland,
Director Carnegie Museum, Pittsburg.

Horse-fly, Gad-fly, or **Deer-fly,** any species of the family *Tabanidæ,* usually large, robust, flies, with a broad head pointed in front and concave behind, with immense eyes, and fitting closely to the thorax. The legs are long and stout; sometimes hairy, but without stiff bristles. The females are provided with a long sharp proboscis with which they pierce the skin of animals, and are especially annoying to such short-haired kinds as horses and deer. No poison is injected into the wound, but injurious bacilli may be introduced, causing bad sores. One of the most widely distributed in the United States is the large black *Tabanus americanus.* These flies attach their eggs to grass and sticks in wet places. The larvæ find their way into water or wet earth, and are carnivorous, feeding on other insects, snails, etc. They pass the winter before pupating and emerge as flies in the early summer. To the same family belong many smaller green or yellow species of the woods more usually called deer-flies.

Horse-mackerel. The horse-mackerel, tuna or tunny (*Thunnus thynnus*), is the largest member of the mackerel family (*Scombridæ*), attaining a length of 10 feet or more and a weight of 1,000 to 1,500 pounds. It is found in all warm seas, both of the Atlantic and Pacific oceans, and wanders as far north as Newfoundland, appearing on our shores with the menhaden and mackerel. See Tunny.

Horse-power, the power of an ordinary horse or its equivalent, the force with which a horse acts when drawing. The mode of ascertaining a horse's power is to find what weight he can raise and to what height in a given time, the horse being supposed to pull horizontally. From a variety of experiments it is found that a horse, at an average, can raise 160 pounds weight at the velocity of 2½ miles per hour. The power of a horse exerted in this way is made the standard for estimating the power of a steam-engine. Thus we speak of an engine of 60 or 80 horse-power, each horse-power being estimated as equivalent to 33,000 pounds raised one foot high per minute, but this estimate is considered much too high, 17,400 foot-pounds per minute being generally considered nearer the truth. As it matters little, however, what standard be assumed, provided it be uniformly used, that of Watt has been generally adopted. The general rule for estimating the power of a steam-engine in terms of this unit is to multiply together the pressure in pounds on a square inch of the piston, the area of the piston in inches, the length of the stroke in feet, and the number of strokes per minute, the result divided by 33,000 will give the horse-power deducting one tenth for friction. As a horse can exert its full force only for about six hours a day, one horse-power of machinery is equal to that of 4.4 horses.

The motive power used in the manufacturing establishments of the United States in 1900, according to the census report, aggregated 11,300,081 horse-power, as compared with 5,954,655 horse-power in 1890, 3,410,837 horse-power in 1880 and 2,346,142 in 1870. Of the total power used in manufactures during the census year, steam-engines furnished 8,742,416 horse-power, or 77.4 per cent of the aggregate; water wheels supplied 1,727,258 horse-power, or 15.33 per cent; electric motors, 311,016 horse-power, or 2.7 per cent; gas and gasoline engines, 143,850 horse-power, or 1.3 per cent, and other forms of mechanical power 54,490 horse-power, or five tenths of 1 per cent. Rented power was used to the extent of 321,051 horse-power, or 2.8 per cent of the total. Of this rented power 183,682 horse-power was electric and 137,369 horse-power was from other sources of energy. See POWER.

Horse-racing, a national pastime, which has been called the sport of kings because it has been one of their amusements since the earliest dawn of civilization. The racing horse is of three distinct types, the running horse, the pacing horse, and the trotting horse. For many centuries the running race has been the traditional turf sport in Great Britain and on the continent, with many varieties, such as flat racing, or racing on level ground; steeple-chasing, or racing over ground not specially prepared for the purpose, and hurdle-racing, in which the horses have to leap over obstacles purposely placed in the way. Trotting is primarily an American institution, the outcome of thoroughbred development. Late in the 19th century horse-racing made a wonderful advance in the United States and easily became the great national pastime of the country.

Early History.— Thothmes I., of the 18th Egyptian dynasty, left a papyrus letter telling of his conquest of Mesopotamia, and priding himself upon the acquisition of the racing horse (the Arab) and being the first to introduce him in Africa. Somewhat later the records tell of King Solomon buying horses from Egypt, and paying as much as $3,000 for some of them. Among the Greeks it was introduced into the Olympic games in the 33d Olympiad (648 B.C.). From Greece it was introduced into Rome, where it gained a place as one of the games of the circus. The institution of horse-races in England, where the sport has become a great national pastime, belongs to a very remote period. The first regular horse-races, however, did not take place till the reign of James I. The successors of James I. down to Queen Anne were all more or less attached to the sport. In the reign of the latter, in 1711, the York Plates were founded, and about that date the passion for betting on the turf began to be general. Under George I., the successor of Queen Anne, horse-racing became more flourishing. The two most celebrated horses of that period were Flying Childers (foaled in 1715) and Eclipse (foaled in 1764), which long had the reputation of being the fleetest horses that ever ran. From the latter are descended many of the first-class thoroughbreds of the present day. None of the English sovereigns was more devoted to horse-racing than George IV. Between 1784 and 1792, while yet Prince of Wales, he gained 185 prizes, including the Derby of 1788. Horse-racing was introduced into France from England during the reign of Louis XIV., and under Louis XV. was pursued with the utmost enthusiasm.

Breeding and Training.— The training of a running horse begins with its second year, and is a slow process, requiring great care and attention. During the period of training the horse is under the charge of a stable-boy. In the first part of the training the exercise to which the horse is subjected is comparatively gentle, but in the latter part a gallop of half or three quarters of a mile is taken every other day. Before a race takes place the powers of the horse are put to the test by its being made to run over about half a mile against an older horse, which is weighted to make up for the difference in age. The breeding of thoroughbred horses, that is, of horses which can trace an unbroken pedigree through the best sires and the best dams, is when well conducted a very profitable business. The prices given for stallions are sometimes enormous. In 1900, when the Duke of Westminster's racing stud was sold, the average price reached the high level, and the world's record price of $187,500 was brought by Flying Fox, which had won the Derby the year before. Before this, Ormonde, another Derby winner, had sold for $150,000. The large sums now given for the use of stallions in breeding studs are the cause of race-horses being withdrawn much earlier than they used to be from the turf, for as soon as they have acquired a reputation the owner of a good race-horse can make much larger sums by hiring it out for breeding purposes than he could by entering it for races. The pedigrees of all thoroughbred horses are registered in the stud-book, so that if any particular animal is omitted in that register the inference is that its pedigree is not without some blemish more or less remote. The effects of a careful system of breeding in improving the quality of horses are very marked. No pure Arabian horse can be compared in point of speed with a thoroughbred. In size and shape, too, the horses of the present day surpass those of former times, the average height of a thoroughbred now being 15 hands 3 inches, while formerly it seldom reached 15 hands. See also HORSES, AMERICAN THOROUGHBRED.

Race Meetings.— In Great Britain the chief race meetings are those at Epsom, Newmarket, Ascot in Berkshire, Doncaster, Goodwood, Liverpool, Manchester, and Leicester. Those at Newmarket are the oldest of all, dating from the reign of Charles II. The Ascot races are considered the most fashionable, being largely attended by the aristocracy, and sometimes honored with the presence of royalty. The Goodwood races, which are held in the Duke of Richmond's park in Sussex, are also a favorite rendezvous of the aristocracy. But the most popular meeting throughout the year is the Epsom, which owes its popularity partly to the proximity of Epsom to London and partly also to its being the meeting at which the Derby and the Oaks are run. At the Oaks the ladies are the chief bettors, and the bets are not thousands of pounds, but dozens of Paris gloves. The principal racing meetings in France are those held in spring and autumn at Chantilly and the Bois de Boulogne.

In the United States the season opens at the Bennings track at Washington early in the spring and closes there in the fall. Following Bennings comes the Aqueduct, and Morris Park, Gravesend and Sheepshead, the latter track being the show track of this country, occupying the same position as the Ascot of the English turf, which is also named "The Ladies Meet." Then follows the Brighton Beach season during July and August. Although the classic events of England and France are of longer standing they cannot be said to outrank or outinterest the famous Brooklyn Handicap, founded in 1887; the Suburban (1884); the Futurity (1888); the Realization (1889), and numerous other events. There are racing parks and tracks in nearly every city in the country, and there are many famous meetings in the West and South, like the Latonia in Kentucky, the Harlem and Washington Park in Chicago, Saratoga and others.

Racing Rules.— The conditions under which the most of the races are run are the following: Every horse that takes part in a running race must be entered as a yearling, that is, before the close of the year in which it is foaled, for a horse's age is always reckoned from the 1st of January of the year in which its birth takes place. On being entered a certain sum is paid by the owner, which is called a forfeit, because it is forfeited if the horse is afterward withdrawn, or, in the language of the turf, "scratched." The racing is conducted under association rules, and in England under regulations laid down by the Jockey Club, a body instituted in 1750. The stewards of the Jockey Club have power to grant and to withdraw licenses to racing officials, jockeys, and race-courses; to fix the dates on which all meetings shall be held, and to make inquiry into and deal with all matters relating to racing. At every regular race-meeting there must be at least two stewards, with a clerk of course, a handicapper, a stake-holder, a clerk of the scales (since the jockeys of course must be carefully weighed), a starter, and a judge, each of these officials being licensed by the club.

Handicapping.— Formerly all running races were what is called weight-for-age races, that is, all the horses entered to compete were of the same age and bore equal weights, or if in certain cases there was an inequality in point of age there was also a fixed difference in the weight carried. But it was found that when races were conducted on this plan the best horses came to be known, and the inferior ones withdrew, not venturing to compete with them, so that the race resulted in a walk-over. Hence arose the practice of handicapping, that is, of adjusting as nearly as possible the weight to be carried to the previously ascertained powers of the horse, so as to reduce the chances of all the horses entered to an exact equality. In England the principal weight-for-age race for two-year-olds is the Middle Park Plate, and for the three-year-olds the principal for both colts and fillies are the Two Thousand Guineas, the Derby, and St. Leger, and for fillies only the One Thousand Guineas and Oaks. The most important handicap races are the Great Northampton Stakes, the City and Surburban and Metropolitan Stakes at Epsom, the Northumberland Plate, the Goodwood Stakes, the Ascot Stakes, the Ebor Handicap (run at York), the Great Yorkshire Stakes (run at Doncaster), the Liverpool Spring, Summer, and Autumn Cups, the Cesarewitch, Cambridgeshire, and Newmarket Handicaps (run at Newmarket).

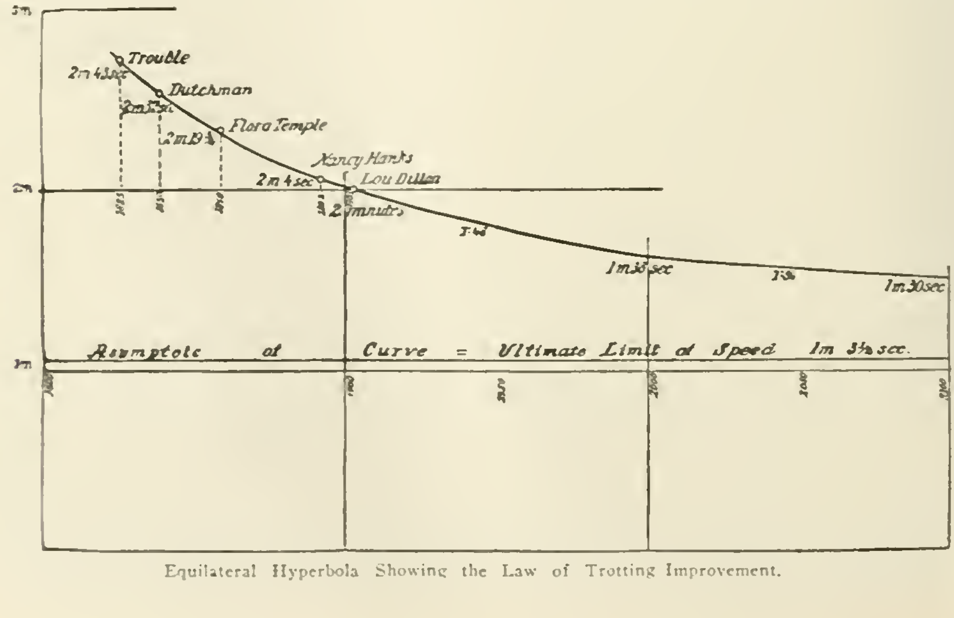
Betting and Book-making.— The prevalence of the practice of betting in connection with horse-racing is a fact so well known that it is needless to enlarge upon it, although it will be of interest to some to explain in what manner it is conducted. Bettors are divided into two classes — the backers of horses, and the book-makers, or professional bettors, who form the betting ring, and make a living by betting against horses according to a methodical plan. Backers of horses may be again divided into those who have special information about the qualities of the horses which are to engage in a race, which enables them to back a particular horse with a certain amount of confidence; and those who have no such means of information, and accordingly back horses pretty much at random. The former class, if their information is good, have a very fair chance of success in their speculations, and the horse that wins any great race usually brings in to his owner vast sums in payment of bets, compared with which the stakes, considerable as they often are, are insignificant; but the latter class are pretty certain in the long run to lose. By the method adopted by the professional bettor the element of chance is as far as possible removed. Instead of backing any particular horse, the professional bettor lays the same sum against every horse that takes the field, or a certain number of them, and in doing so he has usually to give odds, which are greater or less according to the estimate formed of the chance of success which each of the horses has on which the odds are given. In this way, while in the event of the race being won (as is usually the case) by any of the horses entered in the betting-book of a professional bettor, the latter has always a certain fixed sum (say $5,000) to pay, he receives from the backers of the losers sums which vary in proportion to the odds given. Thus, if a book-maker is making a $5,000 book, and the odds against some horse is 4 to 1, he will, if that horse wins, have to pay $5,000, while, if it loses, he will receive $1,250. If the sum of the amounts to which the horses in a particular race have been backed in some professional bettor's book is $6,500, and if the odds against the first favorite were 5 to 2 (or $5,000 to $2,000), then the total sum received by the book-maker, in the event of the race being gained by the first favorite, would amount to $6,500, $2,000 or $4,500, so that he would suffer a loss of $500; while if a horse had won that had long odds against him (say 200 to 1, or $5,000 to $25), his total receipts would amount to $6,475, and his gains to $1,475. Very frequently the receipts of the book-maker are augmented by sums paid on account of horses which have been backed and never run at all.

Americans Abroad.— In 1855 an American horse had never won a race abroad and an American jockey had never ridden in an English race. The first American to go to England with a stable of thoroughbreds was Richard Ten Broeck, who sailed for England in 1856, taking with him Lexington, Lecompte, the only horse that ever beat Lexington: Pryor, and Prioress. Lecompte died of influenza the first year, and Pryor soon followed. It was left for Prioress to retrieve the fortunes of the stable. Her great victory was in the Cesarewitch, a race at 2 miles, 2 furlongs, and 28 yards. There were 37 starters, the very best horses on the English turf. After one of the most exciting races ever run, Prioress, El Hakim, and Queen Bess finished in a dead heat. In the run off, the American horse won by a length in 4 minutes and 15 seconds. American successes really began in 1878, when Pierre Lorillard and James R. Keene shipped stables to England. The former's Parole won the Newmarket Handicap, defeating the English favorite, Isonomy, a horse that was called the best ever foaled on English soil. The American gelding next took the great Metropolitan, the Great Cheshire, and the Epsom Gold Cup in quick succession. Iroquois followed Parole, winning four important stakes in 1880, including the St. Leger. The subsequent invasion of England by W. C. Whitney, Clarence A. Mackey, Richard Croker and others with famous winning horses, and the successes of Sloan, Reiff, Martin and other American jockeys, have brought renown to the American turf. In 1902, American horses ridden by American jockeys took part in 561 races in England, of which they won 85, were second in 80, third in 52, and unplaced 344 times. The stakes and purses won amounted to $234,120. In 1903, up to 15 September the Americans have done even better proportionately, starting in 453 races, winning 74, second in 81, third in 47, and unplaced 251 times. The winnings amount to $259,000. American horses were second in the Oaks and third in the Derby.

Trotting.— The evolution of the trotting horse in America, and the gradual reducing of the one mile record, is a history coincident with the improvement and progress made in breeding. Beginning with the record of Trouble, who trotted a mile in 2.43 in 1826, of Dutchman (2.32) in 1839, and Flora Temple (2.19¾) in 1859, the evolution proceeds to George Wilkes, Dexter, Goldsmith Maid and the others who followed. In 1818, at a Jockey Club dinner, discussion drifted to the trotter, and a wager was made that no horse could be produced which could trot a mile in three minutes. Boston Blue was named at the post by Maj. William Jones, and the old chronicle says that he "won cleverly and gained great renown." The New York Trotting Club was organized in 1825, for the purpose of improving the speed of road-horses. The initial purses were for races of two-mile and three-mile heats. In 1835 trotting was in almost daily vogue in New York. It was not until 1845 that a mile was trotted in less than 2.30. In 1863, the American trotting horse was an unknown quantity abroad, while in 1903, American trotting stock was in demand throughout Europe. Germans, French, Russians, and Austrians have bought some of our best bred animals.

The National Trotting Association was formed in 1870 as a result of a meeting of breeders and track owners the previous year. In 1887 the American Trotting Association was formed with headquarters in Chicago, and it works with the National Trotting Association to detect and punish fraud. Some of the ablest men in the country sit on the boards of appeals, and the decisions command respect and are accepted as final. The careers and records of famous trotters like George Wilkes; Dexter; Harrietta; Axtell (2.12); St. Julian (2.11¼); Sunol (2.10½); Maud S. (2.08¾); Kremlin (2.07¾); Stamboul (2.07½); Beuzetta (2.06¾); Directum (2.05¼); Nancy Hanks (2.04); Alix (2.03¾); The Abbot (2.03¼), and the mile of Major Delmar (2.00¼), Cresceus (1.59¾), and Lou Dillon (1.58½) in 1903, tell the brief but wonderful story of the trotting horse in America. See also Horses, Trotting.

Record Possibilities.— The gradual lowering of the trotting record from a mile in three minutes to the 1.58½ record of Lou Dillon on 24 Oct. 1903 has led many to question if a limit is ever to be reached. The mathematician has a rule to guide him in a guess at the answer to such questions, and the 'Scientific American' has prepared the accompanying chart which is of vast interest. The vertical lines represent the years in which the record has been lowered, the spaces between the lines indicating the time interval, the length of each vertical line indicating the record for that year. A curve is next sought that will pass through as many of the points as possible, or close to them, and the continuation of this curve across lines indicating future years shows the best answer to the main question that the facts warrant. If the curve



Equilateral Hyperbola Showing the Law of Trotting Improvement.

proves to be a hyperbola, it will afford confidence in the accuracy of the solution, for a peculiar property of the hyperbola is that it constantly approaches but never reaches a straight line called an asymptote, and this asymptote represents the ultimate rate of speed. With Lou Dillon at the two minute mark, a point is indicated on the chart showing this hyperbolic curve as the law of improvement. It is now possible to pass the curve of a hyperbola through the record points of Trouble in 1826, Dutchman in 1839, Nancy Hanks in 1892 and Lou Dillon in 1903. This curve will be within a few seconds of many other records in which the time was notably reduced.

The hyperbola is represented by the equation $xy = 10.000$, in which x equals the number of years since 1726, y equals the number of seconds over 63½ seconds to trot a mile. The notable records of Maud S. in 1881 and 1885, with the high-wheel sulky, are 2¼ to 3¼ seconds above the curve, which would indicate that the change to the pneumatic sulky will account for this measurement of the improvement. This curve places the ultimate limit of trotting speed at a mile in 63½ seconds, which, though constantly approached, will never be reached actually, and it indicates the minute and a half mark as two centuries away.

Horse-radish, a species of water-cress (*Roripa armoracia*), native to Europe, but now cultivated everywhere, and becomes naturalized in most parts of the world. Its basal leaves are oblong, finely crenelate and irregular in outline, and its flowers are white and showy. The roots furnish the highly pungent ingredient of a well-known sauce, prepared by grating them, adding vinegar and sealing. They have also some medical use.

Horse-radish-tree. See Ben, Oil of.

Horsefoot Crab, Horse-shoe Crab, or King Crab. This marine animal (*Limulus polyphemus*) was formerly regarded as a crustacean, and is the sole survivor of an extinct group of arthropods intermediate between the trilobites and arachnids. It belongs to the order *Xiphosura,* class *Merostomata,* and phylum *Palæopoda.* By some English authors it is regarded as an arachnid allied to the scorpion. This difference of opinion regarding its affinities is due to the generalized structure of the animal, and to the fact that its nearest allies are extinct.

The body of the horsefoot crab is sometimes two feet in length, and consists of a head and a hind-body or abdomen, the latter ending in a long spine (telson), which is elevated by the creature in defense. The head is in shape somewhat like a horse's hoof, and in burrowing it acts as a shovel, being bent down at nearly right angles to the hind-body. There are a pair of compound and of simple eyes; the mouth is on the under side, nearly surrounded by six pairs of walking legs, while on the hind-body are six pairs of broad swimming legs. There are no antennæ, jaws, maxillæ, or foot-jaws, as in the lobster. The horsefoot crab breathes by means of gills attached to the under side of the last five pairs of abdominal legs, which consist of a pile of about 100 thin broad sacs growing out, one pile on each side, from the base of the legs. The nervous system is peculiar from the nature of the brain, and the œsophageal ring; while the entire system behind the brain is enveloped by the arteries, the latter ending in remarkably fine branches. The heart is large, tubular, the liver very voluminous, and the kidneys are represented by four pairs of excretory red glands, arising from a stolon-like base. The animal is bisexual, the male differing from the female in the second pair of legs ending not in a forceps, but in a sort of hand, with an opposing thumb. The ovaries and testes are voluminous, and the sexual products, eggs and sperm, pass out through a pair of papillæ situated on the under side of the first pair of abdominal legs.

The female lays her large round eggs loosely in the sand between high and low water, spawning in May and June; in about a month they hatch, and the young, after passing late in embryonic life through a trilobite stage, assumes the form of the parent, differing in the short rudimentary caudal spine. It molts frequently, and during the process the front edge of the carapace or head splits open, enabling the animal to draw itself out of the old shell. The recently hatched Limulus is strikingly like a trilobite, but while in the latter new segments are added after birth, in Limulus no new ones are added. The young horsefoot is about 4 millimetres in length. Specimens an inch long are about a year old, and it probably requires several years to grow to the length of a foot or more.

Limulus polyphemus inhabits the eastern coast of North America from Boothbay, Maine, to the West Indies and Honduras, but is most abundant in shallow, retired, sandy, or muddy bays on the coast of New Jersey, Virginia, and North Carolina. Several other species inhabit the seas of the Eastern Archipelago, China, Philippines, and southern Japan. In the United States it is used as a fertilizer, while in the Malayan markets the animals are sold as food.

The Limuli date from the Devonian. An allied group, in shape and structure approaching scorpions, is the Eurypterida (q.v.), one of which (*Stylonurus laccoanus*) of the Devonian of New York and Pennsylvania was about five feet in length, while the British *Pterygotus anglicus* is estimated to have been about six feet in length and two feet across. It is now thought that the scorpions have descended from some merostome, which became adapted for a terrestrial life.

Alpheus S. Packard,
Late Professor of Zoology, Brown University.

Horseheads, N. Y., village, in Chemung County; on the Erie & Central N. Y., and branches of the Delaware, L. & W. and the Northern C. R.R.'s; about six miles north of Elmira. It is in a fertile agricultural region. Its chief manufactures are creamery products, bricks, screens, doors, blinds, men's clothing, cigars, cattle-feed, shoes, and hardware. Pop. (1900) 1,901.

Horses, American Thoroughbred. The American thoroughbred is the production of pure breeds imported from England, first during the 17th and 18th centuries. They first found their way into the Old Dominion of Virginia, where they founded a tribe of early racehorses, to which trace to-day many of the most fashionable pedigrees. From Virginia the thorough breds finally found their way into the Carolinas and as far south as Mississippi and Louisiana, and, upon the formation of Tennessee and Kentucky as States, the breeding of thoroughbreds became with them what might be termed an industry.

The early part of the 20th century finds Kentucky in the lead in the production of thoroughbred horses, followed next by California and then by Tennessee. Missouri and Illinois have recently greatly increased their thoroughbred holdings, while both New York and New Jersey produce a goodly number. Many of the other States take rank as fair producers of thoroughbreds, and, in fact, the breed has found its way into every section of the country, even as isolated a State as Oregon annually producing a number of thoroughbred horses.

The requirements of an American thoroughbred horse are that the pedigree contains five uncontaminated crosses, but the average pedigree traces through 16 to 18 crosses, some having as many as 25. Those reaching an origin of a Natural Barb source are considered the most fashionable, but many great racehorses have descended from lines unknown to early English or Arabian pedigrees.

Diomed, the winner of the first English Derby, imported to this country in 1799, when he was 20 years old, is classed as the greatest of early importations, and he has left a marked impress upon American pedigrees. The most successful importation of the 19th century was unquestionably Glencoe (imported in 1836), and in later days Leamington ranks the highest. In more recent years, the ranks of the American thoroughbred have been greatly increased by almost unlimited importations from England, France, Australia, and other foreign countries, and horses are produced in this country now that are of entirely foreign pedigrees, while there are numerous instances where the first few crosses are strictly foreign lines.

The average height of the early thoroughbred horse was something less than 15 hands, but at this time they average over 15 hands 2 inches, and weigh 150 pounds more than they did a half century ago. In individuality, too, the improvement is very marked, the types now being far superior in form to the horses of early times.

In soundness and general service the American thoroughbred has no superior, this being the result of judicious breeding and favorable rearing conditions. The statistics of the American turf (commonly known as Turf Guides) extend over a period of about 30 years, and in this time these records show that the thoroughbred horse has improved some 30 pounds, which is an equivalent of from 5 to 6 seconds to the mile. This marked improvement can be attributed to an accepted theory of breeding that like begets like, to intelligent methods of training, and to superior riding.

The most favorable condition which has proved so successful in raising the thoroughbred in this country is that he is housed less and has, at all times, access to lands covered by the finest of grasses, which brings his feet constantly into contact with moisture. The frog of the foot, being like a sponge, absorbs this moisture, thus creating a gentle pressure which spreads the hoof. A horse having bad feet naturally favors them, which has a tendency to make bad ankles and tendons on account of their not being freely used, and it is a conceded fact that "no foot, no horse."

In America the horse has been bred more for business than pleasure. The invention of the elliptic spring and the use of American hickory in the production of light vehicles for pleasure and business, together with the invention of macadam and Telford roads, turned the demand from the running to the trotting horse. The first private coach was introduced into New York in 1745; but coaches were scarce until after the Revolutionary War, and not until after 1840, when the light one-horse vehicle came into use, did the changed conditions of travel develop a harness-horse for purposes of business and pleasure. Along with the change in vehicles incident to the evolution of the trotter came as great a change in the style of harness and trappings.

About the beginning of the 19th century there came from the lines of breeding of the thoroughbred, traceable to Flying Childers, Byerly Turk, and the Darley Arabian, Messenger, a gray, stoutly built horse, of wonderful power and stamina, with a slashing, open gait, fitted to found a race of trotters. He was foaled in 1780, and became the progenitor of the trotting families in America. In 1793 Justin Morgan was foaled, sired by one believed to be thoroughbred. Three of his sons, Bulrush, Sherman, and Woodbury, became noted as the sires of horses of intelligence, courage, and speed, and the get of some of them excelled as roadsters and stage horses. From Black Hawk Morgan, sired by Sherman out of a fast trotting English mare, has come the beautiful, useful, and courageous line of Morgans. The original horse (2.40) died in 1856 at the age of 23. In 1849 was foaled Rysdyck's Hambletonian, the founder of the most noted family of trotters, sired by Abdallah, who traced to Messenger by both the sire and dam, out of a dam by Bellfounder, with Messenger crosses on the dam's side. As early as 1876 the interest in breeding and rearing trotters had become so great that fabulous prices were paid for colts, simply on the strength of their breeding. Two fillies, untrained, sold for $13,000. The three-year-old colt Steinway was sold for $13,000 in 1879. Maud S., bred at Alexander's noted stock farm in Kentucky, was sold to Mr. Bonner for $21,000 when four years old, with a record of 2.10¼, and the title "Queen of the Turf." Smuggler sold for $40,000, Pocahontas for $45,000, Goldsmith Maid for $36,000, Dexter for $36,000, and so on, until we come to Axtell, who sold for $100,000 after he had eclipsed the time of all stallions, and retired to the stud, where his service fee was $1,000. The stallion, Rysdyck's Hambletonian, was purchased with his dam for $125, and earned in the stud $205,750. Thirty-six of his get trotted in 2.30 or better, and the prices for which they could have been sold in their best days amounted to $325,000. Among them were Sentinel, George Wilkes, Jay Gould, and Administrator, all noted sires. Their united progeny was worth many thousands for stud and track uses. Some of his sons, without a 2.30 record, became successful in the stud. Alexander's Abdallah was sold for about $3,500, but he got Goldsmith Maid, who made a record of 2.14, and won on the turf close to $250,000; Almont sired 22 2.30 trotters; Bel-

mont got nine with records better than 2.30. So the descendants of Alexander's Abdallah have been worth to their owners hundreds of thousands of dollars. Volunteer was another who ranked among the most successful of the noted Hambletonian sires, having to his credit 23 2.30 performers. Electioneer, bought by Gov. Stanford, proved a noted sire, getting the fastest yearling, 2.36½; the fastest two-year-old, 2.21; the fastest three-year-old, 2.19½; and the fastest four-year-old, 2.18¾. The bracing climate of Palo Alto, and the methods of handling peculiar to Gov. Stanford's breeding farm, aided in these accomplishments. These are but a few of the thousands of good horses that owe success to the Hambletonian blood. The value of trotters has been measured largely by their speed, taken as a measure of ability to win future races, or as evidence of blood lines that will make the animal valuable in the stud. Success in campaigning is undoubted evidence of pluck and stamina; and the breeding and training of the trotter, and his contests on the track, have developed these qualities in so high a degree that no other class can equal him. The evolution of the trotting horse has also shown the value of a training peculiar to America as a factor in breeding.

It is pertinent to notice that in the first years of the last century running races became common in the Middle and Southern States, while a strong sentiment against racing prevailed in the Northern States. In 1820, Pennsylvania, for example, not only forbade racing, but also enacted that no person should "print or cause to be printed, set up or cause to be set up, any advertisement mentioning the time and place for the running, trotting, or pacing of any horses, mares, or geldings," etc. A similar law was in the statutes of Connecticut until within 30 years. New York passed an act to prevent horse-racing 19 March 1802, which was amended 30 March 1821, permitting the "training of pacing, trotting, and running horses" in Queens County for five years. The sheriff was required to be on hand to witness these "trials of speed," as called in the statute. This amendment was re-enacted 3 April 1826, without a time limit. In 1825 the New York Trotting Club was organized, with a view of "improving the speed of road horses." This track was probably the first trotting course in the world. The Hunting Park Association was formed in Philadelphia in February 1828, and the next year a trotting club was organized in Baltimore. These facts show a changing public sentiment, and the records begin to fall. The keeping of records became an established custom as early as 1829, when the 'American Turf Register' began. The English had not then begun to keep records, but the American custom has enabled us to mark the development of speed and establish well-defined breeds during the threescore and more years it has been in use. Wallace's 'American Trotting Register' was started in 1871 by J. H. Wallace, New York, since which time the business of breeding trotters has increased, until now it is estimated by good authority that the number of registered standard-bred trotters exceeds 120,000. In the early history of the record many animals were admitted to registry that are not now classed as standard-bred. The term "standard" indicates to-day ability of one or more ancestors to trot within 2.30.

Before the days of macadam roads and light vehicles, saddle-horses were as common as trotters are to-day. They were of no particular breeding, but traced to the thoroughbred, the Narragansett pacer, or the Scottish Galloway. Herbert suggests that they were of Spanish origin, their ancestors coming from Cuba. There is now a revival of interest in the saddle-horse as a luxury, the demand being beyond the supply. From the ideal set up, especially in Kentucky, it is safe to predict that there will soon be an improved breed of American saddle-horses.

Prior to the introduction of railroads Vermont had what Herbert called a distinct breed of cart-horses. He described them as "the models of what draft-horses should be, combining immense power with great quickness, a very respectable turn of speed, fine show, and good action." They had "none of the shagginess of mane, tail, and fetlocks which indicates descent from the black horse of Lincolnshire," and none of the curliness of mane and tail which marks the Canadian or Norman blood, and were characterized by short backs, close ribbing up and round barrels. The only other breed of American horses we have to notice is the Conestoga, which before the days of the Pennsylvania Railroad was common on the farms and highways of Pennsylvania. It seems to have descended from the stock brought by emigrants from Flanders, Denmark, and Germany. It was a mixture of several breeds, resulting in a large, patient burden bearer, held in high esteem by the Germans of that State. Although we have not originated and permanently established any American breed of draft-horses, the number of heavy horses has greatly increased, and the quality has improved. The increasing heavy business of factories, jobbers, importers, and transfer and express companies in our well-paved cities has called for a great number of powerful horses. This demand has led to the importing of heavy horses from France, England, Scotland, and Germany. The Vermont cart-horse and Conestoga draft-horse excelled the types of foreign heavy horses, as a rule; and it is to be regretted that our pride in American animals has not led our people to perpetuate and further develop these useful horses. Tens of thousands of dollars have been sent abroad since the fad of importing heavy elephantine horses became common in the Western States. The enterprising importers scoured France, England, Scotland, and Germany for the heaviest animals. They imported more than they could sell, and then adopted the plan of leasing stallions for a term of years. Since 1890 there have been many disastrous failures among this class of importers. There were, however, several importers who imported the best type of the draft and heavy coach breeds to be found abroad, establishing breeding farms not excelled in the world. The earliest importer of high-class draft-horses was Edward Harris, of Moorestown, N. J. In 1839 he imported two mares and the stallion Diligence, who was in many respects similar to the McNitt horse, but heavier and more compactly built, being a little over fifteen hands high. The next valuable importation was made by Charles Fullington, of Union County, Ohio, in the spring of 1851. He bought and brought home from France the famous Louis Napoleon, a "short-legged, closely ribbed, blocky, and compact gray, three years old." In 1853 he was sold to A. P. Cushman, of De Witt County, Illinois, and after his colts in Union County proved his worth, a company was formed for importing other horses of his type. The author of the 'Percheron-Norman Stud-Book' says of him that he was undoubtedly the best-known and most popular French horse ever brought to America. The first importations west of the Wabash were made in 1868 by W. J. Edwards, of Chicago, in the great stallions Success and French Emperor. The latter went to Iowa as the property of Hon. J. B. Grinnell. Success was sold to the Fletcher Horse Company, of which M. W. Dunham, of Wayne, Ill., was an active member. In 1874 he purchased the entire interest of the company, establishing his celebrated importing and breeding farm at Wayne. Success's colts at the average age of two years and eight months sold at the average price of $450 per head, and in 1874 alone the sales of his get amounted to $36,000. The Clydesdale has been the strong rival of the Percheron-Norman; is popular in Canada, and has numerous representatives in the Northwest. The secretary of the American Clydesdale Association, Alexander Galbraith, says: "No importations into the United States appear to have been made until about 1870 and 1872, when John Reber, of Lancaster, Ohio, and the Fullingtons, of Union County, began the work. From that date small importations were made by various parties, the most prominent being the Powell Brothers, of Shadeland, Pa. Importations steadily increased up to 1888. To-day the largest breeder in America is Col. Holloway, of Illinois; N. P. Clarke, of Minnesota, and R. B. Ogilvee, of Wisconsin, coming next. These three breeders have among them about 175 brood-mares, and have the very cream of Scotland both in blood and individual merit. As high as $10,000 has been paid for one Clyde. Eight volumes of the 'American Clyde Stud-Book' have been published, containing 8,000 entries." The Shire horse is little esteemed in Canada, but in the American craze for heavy horses he finds admirers. There is an American stud-book of three volumes, with 4,100 entries, 3,500 of which represent imported horses. See HORSE-RACING; HORSES, TROTTING AND PACING.

MILTON YOUNG,
Lexington, Ky.

Horses, Military. The relative importance of the horse as a factor in the progress of civilization has been somewhat reduced by the introduction of steam and electricity, but mechanical devices such as the bicycle and automobile are not likely to wholly supplant the indispensable ally of man for war purposes. The value of cavalry has not, within the century, been so fully recognized as during the recent South African campaigns, where the supply of horses reached enormous proportions. The kind of horse for cavalry and artillery use is controlled by the character of service for which he is to be used. Hardy range horses are desirable in a campaign where the question of forage supply is a difficult one, but, if fully armed and equipped men of average size are to be transported and held in readiness for mounted combat with opposing cavalry, then larger and better trained horses are desirable.

The source from which cavalry horses are obtained differs in various countries. Some European nations breed and raise their remounts, while others provide the services of selected stallions gratuitously to breeders, the foals being held subject to purchase by the state. The American plan differs from the European practice and involves only the inspection of such animals as are presented by contractors. This encourages all farmers to breed a fair class of horses, and whenever the requirements of the markets increase the breeding usually increases until prices sometimes fall below a level at which colts can be profitably reared. Only a small percentage of horses raised in the United States are adapted to the requirements of cavalry service. This arises from the existence of a special and narrowly defined object to be attained, and which requires animals of particular conformation and character. The inspection of remounts for soundness and conformation is a very important duty, demanding technical training and intelligence. It requires judgment, much instruction and long practice to correctly estimate the relative value of various points of the horse and to determine whether the good qualities counterbalance the existing defects. Contractors do not usually present ideal animals, but the market from which they draw is so large that there is no serious difficulty in supplying the remounts annually required for the United States cavalry.

In European armies horses are accepted at four years of age, and sometimes under that age. It has been found in practice in the United States preferable to buy no horses under six years of age for immediate use in field service. Younger horses may be accepted during peace when there is no likelihood of immediate hard service, but they are subject to influenza or shipper's fever to a degree which often renders them unserviceable for many months. Good points in a cavalry horse are not mere matters of beauty, but shapes which, on mechanical principles, are likely to answer required ends. Cavalry horses must have certain qualifications, the most important of which are the possession of sufficient mobility to execute tactical maneuvers at varying degrees of speed and the ability to stand hard service while carrying great weight. The weight of trooper and equipment averages about one fourth the weight of the horse. Ability to carry flesh under stress of short rations is a commendable quality in a cavalry horse, since it enables him to stand hard work and to avoid a sore back. As a result of many years of experience the requirements demanded in the cavalry horse of the United States are laid down in the regulations in this language:

"The cavalry horse must be sound and well bred; gentle under the saddle; free from vicious habits; with free and prompt action at the walk, trot, and gallop; without blemish or defect; of a kind disposition; with easy mouth and gait, and otherwise to conform to the following description:

"A gelding of uniform and hardy color; in good condition; from fifteen and one fourth to sixteen hands high; weight not less than 950 nor more than 1,150 pounds; from four to eight years old; head and ears small; forehead broad; eyes large and prominent; vision perfect in every respect; shoulders long and sloping well back; chest full, broad, and deep; fore legs straight and standing well under; barrel large and increasing from girth toward flank; withers elevated; back short and straight; loins and haunches broad and muscular; hocks well bent and under the horse; pasterns slanting, and feet small and sound." See also HORSES, RIDING AND DRIVING.

W. H. CARTER,
Brigadier-General, U. S. Army.

Horses, Riding and Driving. In the latter days of this country one can hardly go to even an insignificant town or village without finding that a number of its residents spend time and money in raising, training, and driving as good horses as their means will afford. Another striking feature of this country horsemanship is the rivalry and constant vying of each horse-fancier to excel among his fellows, and the interest manifested to-day in buying, selling and "swapping" horseflesh is typical of the American.

The county and state agricultural fairs, which now make the exhibition of horses a special feature, are largely the outgrowth of this far-reaching interest in horses. Nearly every country fair has, besides trotting and perhaps running races, a department for harness horses and breeders' competitions. As freight and passenger rates are commonly commuted by the railroads or the fair corporations, these meetings enable the farmer to see the best the country for miles around can produce, raise his standards and teach him the results to be attained by proper breeding.

The horse shows, held annually in many of our large cities, at regular seasons throughout the year, and so arranged that they may not conflict as to dates, invite competitors from all parts of the country, who exhibit what they have with fair prospects of making their expenses from the prize money won. These horse shows are fostered both as sporting and business institutions, and the best horsemen in the country form their directorates and act as judges. These large shows do much to establish the types of animals that meet with favor, and their growth and popularity has cultivated the taste and interest of the general public in horses more than any other factor.

The types of horses highly valued in the large cities and in the country are, of course, similar to a large extent. A good horse is good anywhere. Nevertheless, the requirements of a metropolitan market are much more exacting and extend to the many qualities which we will try to outline in this article. While the country is often satisfied with mere "getting there" qualities in the horse, regardless of how it is done, or perhaps a mere combination of speed and endurance, the standard of a large city calls for certain definite requisities and qualifications — "points" — which are well nigh indispensable if the horse is to command a good price.

To fill the requirements of the affluent class it is estimated that not more than 5 per cent of the horses throughout the country, including those raised with this object solely in view, can be utilized. Indeed, taste has become so fastidious that the right kind can only be found by diligent search, and prices verge into sums that 10 years ago would have been unbelievable. It must not be thought that the general run of horses in this country, or indeed that the quality of our native bred horses, has deteriorated in the past few years. Such, in the writer's opinion, is not the case. The fact is, that to fill the high requirements of the metropolitan market has become the recognized goal of all horse breeders; and it is now generally understood throughout the country that the market for the inferior horse is limited to those who can afford to pay so little that the breeder is not compensated for his care and outlay in breeding anything but the best. The general introduction of trolleys and electric vehicles has been an important factor in curtailing the market for horses that are merely "serviceable" and has reduced it to a competitive point that is unprofitable.

The high qualifications for the metropolitan market have reduced the available horses to such a small number that expert buyers search this country and the Dominion of Canada from one end to the other. Buying as cheaply as possible, so thorough has been the scouring of the country that the prices paid would seem fabulous to the seller if the cost alone of raising the horse were taken into consideration. The buyer must also assume the risk and expense of transportation to market.

The "points" for which the breeder is striving are well defined, but the individual may vary so much in combining them that the interesting feature of personal taste remains as the determining factor in selecting horses for personal use.

Heavy-Harness Horse.— The term "heavy-harness horse" is a general one. Under it may be classed anything from the 12 hand pony for basket-phaeton or village cart, through the various types suitable for the runabout, gig, brougham, victoria and other vehicles that fashion prescribes for various uses, to the 16–1 hand carriage horse for pulling the capitalist's omnibus.

The importation into this country, since 1883, of English hackneys and the exhibition of them has undoubtedly done much to educate the public to a type of carriage horse. While no disparagement is intended to the standard bred trotting horse, whose origin, indeed, is allied to the hackney — although his later history is somewhat different — the serviceable, short-backed, straight-legged and intelligent horse now the standard for metropolitan use is nevertheless nearer the hackney type than the old style American trotter. It should be stated, however, that very few either of the trotters or hackneys of 25 years ago would generally fill the requirements of the harness horse to-day. A type having been once well established, however, horses filling the requirements can be selected from carefully bred trotters as well as from hackneys, and one breed is often mistaken for the other, such is their closeness in resemblance and the result of breeding with particular ends in view. The elements to be taken into consideration in the harness horse are as follows: Conformation, manners, action, speed, color, size and age. Conformation ranks first in point of importance, but manners are an absolute essential also. These two although somewhat variable must be present in any horse required for harness; the others vary considerably according to the type and weight of the vehicle to which the horse is to be harnessed and the purchaser's personal taste.

The elements in the order of their importance from a purely selling point of view are:

1. Conformation as to head and neck. This is probably the first feature the average purchaser will look for. The horse should possess a small head, delicately molded nostrils and a small tapering muzzle. His jaw-bones should be well apart so that when the head is reined in they will not interfere with his breathing. He should have good sized eyes, well separated; a narrow forehead or small eyes being general indications of lack of intelligence, nervousness or a tendency to fright or bad temper. The ears should be small and well apart. The neck should be gently tapering and well cut out in the throat, and the so-called "crest" from which the mane grows should have the slight convexity which indicates strength, maturity and condition. The neck should be set on sloping shoulders, so that the head will be naturally held erect, turning upward from the forward line of the trunk nearly perpendicular. A tapering neck is an indication of breeding and fineness as distinguished from the coarseness of draft blood and the common horse in ordinary use.

2. Conformation as to legs. The general requirements are that all four legs shall be approximately straight and not too long. A moderately short-legged horse is generally preferred, both for looks and service, to one that depends upon long legs for height. The forelegs should be perpendicular when the horse is standing erect, bones flat, but not heavy or coarse. The hind legs, when in a natural position, should be so formed that a plumb line dropped from posterior point of the haunch will be nearly tangent at the point of the hock, the rear line of the leg below the hock being approximately parallel to the plumb line. The thighs should be moderately heavy at the height of the lower line of the trunk. The modern idea is that the horse's buttocks should be round and muscular viewed from behind. The pasterns of all four legs should be springy and long rather than short.

3. In general. The horse should be "close-coupled"; in other words, there should not be too much space between the last rib and the quarter. His trunk should be round and just fleshy enough so that his ribs may be felt — not seen. Standing on level ground the height of his withers and croup should be about the same. The trunk, directly under the withers, should be deep and the chest from the front view broad, giving room for the heart and lungs and an appearance of power. The belly should be well picked up beneath the kidneys with a gentle, convex, upward curve from between the front legs — not enough, however, to produce the waspy effect sometimes seen in horses otherwise well formed. The back should be short, lending to the trunk an appearance of compactness and solidity. The quarters should not fall away back of the kidneys more than an inch or so to the root of the tail. The tail, if set well forward of the posterior line of the horse's haunches, is generally admired, and in this position will be carried at the proper angle naturally.

Under the subject of *Manners*, full technical treatment should be sought in various books relating to horse training and breaking. We will endeavor to point out, however, to what extent manners in a harness horse is supplemental to ordinary training; to treat the subject fully being like attempting to describe what a gentleman should do under all circumstances. A few salient points will perhaps give a fair indication of the general subject.

The well-mannered horse should be so trained that when bitted his head is carried almost vertical, and close to his neck, which will be gently curved; the head and neck taken together being straight with the line of direction in which he is traveling. This position is not only graceful but gives the driver the utmost command over him. He should "fill his collar" without urging, but be light mouthed and susceptible to the slightest hint from the reins, voice or whip. He should be afraid of nothing and possess sufficient intelligence so that after first acquaintance with motor vehicles, railroad trains and other startling objects, he will pay no attention to them.

Into this subject therefore the question of natural disposition necessarily enters, as without a sensible but willing and high-strung disposition, it is impossible to produce a fashionable carriage horse. The horse should be trained to back and turn for the voice or with the slightest pressure of the reins without manifesting any disposition to shake his head or bore upon the bit. Plunging, rearing or trickiness must be absolutely eliminated, so that he is safe for a lady to drive through crowded city streets. He should be broken single, double and tandem, and to the saddle for convenience sake, and should be ready at any moment to serve in any one of these capacities.

All this mannering constitutes a supplemental or post-graduate education, for the horse as delivered from the country is broken, but commonly utterly devoid of manners. To accomplish this a training extending over a period of as much as three months is often necessary even with a horse that would be considered thoroughly broken in the country; and after mannering him as to how he shall carry his head and respond to the driver, it is necessary, so perfectly must the horse be trained to suit the metropolitan purchaser to spend a week or more in thoroughly accustoming him to city pavements and sights. It is almost superfluous to state that many horses cannot be brought to this high state of perfection, but the question of manners enters very largely into the price consideration, and the schooling should be carried on to as high a point as the disposition of the individual will admit.

While *Action* is not absolutely indispensable, it is nevertheless the feature that many amateur horsemen will look for first, often neglecting much more important points to secure the flashiness of the high actor. Many dealers say, "Give me action and I can sell anything." Without going to this extreme, it is undoubtedly true that high action will cover many sins, and if a horse will only "get his head up and act" he is apt to be salable. Without action speed seldom attracts the city purchaser, and while it is undeniable that high action, except with careful driving and stable attention, will often cripple a horse on hard pavements who might otherwise go sound for years, the average high-price buyer not only asks for clean, straight action, but verges to the danger point in its height. The expert will seek horses having action both in

1. Pure Arabian.
2. Arabian Stallion.
3. Shetland Pony.
4. Welsh Mountain Pony.
5. English Shire Stallion.
6. Clydedale Gelding.
7. French Coach Horse.
8. English Hackney.

front and behind as he knows that without hock action, little, if any, speed will be produced, the propelling force lying in the power of the thighs. He will look at the horse going, coming and sideways, first to see that the horse neither toes in, paddles or interferes in front; second, to see that he keeps his hocks close together as they pass, and consequently does not "straddle" or place his hind legs at the extreme forward stride outside of the line taken by his fore legs, or interfere by brushing either fetlock joint; third, that he does not forge and that his action is even when looked at from the side, each leg advancing at a stride the same distance and height as the corresponding leg on the other side.

The only gait admissible in the heavy harness horse is a trot. Pacing, racking, single-footing, or any gait other than a square line trot, by whatever term it may be called, have no place in the metropolitan market. The horse should strike out straight from the shoulder in front, the whole leg straightening at the instant the hoof touches the ground, the hoof striking flat. The straightened foreleg then passes under the body of the horse and is rolled up when it leaves the ground, the hoof nearly touching in extreme cases the point of the elbow joint. While still "folded" the arm bone reassumes the position for the next forward stride. As indicated above, the action of any single leg and hoof should be in a single longitudinal vertical plane. Some writers have endeavored to demonstrate, by projecting upon a longitudinal vertical plane the arc described by the forward point of the hoof from the time the horse picks up his foot from the ground until he touches it again, that the ideal action thus projected would form a symmetrical arc of an ellipse. While it is conceivable that such may be the case, it is practically impossible to determine slight variations from this ideal, and if the horse acts high, clean and straight without interference or forging he will not generally be open to criticism.

The modern buyer looks more and more nowadays for strong hock action, which means that the horse will cover ground and retain much of his action regardless of the amount of weight behind him.

While *Speed* is not a very important element in horses for carriage use, it would be a truism to state that people like to go fast, and of two individuals equal in other respects, the purchaser will prefer the horse that has the most "step." A discriminating dealer will commonly aim to secure horses that can go a mile under ordinary circumstances in 3½ minutes, and if possible in 3 minutes. This is, ordinarily, quite fast enough for salability, and the horse that will "road" steadily at 10 to 12 miles an hour and can increase the speed a little for a short spurt, fills the market requirements pretty fully.

In *Color,* modern fashion prescribes bays, chestnuts and browns, a dark seal brown being perhaps the most popular. Golden chestnuts are also popular, and blood bays are in high favor. Very few purchasers will consider a white or black horse, regardless of any number of other good qualities. Grays, except of the dark dapple variety, are rarely used, except in a cross-matched pair, and then only as a matter of personal fancy. In a road coach four, however, they are approved by the best authorities.

The amount of white on a horse is a matter of personal taste, many people liking white fetlocks and a star, stripe or blaze on a chestnut or bay's head, others preferring solid color. Bays are generally most popular with black points, but in general it may be stated that the horse possessing too much white will not please. One or two white legs, with white extending a short way to the knee or hock, will not be objected to, but it can be stated positively that, except for a leader or wheeler in a road coach team, where a showy effect is desired, there should be no white upon the body of the horse.

A sleek, shiny coat is a recommendation for any horse, as it usually bespeaks condition and breeding.

The question of *Size* is one that is a matter of personal taste primarily, and secondly, one of suiting the vehicle to which the horse is to be harnessed. The salable horse for ordinary city use is rarely under 14½ hands, and in the opinion of most judges should not exceed 16¼ hands. For a lady's phaeton a small team with considerable substance and not usually less than 14½ hands in height is required, and for a heavy omnibus sufficient weight and strength are usually secured in the horse whose height does not exceed 16 hands. The most salable size for horses in general use is about 15–2½ hands. Most buyers will restrict their purchases to horses between 15–1 and 16 hands, unless the animal is very remarkable in other respects, because customers for extremes in size are few in number, and such horses are consequently less readily salable.

A word should be said as to the *Age* of the marketable horse. It is pretty well understood that colts suitable for heavy harness do not attain maturity and maximum strength until they reach the age of five or six years, and the ordinary purchaser will prefer the six-year-old horse. From seven to 10 years the horse is at his best. While some horses hold their good qualities and are serviceable up to an extreme age of perhaps 20 years,— in the city horses rarely stand the strain of travel on hard pavements for many years without showing signs of usage sufficient to render them unsalable, except at small prices.

Horses kept for the show-ring and therefore not subject to usage on hard pavements exemplify the fact that there is little or no advantage *per se* in the young horse. Indeed, the horse may be at his best at the age of 10 years, and many of the blue ribbon winners of the past few years are even somewhat older.

The Saddle Horse.— Neglecting the subject of chargers and hunters, the former having but a limited market and being generally subject to army specifications, and the latter constituting too large a subject for discussion in an article of this character, and of more interest abroad, especially in England and Ireland, than in America, we shall say a few words of the saddle horse, presenting as briefly as possible some of the facts which should be borne in mind in supplying the market.

The conformation of the saddle horse will not be found to differ very materially from the carriage horse, and many private owners, who do not feel able or warranted in stabling horses for saddle purposes only, will find a combination horse for saddle and harness use a possibility. A saddle horse is not improved in gait by being harnessed to a vehicle, particularly a heavy one, in fact is impaired thereby, but moderate driving to light vehicles will not incapacitate him wholly for the saddle.

In a "park hack" we should look for somewhat substantial conformation. As in a carriage horse, depth of girth should be sought and the back should be short, all the distance possible, however, separating the forelegs from the hind, the horse having much of his length in his shoulders and quarters. The croup should be long, so that, taken in combination with high and prominent withers and heavy shoulders, the saddle will have a good seat and be prevented from slipping forward. As in the hind legs reside the seat of propelling power the thighs should be long and muscular, and some people prefer the hocks well bent. The pasterns should be somewhat longer and have more spring than in the harness horse.

As in the harness horse the saddle horse should be about the same width in front as behind. Many will not object, however, to a horse slightly wider behind than in front, as the claim is made that, in a gallop, the hind legs will better pass outside of the forelegs; but, under no conditions should the horse be wider in front than behind. He should have a moderately long and upright neck and a prominent crest, as this is the muscle that supports his head, and the neck should be arched. With this combination a horse will usually carry his head erect without support from the reins, and the rider will have better control and feel that he has something in front of him.

The manners of a saddle horse is an element worthy of particular notice. Besides the qualities and disposition valuable in a harness horse, primarily he must possess a high degree of intelligence and be absolutely fearless: and he needs a further education to make him "bridle wise." By this term is indicated response to the slightest pressure of the rein on either side of the neck, so that the horse turns readily by the lateral movement of the rein hand. This allows the rider one hand free for use or emergency.

As to gait and action, the horse should have a fast walk, so that when ridden in company he will keep up without breaking into a jog. The trot should be even, springy and regular, so as not to jolt the rider. Extreme action is not a necessary feature, but the horse should possess enough action to be noticeable in company; and high action is not a detriment if unaccompanied by pounding. An easy canter and gallop are necessities, and particularly is this true of the horse intended for long rides or to be used in the country. These gaits should be accomplished with a maximum of forward motion and a minimum of rocking.

Types and sizes of saddle horses vary greatly according to personal taste and the weight to be carried. Some desire a short-legged, thickset cobby horse for weight-carrying, while those of lighter build may prefer a taller horse of less substance and more speed. Above all things the horse should be free and willing, as no man desires, or will tolerate, a horse needing constant urging.

Breeding.— A word or two as to breeding may not be inappropriate, as the requirements of the market are so exacting that every breeder should take them into consideration, in order to produce and raise as large a percentage of marketable horses as possible.

Much has been written upon the subject of horse breeding and genealogy in America, and careful investigation reveals much shallow erudition. The results of recent research have shed sufficient light upon this subject to show that much of the published matter as to the ancestry of the American trotter will not bear close investigation. Heretical as it may seem, the history and origin of the Hambletonian strain of blood, which for years has been held in high esteem among breeders throughout the country, we believe is open to reasonable doubt as to its authenticity. It does not seem unlikely that some of the breeders, in their desire to create a lineage for their horses, drew on their imagination for the breeding of the ancestors. After many years of assumption that the published facts were correct, grave doubt is now cast upon the breeding of some of the original stock. Perhaps, therefore, the less we attempt to demonstrate results by referring to the lineage of the standard bred trotting horse the safer.

Of the other breeds of this country perhaps the best known are the Morgans and Clays, but generally speaking, such numerous and often careless crosses have been tolerated that these breeds in anything like purity of blood have mostly disappeared. In the author's opinion, up to a recent date, the breeder in America has sought speed to the detriment of action, even going so far as to make conformation a secondary element.

A word should be said about the Hackney. Much confusion has resulted temporarily, and probably only temporarily, from the placing on the market of so-called Hackneys, which are such only in conformation and not in the action and speed which are characteristic of the Hackney of honest blood. This breed lends itself exceedingly well to the requirements of the heavy harness horse when proper individuals are used in the stud. Although at present there are but few such individuals in this country, the Hackney dates back in England to the 18th century. It was originally a cross between the shire or English cart horse, an animal somewhat coarse but of much substance, power and action, and the sleeker thoroughbred of delicate conformation and high strung temperament. So well has this breed been cultivated, to the elimination of the coarser individuals by a few reputable breeders in this country, that it is not difficult for the careful judge to discriminate.

Recently, American breeders have achieved extremely satisfactory results by crossing hackney stallions with clean-limbed, nicely turned trotting-bred mares, and while this cross is one that breeders claim should not be carried beyond one generation for fear of the infusion of cold blood in the offspring, a single cross certainly produces a large percentage of good marketable stock. This cross commonly combines high action and much substance with speed and breedy appearance.

As most scientific breeders now acknowledge, the main fact of all breeding is that it is a matter primarily of individuals, good lineage counting for little in the produce if the breeding stock do not themselves fill all the requirements desired. Not only should care be taken to use proper individuals, but if a slight fault exists in either parent — no horse being absolutely perfect — the other should be selected especially proficient in what the one lacks.

Back of the standard bred trotting horse, Morgan, Hackney and French coach horse — another imported breed — stand practically the same Arabian ancestors, and as all are to-day bred with one end in view, the choice of one breed as against the others is a matter of selecting the individual best filling requirements.

If the main purpose be to breed for that market which is the most profitable, that of the heavy harness horse, it seems to the author that, instead of horses becoming standard by performance on the track if they became standard by performance in the show-ring all the qualities desired as well as speed would be more properly conserved. Of course, many practical difficulties, some of which would defeat the very ends sought, stand in the way of such a movement unless it were conducted by the government. A stud book formally conducted by the government and authentically recording the lineage and performances of stock, so that the history of a strain and the results of crosses might be generally published and read, would be of immense value to the horse breeder and to the government itself by raising the quality and value of the horses raised both for domestic use and export.

An interesting commentary on the subject of the harness horse and an evolution well worth notice is the gradual elimination of the unreliable small dealer in the metropolis: in fact, the market is fast falling into the hands of the comparatively few reputable dealers who endeavor to conduct their business on broad commercial lines. The purchasing public are beginning to recognize that it is best for their interests to patronize such dealers as can rather afford to take a loss on an unsound or unsafe animal by giving him away than to sell him under a misrepresentation and make a financial gain at the expense of reputation. This fact is not only an assurance that the interest manifested in the horse in our large cities will not decrease, but the business being in good hands that many who have in the past been slow to venture into this field of pleasure and sport can now enter into it as beginners without a long, unsatisfactory and expensive experience as a preliminary. See also Horses, American Thoroughbred.

Arthur Max,
Sec'y Standard Coach Horse Co., New York.

Horses, Trotting and Pacing. The harness racing horse has two gaits, namely, the trot aand the pace. They were both originally the connecting link between the walk and the gallop, but by development and careful training have come to take the place of the latter so far as extreme speed in harness is concerned. The term "diagonal gait" is applied to trotting because the horse employing it raises simultaneously a front and hind foot at opposite sides of the body. In pacing the front and hind feet on the same side move together, and this is best expressed as the "lateral gait." No one has yet been able to explain why a horse goes at one or other of these gaits when urged from the walk and guided by the rein to keep from the gallop.

The history of harness racing in America is practically contemporaneous with that of the Republic of the United States. After the Revolution the development of speed in the horse had its attractions here as in Europe. At first the running gait was the only one considered, but the importation of an English sire called Messenger marked the beginning of a new era. He was brought over in 1788 and landed at Philadelphia. Though descended from stock that inclined to the gallop and practically a thoroughbred, this horse was more inclined to the trot. What is more remarkable he transmitted this habit or instinct to so marked a degree that he made a great reputation in the New World through the superiority of his progeny over all other breeds. So "Imported Messenger," as he was popularly known, was the patriarch of the American trotter, and nearly all of the immense troop of harness racers in this country to-day trace descent to him. His death in 1808 near Oyster Bay, N. Y., was looked upon as a national calamity, and he was buried with military honors, the funeral being attended by prominent horsemen from all the neighboring States. As this horse was the founder of a notable family and represents a type in some respects separate and distinct from others of the *genus equus* it seems unfortunate that no portrait or drawing of him was ever made. There is a pen picture which in some measure atones for this, and is worth quoting. It describes Messenger as of a gray color, standing full 15 hands 3 inches in height, with a thin mane and tail, ears larger than most well bred horses, but erect and lively.

At the time of Messenger's death the limit of speed at the trot was in round numbers a mile in three minutes. The saddle was chiefly in vogue for this gait as well as running, but the employment of a vehicle with two wheels followed the building of better roads. According to J. H. Wallace, an authority on the thoroughbred, a chestnut horse trotted at Philadelphia in a sulky 25 Aug. 1810, one mile in 2:48½ for $600. The horse was fourteen years old and barely 15 hands high. There is an earlier feat now accepted as authentic of a horse called Yankee, trotting a mile in 2:59 in 1806 on Harlem Lane, a favorite driving place for New Yorkers. The breeding of these first champions of the sulky remains in obscurity, but it was not long before the descendants of Imported Messenger began to do greater things Topgallant, who is credited with three miles in 8:11 and easily the best trotter of his day, was inbred to Messenger, his sire and dam both being by the potent English stallion. Screwdriver, who went three miles to saddle in 8:02 a year before this, was another of the stars descended from Messenger, as was Dutchman, another long distance trotter, who went his three miles under saddle in 7:32¼; but the most famous of the Messenger brood in the nearer generations was Lady Suffolk. She was the first queen of trotters, her reign being a long and undisputed one from 1838 to 1852. She enjoys the special distinction of being the first trotter to score as fast as 2:30 for a mile in harness. Following Lady Suffolk there were a few lesser lights that improved slightly on her best record, but her real successor as a conqueror of time was Flora Temple. She was foaled in 1845, her turf career beginning in 1852. Five times this wonderful mare reduced the figures that represented the speed limit, her greatest effort being 2:19¾. Then came the mighty Dexter, who reduced the record to 2:17¼. His public career was cut short when Robert Bonner purchased him and took him to New York for his private driving on the road. Goldsmith Maid came out in 1871 and clipped a fraction from Dexter's mark. She was foaled in 1857, made her debut at 10 years and continued to fill engagements in races and against time up to 1877. Rarus managed to improve Goldsmith Maid's record a trifle during a very creditable career. The gelding St. Julien eclipsed him a year after by a full second. Then a new queen appeared in Maud S., and between this fleet pair was a lively duel for the championship. The figures were improved by fractions of a second until the mare reached 2:10¾ in 1880, which proved too much for the gelding. After his surrender another candidate appeared in Jay Eye See. Meantime Maud S. had got down to 2:10¼, but Jay Eye See enjoys the distinction of being the first to touch the even 2:10. This was in 1884, and then the mare showed that she was the better horse by compassing the track in 2:09¾, and again in 2:08¾.

The greatest mechanical aid to the harness horse that has yet been devised came into use during 1892. This was the application of the ball-bearing axle first applied to the bicycle, with the pneumatic tire and a wheel of about 28 inches diameter. Its first public trial was in a race at Worcester, Mass., early in May, where its manifest advantage enabled a slow horse to fairly play with a field of faster competitors. None of the prominent trainers had seen this new contrivance, and it was not until well along in July when they awoke to a full realization of its merits. The writer was privileged to see and try this sulky with its frictionless gear before it had come into general use, and on exploiting it with a conservative opinion that a horse could go at least two seconds faster than if hitched to the high wheel sulky, was informed by Budd Doble, the leading reinsman of that day, that he was the victim of a hoax. Less than three months after this same Doble had driven Nancy Hanks to one of these smooth running machines a mile in 2:04, or nearly five seconds faster than the record of Maud S. This material reduction was only the beginning of a new era in speed, as four other trotters have taken advantage of this appliance and earned the championship in turn. Alix only clipped a quarter of a second from the mark set by Nancy Hanks, but she did this after a hard race campaign that took away from her real ability. It was six years before this resolute overworked mare had to surrender the crown, when in 1900 the Abbot trotted in 2:03¼. He had previously won his spurs in several creditable races, but his successor and conqueror, Cresceus, proved to be a much more remarkable representative of his kind. Starting at three years this Hercules among trotters met and defeated older and more seasoned campaigners in his colthood, scoring 2:11¼ in the eighth heat of a winning race. Then each successive season found Cresceus able to add to his laurels until in 1901 he earned the championship twice. His record of 2:02¼ was followed by the famous match against The Abbot at Brighton track, Brooklyn, N. Y., 15 August, when, in the presence of an immense crowd, many of whom came hundreds of miles to see this battle of the giants, Cresceus was the victor. It was no light task at first, as The Abbot forced him to go in 2:03¼, the fastest mile by nearly two seconds ever scored in a trotting race. Besides these feats Cresceus has lowered many other records, including the one for two miles which he placed at 4:17 late in 1902. During the season of 1903 he again battled against time, and after his previous championship record had been several times beaten by Lou Dillon and Major Delmar this stout warrior trotted in 1.59¾ at Wichita, Kan., in October 1903.

Before this great feat his star was momentarily eclipsed by the advent of the long expected and much desired two-minute trotter. So suddenly has this new marvel appeared, and so rapidly has she reached the goal that hitherto seemed unattainable that the world at large cannot fully appreciate the merit of what Lou Dillon has accomplished. To begin with, she is the youngest of all the champions, being but five years old. What is even more remarkable, her turf life extends over little more than 12 months, and up to last June she had never filled a public engagement. Yet within a few weeks this marvelous mare has smashed records and on 22 Aug. 1903 she electrified the country by a mile in two minutes. This was done over the track at Readville, near Boston, where six years before the pacer Star Pointer scored the first mile ever made faster than "even time." An analysis of Lou Dillon's unparalleled flight for a trotter shows that she was rated with great skill. At the Brighton track just a week before she had gone a first quarter in 28¾ seconds, and a half mile in 59 seconds, a killing rate, which destroyed any chance she had of finishing in time to break the record. Profiting by this experience her driver and those who handled the two gallopers hitched to separate carts that accompanied her as pace makers, did much better work at Readville. This is shown by the time at the various quarters, which was 30¼, 30½, 30¼, and 29 seconds, respectively. While a full meed of praise is always due to the man or horse that does something better than what has previously been achieved, it is only fair to state that Lou Dillon has enjoyed special advantages in her preparation for record breaking. She was first trained in the winter of 1902 on the track at Pleasanton, California, her native State, and on the death of her breeder and owner this year was brought to Cleveland and sold at auction. The purchaser, C. K. G. Billings, of Chicago, got a rare bargain at $12,500, and being strictly an amateur he promptly canceled all engagements previously made for this promising mare. She then received special training for miles against time, and not only astonished the world by her mile in even time at Boston, but a few days later drew the old-style sulky with high wheels, in 2:05 at Cleveland, clipping three seconds and three quarters from the record Maud S. made nearly 20 years before. Later on, at Memphis, Lou Dillon added to her fame by another mile in 1:58½ to sulky, and one to wagon in exactly 2 minutes. She also defeated Major Delmar in a race for the Memphis Gold Cup, and being only in the heyday of her power, it is within the realm of possibility that she will pass the mark for pacers. This now stands at 1:56¼, made by Dan Patch at Memphis, 22 October 1903.

The following table gives the names of all the record makers among the trotters, and shows how the figures have been reduced from 2:30 to 2:00:

Lady Suffolk, gr. m. foaled 1833, by Engineer 2d, dam by Don Quixote. Driven by David Bryan, Beacon Course, Hoboken, N. J., Oct. 13, 1845, *2:29½*.

Pelham, b. g. foaled 1837, pedigree not traced. Driven by William Whelan, Centreville, N. Y., July 2, 1849, *2:28*.

Highland Maid, b. m. foaled 1847, by Saltram; dam Roxanna, by Hickory. Driven by F. J. Nodine, Centreville, N. Y., June 15, 1853, *2:27*.

Tacony, ro. g. foaled 1844; by Sportsman; dam not traced. Union Course, N. Y., July 14, 1853, *2:27*.

Flora Temple, b. m. foaled 1845, by Bogus Hunter; dam Madam Temple, by Terry Horse. Driven by Hiram Woodruff, Union Course, East New York, N. Y., Sept. 2, 1856, *2:24½*.

Flora Temple. Driven by James D. McMann, Centreville, N. Y., Aug. 9, 1859, *2:23½*.

Flora Temple. Driven by James D. McMann, Centreville, N. Y., Aug. 9, 1859, *2:22*.

Flora Temple. Driven by James D. McMann, Cincinnati, Ohio, Oct. 7, 1859, *2:21½*.

Flora Temple. Driven by James D. McMann, Kalamazoo, Mich., Oct. 15, 1859, *2:19¾*.

Dexter, br. g. foaled 1858, by Hambletonian; dam Clara, by American Star. Driven by Budd Doble, Riverside Park, Boston, Mass., July 30, 1867, *2:19*.

Dexter. Driven by Budd Doble, Buffalo, N. Y., Aug. 14, 1867, *2:17¾*.

Goldsmith Maid, b. m. foaled 1857, by Alexander's Abdallah; dam Ab. by Abdallah. Driven by Budd Doble, Milwaukee, Wis., Sept. 6, 1871, *2:17*.

Goldsmith Maid. Driven by William H. Doble, Mystic Park, Boston, Mass., June 9, 1872, *2:16¾*.

Occident, br. g. foaled 1863, by Doc; dam Mater Occidentis, pedigree not traced. Driven by George Tennet, Sacramento, Cal., Sept. 17, 1873, *2:16¾*.

Goldsmith Maid. Driven by Budd Doble, East Saginaw, Mich., July 16, 1874, *2:16*.

Goldsmith Maid. Driven by Budd Doble, Buffalo, N. Y., Aug. 7, 1874, *2:15½*.

Goldsmith Maid. Driven by Budd Doble, Rochester, N. Y., Aug. 12, 1874, *2:14¾*.

Goldsmith Maid. Driven by Budd Doble, Mystic Park, Boston, Mass., Sept. 2, 1874, *2:14*.

Rarus, b. g. foaled 1867, by Conklin's Abdallah; dam Nancy Awful, by Telegraph. Driven by John Splan, Buffalo, N. Y., Aug. 3, 1878, *2:13¾*.

St. Julien, b. g. foaled 1869, by Volunteer; dam Flora, by Harry Clay. Driven by Orrin Hickok, Oakland, Cal., Oct. 25, 1879, *2:12¾*.

Maud S., ch. m. foaled 1874, by Harold; dam Miss Russell, by Pilot Jr. Driven by W. W. Bair, Rochester, N. Y., Aug. 12, 1880, *2:11¾*.

St. Julien. Driven by Orrin Hickok, Rochester, N. Y., Aug. 12, 1880, *2:11¾*.

St. Julien. Driven by Orrin Hickok, Hartford, Conn., Aug. 27, 1880, *2:11¼*.

Maud S. Driven by W. W. Bair, Chicago Driving Park, Chicago, Ill., Sept. 18, 1880, *2:10¾*.

Maud S. Driven by W. W. Bair, Homewood Park, Pittsburg, Pa., July 13, 1881, *2:10½*.

Maud S. Driven by W. W. Bair, Rochester, N. Y., Aug. 11, 1881, *2:10¼*.

Jay Eye See, bl. g. foaled 1878, by Dictator; dam Midnight, by Pilot Jr. Driven by Edwin Bither, Providence, R. I., Aug. 1, 1884, *2:10*.

Maud S. Driven by W. W. Bair, Cleveland, Ohio, Aug. 2, 1884, *2:09¾*.

Maud S. Driven by W. W. Bair, Lexington, Ky., Nov. 11, 1884, *2:09¼*.

Maud S. Driven by W. W. Bair, Cleveland, Ohio, July 30, 1885, *2:08¾*.

Sunol, b. m. foaled 1886, by Electioneer; dam Waxana, by Gen. Benton. Driven by Charles Marvin, Stockton, Cal., Oct. 20, 1891, *2:08¼*.

*Nancy Hanks, br. m. foaled 1886, by Happy Medium; dam Nancy Lee, by Dictator. Driven by Budd Doble, Chicago, Ill., Aug. 17, 1892, *2:07¼*.

Nancy Hanks. Driven by Budd Doble, Independence, Ia., Aug. 31, 1892, *2:05¼*.

Nancy Hanks. Driven by Budd Doble, Terre Haute, Ind., Sept. 28, 1892, *2:04*.

Alix, b. m. foaled 1888, by Patronage; dam Atlanta, by Attorney. Driven by Andy McDowell, Galesburg, Ill., Sept. 19, 1894, *2:03¾*.

The Abbot, b. g. foaled 1893, by Chimes; dam Nettie King, by Mambrino King. Driven by Ed. Geers, Terre Haute, Ind., Sept. 25, 1900, *2:03¼*.

Cresceus, ch. h. foaled 1894, by Robert McGregor; dam Mabel, by Mambrino Howard. Driven by George H. Ketchum, Cleveland, Ohio, July 26, 1901, *2:02¾*.

Cresceus. Driven by George H. Ketchum, Columbus, Ohio, Aug. 2, 1901, *2:02¼*.

Lou Dillon, ch. m. foaled 1898, by Sidney Dillon; dam Lou Milton, by Milton Medium. Driven by Millard F. Sanders, Readville, Mass., Aug. 24, 1903, *2:00*.

Lou Dillon. Driven by M. F. Sanders to high wheel sulky, Cleveland, Ohio, September 12, 1903, 2:05.

Cresceus. Driven by George H. Ketchum, Wichita, Kan., Oct. 19, 1903, *1:59¾*.

Lou Dillon. Driven by M. F. Sanders, Memphis, Tenn., Oct. 24, 1903, *1:58½*.

*First champion mile to bicycle sulky.

The progress and development of the lateral or pacing gait has kept side by side with trotting. Before Lady Suffolk had opened the door for the 2:30 list, the pacer Drover had gone a mile in 2:28. For over a century the lateral gait has kept a second or more ahead of the diagonal one. Dividing the century, since speed in harness for a mile was first considered, into two decades we are able to compare the two gaits and note the progress of each by the following table. The names of pacers are in italics:

	1800-1810.		
Yankee, b. g.	Harlem, N. Y.		2:59
	1810-1820.		
Boston Horse, ch. g.	Philadelphia, Pa.		2:48½
Bolton Blue, bl. g.	Jamaica, N. Y.		3:00
	1820-1830.		
Topgallant, b. g.		1829—3 miles	8:11
Bowery Boy.		1829—2 miles	5:04½
	1830-1840.		
Edwin Forrest, bl. g.	(to saddle)	1834	2:31½
Sally Miller, b. m.		1834	2:37
Drover, b. g.		1839	2:28
	1840-1850.		
Lady Suffolk, gr. m.		1845	2:29½
Moscow, b. g.		1845	2:30
Pelham, b. g.		1849	2:28
Jomes K. Polk, ch. g.		1845	2:27
	1850-1860.		
Flora Temple, b. m.		1859	2:19¾
George M. Patchen, b. h		1859	2:26¼
Ethan Allen, b. h.		1858	2:28
Pocahontas, ch. m.		1855	2:17¼
Pet, ro. g.		1852	2:18½
	1860-1870.		
Dexter, br. g.		1867	2:17¼
Goldsmith Maid, b. m.		1869	2:19½
George Wilkes, br. h.		1868	2:22
George M. Patchen, b. h.		1860	2:23½
Ethan Allen, b. h.		1860	2:25½
Billy Boyce, b. g.	(to saddle)	1868	2:14¼
	1870-1880.		
St. Julien, b. g.		1879	2:12¾
Rarus, b. g.		1878	2:13¼
Goldsmith Maid, b. m.		1874	2:14
Smuggler, br. h.		1876	2:15¼
Sleepy Tom. ch. g.		1879	2:12¼
Rowdy Boy, bl. g.		1879	2:13¾
	1880-1890.		
Maud S., ch. m.		1885	2:08¾
Jay Eye See, bl. g.		1884	2:10
St. Julien, b. g		1880	2:11¼
Axtell (3 yrs.), b. h.		1889	2:12
Maxie Cobb, b. h.		1884	2:13¼
Phallas, b. h.		1884	2:13¾
Johnston, b. g.		1884	2:06¼
Gold Leaf (4 yrs.), ch. m.		1889	2:11¼
Little Brown Jug, b. g.		1881	2:11¾
Brown Hal, br. h.		1889	2:12½
	1890-1903.		
Lou Dillon, ch. m.		1903	2:00
Cresceus, ch. h.		1903	1:59¾
Major Delmar, b. g.		1903	2:00¼
Cresceus, ch. h.		1901	2:02¼
The Abbot, b. g.		1900	2:03¼
Alix, b. m.		1894	2:03¾
Nancy Hanks, br. m.		1892	2:04
Azote, b. g.		1895	2:04¾
Directum, bl. h.		1893	2:05¼
Stamboul, br. h.		1892	2:07½
Arion, b. h.		1893	2:07¾
Kremlin, b. h.		1892	2:07¾
Martha Wilkes, b. m.		1892	2:08
*Lou Dillou.		1903	2:05

*Sunol, b. m.	1891	2:08¼
*Palo Alto, b. h.	1891	2:08¾
*Direct.	1891	2:06
Dan Patch, br. h.	1903	1:56¼
Prince Alert	1903	1:57
Star Pointer, b. h.	1897	1:59¼
John R. Gentry, b. h.	1896	2:00½
Prince Alert, b. g.	1902	2:00
Joe Patchen, bl. h.	1897	2:01¼
Robert J., b. g.	1894	2:01½
Mascot, b. g.	1892	2:04
Hal Pointer, b. g.	1892	2:04½
Direct, bl. h.	1892	2:05½

*Made to high wheel sulky.

In the matter of breeding, reference has already been made to the fact that the imported horse Messenger, who played so important a part in the generation of harness horses, was of running stock. His descendants that have influenced this type more than any others were Rysdyck's Hambletonian and Mambrino Chief. The former was the son of Abdallah, whose sire Mambrino was by the English Messenger. This same Mambrino was also the grandsire of Mambrino Chief, so that his blood more than that of any of the get of Messenger has been potent in the production of the numerous fast exponents of the two harness gaits. Bellfounder, another English horse, brought over to Boston in 1823, had also much to do in founding the American trotter. His origin seems to be obscure, but he was probably of the type known as the Norfolk Roadster, from which the hackney has sprung. The most famous of his progeny in the first generation was the Charles Kent Mare, the dam of Rysdyck's Hambletonian. At least 75 per cent of what are called "Standard bred" trotters trace to this sire, and as none of the rest of Abdallah's get amounted to much there is every reason to believe that this daughter of imported Bellfounder had the inherent quality which made the Hambletonian strain so valuable. Every one of the champion trotters that succeeded Flora Temple are descended directly from this horse, Dexter himself being one of his sons.

To show how the "fast list," as it is called, has increased since the day of Lady Suffolk and Drover, it may be stated that up to the close of 1902 there were 18,548 trotters with records of 2:30 or better, and 9,713 pacers credited with marks of 2:25 or better. In each case these figures represent what is known as "standard" speed at the respective gaits. See HORSE-RACING.

CHARLES ARNOLD MCCULLY,
Secretary New York Trotting Association.

Horseshoe Falls. See NIAGARA FALLS.

Horstmann, Ignatius F., American Roman Catholic prelate: b. Philadelphia, Pa., 16 Dec. 1840. In 1857 he was graduated from the Central High School, and afterward attended Saint Joseph's College, Philadelphia. Desirous of studying for the priesthood, he went to the Preparatory Seminary of Glen Riddle in 1859, and in 1860 entered the American College, Rome, where, after completing his course, he was ordained priest by Cardinal Patrizzi, 10 June 1865. In 1866 he took in Rome the degree of doctor of theology, and in the same year returned to Philadelphia and accepted the chair of mental philosophy in the diocesan seminary of Saint Charles Borromeo, continuing to hold the same position in the new seminary at Overbrook. In 1877 he became pastor of Saint Mary's Church, Philadelphia, and in 1885 was named chancellor of the archdiocese. On 29 Nov. 1891 Leo XIII. appointed him to the vacant see of Cleveland, Ohio, and he was consecrated bishop 25 Feb. 1892. The diocese now (1905) has a Catholic population of 300,000; 296 priests; 287 churches; 1 seminary; 166 parochial schools; 7 orphanages; 9 hospitals, and several charitable institutions.

Horticulture, the art of growing plants, flowers, and vegetables for aiding in sustaining life, maintaining health, and for ornamental purposes. While as an art it is the highest type of work which pertains to the cultivation of the soil, its principles are based on many branches of science. Plant physiology, chemistry, and physics play important roles in every branch of this work and the application of their laws, directly and indirectly, constitutes the more essential features of the art.

Adopting Bailey's plan of division (Annals of Hort., 1891), horticulture may be discussed under four heads: (1) Pomology or fruit-growing; (2) olericulture or vegetable-growing; (3) floriculture or the growing of flowers and plants for ornamental and other purposes; (4) landscape gardening, or the growing of plants and the grouping of them for the purpose of enhancing the beauty and value of landscape.

In no country in the world has pomology or fruit-growing made such advances as in America. In the early history of the country fruit-growing was of necessity given minor attention. The clearing of the wilderness and the opening of new territory always involve attention to purely utilitarian projects first; hence there is little record of systematic or extensive fruit planting in this country prior to the beginning of the 19th century. Naturally, fruit was planted by the very earliest settlers, but this was done more as an effort to supply individual needs than as a means of profit. Thus, in the middle of the 16th century the early Spanish settlers made plantings of fruits in Florida and elsewhere, and early in the 17th century the English did considerable in the matter of planting fruits in Maryland and Virginia and elsewhere in what is now the eastern United States. Grapes especially received early attention, and numerous attempts were made to establish vineyards of European sorts in different parts of America. None of these early attempts, however, was very successful; and when it was found that the European kinds were so poorly adapted to the conditions of the regions then occupied by settlers, attention was turned to the improvement of our native forms. There is probably no more striking example of what can be accomplished by careful horticultural work than the results secured in the improvement of our native forms of American grapes. From the wild types so abundant in our native woods have come practically all of the fine table and wine varieties that are grown in the United States and Canada east of the Rocky Mountains to-day. The work mentioned did not involve any questions of fruit-growing on an extensive scale such as we find now. Nearly every farm in those early times had fruit grown upon it, partly for home use and partly for sale if there was produced more than was required for home consumption. With varying changes caused by the increase in population, the improvement in living conditions, and the demand for more fruits, fruit-growing progressed, until about 50 or 60 years ago it began to take on a new aspect. It was at this time that fruit culture in its broadest sense showed marked development as an independent commercial industry; hence in looking back we find the beginning of such important lines of work as commercial apple, pear, peach, and grape growing, commercial small-fruit-growing, etc. With the advancement of this work came the gradual development of horticultural sections or the localization of horticultural work in certain special localities where experience had shown that the best results were secured in the matter of production, marketing, etc. The peach districts of Delaware, Maryland, New Jersey, Michigan, Connecticut, and Georgia, the grape districts of New York and Ohio, and the apple region of western New York are examples of this movement toward centralization or specialization. With the further increase of population, especially in cities, the improvement in transportation facilities and better knowledge as to climatic and soil conditions, more and more centralization and specialization resulted. With the growth of the fruit interest of the Pacific coast and of Florida and other portions of the South, new features were added to the entire work. Thus has been developed commercial pomology as we find it to-day in this country, involving (1) the production of fruits of high quality, and (2) the harvesting, packing, storing, and transportation of such fruits to market so as to secure the highest prices with a minimum expenditure of outlay for the work. Still further involved in these questions are, of course, other important ones, such as tillage, pruning, spraying, etc., which it is not necessary to discuss here.

According to the figures of the 12th census, the value of all fruits produced in the United States for 1899 was, in round numbers, $131,000,000. Of this amount the orchard fruits had a value of $83,000,000, grapes $14,000,000, small fruits $25,000,000, and sub-tropical fruits $8,000,000. The great fruit districts are shown by the fact that of the $131,000,000 of fruit produced, California furnished $28,000,000 worth, New York $15,000,000, Pennsylvania $10,000,000, Ohio $9,000,000, Michigan $6,000,000, Illinois $5,500,000, Missouri $4,500,000, and Indiana $4,500,000, all in round numbers. The exportation of American fruits to foreign countries is rapidly assuming important proportions. For the fiscal year 1902 the total value of fresh, dried, and canned fruits and nuts exported from the United States was $8,719,344. With the rapid development of fruit-growing in this country there has been felt the need for careful systematic studies of the many varieties in cultivation and offered for cultivation. Systematic pomology, therefore, is an important branch of the work, and is being given special attention by the General Government and by the various State experiment stations and agricultural colleges.

Olericulture or vegetable gardening is an important branch of horticulture, and from time immemorial the art has been practised both for pleasure and for profit. Vegetable gardening proper does not include the growing of such crops as Irish potatoes, sweet potatoes, sugar-beets, shell beans, etc., where the same are produced in large quantities and are handled as ordinary farm produce. Vegetable gardening proper, as we understand it, embraces market gardening, truck-growing, and the growing of vegetables under glass. No sharp lines can be drawn between any of these industries, as they merge in many cases one into the other. Growing vegetables, as already indicated, has long been practised and was a feature in nearly every home in the early days of the country. With increasing population and the consequent demand for more luxuries and more variety, gardens began to expand, and thus was developed the work of market gardening in the vicinity of the larger cieies. Although market-gardening and truck-farming merge closely into each other, market-gardening proper, as a rule, is held to apply to the growing of vegetables for the local market, while truck-growing and truck-gardening imply the shipment of produce to a considerable distance, either by rail or in other ways. Truck-growing proper, on a large commercial scale, has developed practically within the last 25 years and owes its rapid growth largely to the improved transportation facilities and the rapid extension of railroads north and south along the Atlantic coast. The trucking interests proper were an outgrowth from the market garden work in the vicinity of New York. Gradually this work was pushed out to Long Island, and thence it spread to the lands adjacent to Chesapeake Bay, where fast sailing boats made it possible to bring the produce quickly into the markets of the larger cities. The work at first centralized at points where good harbors made regular steamship service available, but rapidly extended south along the lines of the Atlantic coast railways, and now has reached important developments in Virginia, North Carolina, South Carolina, Florida, and other Southern States. There is also another important truck region which has developed along the lines of the Illinois Central Railway in the Mississippi Valley, the crops grown in this region being shipped to the cities north and from them disseminated to large towns and cities, both east and west. More recently there have been large developments in this line in eastern Texas and southern and central California, each region now shipping early vegetables northward and eastward to the extent of thousands of carloads annually. The development of the winter growing of vegetables in the South and elsewhere has to some extent modified the methods of producing crops in the North, especially where glass is used. There is still, however, important work of this nature in progress in the vicinity of all large cities, particular attention being given to the growth of vegetables in greenhouses and under frames. According to figures secured by the writer in 1899, there were at that time 4,500,000 square feet of glass devoted to the growing of vegetables. The value of the establishments aggregated $2,250,000; the wholesale value of the annual product amounted to $2,250,000, and the retail value to $4,500,000. The number of men employed in this work — that is, the growing of plants under glass — was 2,250. According to the figures of the 12th cen- us there were devoted to the growing of vegetables for market in 1899, 1,175,200 acres, and the ma ket value of the product was $67,399,348. There were devoted to the production of vegetables for home use 940,370 acres, yielding a product valued at $46,477,087. This includes only miscellaneous vegetables, and does not cover such crops as Irish potatoes, sweet potatoes, onions, sugar-beets, etc. Thus it appears that, exclusive of glass, there were devoted to the growing of vegetables for the market and for the home 2,115,570 acres, giving an annual product valued at $113,876,435.

The development of floriculture in America has been coincident with that of vegetable gardening and pomology, excepting, of course, that flowers, being more or less of a luxury, were the last to receive special attention. Flower gardens, to a certain extent, formed a part of nearly all the home surroundings of the early settlers. See article FLORICULTURE IN AMERICA.

Landscape gardening literally means the creation of landscape pictures with plants. The pictures may be formal or they may be natural; that is, they may deviate widely from the bits of beautiful scenery which nature so lavishly bestows, or they may attempt to copy these bits of nature or perchance improve upon them by modifying them to meet the immediate surroundings. The picture created may be a matter of taste. Hence, in one country and in one place we find extreme formality, grotesque figures, and various-colored foliage beds forming a part of these pictures, while monstrous forms carved from shrubs and evergreen trees may form another part. Again we see the true lover of nature copying as closely as possible nature's own landscape, which is, after all, true landscape gardening. A bit of lawn, a fringe of foliage, and a clustering group of trees may be all that is required to form this picture, but it is a natural picture, and if harmony is kept in view the results are always charming. The art has long been practised, and its various types and modifications are to be found in our public parks and in private grounds throughout the country. There has been a growing interest in landscape gardening in America in recent years, owing chiefly to the advanced ideas set forth by such men as Downing and Olmsted, who have done much to create an appreciation and love for the purely natural in this work. More recently a still broader conception has been given to landscape effort, and work in this direction has been made to cover important matters connected with the relation of landscape surroundings to buildings, the proper arrangement of roads, etc. Thus we have had developed the field of landscape architecture, which is a broader term than landscape gardening. The landscape architect makes a study of his problem and works out a scheme of operation involving everything that may be connected with it. The landscape gardener may be called upon to carry out part of this scheme, but the architect proper will also be involved.

The literature on horticulture is exceedingly voluminous, covering many writings and textbooks, special papers, reports, etc. The more important standard American pomological works are Downing's 'Fruit and Fruit Trees of America,' Barry's 'Fruit Garden,' and Thomas's 'American Fruit Culturist.' In vegetable culture, Henderson's 'Gardening for Profit,' Bailey's 'Forcing Book,' and Rawson's 'Market Gardener' are standard works. Of the American publications on landscape gardening may be mentioned: Downing, 'Landscape Gardening'; Parson, 'Landscape Gardening'; Long, 'How to Plant the Home Grounds'; Waugh, 'Ornamental Gardening.' The most useful work on horticulture recently issued is Bailey's 'Cyclopedia of American Horticulture,' published in four volumes, the last of which appeared in 1902.

B. T. GALLOWAY,
U. S. Department of Agriculture.

Hor'ton, Robert Forman, English Congregational clergyman and author: b. London 18 Sept. 1855. He was educated at New College, Oxford, and in 1879 he was made a fellow of New College, and lecturer on history. In 1880 he became the pastor of the Congregational church at Hampstead, and in 1893 pastor of the Lyndhurst Road church there. In 1893 he delivered the Lyman Beecher lectures at Yale; in 1903 he was chairman of the Congregational Union of England and Wales. His writings include 'History of the Romans' (1885); 'Inspiration and the Bible' (1887); 'The Teaching of Jesus' (1895); 'Oliver Cromwell' (1897); 'Women of the Old Testament' (1897); 'The Commandments of Jesus' (1898); 'England's Danger' (1898); 'The Pastoral Epistles' (1901); 'The Trinity' (1901).

Horton, Samuel Dana, American publicist: b. Pomeroy, Ohio, 16 Jan. 1844; d. Washington, D. C., 23 Feb. 1895. He was graduated from Harvard in 1864, and from the law school in 1868, and also studied abroad. He began the practice of law in Cincinnati, but devoted himself mainly to the study of monetary questions, spending much time abroad; he was one of the first to advocate the establishment and maintenance of an international ratio between gold and silver. He was a recognized authority on all questions concerning coinage, was secretary of the international monetary conference at Paris in 1871, and a delegate from the United States at the conference of 1881; shortly before his death he went to Washington at the request of the administration for a conference concerning the financial situation. His writings include 'Silver and Gold and their Relation to the Problem of Resumption' (1876); 'The Silver Pound and England's Monetary Policy since the Restoration' (1887); 'The History of the Guinea' (1887); 'Silver in Europe' (1890).

Hosack, hŏs'ak, **David**, American physician and author: b. New York 31 Aug. 1769; d. there 23 Dec. 1835. He was graduated from Princeton College in 1789, and concluded his medical studies in Philadelphia in 1791. In 1795 he was appointed professor of botany in Columbia College. In 1796 the chair of materia medica was assigned to Hosack, who held it with that of botany until 1807, when he accepted the department of materia medica and of midwifery in the College of Physicians and Surgeons. He held at different times several public trusts, as physician to the New York hospital, and the Bloomingdale asylum, resident physician of the city of New York, etc. He was among the original projectors of the New York Historical Society, of the Horticultural Society, and of the New York Literary and Philosophical Society. He was the author of 'Annals of Medicine' (1793); 'Hortus Elginesis' (1808); and numerous papers on medical subjects.

Hosea, hō-zē'a, the first in order among the minor prophets of the Old Testament, but more probably the third in order of time. Nothing is known of his life, except what can be gathered from the introduction to his prophecies, namely, that he was the son of Beeri, and that his ministry belonged to the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah, beginning probably about the end of the reign of Jeroboam II., king of Israel. His prophecies are addressed almost equally to both kingdoms. His book was admitted into the canon after the Babylonish captivity. He has represented in the three first chapters of his book, the guilty violation of their covenant with God by an allegory, very common among the Hebrew poets, of a marriage covenant which the wife has violated, referring to the covenant which God had concluded with the Israelites. The remaining chapters treat of the same subject, under different figures, with reproaches, exhortations, and threats; he predicts the approaching exile of his countrymen, and the consoling promise of the final return of an improved people forms the conclusion of this prophetical book. He is remarkable for his laconic style, hastening from image to image, and from reflection to reflection. The stream of a powerfully excited fancy forces him irresistibly onward. Hence he does not exhibit the roundness, grace, and harmony which characterize the other prophets.

Hosiery, hō'zhėr-ĭ, a word properly applied only to the making of hose or stockings, but used as a general term for all kinds of knitted articles. The materials used for the purpose are cotton, linen, and wool, the last of which is sometimes mixed with cotton or silk. Silk is also frequently used alone. Since 1841 the Jacquard loom, and similar looms have been employed in the manufacture of articles of hosiery. See *Knitting; Textiles*, under KNIT-GOODS,

Hos'mer, Harriet, American sculptor: b. Watertown, Mass., 6 Oct. 1830. She early showed skill as a modeler in clay, and after receiving a general education studied anatomy in a medical college at St. Louis. Her first work, a reduced copy of Canova's Napoleon, was followed by an ideal head of Hesper (1852). She went to Rome in 1852 and studied under John Gibson, the English sculptor. About this period she produced ideal busts of Daphne and Medusa, and in 1855 completed her first life-size figure, Œnone. To the same year belongs Puck, which gained her a great reputation in the United States, and the next year she executed a Will-o'-the-Wisp. The statue of Beatrice Cenci in the public library of St. Louis was finished in 1857, and her colossal statue of Zenobia in 1859. Her next work was a statue of Benton, the Missouri statesman, a bronze cast of which was erected in Lafayette Park, St. Louis. Other works are: Sleeping Faun, exhibited at Dublin in 1865 and at Paris in 1867; a statue of the Queen of Naples as the Heroine of Gaëta; a monument to Abraham Lincoln; and Waking Faun.

Hosmer, James Kendall, American librarian and biographer: b. Northfield, Mass., 29 Jan. 1834. He was a professor in Antioch College, Ohio, and the University of Missouri, in 1874–92, was professor of English and German literature in Washington University (St. Louis, Mo.), and in 1892 became librarian of the public library of Minneapolis. Among his works are: 'The Color Guard' (1864), a record of experiences as a private in the Civil War; 'The Thinking Bayonet' (1865), a novel; 'History of German Literature' (1879); 'Life of Samuel Adams' (1885); 'Life of Sir Henry Vane' (1888); 'A Short History of Anglo-Saxon Freedom' (1890); 'How Thankful was Bewitched' (1894); and a 'Life of Thomas Hutchinson' (1896).

Hos'pital, an institution for the treatment of sick, injured or infirm persons, supported in most cases by voluntary contributions, but in special instances from the funds of the government, state or civic municipalities. Hospitals are of various kinds: medical; surgical; for the reception of incurables; for consumptives; for the deaf, dumb, and blind; for the aged and infirm; for the care and treatment of the insane; emergency and field hospitals for the care of wounded in battle, etc. Modern hospitals are so constructed and their interior is so arranged as to enable a limited staff of physicians and nurses to attend to the wants of the greatest possible number of patients with a view to the most speedy recovery.

The site selected for a hospital should be on high ground; the soil should be clean and dry, free from damp ravines and undrained marshy ground, and the drainage should be ample. If possible it should not be surrounded by other buildings than those belonging to the hospital itself. The structural arrangements should be such as to secure perfect, free circulation and sunshine. The size of the wards depends on the number of patients to be therein maintained and having a capacity of 3,000 cubic feet for each inmate. The disciplinary and economical disposition in a hospital requires that each nurse should have the patients allotted to her under constant observation and personal supervision and that the arrangements are so constructed that the greatest number of patients can be attended and nursed by a given number of nurses. From 20 to 32 beds have been taken as a basis for ward construction. In some hospitals there are wards of one and two beds for cases of unusual gravity. The general form of ward construction is governed by the question of renewal of air and the superficial area allowed to each patient, for on this depends the distance of the sick from each other, the facility of changing the beds, cleanliness and many other important features. In a ward 24 feet wide, with a window for every bed or two, a 7 foot 6 inch bed space along the outer walls is sufficient. That would give 90 superficial feet per bed, which must however be increased in pernicious fevers, surgery and lying-in cases. In the Herbert hospital the smallest allowance is 99 feet per bed. The ceilings should be 12 to 14 feet high. With a view to economize heat in winter and to keep the wards cool in summer the walls should be hollow and all walls ceiled. The walls should be of an impervious polished surface, easily cleansed with soap and water. All corners should be rounded off and no cracks are to be tolerated, since they fill with impurities. Plaster, wood, paint and varnish all absorb organic impurities. The safest arrangement for walls is plaster, lime-whited or painted, which should often be scraped off or renewed.

The floors and woodwork throughout should be of oak, closely jointed, oiled and waxed, rubbed and polished. Confine the woodwork to absolute necessity. The forms of windows must be adapted to facilitate the entrance of light, as a factor to promote health, to promote ventilation, to facilitate nursing and to allow the patient to read in bed. In order to give cheerfulness to the ward and to renew the air easily, the windows should be inserted opposite each other; should extend to 2 feet 6 inches from the floor to within a foot of the ceiling. One cubic foot of window glass to every 50 or 55 cubic feet of space will afford a well lighted, cheerful ward.

The ward offices are those necessary for facilitating the nursing and administration, as the nurses' rooms, ward scullery, bath-rooms and lavatories.

They should all be well ventilated and lighted and all fittings finished in light color so that dirt can be at once detected. The nurses' room should command a view over the whole ward. The lavatory table should be constructed out of an impervious material, as slate or marble, with a row of sunk porcelain basins supplied with hot and cold water. The bathtubs should be porcelained iron. The toilets and urinals should invariably be placed against an outer wall, supplied with a siphon carrying a sufficient water capacity to thoroughly flush the basins. For the floor of these quarters, cement, marble or slate is preferable, and the walls are to be lined with glass, white-glazed tiles, marble, slate or Parian cement.

The administration building, that is, for offices, reception rooms, lodging the staff, operating rooms, kitchen, store-rooms, dispensary, etc., should always be subordinate to the question of the accommodation of the sick. In hospitals where a school is to be established, the necessary lecture rooms, laboratories and amphitheatre should be kept entirely separate from the sick: the morgue and dissecting rooms should be as far removed as possible. The consensus of professional opinion is opposed to the present plan of constructing large edifices for hospital purposes; that the benefits they confer are greatly diminished by the risk of hospital diseases — fevers of certain forms, erysipelas, pyæmia, etc., and which when once installed are most difficult and often impossible to eradicate. A system of cottage and hut construction, any of which could easily be destroyed and replaced, should the emergency demand, has been seriously advocated, but found impracticable because of the great expense and administrative difficulties. The profession to-day favors a system of construction known as the "pavilion plan," which can be called a compromise measure between the large block edifice and the cottage and huts. According to this system the wards are separate and distinct from the administration building and should be arranged to form pavilions, one story high, never more than two, and they should always surround the administrative blocks. This mode of construction is both applicable to large and small establishments. The Royal Infirmary of Edinburgh, the Herbert hospital of Woolwich, the New York hospital, the United States Marine hospital of San Francisco are among the best examples of the pavilion style. There should be free circulation of air between the pavilions, and the space between them should be exposed to the sunshine. The arrangements should be of a character to allow a covered communication between the wards, and each pavilion should have its own broad stairway.

The pavilion and general construction of the administrative building should be made quite subservient to the accommodation for the sick and should never interfere with the light and air of the wards.

Hospitals or asylums for inebriates, likewise hospitals for those addicted to the use of opium and other narcotics, have lately been established throughout the United States. Fever hospitals are maintained in all communities to secure isolation in infectious diseases, and hospital ships and floating hospitals are extremely valuable to promote complete isolation in cases of virulently infective disorders, such as smallpox (q.v.), etc. Children's hospitals are often provided with swimming tanks, indoor and outdoor playing, large ball and tennis grounds and in fact any and everything to promote healthy exercise and pastime for the inmates.

Military and naval hospitals, establishments for the care of sick and wounded soldiers and seamen, exist in all civilized nations. They are either temporary or permanent and if the former located in the immediate vicinity of the scene of operation. Hospital ships are ships fitted out as hospitals in all expeditions beyond the sea. They serve either as stationary hospitals or, if the sick accumulate sail home, or to the nearest station. See also QUARANTINE: RAILROAD HOSPITALS.

Hospitallers, charitable brotherhoods who devote themselves to tend the sick in hospitals. The name is specially applied to an order of knights, the Knights of Saint John. See ORDERS, RELIGIOUS.

Host, or **Hosta Sacra** (sacred host), in the liturgy of the Roman Catholic Church, the body of Christ present in the sacrifice of the Mass under the appearance of bread. The Latin word *hostia* denotes that which is offered in sacrifice; hence in the Mass, where the victim is the same who offered himself on the cross, "the cup" is no less the *hostia* than is "the bread"; but usage has sanctioned the appropriation of the word host to the latter. In the canon of the Mass, the priest, in offering the consecrated elements to God the Father, speaks of both the "bread" and the "cup" as *hostia*; and in the ancient Spanish missal (the Mozarabic) occurs the phrase "this host of bread and wine." But the word *hostia* is also employed to signify specially the bread before consecration: and this usage has its sanction in the Roman liturgy itself and in the rubrics of the Missale Romanum. In the rubric of the *ordo missæ* the altar-bread before consecration is called *hostia*, and after consecration it is called *hostia consecrata*. "Host" in the former sense, that is, the "altar-bread," is, in the Latin Church, a circular wafer made of fine wheaten flour mixed with water only, and it is unleavened. Usually the wafers are stamped either with an image of Christ crucified or with the letters I H S. They are of two sizes, a larger one which the celebrant himself receives (a host of this size is also reserved for the benediction (q.v.) of the Blessed Sacrament); and a smaller size for administration to those who may communicate at the Mass, or to the sick in their houses. The hosts destined for this use are kept in the pyx (called also *ciborium*), a silver vase gilt inside, and deposited in the tabernacle of the altar. As long as the host is thus reserved in the tabernacle the sanctuary lamp is kept alight before it. The Eastern churches in communion with the See of

Rome, except the Maronite and Armenian churches, retain the use of leavened bread in the Eucharist.

Hostage (French, *ôtage;* Latin, *obses;* Low Latin, *obstagius*), a person left as pledge or surety for the performance of the articles or conditions of a treaty. The taking or giving of hostages is now scarcely known in the relations of modern communities, but was formerly almost universal, and many questions in the law of nations arose out of the practice. Writers on international law have discussed how far the rights of conquerors extend over hostages, what circumstances may release them from their obligation, and what effect their escape will produce on the treaty proposed by the contracting parties. In modern civilized warfare hostages are not usually interchanged.

Hos'telry. See HOTEL.

Hot-bed. See HORTICULTURE.

Hot Springs, Ark., city and county seat of Garland County, and one of the most famous sanatoriums of the United States; in the southern centre of the State, 55 miles southwest of Little Rock and 397 miles from Saint Louis; on the Choctaw, O. & G., and Little Rock & H. S. W. R.R.'s. The location is 600 feet above sea-level and lies principally at the easterly base of the mountain complex known as the Ouachita Range, the nearby peaks of which are oftentimes called the Ozark Range — in a valley between two rocky and heavily wooded ridges called West Mountain and Hot Springs Mountain, 400 feet higher — and in its sheltered situation has a mild and pleasant climate. Lat. 34° N.; lon. 93° W. Through the valley runs the Hot Springs Creek starting two miles above; and into this the water from 47 hot mineral springs — originally 73, but many merged artifically or run dry — springing from vents in the gray volcanic tufa near the base of the Hot Springs Mountain on the east. Forty-four are in use or usable; the others rise in the bed of the creek. The former yield 830,000 gallons a day; contain large amounts of calcium and magnesium carbonates, and the presence of lithium, iodides and bromides, etc.; the total mineral matter in solution is between 275 and 280 parts per million and the results, as to the percentage composition of the mineral matter in each hot spring, are very much the same. The waters are prescribed for bathing and drinking and have remarkable curative properties. De Soto, it is said, sought to explore them as the veritable fountain of youth. The ordinary tub bath is the principal feature of treatment, but vapor, shower and plunge baths are also used. People suffering with consumption of the lungs; those afflicted with dilation of the heart; very old people, whose arteries are atheromatous; and paralytics, when their condition is the result of organic central lesions, should not bathe. Relief or cure may be expected in rheumatic, syphilitic, and numerous other conditions. The surgeon-general of the United States army, in an official circular of information issued by the War Department, says:

> The various forms of gout and rheumatism, after the acute stage, or inflammatory stage, neuralgia, especially when depending upon gout or rheumatism, metallic or malarial poisoning; paralysis, not of organic origin; the earlier stages of locomotor ataxia; chronic Bright's disease (the earlier stages only), and other diseases of the urinary organs; functional diseases of the liver; gastric dyspepsia, not of organic origin; chronic diarrhœa; catarrhal affections of the digestive and respiratory tracts; chronic skin diseases, especially of the squamous varieties, and chronic conditions due to malarial infection.
>
> In all forms of dyspepsia and in ulcers of the stomach and intestines the actual bathing which the diseased surfaces receive from the hot water drank materially aids in hastening cures.

As many as 90,000 patients and pleasure seekers visited here in 1902–3. The temperature of the springs varies from 97° to 147°. All issue from a space something over a quarter of a mile long and 200 to 300 feet up the slope, some 10 acres in all. By treaty with the Quapaw Indians in 1818 and by act of Congress in 1832, four sections (2,529 acres) became a reservation, and the springs are in the centre. Dunbar and Hunter of the Lewis and Clark expedition visited the place in 1804 and settlement was made in 1807. After 1832 numerous attempts were made to enter the lands, and title to property involved many years of contention and "shot-gun right." In 1870 Congress authorized suits against the United States in the court of claims. In 1876 title was held to be in the United States by the Supreme Court. Justice Field of the Supreme Court, in an opinion, said: "From the protracted litigation to which it has given rise the Hot Springs reservation is famous in the history of land titles of the country." And Justice Bradley: "The title to a well-known watering place in the State of Arkansas, called the Hot Springs, has been contested by a number of claimants for nearly half a century." In 1877 Congress created a commission to adjudicate squatter rights, giving right of purchase from the United States and to lay off the town. Under this act the Hot Springs were reserved by the United States to prevent monopoly or injury, and 911 acres are used as permanent parks. The government has expended nearly a million dollars in arching the creek, erecting the Army and Navy hospital (open to soldiers and sailors of the Civil War), and in developing and beautifying a system of parks not yet finished. These parks are covered with forest trees, and some are thoroughly fitted up for public enjoyment. Large sums have been spent on boulevards, walks, artificial lakes, landscape gardening, and handsome marble hot-water fountains scattered plentifully through the city. The grand entrance to Hot Springs Mountain, from Central Avenue, is a noble architectural feature, and the initial point of 15 miles of fine drives around the summits of Hot Springs, North and West Mountains.

With one exception, the springs are all enclosed in solid masonry, and the water is conducted by protected pipes into reservoirs near the base of Hot Springs Mountain or to the 23 bath-houses on and off this reservation. The exception is left open and accessible to the public. The government maintains a free bathing establishment for the indigent at which over 10,000 bathe annually, over 90 per cent being benefited. The prices of baths and fees of attendants are fixed by the Department of the Interior, with severe penalties for deviation. A rental of $30 per annum is collected for each tub; 716,053 baths were administered in 1902–3. A handsome city has grown up to house the guests and permanent residents. Along the front of the reservation bath-houses and on the slope of Hot

Springs Mountain is a fine park of 100 acres, with the most elegant buildings facing it. The creek is covered in, and sidewalks and roadways built over it. Several of the hotels, as the Arlington, Eastman, Park and Majestic, are among the largest and best appointed in the country.

Hot Springs received its city charter in 1876. It has a biennial mayor and a council. Being a pleasure resort, as well as a health resort, it has a large itinerant population. Large quantities of novaculite rock, "Arkansas" and "Ouachita," are quarried in the surrounding mountains, and 5,000 bales of cotton are marketed annually. The country abounds in cold springs, some of which have remarkable curative properties, notably Mountain Valley and Potash-Sulphur, 10 and 7 miles distant from Hot Springs; these are efficacious in conditions affecting the kidneys and intestinal tract. Pop. (1870) 1,276; (1880) 3,554; (1890) 8,086; (1900) 9,973.

CHAS. D. GREAVES,
Prest. School Board, Hot Springs, Ark.

Hot Springs, S. D., city, county-seat of Fall River County; on Fall River, the Fremont, E. & M. V. and the B. & M. R.R.'s; about 100 miles south of Deadwood. It is the trade centre for stock, lumber, and mining interests. The water-power is used for several manufactories, a stucco-mill, board and planing-mills, and machine shops. It has thermal and medicinal springs, and is the seat of the Black Hills College (M. E.), opened in 1890, and the State Soldiers' Home. Pop. (1900) 1,319.

Hotch'kiss, Benjamin Berkely, American inventor: b. Watertown, Conn., 1 Oct. 1826; d. Paris, France, 14 Feb. 1885. He was in early life a machinist and turned his attention to the invention of deadly weapons, among them the Hotchkiss magazine gun and the Hotchkiss machine gun, adapted for use in the fighting-tops of warships. In 1870 he established a factory at Paris. His guns were widely used by navies and armies until supplanted by other devices. He also improved heavy ordnance and projectiles.

Hotchkiss Gun. See MACHINE-GUN; ORDNANCE.

Hotel, or Hostelry, an inn or public tavern. The palatial hotels that have sprung up since the introduction of railways are too well known to require notice. One point of difference between the European and the American systems is that under the former, except in the case of a *table d'hôte*, the charge is for each dish ordered, while under the American plan a fixed price is charged for every meal. The modern French word is still used for the house of a rich or distinguished man, or for a public building, such as the *Hôtel de Ville*. See HOTELS IN AMERICA.

Hotels in America. The public house, or hotel, was established in the early days of the colonies to afford accommodation for those who might be compelled to journey from one place to another. As roads were poor, in those days, and stage transportation was slow, many of these houses were opened along the principal roads, or turnpikes, and the majority of these so-called inns bore such names as "King's," "Queens," "The Red Lion," etc. As public opinion changed, however, and the colonies inaugurated their revolt against the Crown, there was a corresponding change in the names of these hotels which brought them into closer harmony with the spirit of the times. From being mere public houses, wherein beds and food might be obtained by travelers, they became the meeting places of patriots, so it was but natural that the portrait of Washington, or of some other great American, should have taken the place of that of George III., and other royal personages, on the swinging signs before these doors. As time passed and the patriotic spirit rose to greater heights, these inns became the scenes of many events that brought them into the closest relation with the progress of the Revolutionary period and with the formative days which followed the declaration of peace. There was, for example, the City Tavern, in Philadelphia (1775), at which General Washington was frequently a guest; the Bunch of Grapes Tavern, Boston, where he enjoyed that "elegant dinner provided at public expense, while joy and gratitude sat on every countenance and smiled in every eye" (28 March 1776); the True American Inn, at Trenton (1777); Arnold's Tavern, Morristown; Sufferin's Tavern, Smith's Clove, N. Y.; the Buck Tavern, near Philadelphia; Smith's Tavern, Smith's Clove, N. Y. (1779); the tavern at East Chester, N. Y., where he was ill (1780); the Fountain Inn, Baltimore (1781); Day's Tavern, Harlem, where he stopped with Governor Clinton (1783); Fraunces Tavern, New York, where, in the assembly-room, he bade farewell to the men who had followed his fortunes so faithfully; Mann's Hotel, Annapolis, from which he proceeded to Congress on the day when he resigned his commission, and the City Hotel, Alexandria, where he was afterward entertained by the Alexandria Lodge, of which he was a member. The tavern at East Chester, where Washington stayed, during his illness, was erected soon after the beginning of the 17th century. At one time Lafayette was entertained in the house, and, for a season, it was practically the seat of the national government, President John Adams having taken refuge at East Chester during the yellow fever epidemic at Philadelphia, then the federal capital. This tavern now stands within the New York city limits, and the rooms which have the greatest historic interest still preserve the same appearance which they had in those old days.

Among the other taverns of the country which are rich in historic memories, but which were not directly associated with the career of the first President, were the Catamount Tavern, at Bennington, Vt.; George Burn's Coffee-House, in New York, long the lounging place of the British officers, although privately frequented by the Sons of Liberty during the occupation of the city by the British; the Tun Tavern, Philadelphia, the house in which the first Masonic lodge in America was organized; the City Tavern and the Bird in Hand, at Richmond, Va., and the Rose Tree Inn, at Media, Pa.

The first hotels in this country were conducted on the so-called American plan, which provided a fixed price for a day and for each fraction of a day. In those times $1 a day was considered a "good round price," and taverns were ordinarily so small that one which was provided with 20 rooms was regarded as a most commodious house. The rooms were usually comfortable, however, and were neatly, if plainly furnished with strongly-made furniture. Carpets were rarely found, although hand-woven rag-rugs frequently appeared on the floors. Meals, which were served at fixed hours only, were announced by the ringing of a bell or gong, and all guests were expected to respond as quickly as possible. The table was abundantly supplied with dishes that were both substantial and palatable, the cooking being done by the wife of the landlord, with such assistants as the patronage of the inn might authorize, and while meat dishes predominated, game was so plentiful that its appearance attracted no comment.

At this time in the history of the American public house there were comparatively few inns that made an extra charge for wines. Instead decanters of liquors and of some favorite wine, like Madeira, port, or sherry, frequently stood upon the tables, and from these the guests served themselves freely. There were no printed bills of fare in these days, but practically all the food to be served was placed on the table at one time. Guests helped themselves, some slight assistance being given by the waiter who stood at hand. When Congress met in New York, in 1789, the members found accommodations chiefly in the boarding-houses which abounded in the neighborhood of the Battery — on lower Broadway, in Cedar street, and in Maiden Lane. It is rather amusing to note that people from other parts of the country complained about the "high prices" that were charged at the taverns and boarding-houses in New York, for that was the time when the "board of the Congressmen was paid out of the common treasury, to which every citizen of the United States contributed his share." In reply to this charge of exorbitant prices it was stated that board in New York "ranges from $3 to $7 per week," and one house was cited as furnishing "from 7 to 9 dishes a day, with 4 sorts of liquor."

The most important American taverns in 1795 were located in New York, Philadelphia, Baltimore, and Boston. The best New York taverns were Fraunces', opened in 1762, and formerly known as the Queen Catherine, one of the largest inns during the Revolutionary period, as it contained some 30 rooms; the City Hotel, which was erected on the site of the George Burns' Coffee House, in 1793, and which was not only the meeting place of the fashionable City Assembly, but was patronized by the so-called "Three Hundred" of that day; Bunker's, the Washington Tavern, and the Tontine Coffee House, on Wall street.

The National Hotel, in Washington, which was for many years the home of the most eminent public men of the nation, was opened in 1827. In 1829, the Tremont House was opened in Boston, and for years it was noted as being the grandest hotel in the land, if not the most elegant public house in the world. Prior to that time the principal hotels in Boston had been the Eastern Stage House, Doolittle's City Tavern, and the Lamb Tavern.

It was about that time, or, to be exact, in 1830, that Delmonico opened the first high-class restaurant in New York. High as his prices were, when compared to those which prevailed elsewhere, epicures and persons of fashion flocked to his support and the enterprise prospered from the day of its inception. In 1833, the United States Hotel, in New York was opened; in 1834, the Louisville Hotel, and, in 1835, the Galt House, also at Louisville, all of which immediately became noted as fine houses. The United States Hotel, at Boston, which has since been greatly enlarged and is still standing, was opened in 1835, while, about this time, the old Washington Hotel, at Portland, Me., which had been established since 1823, also took the name of the United States. The Rockingham, at Portsmouth, N. H., once the home of Governor Langdon, was opened in 1834, but, like other hotels of that time it was not particularly commodious in the modern sense of the word. In fact, up to 1836, there were comparatively few hotels in the United States that were capable of accommodating as many as 200 persons. In 1836, the Astor House, in New York, was opened. Built of massive granite, and furnished with all the conveniences of that day, it was a fitting rival to Boston's Tremont House. Barnum's Hotel, at Baltimore, which was opened at about this time, eclipsed the best houses which had hitherto been built in that city, while the opening of the St. Charles Hotel, at New Orleans, in the same year, was an event which was heralded from one end of the land to the other. Situated in the centre of the "American" portion of the city, its stately portico built in the style of a Corinthian temple, made it, next to the Capitol, at Washington, the most imposing structure in the land. It was also one of the best appointed and most commodious houses in America, having accommodations for more than 700 persons. The original buildings were burned in 1851, but it was almost immediately rebuilt, and it continued to enjoy its position as the centre of southern hotel life, until the outbreak of the Civil War. In 1894, the structure was once more burned, but it has since been rebuilt, and still ranks as one of the best hotels in America.

The Charleston Hotel, at Charleston, had the distinction of being the only hotel in the country that had been burned to the ground on the same day on which it was opened. This was in 1839, but as it was rebuilt at once, it was again opened in 1840, and afterward becoming the favorite resort of Calhoun and other great southern statesmen. When the Planter's House, at St. Louis, was opened in 1841, it justly prided itself upon being "the largest hotel west of the mountains." It had 215 well-furnished rooms, a classic ball-room with a floor-space "8,911 square feet more than the celebrated Tremont House, in Boston," while the china and cutlery, all of which was made in England, bore the name of the house. Charles Dickens, who stopped there in 1842, spoke favorably of the hospitality of this hotel in his "American Notes." The Massassoit House, at Springfield, Mass., one of the celebrated New England hotels, and the New York Hotel, were both opened in 1848. The Delevan House, at Albany, was opened in 1845. The year 1847 will always be a memorable one in the history of the American hotel, for it marks the date of the opening of the Revere House, Boston, a house which, under the management of Paran Stevens, soon became the pattern which all other hotels in this country sought to imitate.

Up to 1855, the principal hotels in Philadelphia were the Mansion House, the United States, the Washington City, and the Girard House, and it was in that year that the Burnett House, at Cincinnati, was opened with 250 bed-rooms, besides many drawing-rooms, and especially spacious corridors. The Eagle Hotel, at Richmond, where Lafayette had stopped in 1824, was burned in 1840, and the Exchange and Ballard's were afterward opened. The Clarendon and the Irving House, in New York, were opened about 1850. The first Tremont House, at Chicago, which for some time was the leading hotel in that city, was opened about this time, while the Battle House, at Mobile, the St. Louis Hotel, at New Orleans, and the St. Nicholas and the Metropolitan, in New York, were opened about 1852. All were large houses, and were conducted upon an expensive scale, while the two New York houses were particularly conspicuous in having introduced "bridal chambers" and other novelties.

In 1854, the Brevoort and the Everett were opened, on the European plan, in New York; the famous Parker House, in Boston, also on the European plan, was opened in 1855, while the Fifth Avenue Hotel, in New York was finished in 1859. It was the first hotel to introduce a passenger elevator.

Willard's Hotel, at Washington, was the focus of many thrilling scenes and events during the Civil War, and among the houses that were opened during the next few years were the Lindell and Southern hotels, at St. Louis; the Albemarle, Hoffman, St. James, and Grand, in New York, and the Arlington, at Washington. The Gilsey House, which was opened in 1871, in New York, at once took rank as one of the best European-plan hotels, while the Windsor House, in New York, began the successful career that ended so disastrously in the fire of 1899, in 1873. The Brunswick, in Boston, and the Palmer and Grand Pacific, both in Chicago, were opened about this time, while the Palace Hotel, at San Francisco, one of the most famous and palatial houses in the far west, began to receive guests in 1875.

The last two decades of the 19th century were conspicuous, not only for the sudden increase of new and more splendid hotels, but also for the enlargement and improvement of those already built, in every part of the country, while, in such a brief review of the hotel business, it is impossible to name all the hotels worthy of mention that have been built during the past 25 or 30 years, it may justly be said that the revival of interest in the making of new and better houses extended from the Atlantic to the Pacific, and from our northernmost boundary to the Gulf. Beginning with the Vendome and Young's, at Boston, the list would include the Narragansett, at Providence; the Grand Union, Park Avenue, and Murray Hill, in New York; the Lafayette and Stratford, at Philadelphia; the Rennet, at Baltimore; the De Soto, at Savannah; the Kimball, at Atlanta; the Iroquois, at Buffalo; the Hollenden, at Cleveland; the Grand, at Cincinnati, and the Cadillac and Russell, at Detroit. Later came the Auditorium, at Chicago; the Plankinton, at Milwaukee; the Ryan, at St. Paul; the West, at Minneapolis; the Coates House, at Kansas City; Brown Palace Hotel, at Denver; the Portland, at Portland, Oregon, and the Tacoma, at Tacoma. The impetus to the hotel business, which began some 30 years ago, however, has continued up to the present time for the last few years have witnessed the construction of many new and finer hotels than any that had hitherto been built, among them being the Imperial, the Savoy, the Holland, the Waldorf, the New Astor, and the St. Regis, while one of the most unique experiments in the hotel line was the establishment of the Martha Washington, a hotel exclusively for women, which is now being successfully operated, also in New York.

The watering-place and summer-resort hotels also represent an important and rapidly increasing branch of the business. At the beginning of the 19th century there were a few inns at places like Saratoga, while a tavern at the White Mountains was built by Crawford in 1803. In 1822, the Catskill Mountain House was opened, and, by 1840, there were good houses at Trenton Falls and Delaware Water Gap. Twenty years later, Newport, Nahant, the White Mountains, Lake George, Saratoga, Niagara, Cape May, Old Point Comfort, and the Virginia springs, all had good hotel accommodations, but, since that time this branch of the business has grown to such an extent that splendid hotels are now located on almost every available spot on the coast from Maine to Florida, while the Adirondacks, the Catskills, and many interior resorts have accommodations for guests that can compare favorably with the best hotels in the country. At such hotels the American plan usually prevails, as it does to a considerable extent throughout the smaller cities and towns. In the large cities, however, the European plan, which fixes a price for the room, and which charges for extra service and for each item on the bill of fare, has become more popular, for while, in some instances, the two plans are combined, it is the European plan that is generally followed by the large hotels. Moreover the charges at the best hotels are about twice as great as they were in 1850.

When compared with the palatial hotels of to-day even the fine houses like the Tremont and the Astor House were primitive in their construction and management. The modern hotel is equipped with running water and set basins in every room; many rooms also have water-closets and baths with exposed plumbing; everywhere there are open grates and steam heat, improved ventilation, elevators for both passengers and baggage, electric bells, telephones, and every possible device to prevent fire, or to assure the safe escape of guests in case of a conflagration. Utensils and machinery have also multiplied greatly during the past few years, for the best hotels now run a thoroughly up-to-date laundry, an electric lighting plant, apparatus for the distilling of water, and the most elaborate cold-storage conveniences, often including an individual ice-making plant, while, among the other necessary conveniences of every well-equipped hotel one may mention the reading, writing, and music rooms; the coat, package, and baggage rooms; the barber shop, with its manicuring, boot-blacking, and other accessories; the billiard-room; telephone, telegraph, and ticket offices; the book and news-stand; the stenographers and typewriters, and the carriage and messenger services, not to mention a score of other details that are just as imperative a necessity. It is no uncommon thing to-day to find single hotel structures valued at $3,000,000 or $4,000,000, equipped with furnishings costing many hundred thousand dollars.

A conservative estimate of the number of hotels in the United States, in 1905, exclusive of those in process of erection, places the number at 44,250. Of these about 3,750 are summer or winter resort hotels, 3,000 are family, or private hotels, while the balance are commercial houses. These hotels now give employment to no less than 3,250,000 persons, and the amount of capital invested in the business is undoubtedly in excess of $6,000,000,000.

Hottentots, hŏt'ĕn-tots, an African race, the aboriginal occupants of the south end of that continent, near the Cape of Good Hope. The name now given to the whole race was that of the tribe in the immediate vicinity of the Cape of Good Hope, with which the Dutch settlers first became acquainted. The origin of the name is unknown. They are, when young, of remarkable symmetry; but their faces are ugly, and this ugliness increases with age. The complexion is a pale olive, the cheek-bones project, the chin is narrow and pointed, and the face consequently is triangular. The lips are thick, the nose flat, the nostrils wide, the ears large and lobeless, the hair woolly, and the beard scanty. The women in early life are often models of proportion, and their gait by no means deficient in grace. Their bloom, however, is transient, for, marrying at twelve or thirteen, after the first child they lose their grace and proportion, and soon become hideous. Both sexes are distinguished by excessive incurvation of the spine. When the Dutch first settled at the Cape the Hottentots were a numerous nation, and occupied a territory of 100,000 square miles. They had abundance of horned cattle and sheep; and it is supposed that the seven tribes into which they were divided made up together a population of at least 200,000. At the present day this race is nearly extinct within the wide territory which formerly belonged to it. They may amount to about 20,000. The Koras or Korannas (shoe-wearers), south of the Kalahari Desert, still remain a favorable specimen of the Hottentot race. They are taller, stronger, and more cleanly than some of the other tribes. Most of them possess cattle; those who do not, soon degenerate into Bushmen. On the eastern frontier of the colony are still some remnants of the Gona or Gonaqua tribe; but they have nowhere preserved their ancient usages and purity of blood, but are much mixed with the Amakosa Kafirs. The Namas, who are the purest type of Hottentots now existing, dwell in Namaqualand, in German Southwest Africa. The Namas are a pastoral people almost exclusively. Their dwellings are low, rude huts, surrounded by fences. Many of them have been Christianized. The Hottentots generally are very indolent and lethargic.

Hottentot's-bread. See ELEPHANT'S-FOOT.

Houdon, Jean Antoine, zhŏn äṅ-twän oo-dŏṅ, French sculptor: b. Versailles 20 March 1741; d. Paris 15 July 1828. Having gained the first prize for sculpture in the royal academy at Paris, he visited Italy, passed 10 years in Rome in the study of the antique, and finished, among other works, the statue of St. Bruno in the church of St. Maria degli Angeli. Returning to Paris, he executed admirable busts of Rousseau, Diderot, D'Alembert, Franklin, Turgot, Mirabeau, Gluck, and many other distinguished men; statues of Voltaire and Tourville; the celebrated 'Diana' for the empress of Russia; and other works, which placed him in the first rank of French sculptors. In 1785 he accompanied Franklin to the United States, to prepare the model for the statue of Washington ordered by the State of Virginia, and passed two weeks at Washington's residence at Mt. Vernon for that purpose. The statue, bearing the sculptor's legend, "*Fait par Houdon, citoyen Francais*, 1788," now stands in the hall of the capitol of Virginia at Richmond. Among Houdon's later works is the celebrated statue of Cicero in the palace of the Luxembourg.

Hough, hŭf, **Emerson,** American author: b. Newton, Ia., 28 June 1857. He was graduated from the State University of Iowa in 1880, traveled extensively in the wild portions of the West, was for several years a writer in Chicago, and there became in 1899 western manager of the New York periodical 'Forest and Stream.' His publications are: 'The Singing Mouse Stories' (1895); 'The Story of the Cowboy' (1895); 'The Girl at the Half-way House' (1900); and 'The Mississippi Bubble' (1902).

Hough, George Washington, American astronomer: b. Montgomery County, N. Y., 24 Oct. 1836. He was graduated at Union College in 1856; appointed astronomer at the Cincinnati Observatory in 1859, and the following year became astronomer and director of the Dudley Observatory, Albany, N. Y. In 1879 he became director of the Dearborn Observatory and professor of astronomy at the Chicago University; and later accepted a similar position at the Northwestern University. He has invented several astronomical instruments and has discovered more than 600 double stars. He has written 'Annals of the Dudley Observatory' (1866–71).

Hough, Walter, American ethnologist: b. Morgantown, W. Va., 23 April 1859. He was graduated from the West Virginia University in 1883 and since 1885 has been connected with the ethnological department of the United States National Museum, becoming in 1895 assistant curator. He has published several important professional monographs.

Hough, Warwick, American jurist: b. Loudoun County, Va., 26 Jan. 1836. He was graduated from the University of Missouri in 1854, subsequently studied law and was admitted to the bar in 1859. In January 1861 he was appointed adjutant-general of Missouri, as such issuing the general order under which the State military organizations went into camp on 3 May. He was for a short time secretary of state in Missouri, resigning in 1863 to enter the Confederate service, and serving on the staffs of General Polk and other Confederate commanders. For a few years after the war he practised law in Memphis, Tenn., but afterward returned to Missouri, establishing himself in Kansas City. He was a judge of the Missouri supreme court 1874–84, for two years of that period serving as chief justice of the State. In 1884 he removed to St. Louis, where he has continued in the active practice of his profession.

Houghton, hō'tŏn, **Henry Oscar,** American publisher: b. Sutton, Vt., 30 April 1823; d. North Andover, Mass., 25 Aug. 1895. He was apprenticed to a printer in Burlington, Vt., and later entered the University of Vermont, where he was graduated in 1846. Going soon after to Boston he became a member of the printing firm of Bolles & Houghton at Cambridge in 1849, and founded later the 'Riverside Press.' In 1864 he entered the book publishing firm of Hurd & Houghton, now the widely known house of Houghton, Mifflin & Co.

Houghton, how'tŏn, **Richard Monckton Milnes,** Baron, English poet: b. Fryston Hall, near Pontefract, Yorkshire, 19 June 1809; d. Vichy, France, 11 Aug. 1885. He was educated at Oxford and was long prominent in Parliament as a moderate Conservative. He was raised to the peerage in 1863. He was the author of several volumes of verse and prose, including a 'Life of Keats' (1848).

Houghton, hō'tŏn, Mich., a village and the county-seat of Houghton County, 94 miles northeast of Marquette: on the south bank of Portage Lake, and on the Copper Range, Mineral Range, and Duluth, S. S. & A. R.R.'s. Portage Lake is connected with Lake Superior at the south by the Portage River and at the north by a ship-canal by means of which steamers avoid the detour around Keweenaw Point.

Industries, etc.— Houghton is the centre of the rich mineral district in the peninsula of Keweenaw, the total output of which was in 1901 nearly 150,000,000 pounds. The larger part of the copper export of the region is shipped from this port. There is also considerable lumbering, manufacture, and commerce, and the shipping interests are important. The various industries have about 1,000 employees.

Public Institutions, Buildings, etc.— It is the seat of the Michigan College of Mines, which was founded in 1885 and occupies a fine structure. There are Episcopal, Methodist Episcopal, Catholic, and Presbyterian churches. Mention should also be made of the county court-house. The two banks have a combined capital of $250,000 and deposits of about $3,000,000.

History and Government.— Houghton was first settled in 1851. Its government is by a president and a council of six members elected biennially, three in each year. Pop. (1903) 4,000.

Horace J. Stevens,
Editor of the 'Copper Handbook.'

Houlton, hōl'tŏn, Maine, town, county-seat of Aroostook County, in the eastern part of the State; on the Canadian P. and the Bangor & A. R.R.'s; about 145 miles northwest of Eastport. It is the trade centre for a large lumbering region, and in the near vicinity there is quite an acreage of good agricultural lands. The chief manufactures are flour, butter, starch, foundry and machine-shop products, lumber, woolen goods, and furniture. It has a large slaughter-house and planing- and molding-mills. It is the seat of Ricker Classical Institute, a Baptist school. It has a town public library. Pop. (1900) 4,686.

Houma, hoo'ma, La., town, parish-seat of Terrebonne Parish; on the Bayou Terrebonne, and the Southern Pacific R.R.; about 72 miles southwest of New Orleans. It is situated in an agricultural region where the principal crops are rice, sugar-cane, and grain. The canning of oysters is one of the important industries; it has a large moss-factory and lumber yards. From 1890 to 1900 the increase in population was over 100 per cent. Pop. 4,686.

Hound, a dog that hunts by scent, a definition which excludes the greyhound (q.v.). It is difficult to determine from what stock the English hound has originally sprung, but the old "Southern hound" or talbot was most probably the source of the various hounds now known, among which the bloodhound, foxhound, beagle, harrier, dachshund, turnspit, otterhound and hoarhound (now known as Great Dane) are the principal varieties. The mastiff (q.v.) ought also to be included in this group. See Dog.

Hour-glass, a species of chronometer or instrument for measuring time. It consists usually of two hollow bulbs placed one above the other, and having a narrow neck of communication. Dry sand is introduced in quantity sufficient nearly to fill one of the bulbs and fine enough to pass freely through the orifice of the connecting neck. The quantity of sand is adjusted to the time which the glass has been constructed to indicate. In the case of an hour-glass the sand in the upper bulb takes an hour to pass into the lower bulb; and so on for any other definite division of time. This instrument is always subject to slight error in its indications of time, owing to the expansion and contraction of the glass by changes of temperature, and by the variations of dryness in the sand. The hour-glass was commonly used in churches during the 16th and 17th centuries to regulate the length of the sermon, and in some places it continued in use down to the beginning of the 19th century.

Houris, hoo'- or how'rĭz, the "black-eyed" nymphs of Paradise, whose company, according to the Koran, is to be one of the rewards of the faithful. They are described as most beautiful virgins endowed with perpetual youth. They dwell in beautiful gardens, by flowing streams, and the very meanest of the faithful will have at least 72 of them.

Housatonic, hoo-sa-tŏn'ĭk, a river which has its rise in the Berkshire Hills, in the western part of Massachusetts, and flows south, through Connecticut, into Long Island Sound. Its course of about 155 miles is through a hilly, mountainous country, noted for its scenic beauty.

House, a place of abode of a family or individual. The common expression, "a man's house is his castle," is in most instances true. Except in criminal cases a man can hold his house against all comers. No sheriff can break open his door to arrest him, or seize his goods for debt, except by a writ, affidavit, or search-warrant. But the house is no protection where there has been a criminal offence. Breaking into a house with the intent to rob is burglary, and to set fire to a house constitutes arson. A man may defend his house against trespassers and thieves attempting forcible entrance, even to the killing of the intruder, if it can be shown that he has used no greater force than was absolutely necessary.

House-boat, a combination of boat and house, used largely as pleasure craft on rivers, canals, and lakes, in Great Britain and the United States. The houseboat had its origin in England about 1860. Its growth there has been comparatively slow. It was transplanted to this country late in the 19th century, and at first found favor with only a select few; but as soon as its advantages became manifest it began to develop rapidly, and advanced to a most remarkable state of perfection. A "house-boat" is not a boat with two, three or four decks and a number of staterooms, but a commodious, comfortable craft arranged for the accommodation of a family party, a company of bachelors or any suggestible combination of people. It might be likened to a suite of apartments afloat.

The house-boat in England has been particularly a Thames attraction and is seen to the best advantage at Henley. In 1903 there were several hundred of these floating houses on the water of the Thames. The price of a house-boat ranges from $300 to $25,000. But a comfortable craft, containing saloon, kitchen and four bed-rooms, may be purchased for $2,000. The Thames season lasts from June to September, and is at its height in July and August. A large house-boat may be hired for the season, including Henley, for $1,000.

In the United States the house-boat is seen most frequently during the summer months on the Hudson River, the St. Lawrence River, and Long Island Sound. The American vessels are even larger than the English boats and more expensive. They are constructed on approved plans, and contain every possible comfort and convenience that may be found in the best equipped dwelling or suite of apartments ashore. There are spacious sleeping rooms, larger than the staterooms on ocean steamers, a cosy sitting-room, a parlor, a library, a reception room, all the necessary storerooms, a lavatory, a cook's galley and, in fact, everything that a well-ordered household might demand. The properly constructed houseboat has a promenade deck and a high rail encloses it so that children may play about the deck with the utmost freedom and safety. The more pretentious are lighted with gas supplied from a naphtha gas-making machine, or electric light, with the energy supplied by storage batteries.

The great charm of the house-boat is the power that its occupants possess to move it from one place to another. On dry land when a man or a family does not fancy a place he or they move away and leave the house behind. On the house-boat they take their house along with them, and they can go wherever navigable water exists. The boat can be anchored in midstream or moored to a pier. No persons can interfere with the privacy of those on board. It is their own floating castle. When they are tired of one place they can go to another, and they have the advantage over their land-living friends that they not only take their house along, but all their belongings, and without the aid of the baggage master.

A typical American house-boat is the Idler, owned by a New York gentleman and used about Alexandria Bay, in the St. Lawrence River. The cabin has a dozen or more windows of goodly size; there is a saloon and opening from it a dining-room. The kitchen, store-rooms and quarters for a servant or two are "aft." The promenade deck has hammocks, steamer chairs, camp stools, rugs, tables, books, work baskets, and flowers; here the family live, move, and have their being for three quarters of the time spent on the boat. Among the well known house-boats on the St. Lawrence, are the Nydia, Mavis, River God, Bohemia, Amaryllis, Merrivale, and Summerholme.

On the Mississippi River, Ohio River and other large streams in the Western States the house-boat is utilized for business as well as for pleasure, and floating grocery stores, photograph galleries, and dry goods and notion shops are not uncommon. There is on the Mississippi at least one floating theatre built on the house-boat plan, and hundreds of small families have adopted a rudely constructed inexpensive type of boat for permanent residences.

House-Boat on the Styx, A, a humorous book by John Kendrick Bangs (q.v.) published in 1895. It purports to be an account of the doings and conversations of a company of literary ghosts assembled in a house-boat managed by Charon. Among the ghostly personages represented are Shakespeare, Raleigh, Dr. Johnson, and many more of various degrees of renown.

House-cricket. See GRYLLIDÆ.

House-finch, A familiar garden finch (*Carpodacus frontalis*) of California, grayish, with the head, neck and breast scarlet-carmine. It represents a group of beautiful and interesting Pacific Coast and Mexican finches also known as linnets and burions.

House-fly. See FLIES.

House Industry, a modern system of labor in which the workmen carry to their homes raw materials and other goods to be manufactured within their own houses. In New York and other large cities this form of labor particularly applies to the Polish Jews, who are employed to the number of many thousands by the manufacturers of coats, cloaks, and other wearing apparel. The abuses of house industry have become notorious under the name of the sweatshop system, which will be found described more in detail in the article FACTORIES AND FACTORY INSPECTION.

House of Lords. See PARLIAMENT.

House of Representatives, the branch of most State legislatures, and of Congress, which has the more numerous members, elected from smaller districts, and in some cases for shorter terms. It is very commonly termed the "lower house" or "popular branch," implying a misunderstanding at once of its origin and functions. The House, for instance, is commonly supposed to be related to the Senate as the British House of Commons is to the House of Lords, and to have been modeled on that relation; the former is wholly untrue and the latter largely so. The House of Commons represents popular constituencies, the House of Lords represents only itself; the former is the less dignified theoretically, in practice it has not only more power but all the power; the individual members of the former have mostly less power than those of the latter, but as a body they are incomparably more powerful. None of these things is true about the House and Senate of Congress. Both represent constituencies and the public equally; both are not only theoretically but practically equal — the Senate's power of confirming appointments and treaties being fully balanced by the House's power of impeachment, of originating revenue bills, and electing a President if the electors fail of a choice. Nor are the members of either as individuals presumptively superior in power to those of the other. The actual superiority of the Senate is due to the longer terms, which give the older members a parliamentary experience before which the mass of raw members of the House bow; to the seats being the subject of eager competition among the ablest politicians, so that the average public position is higher: and to the lesser membership and smaller number of new bills, which enable it to preserve more independence of the chairman's tyranny than the House. Still, a certain glamour always surrounds the latter as the "popular branch"; partly due to the fact that, owing to its great number and short terms, popular movements are more quickly transformed into legislative action than in the Senate. In this respect alone the idea is correct: a party intrenched in the Senate has often boasted that no matter what the majority of the people wished it could not be dislodged for at least eight years, or the time of two presidential elections, in which anything might happen.

In its formation, the model in the State legislatures was simply to follow the old colonial form of council and assembly, itself not copied from Parliament but an independent development; and in Congress the model was partly those legislatures and doubtless partly Parliament — the political theory of "checks and balances" being more potent, however, in defining the distribution of powers than in creating the forms of the houses. The actual form of Congress was a compromise, without which the Union could not have been formed. The large States were averse to being outweighed by the small, and wished for a two-chambered body, with representation in each proportionate to population: the small ones were determined on a single-chambered one, with each State having one vote. The present arrangement was the suggestion of the Connecticut members; a final item of the compromise was that the senators should vote individually and not by States, so that a State should only have its power on condition of keeping its members in place. For the general functions of the House, and its relations present and prospective to the Senate, see CONGRESS.

The members of the House, according to the Constitution, must be 25 years of age, seven years citizens of the United States, and residents of the States which send them; by act of 25 June 1842 they must be chosen from districts formed of contiguous territory (but see GERRYMANDER for the observance of this). This put an end to electing on general ticket, but there is no provision that the representatives shall be residents of their districts, and the people have a perfect right to choose them in the British fashion, from any part of the State. What prevents this is not law, but the intense local particularism which, even in State senatorial districts made up of several towns, insists on passing the office around among the towns; at bottom, the American conviction that public office demands no training. The number of members is fixed by Congress after each new census.

A quorum of members is a majority of those actually chosen. The House organizes by having the clerk of the last House call the new members to order, and if a quorum is present he calls the roll for a vote on choice of Speaker. The members choose their seats in turn as their numbers are drawn by lot. The principal officers are the Speaker, clerk, sergeant-at-arms, doorkeeper, postmaster, and chaplain. (For the Speaker's powers, see CONGRESS.) The sergeant-at-arms is the constable. The symbol of his authority is the mace, made on the pattern ordered by the House 14 April 1789; a Roman device, ebony fasces, of which each rod ends in a spear-head, bound at the ends and in the middle with silver bands, and on the end a globe surmounted by an eagle with outspread wings. The House is governed by Jefferson's Manual of Parliamentary Practice, plus its standing rules and orders and the joint rules of the two houses.

House of the Seven Gables, The, a novel by Nathaniel Hawthorne (q.v.).

House Snake, or **Milk Snake**, a variety of *Lampropeltis doliatus*, the corn-snake (q.v.) of the South, found abundantly in most parts of the northern half of the United States westward to the Rocky Mountains. The dorsal scales are not at all keeled and the ventral plates often exceed 200 in number; the ground-color is gray with three series of rounded black-bordered brown blotches, and the belly checkered with black and white; a length of 4 feet is sometimes attained. This is a handsome and mild-tempered colubroid snake, very abundant in farming districts, where it frequently enters houses, but probably in search of mice rather than for the purpose of drinking milk, as is popularly believed. It is an expert climber, often ascending porches and vines attached to the walls of houses. As usual, the eggs are deposited in a hole dug in a sandy field.

House Sparrow. From the circumstances of the chief importations into this country having been from England this species, the *Passer domesticus* of ornithologists, is almost exclusively known in the United States as the English sparrow, although it is distributed quite as plentifully throughout most parts of Europe. The appearance and general habits of this familiar and ubiquitous bird require no description. The presence of the house-sparrow in America is a most noteworthy instance of the folly of disturbing the proper "balance of Nature" by the thoughtless introduction into new regions of vigorous species which are relieved from the restraining influences of those checks that usually operate in their original habitats. The motives which led to its importation seem to have been two-fold: the desire to combat the plague of measuring-worms (*geometridæ*), with which the parks of many of the eastern cities were affected, and the sentiment which moved many of our foreign born citizens to look with favor upon the introduction of a familiar bird of the fatherland. The importations began in 1850, when the directors of the Brooklyn Institute, led by the Hon. Nicolas Pike, liberated 8 pairs in that city, followed by larger numbers in 1852 and 1853. The following year saw their introduction into Portland, Me. Within the next 15 years direct importations were made to the eastern seaboard, the city of Philadelphia liberating 500 pairs in 1869 in her parks, which were carefully nurtured by a paid caretaker. During the next decade small lots were set free in nearly every State of the Union, including those on the Pacific coast. Thus, purposely distributed by man, carried in grain cars on the railroads and aided by its remarkable hardiness, fecundity, boldness and adaptability, the house-sparrow has in 50 years spread to practically all parts of this country, except a few remote and isolated regions, and to many parts of British America. It keeps close to the abodes of man and has become extraordinarily abundant in many large cities and towns, where it acts as a scavenger and befouls the buildings with its droppings and slovenly nests. Because of its presence and pugnacity many smaller native birds have withdrawn from the parks and open spaces, and it has in many other ways become a nuisance, though it does not altogether lack virtues. In its relation to agriculture little that is favorable can be said of the English sparrow. About three fourths of its food consists of grain, much of which is obtained by raids on the fields and store houses; serious injury is also done by its attacks on flower and leaf buds and on all kinds of fruits. On the credit side may be mentioned the relatively small quantity of insects and the considerable quantity of weed seeds devoured. Consult, Gentry, 'The House-Sparrow at Home and Abroad' (1878); Barrows, 'The English Sparrow in North America' (1889).

Housing Problem. See Tenement House, *Reform.*

Hous'man, Laurence, English author and illustrator: b. London 14 July 1867. He has illustrated 'The Goblin Market'; 'Weird Tales'; 'The Were Wolf'; 'Jump to Glory Jane'; and other books, his work being mostly engraved on wood by his sister Clemence. He is the author of 'The Writings of William Blake' (1858); 'A Farm in Fairyland' (1894); 'The House of Joy' (1895); 'Green Arras' (1896); 'All Fellows' (1896); 'Gods and Their Makers' (1897); 'The Field of Clover' (1898); 'The Little Land' (1899); 'Rue' (1899); 'The Seven Young Goslings' (1899); 'Bethlehem' (1902), and 'Love Letters of an Englishwoman' (1901), which appeared anonymously and was attributed to various writers of the day.

Houssa, how'sä, or **Haussa**, Central Soudan, a former important negro kingdom, north of the junction of the Benue and Niger rivers. After internecine divisions it was succeeded by a Mohammedan Fulah empire in 1802, and is now incorporated in Nigeria. The name is perpetuated by a negritic race and language distributed far beyond the ancient Houssa boundaries. The race is distinguished as able traders and craftsmen, and the language, for its euphony, simplicity and literary adaptability.

Houssaye, Henri, ŏñ-rē oo-sā, French historian: b. Paris 24 Feb. 1848. He was educated at the Lycée Napoléon, fought with distinction in the Franco-German war, became an editor of the 'Revue des Deux Mondes' and the 'Journal des Débats,' and was chosen president of the Société des Gens de Lettres. In 1864 he obtained election to the French Academy, which in 1873 awarded the Thiers prize to his 'Histoire d'Alcibiade.' He published in three parts — '1814,' and '1815' (2 vols.) — a study of Napoleon's downfall, which enjoyed wide sale in France, and is considered one of the best extant works on the subject.

Houston, hūs'tôn, **Sam**, American soldier and statesman: b. Lexington, Va., 2 March 1793; d. Huntsville, Tex., 25 July 1863. Leaving home when a boy he crossed the Tennessee River and took up his abode with the Indians, by whom he was kindly received, and with whom he lived after their own fashion for several years. Oolooteka, one of their chiefs, adopted him as his son. In 1811 he returned to his family, and to maintain himself opened a school. In 1813 he enlisted as a common soldier in the United States army, was promoted ensign, and fought under Gen. Jackson against the Indians at the battle of Tallapoosa, in March 1814. In November 1817 he was appointed a subordinate Indian agent to carry out the treaty with the Cherokees just ratified. In the following winter he conducted a delegation of Indians to Washington. On arriving he found that complaints had been made against him to the government on account of the zeal with which he had exerted himself to prevent the unlawful importation of African negroes through Florida, then a Spanish province, into the southern States. He was acquitted of all blame, but conceiving himself to be ill treated he resigned his commission in the army, and returning to Tennessee settled in Nashville and began the study of law. In 1819 he was elected district attorney, and in 1821 was chosen major-general of militia. Two years later he was elected to Congress; re-elected in 1825, and in 1827 was chosen governor of Tennessee.

In 1829, for reasons unknown, he resigned his office, separated from his family, and deserting civilization, went to Arkansas, where his former Indian friends, the Cherokees, had removed. He was kindly received and for years remained with the Indians. In 1832 he went to Texas and at the outbreak of the Mexican war was elected commander-in-chief of the Texan army.

After the massacre of the Alamo, the Mexican President-general Santa Anna was defeated by Houston at the battle of San Jacinto, 21 April 1836. Santa Anna was captured by the Texans and the independence of Texas was achieved. On 23 July a general election for president, vice-president, and members of Congress of the republic of Texas was ordered to take place on the first Monday of the following September. Houston was solicited to be a candidate, but declined; but as the day of election approached the popular feeling in his favor became so manifest that he had no alternative but to accept. He was elected by a large majority and was inaugurated 22 Oct. 1836. One of his first acts was to liberate Santa Anna, who had been kept in captivity, and to send him to Washington to confer with the president of the United States. He next opened negotiations with the United States government for the annexation of Texas to the Union, but the measure encountered such strong opposition in the United States that it did not succeed till several years later.

Texas became one of the United States in

1845, and Houston and Rusk were the first senators sent to Washington. Houston was re-elected at the end of his term in 1853, and remained in the Senate till March 1859. As a senator he was opposed to the Kansas and Nebraska bill, against which he made one of his most elaborate speeches, in which he declared that the repeal of the Missouri Compromise was a flagrant breach of faith, which would involve the country in interminable agitation and difficulty. He was prominently mentioned in 1854 as a presidential candidate of the 'Know-Nothing' party. He was elected governor of Texas 1 Aug. 1859, but was deposed for adherence to the Union in 1861. See Williams, 'Sam Houston and the War of Independence in Texas' (1893).

Houston, Texas, city and county-seat of Harris County, at the junction of White Oak and Buffalo bayous; the highest inland point in the State permanently accessible by water from the Gulf of Mexico. Buffalo Bayou, which furnishes an outlet to the sea, 50 miles distant, has been navigated from the earliest days of the city's history, and is being widened and deepened by the Federal government at a cost of $4,000,000 so as to admit of the passage of the largest ocean-going craft.

Houston was settled shortly after the battle of San Jacinto, which was fought on 21 April 1836, within a few miles of its location. The city was named after Gen. Sam Houston (q.v.). It was made the seat of government for the Republic of Texas, and so remained until 1840.

Government.— Houston was first incorporated under an act of the Texas Congress passed 29 Dec. 1837. It now has a charter granted by special act of the legislature in 1903. Under the charter a mayor is its chief executive officer, and 12 aldermen (two for each of the six wards into which the city is divided) constitute the legislative division of its government. The mayor and the aldermen are elected for two years as are also the city treasurer, the city tax assessor and collector, the city attorney, the city health officer, the street commissioner, the chief of police and the judge of the corporation court, which has jurisdiction of police cases. The cost of Houston's city government, including the amount appropriated out of the general revenue fund for the public schools, ranges between $600,000 and $650,000 per annum. The city owns a sewer system with 37½ miles of conduits. The city has about 30 miles of paved and otherwise improved streets. The city maintains a paid fire department at a cost on an average of $60,000 per annum. The cost of police protection averages about the same.

Public Buildings.— Houston's chief buildings are the city-hall and market-house, the Central fire station, the Binz office building, the Commercial National Bank building, the Stowers building, the Houston Post building, the High School building, the Mason building, the Carnegie Library building, the First Presbyterian Church house, the Christ Episcopal Church house, the Waddell building, the Kiam building, and a provided-for Federal building to cost $500,000 and the Rice Institute building for the erection and maintenance of which an endowment of between $4,000,000 and $5,000,000 has been left. The William M. Rice Institute was founded in the year 1892 by the late William Marsh Rice, of New York. This institute contemplates the establishment and maintenance of an industrial or polytechnic school for males and females, designed to give instruction on the application of science and art to the useful occupations of life. It establishes and maintains a free library and reading rooms, and galleries of art.

Education.— The city has 20 public schools (including a high school for whites and one for negroes), and 26 private schools — and one Carnegie library building. The city's school affairs are managed by a board of seven trustees appointed by the mayor with the approval of the city council. The schools are maintained by direct appropriation from the general revenue fund and get from $80,000 to $1,000,000 from that source annually. In addition they receive each year from the State a per capita apportionment of the State school fund which runs from $4.50 to $5.00 for each pupil between the ages of 7 and 17.

There are 5 Baptist, 5 Catholic, 3 Christian, 2 Christian Science, 3 Episcopalian, 2 German Methodist (North), 5 Methodist (South), 1 Methodist (North), 1 Cumberland Presbyterian, 5 Presbyterian and 2 non-denominational churches for whites, besides one Episcopalian chapel and two missions, a Salvation Army barrack and a Spiritualist association. The negroes have 29 churches of all denominations. The city's eleemosynary institutions consist of the Bayland Orphans' Home, the De Pelchin Faith Home, the Florence Crittenton Rescue Home, the Sheltering Arms Home of Christ's Episcopalian Church and an Infants' Home for foundlings. The city has one public park and zoological garden valued at $80,000.

The city has six national banks with a combined capital stock of $1,450,000; an average surplus of $900,000 and average undivided profits of $500,000. Their deposits range around $11,000,000 in amount and their loans around $7,000,000. In addition there are three private banks with combined resources of $3,000,000. Bank clearings in excess of $600,000,000 are annually effected through the city's clearing house.

Trade and Commerce.— In point of trade and commerce Houston distributes more groceries, hardware and machinery than any other city in the State. It is the most important spot cotton market in the world, barring Liverpool, 1,927,007 bales, or a little less than 19 per cent of the entire crop of the United States, constituting the volume of its transactions in the staple for the year 1903, said transactions involving an approximate outlay of $86,742,315. Houston is also the principal lumber market of the Southwest. In sugar Houston is second to New Orleans only, while in rice, a comparatively new industry in Texas, it ranks as one of the four principal markets west of the Mississippi.

More produce, fruit and feed stuff is consumed and distributed in Houston than in any other city in the Southwest.

Transportation.— Houston's pre-eminence as a commercial centre is due to its supply of transportation facilities. In 1856 these consisted, aside from a navigable outlet to the sea, of 56 miles of railroad. In 1861 its rail lines extended a distance of 357 miles, there being but 402 miles of railroad in the entire State at that time. And this ratio has been pretty well preserved until 1903 when 6,500 miles of rail-

SAMUEL HOUSTON.

road, or more than one half the State's mileage were operated by 14 lines for which Houston is an initial point and which during that year moved 16,000,000 tons of freight, or about three fifths of the tonnage which went toward making up the total of the State's railroad business. These 14 lines with their immediate system connections give Houston 30,000 miles of direct rail facilities. In addition to this Houston enjoys direct rail and barge connection with a second steamship line to New York which has tri-weekly sailings from Galveston. By reason of its location at the head of ocean navigation on Buffalo Bayou, Houston enjoys water rates on freight from defined territories as well as from the Atlantic seaboard and finds itself in a most advantageous position for the distribution of merchandise of all classes. Freight to the value of $25,000,000 is annually exported and imported on barges and other craft navigating Buffalo Bayou and plying between Houston and Galveston.

Manufactures.— Houston has 507 industrial plants in operation in the city, an increase of 141 per cent during the last decade. There are $8,000,000 invested in manufacturing enterprises with products to the value of $12,000,000 in 1903. Manufacturing has been stimulated to a great extent by the discoveries of petroleum and the development of the rice industry. The rapid growth of the sawmill and lumber products business — the most important in the State — 85 per cent of which is carried on within easy reach of Houston and in a section for which the city is the natural market has also contributed to the same end. Chief among Houston's manufacturing concerns are the cotton oil refineries of which there are five. These represent an investment of $1,250,000 and annually, on an average, convert 144,000 tons of cotton seed into products bringing $3,168,000 in the markets of the world, in the aggregate. Here are also the general car shops of the Atlantic division of the Southern Pacific and allied lines and the division car shops of three other railroad companies. The city has 35 miles of electric street car lines.

Population.— (1890) 27,557; (1900) 44,663; (1903) 65,000.

R. M. Johnston,
Houston Daily Post.

Hovey, Alvin Peterson, American soldier: b. Mount Vernon, Ind., 1821; d. Indianapolis 23 Nov. 1891. He studied law, and was admitted to the bar in 1843; was appointed successively circuit judge, judge of the supreme court, and United States district attorney. He was a major of Indiana volunteers, and afterward major-general during the Civil War. In 1866 he was made minister to Peru; was elected to Congress in 1886, and became governor of Indiana in 1888.

Hovey, Charles Mason, American horticulturist: b. Cambridge, Mass., 26 Oct. 1810; d. Boston 2 Sept. 1887. He was the first to introduce a pistillate strawberry, known as "The Hovey," a variety that marks the beginning of strawberry culture in the United States. He edited the 'Magazine of Horticulture' for many years, and was the author of 'Fruits of America' (1880).

Hovey, Richard, American poet: b. Normal, Ill., 4 May 1864; d. New York 24 March 1900. He was graduated at Dartmouth 1885, went abroad and led a bohemian life, being in turn actor, journalist, dramatist and poet, and finally lecturer on English literature in Barnard College, New York. His verse was of the idealistic school and marked with the influence of Ibsen and Maeterlinck. His works are: 'Launcelot and Guenevere' (1880); 'Taliesin: a Masque' (1900); 'Seaward: an Elegy' (1893); 'The Laurel' (1897); 'Along the Trail' (1898); and with Bliss Carman (q.v.) wrote 'Songs from Vagabondia' (1893); and 'More Songs from Vagabondia' (1896).

Howard, Blanche Willis. See Teuffel, Blanche Willis Howard, Baroness Von.

Howard, Bronson, American playwright: b. Detroit, Mich., 7 Oct. 1842. Preparing for college he turned to journalism instead of entering Yale, and from 1867 to 1872, was employed on the New York *Tribune, Evening Mail* and other newspapers. In 1864 he had written a dramatic piece called 'Fantine,' which was produced in Detroit, but his first important play was 'Saratoga,' produced by Augustin Daly in 1870, and the first of a long list of successes, which gave him a foremost position among American playwrights. Among his plays are: 'The Banker's Daughter' (1878); 'Young Mrs. Winthrop' (1882); 'The Henrietta' and 'Met by Chance' (1887); 'Shenandoah' (1889); 'Aristocracy' (1892); 'Peter Stuyvesant' (with Brander Matthews); etc.

Howard, Catharine, fifth queen of Henry VIII.: b. about 1520; d. 13 Feb. 1542. She was a granddaughter of the second duke of Norfolk.

Howard, Guy, American soldier: b. Augusta, Maine, 16 Dec. 1855; d. 21 Oct. 1899. He was a son of Gen. O. O. Howard (q.v.) and entered the United States army in 1876 as a second lieutenant. He was promoted chief quarter-master, with rank of lieutenant-colonel 11 Aug. 1898; was assigned to duty in Manila under Gen. Lawton; and had charge of the transportation for Lawton's advance movement. While on the gunboat Oceania he was attacked by Filipino insurgents, and fatally shot.

Howard, John, English philanthropist: b. probably Hackney 2 Sept. 1726; d. Kherson, Russia, 20 Jan. 1790. In 1773 he was appointed high sheriff of Bedfordshire, when the subject of prison discipline came under his notice; and finding many abuses in the management of jails, he resolved to devote his time to investigation of the means of correcting them. With this view he visited most of the English county jails and houses of correction, and in March 1774 laid the result of his inquiries before the House of Commons. In 1781 and 1782 he made a tour through the northern parts of Europe, including Denmark, Sweden, Russia, and Poland. In 1783 he visited Spain and Portugal, and again surveyed the prisons of his own country. At the same time was published a complete edition of his 'State of the Prisons,' with all the supplementary matter. A new subject now engaged his attention, namely, the management of lazarettos, and the means of preventing the communication of the plague and other contagious diseases. In 1789 he published 'Account of the Principal Lazarettos in Europe.' In 1789 he proceeded through

Germany to St. Petersburg and Moscow. Prisons and hospitals were everywhere thrown open for his inspection as a friendly monitor and public benefactor. Consult: Howard's 'Correspondence' (1855); and 'Lives' by Dixon (1849); Stoughton (1853).

Howard, John Eager, American soldier: b. Baltimore County, Md., 4 June 1752; d. 12 Oct. 1827. He joined the army under Washington at Middlebrook, N. J., in the spring of 1777, and subsequently fought at Germantown and Monmouth. In 1780 he joined the army under Greene, and in the battle of Cowpens (1781) he displayed great gallantry, and the bayonet charge of the Maryland troops under his command, whereby the enemy were thrown into confusion, turned the fortune of the day and secured victory to the Americans. For his services in this battle he received from Congress a silver medal. In 1788 was elected governor of Maryland, a position which he filled for three years. From 1796 to 1803 he represented Maryland in the United States Senate. He was a candidate for the Vice-Presidency in 1816.

Howard, Oliver Otis, American general: b. Leeds, Maine, 8 Nov. 1830. He was graduated from Bowdoin in 1850, and from West Point in 1854. He was then assigned to the ordnance department of the regular army, served in Florida against the Seminoles, and was professor of mathematics at West Point 1857–61. At the outbreak of the Civil War he entered the volunteer service as colonel of the 3d Maine regiment. He was in over 20 important battles; in 1861 he was at the battle of Bull Run, and was afterward made brigadier-general of volunteers; in 1862 he served in the Virginia campaign, and at the battle of Fair Oaks lost his right arm. He commanded at the battles of Antietam and Fredricksburg; in 1863 was appointed to the command of the 11th Army Corps and led them at the battles of Chancellorsville and Gettysburg. When the 11th Corps was united with the 12th he was given command of the 4th Corps of the Army of the Cumberland, but was shortly afterward transferred to the command of the Army of the Tennessee, which was the right wing of Sherman's army on his "march to the sea." In 1864 he was appointed brigadier-general in the regular army, and in 1865 made commissioner of the Freedmen's Bureau, which he conducted very efficiently; 1869–73 he was president of Howard University (q.v.), established in Washington for the higher education of the negro. In 1874 he was placed in command of the Department of the Columbia, and there conducted four campaigns against the Indians, including that against the Nez Percés tribe. In 1881 he was superintendent at West Point, and subsequently in command of the Departments of the Platte and of California; in 1886 he was promoted to the rank of major-general, and assigned to the Department of the East, where he remained until his retirement in 1894. In 1895 he founded the Lincoln Memorial University, Cumberland Gap, Tenn. He has written: 'Donald's School Days' (1879); 'Chief Joseph, or the Nez Percés in Peace and War' (1881); 'General Zachary Taylor' (1892); 'Isabella of Castile' (1894); 'Fighting for Humanity'; and 'Henry in the War.' Consult: L. C. Holloway, 'Life of General Howard.'

Howard Memorial Library, established in 1889 in New Orleans, La., is one of the few complete reference libraries in the United States. It was founded by Annie Turner Howard, whose gift of site, building, and endowment amounted to nearly $350,000. The plans for the building were made by Henry Hobson Richardson (q.v.). In addition to the 45,000 volumes of the best books on all subjects, it contains special and nearly complete collections on the history, description, and literature of Louisiana and the Gulf States. It has a dictionary card catalogue.

In the spacious and handsome reading-room are many fine bronzes, including the Houdon bust of Washington, from a life mask. This bronze is on a pedestal which brings the face to the correct height. This library is of great service to students of all the educational institutions of the Southern States, and also to writers on special subjects pertaining to the Gulf States.

William Beer,
Librarian of Howard Memorial Library.

Howard University, a coeducational institution, situated in Washington, D. C., established by the United States government in 1867. It was named for Gen. O. O. Howard, who was head of the Freedmen's Bureau, and had much to do with the foundation of the school. The university is supported by Congressional appropriation, except the medical department, which is maintained by tuition fees, and this is the only department in which tuition is charged. The departments are preparatory, collegiate, medical, agricultural, dentistry, pharmacy, pedagogy, theology, law, music, and agriculture. An industrial department provides instruction in trades for students in the preparatory and English courses. The pupils in this department have practice under competent workmen, in printing, carpentry, bookbinding, and tinsmithing. The university is well known for its work in the higher education of the negroes of the United States. The school has property valued at about $1,000,000, and a general endowment fund of $175,000.

Howe, Andrew Jackson, American eclectic surgeon and author: b. Paxton, Mass., 14 April 1825; d. Cincinnati, Ohio, 16 Jan 1892. Educated in Leicester Academy and Harvard College, from which he graduated in 1853. Attended medical lectures at Jefferson Medical College, Philadelphia; College of Physicians and Surgeons, and the New York Medical College of New York city, and Worcester Medical Institute, graduating from the latter in 1855. He was demonstrator of anatomy in his alma mater in 1855–6; professor of surgery in Cincinnati College of Eclectic Medicine and Surgery, 1856–9; demonstrator and professor of anatomy in Eclectic Medical Institute of Cincinnati, 1859–61; professor in same of surgery, from 1861 to 1892. He wrote 'A Treatise on Fractures and Dislocations' (1873); 'Manual of Eye Surgery' (1874); 'Art and Science of Surgery' (1876); 'Operative Gynæcology' (1890); 'Conversations on Animal Life,' and 'Miscellaneous Papers,' published in 1894, after his death. He was president of the National Eclectic Medical Association in 1882–3.

ELIAS HOWE,

INVENTOR OF THE SEWING MACHINE.

Howe, Edgar Watson, American novelist and editor: b. Treaty, Ind., 3 May 1854. At the age of 12 he entered a printing office, and when only 19 was publisher of the 'Golden Globe' in Golden, Col. Ten years later he became proprietor and editor of the Atchison (Kan.) *Daily Globe.* He has written: 'The Story of a Country Town' (1883), which attracted considerable attention; 'The Mystery of the Locks' (1883); 'A Moonlight Boy' (1887); 'A Man Story' (1888); 'An Ante-Mortem Statement'; 'The Confession of John Whitlock'; etc.

Howe, Elias, American inventor: b. Spencer, Mass., 9 July 1819; d. Brooklyn, N. Y., 3 Oct. 1867. He lived with his father, who was both farmer and miller, till 1836, working upon the farm and in the mill and attending the district school during the winters. He then learned the trade of a machinist, and experimented in inventing a sewing-machine. The model was completed and the patent issued 10 Sept. 1846. A patent was also taken out in England, but from this the inventor realized nothing. After constructing four machines in the United States, he visited England in 1847, remaining two years. He returned to Boston entirely destitute, and resumed his trade for the support of his family. From this period until 1854 he was involved in expensive lawsuits, when the principal infringers of his patents acknowledged his rights, and arranged to manufacture sewing-machines under licenses from him. He served as a private in the 17th Connecticut volunteers during the Civil War. He was the recipient of the Legion of Honor cross and many medals.

Howe, Henry, American publisher and historian: b. New Haven, Conn., 16 Oct. 1816; d. 1893. He entered the publishing business in 1839, and while conducting this business began historical researches in New Jersey and New York. He later moved to Ohio, where he continued his historical studies, and published subscription books. His writings include: 'Memoir of Eminent Mechanics' (1839); 'The Great West' (1851); 'Travels and Adventures of Celebrated Travelers' (1853); 'Adventures and Achievement of Americans' (1858); 'Our Whole Country' (1861); 'Over the World' (1883); and 'Historical Collections' of three States, New Jersey, New York and Ohio.

Howe, John, English Puritan divine: b. Loughborough, Leicestershire, 17 May 1630; d. London 2 April 1705. He was frequently styled "The Platonic Puritan" and is ranked as the greatest of the Puritan clergymen. He was an eloquent preacher and a powerful controversialist, but fortunately free from animosity or theological bitterness. Among his works, 'The Living Temple'; 'The Blessedness of the Righteous'; and 'The Oracles of God' have been especially valued. See 'Life' by Rogers (1836).

Howe, John Ireland, American inventor: b. Ridgefield, Conn., 20 July 1793; d. Birmingham, Conn., 10 Sept. 1876; was at first a physician, but in 1830 invented a pin-making machine. This he perfected later and it was the means of revolutionizing the pin manufacture.

Howe, Joseph, Canadian statesman: b. near Halifax, Nova Scotia, 13 Dec. 1804; d. Halifax, 1 June 1873. He learned printing and in 1827 became connected with the 'Acadian' and in 1828 editor and proprietor of the 'Nova Scotian.' He contributed several remarkable articles to this paper, called "Western and Eastern Rambles" and the papers "Legislative Reviews." He was elected to the Provincial Parliament in 1836. He favored free common schools, one Provincial University and complete, responsible government and it was mainly due to his efforts that Nova Scotia finally received such government. He was a member of the Executive Council in 1840 and Speaker of the Assembly the same year. In 1846 he succeeded in making himself a popular power in the province and turned it over to the Liberals. Howe opposed confederation in the old assembly and even went to London to lay a petition before the throne against "the assertion of Federal supremacy," but lost his fight. He served as secretary of state for the provinces in the Dominion cabinet and superintendent of Indian affairs (1869–72), and later was a member of the Dominion Parliament for Hants County, Nova Scotia. He returned to Halifax in 1873 as lieutenant-governor, but only lived a few months to enjoy it.

Howe, Julia Ward, American author and philanthropist: b. New York 27 May 1819. In 1843 she married S. G. Howe (q.v.) of Boston, and immediately became active in philanthropical work. With her husband she edited the 'Boston Commonwealth,' one of the ablest anti-slavery papers, to which she contributed leading articles, essays, poems, letters, and witty comments. At the same time she also wrote for the New York *Tribune,* and the 'Anti-Slavery Standard.' Since the Civil War she has been active as writer and speaker in other social and philanthropic work, particularly in the agitation for woman's suffrage and for prison reform. She was one of the founders of the New England Women's Club, the first organization of its kind in America; she was delegate to the World's Prison Reform Congress in London (1872); and was president of the women's branch of the New Orleans Exposition (1884). She has also preached occasionally in Unitarian pulpits. She has been president of the Boston Authors Club from its foundation in 1899. Her writings include: 'Passion Flowers' (1854); 'Words for the Hour' (1856); 'Later Lyrics' (1866); 'A Trip to Cuba,' and 'From the Oak to the Olive,' two books of travel; 'The World's Own' (1855), a drama; 'Sex and Education' (1874); 'Modern Society' (1881); 'Is Polite Society Polite?'; 'Life of Margaret Fuller' (1883); and 'Reminiscences' (1899). Her best known poem is 'The Battle Hymn of the Republic' (in 'Later Lyrics'), written early in the Civil War, while she was visiting the camps around Washington. It was set to the music of 'John Brown's Body,' and immediately became popular with the soldiers.

Howe, Mark Antony de Wolfe, American editor and author: b. Bristol, R. I., 28 Aug. 1864. He was educated at Lehigh and Harvard universities, and on leaving college entered the editorial office of 'The Youth's Companion,' Boston. In 1893–5 he was assistant editor of the 'Atlantic Monthly,' and since 1899 has been corresponding editor of 'The Youth's Companion.' He has published: 'Shadows,' verse (1897); 'American Bookmen' (1898); 'The Memory of

Lincoln' (edited) (1899): 'Phillips Brooks' (1899); 'Boston: the Place and the People' (1903). He has edited the series of 'Beacon Biographies' from 1899.

Howe, Richard, Earl, English admiral: b. London 8 March 1726; d. 5 Aug. 1799. At 14 he shipped as a midshipman on board the Severn in which he sailed with Anson for the Pacific, and passed through the usual gradations of the service under that admiral till 1745, when he obtained the command of the Baltimore sloop-of-war, in which he took part in the siege of Fort William, during the last Jacobite rebellion. In 1756 he served in the Channel fleet; in 1758 reduced Cherbourg. In 1759 he defeated a French squadron under De Conflans, and for two years (1763–5) occupied a seat in the board of admiralty. In 1776, as commander-in-chief in North America, he acted against the American forces and against D'Estaing, who commanded a superior French fleet. He sailed to the relief of Gibraltar in 1782 and was successful in spite of the combined fleets of France and Spain. On the outbreak of war with France in 1793 he took the command of the British fleet, and on 1 June 1794, obtained a decisive victory off Ushant for which he received the thanks of Parliament. He was made admiral of the fleet in 1796. His name is one of the highest among those of the famous naval commanders of Great Britain. He greatly improved the service by the introduction of a new system of tactics.

Howe, Robert, American colonial soldier: b. Brunswick County, N. C., 1732; d. there 12 Nov. 1785. He was a member of the assembly and of two provincial congresses, and took a prominent part in the preparation for the Revolution. At the outbreak of the war he was given a command and aided in driving the British out of Virginia; was promoted to the rank of major-general and commanded in the South. In 1778 he was repulsed by the British and compelled to evacuate Savannah; though then deprived of command he was afterward acquitted by the court-martial by which he was tried for the loss of the city. In 1780 he commanded at Charleston; in 1783 assisted Washington in putting down a mutiny; and in 1785 was elected to the North Carolina legislature, but died before he took his seat.

Howe, Samuel Gridley, American philanthropist: b. Boston 10 Nov. 1801; d. there 9 Jan. 1876. He was graduated from Brown University in 1821, and from the Harvard Medical School in 1824. Immediately after completing his studies he joined the Greek army at the time of the war for independence; he created an excellent surgical corps for the Greeks, and was also distinguished as a brave commander in battle; at the declaration of peace he established an industrial colony of Greeks on the Isthmus of Corinth. He returned to the United States for a short time, but becoming interested in the work for the blind, went back to Europe in order to study the schools for the blind there; while in Paris he was chairman of the committee for the relief of the Poles in the time of the Polish uprising; he went to Prussia to distribute the funds collected, and was imprisoned by the Prussian authorities. In 1832 he returned to Boston, and founded the Perkins Institution for the Blind, of which he became superintendent; in this position he did much to improve the methods in the instruction of the blind, and to found similar schools throughout the United States. His greatest success was in the training of Laura Bridgman. (See Defectives, Education of.) He also assisted in organizing the Massachusetts School for Idiots. He was active in the anti-slavery cause; was candidate of the Conscience Whig Party for Congress, but was defeated; and was editor of the anti-slavery paper, the 'Boston Commonwealth,' assisted by his wife, Julia Ward Howe (q.v.). At the close of the Civil War he joined in the work of the Freedmen's Bureau (q.v.). He was always active in many lines of philanthropic work, organized the Massachusetts State Board of Charities and went to Greece in 1867 with supplies for the Cretans. In 1870 he was one of the commission appointed by President Grant to visit Santo Domingo and report upon the advisability of its annexation. He wrote: 'Historical Sketches of the Greek Revolution' (1828); 'Reader for the Blind' (1839). Consult: The 'Life,' by Julia Ward Howe, and Sanborn, 'S. G. Howe, the Philanthropist.'

Howe, Timothy Otis, American statesman: b. Livermore, Maine, 24 Feb. 1816; d. Kenosha, Wis., 25 March 1883. He received a common school education, studied law, was admitted to the bar, and sat in the Maine legislature in 1845. He removed in that year to Wisconsin, entered politics, and in 1861 was chosen United States Senator, serving till 1879. He declined a Supreme Court judgeship on the death of Salmon Chase, but in 1881 became postmaster-general in President Arthur's cabinet.

Howe, Sir William, English general: b. 10 Aug. 1729; d. 12 July 1814. He was a brother of Admiral Richard Howe (q.v.) and was the successor of Gen. Gage in command of the British forces in America. He had previously served under Wolfe at the battle of Quebec. He commanded at the battle of Bunker Hill (1775), in which he lost one third of his men present in the action, and in August 1776, gained the battle of Long Island and took New York city. He won the battle of Brandywine in September 1777, in consequence of which Philadelphia was occupied by his army. At his own request he was recalled in 1778, and was succeeded by Sir Henry Clinton, who repulsed Washington at Germantown in the October following. He succeeded to the Irish peerage as viscount in 1799.

How'ell, Clark, American journalist and politician: b. Barnwell County, S. C., 21 Sept. 1863. He was graduated from the University of Georgia in 1883, entered journalism, became managing editor in 1889 of the Atlanta *Constitution*, and editor-in-chief 1897. He was a member of the Georgia House of Representatives 1890–1 and has been a member of the Georgia Senate from 1900.

Howell, Mich., village, county-seat of Livingston County; on the Pere M. and the Ann A. R.R.'s; about 50 miles northwest of Detroit. It is located in a rich agricultural section of the State. The chief manufactures are flour and condensed milk; and it has a large sash, door,

Photograph copyright, 1902, by Purdy, Boston.

JULIA WARD HOWE.

and blind factory, and a planing-mill. Pop. (1900) 2,518.

Howells, William Dean, American novelist, poet and critic: b. Martin's Ferry, Ohio, 1 March 1837. During his boyhood his father owned and published daily papers in Hamilton and Dayton, Ohio, successively, and he learned the printer's trade and gradually the whole business of conducting a newspaper. In 1851 he was working in Columbus as a compositor; in 1856 he became Columbus correspondent of the Cincinnati *Gazette;* and in 1859 was appointed news editor of the *Ohio State Journal.* At this time he published a small volume of poems, and also some poems in the 'Atlantic Monthly.' In 1860, when Lincoln was nominated, Howells wrote his life, and in 1861 was appointed United States consul at Venice, where he remained till 1865. The impressions of his stay there were embodied in 'Venetian Life' (1866), and 'Italian Journeys' (1867). On his return to the United States, he was for a time connected with the staff of the New York *Tribune,* the *Times,* and the 'Nation.' In 1866 he became assistant editor of the 'Atlantic Monthly,' and editor-in-chief in 1872. In 1886–92 he conducted the critical department of 'Harper's Monthly' called «The Editor's Study»; and in 1892 was editor of the 'Cosmopolitan' for a short time.

His first novel 'Their Wedding Journey,' was published in 1871; his other novels include: 'A Chance Acquaintance' (1874); 'A Foregone Conclusion' (1875); 'The Lady of the Aroostook' (1879); 'The Undiscovered Country' (1880); 'Doctor Breen's Practice' (1882); 'A Modern Instance' (1882); 'A Woman's Reason' (1883); 'The Rise of Silas Lapham' (1885); 'Indian Summer' (1886); 'The Minister's Charge' (1886); 'April Hopes' (1887); 'A Hazard of New Fortunes' (1889); 'The Shadow of a Dream' (1890); 'An Imperative Duty' (1892); 'The Quality of Mercy' (1892); 'The World of Chance' (1893); 'The Coast of Bohemia' (1893); 'A Traveller from Altruria' (1894); 'The Landlord at Lion's Head' (1897); 'An Open-Eyed Conspiracy' (1898); 'The Story of a Play' (1898); 'Ragged Lady' (1899); and 'Their Silver Wedding Journey' (1900). Howells has also written farces and comedies, including: 'The Sleeping-Car' (1883); 'The Mouse-Trap' (1897); 'The Unexpected Guests' (1898); and 'The Albany Depot' (1898); etc., and the following volumes of verse: 'Poems of Two Friends' (1860), with J. J. Piatt; 'No Love Lost, a Romance of Travel' (1868); and 'Poems' (1873). His other works include: 'Tuscan Cities' (1885); 'Modern Italian Poets'; 'Essays and Versions' (1887); 'Criticism and Fiction' (1891); and 'Impressions and Experiences' (1896); 'Literary Friends and Acquaintances' (1899); and 'Heroines of Fiction.'

In American literature, Howells is the leader of the realistic school; his novels portray the average, everyday American life; he has a true and sympathetic understanding of the «common people» of the United States, and types of the American «self-made» man appear and reappear in his stories. His latest phase, that in which he seeks to understand and set forth the American social problems, — the meaning of socialism, the relations of labor and capital, and, more broadly, the mystery of poverty and of human suffering, — is typified in a book like 'A Hazard of New Fortunes'; and 'A Traveller from Altruria,' a picture of an ideal commonwealth. The absence of idealism in Howells' writings has been cited as their gravest defect; but it is by no means true that he entirely excludes the ideal sides of life from treatment. His work is marked by carefulness and thoughtfulness in style and construction, and by fidelity to a high ideal of artistic excellence. His essays, like his novels, have always that indefinable charm which is the enduring note in good literature, and to the charm are added the broad outlook and the deep ethical interest which are typical of the man.

How'ison, George Holmes, American philosopher: b. Montgomery County, Md., 29 Nov. 1834. He was graduated from Marietta College, Ohio, in 1852, and from Lane Theological seminary, Cincinnati, in 1855, and after holding various college professorships elsewhere became Mills professor of philosophy at the University of California in 1884. He has published 'Treatise on Analytic Geometry' (1869); 'Limits of Evolution' (1901); 'The Conception of God' (1897).

Howison, Henry Lycurgus, American rear-admiral: b. Washington 10 Oct. 1837. He was graduated from the United States Naval Academy in 1858. He served in various important engagements, becoming lieutenant-commander in 1865. In 1899 he became rear-admiral and was retired 19 Oct. 1899. In 1901 he was appointed a member of the Schley court of inquiry, but on being challenged, was relieved from service.

How'itt, William and **Mary**, English authors commonly named together. WILLIAM (b. Heanor, Derbyshire, 18 Dec. 1792; d. Rome, Italy, 3 March 1879), showed such a bias to literature that he published verses at 13. In 1821 he married MARY BOTHAM (b. Uttoxeter 12 March 1799; d. Rome 30 Jan. 1888), who wrote both by herself and with her husband. Their first joint work, a volume of poems, 'The Forest Minstrel,' was published in 1823, and in 1827 appeared 'The Desolation of Eyam.' The best lines in these are by Mrs. Howitt, Howitt himself having no great poetic gift. In 1871, however, he published a volume entitled 'The Mad War Planet and Other Poems.' William and Mary Howitt settled first in Staffordshire. In 1823 they removed to Nottingham, where they resided till 1837, and in 1840 visited Germany, where they resided for three years. Results of their residence in Germany appeared in 'Student Life of Germany' (1841) and 'Rural and Domestic Life of Germany' (1842), which, being translated into German, acquired flattering popularity. While at Heidelberg Mrs. Howitt set herself to translate the tales of Frederika Bremer into English, and later the works of Hans Andersen. Their most ambitious work is 'The Literature and Romance of the North' (1852). Howitt's best works are those in which English history and life are treated of in connection with English scenery. The earliest of these was the 'Book of the Seasons' (1831), which acquired great popularity; 'Rural Life in England' (1838) was also well received. Still others are: 'Visits to Remarkable Places' (1840); 'Homes and Haunts of the British Poets' (1847): 'The Year Book of the Country' (1850); and 'The Northern Heights of London' (1869). With his wife he published volumes on 'The Ruined Abbeys and Castles of Great Britain.' Mrs. Howitt's books for young people were long popular in the United States, and 'The Pet Lamb' and a few other unpretending verses of hers have become familiar to thousands of juvenile readers.

How'itzer. See ORDNANCE.

How'land, Alfred Cornelius, American painter: b. Walpole, N. H., 12 Feb. 1838. As an art student he began in the studios of Schultz and Eppindale at Boston, and subsequently went to Dusseldorf and Paris, in which latter place he painted under Lambinet. He excels in genre and landscape, and among his favorite works are 'Ford's Glen' (1878); 'Rendezvous of the Veterans' (1884); and 'The Coming Circus' (1886).

Howland, Gardiner Greene, American journalist: b. New York 1834; d. there 9 May 1903. He was the intimate and confidential friend of the elder James Gordon Bennett, held the same relations with the younger Bennett, was general manager of the *Herald* for more than twenty-five years, and one of the corporators named under the incorporation of the newspaper.

Howley, Michael Francis, Canadian ecclesiastic: b. 1843. In 1857 he entered Saint Bonaventure's College, and in 1863 went to Rome, entering Propaganda as an ecclesiastical student. In 1868 he was ordained a priest and went to Scotland as secretary to Most Rev. Dr. Ayre, but in 1870 returned to Rome with Dr. Ayre and was present on the occasion of the declaration of the dogma of papal infallibility by Pope Pius IX. He accompanied the Rt. Rev. Thomas J. Power to Newfoundland in 1870, and for over 30 years he has labored with great success for the spiritual and ecclesiastical advancement of Newfoundland. In 1886 he was made prefect apostolic of Saint Georges, in 1892 was consecrated bishop in Saint John's and made vicar apostolic of Saint Georges, in 1902 appointed bishop of Saint John's in succession to Rt. Rev. Dr. Power, and in 1904 he was named by the Holy See archbishop of the ecclesiastical province of Newfoundland. Archbishop Howley is not only distinguished as a theological scholar and thinker, a devoted missionary and able preacher, but also as a poet, lecturer, and antiquary. He has also contributed much to the historical study of Newfoundland (q.v.).

Howorth, how'ërth, **Henry Hoyle,** SIR, English author and politician: b. Lisbon, Portugal, 1 July 1842. He was a Conservative member of Parliament for South Salford 1886–1900. In recognition of his works on Eastern history and other subjects, he was created K. C. I. E. in 1892. Besides very many scientific memoirs, he has published: 'History of the Mongols'; 'The Mammoth and the Flood'; 'The Glacial Nightmare and the Flood'; 'Genghis Khan and his Ancestors.' etc.

Howrah, how'rä, India, an independent municipality, suburban to Calcutta (q.v.). Pop. (1901) 157,847.

Hox'ie, Vinnie Ream, American sculptor: b. Madison, Wis., 23 Sept. 1846. She was educated at Christian College, Columbia, Mo., and going to Washington, D. C., studied art, executed busts of Grant, Sherman and others, and a statue of Lincoln for the National Capitol. She then went abroad, where she designed medallions of Doré, Liszt, Buchanan, Read, and others. Among other works of hers are ideal statues of 'Sappho'; 'The Spirit of the Carnival'; and the statue of Admiral Farragut in Farragut Square, Washington. She was married to Major R. L. Hoxie of United States Engineers.

Hoyle, Edmond, English writer on games: b. 1672; d. London 29 Aug. 1769. It is said that he was educated for the law, but nothing definite is known of his career except that he was for many years in London a writer on and instructor in games. His 'Short Treatise on Whist' (1742), a compendium of the laws of the game and many rules for play, sold largely and has been the basis of all subsequent manuals of the kind. So generally has his authority been accepted in the game that "according to Hoyle" has attained a proverbial significance.

Hoyt, Charles Hale, American dramatist: b. Concord, N. H., 1860; d. 1900. He was at one time musical and dramatic critic of the *Post* of Boston. His works comprise 'A Midnight Bell' (1887), and a long series of farce-comedies, such as 'A Trip to Chinatown' (1890).

Hoyt, Henry Martyn, American lawyer and soldier: b. Kingston, Pa., 8 June 1830; d. Wilkesbarre, Pa., 1 Dec. 1892. He was graduated from Williams College in 1849, read law, was admitted to the bar in 1853, practised at Wilkesbarre, at the opening of the Civil War was appointed lieutenant-colonel of 52d Pennsylvania regiment, served during the Peninsular campaign in 1862, and was captured in a night attack on Fort Johnson during the siege of Morris Island. Mustered out with the grade of brevet brigadier-general; he practised his profession until 1867, and was then appointed additional law-judge of the Luzerne County courts. In 1879–83 he was Republican governor of Pennsylvania. His administration was particularly characterized by a wise financial policy, by means of which the State debt was reduced to $10,000,000 and refunded at three per cent. He published: 'The Controversy between Connecticut and Pennsylvania' (1879); 'Protection *v.* Free-Trade' (1885).

Hoyt, John Wesley, American educator: b. near Worthington, Ohio, 13 Oct. 1831. He was graduated at Ohio Wesleyan University in 1849, and later studied both medicine and law. He has had charge of educational exhibits in several international expositions, and was made chairman of the National Committee to Promote the Establishment of the University of the United States. He was the first president of the University of Wyoming, and was governor of Wyoming 1878–83. He has published 'Progress of University Education'; 'Studies in Civil Service'; etc.

Hoyt, Wayland, American Baptist clergyman and author: b. Cleveland, Ohio. He was educated at Brown University and studied for the Baptist ministry at the Rochester Theological Seminary. Since then he has held pastorates at Pittsfield, Mass., Cincinnati, Brooklyn, Minneapolis, and Philadelphia. Among his published works are 'Hints and Helps for the Christian Life' (1880); 'Gleams from Paul's Prison' (1882); 'Light on Life's Highway' (1890).

Huaina Capac, wä-ē'nā kä'päk, or **Huayna Capac**, 11th Peruvian Inca: b. Cuzco, Peru, about 1450; d. Tumibamba, Ecuador, November 1525. He began his reign in 1480, or, according to some authorities, 1491, and made many conquests, even subduing the country as far south as Chile. By his will he divided the empire between two of his sons, Huascar and Atahualpa (q.v.).

Huamanga, wä-män'gä, or **Guamanga**, gwä-män'gä, Peru, the former name of Ayacucho (q.v.).

Huanaco, hwä-nä'kō, the most numerous and widely distributed of the two species of the genus *Lama* (*L. guanaco*), of the camel family, resident in South America. It is somewhat like a large goat in form, but with a much longer neck, surmounted by a small camel-like head, and long, pointed, alert ears, but no weapons. A large male is about four feet tall at the withers, a female somewhat less. The coat is of long, woolly, reddish-gray hair, the improvement of which by selective breeding in domestication has formed the alpaca breed (see ALPACA). It roams the open plains of Argentina and Patagonia, serving as the principal game animal of that region, and furnishing the scattered natives with food, clothing, and shelter. In the autumn it gathers into large herds, and behaves in general like the antelopes of the similar arid plains of other parts of the world. Consult Darwin, Hudson, Spears, and other writers on Patagonia. See LLAMA.

Huascar, wäs'kär, Peruvian Inca, son of Huaina Capac (q.v.). See ATAHUALPA.

Hub'bard, hŭb'ard, **Elbert**, American author: b. Bloomington, Ill., 1859. After working on a farm as a boy, he went to Chicago, where he entered a printing-office, and later was employed in a soap factory. In the latter business he rose to be manager, and finally partner of the firm; selling out his interest, he devoted himself for a time to study and travel, and finally settled at East Aurora, where he established the Roycroft shop, devoted mainly to the artistic printing and binding of books. The organization of the shop is co-operative, and its ideal is for every worker to do that which best expresses his own individuality. Hubbard is editor of the 'Philistine,' a "magazine of protest," and has written 'Little Journeys' (biographical sketches); 'No Enemy but Himself'; 'Message to Garcia' (1898); and 'Time and Chance' (1901); 'The Man of Sorrows' (1904).

Hubbard, Joseph Stillman, American astronomer: b. New Haven, Conn., 7 Sept. 1823; d. there 16 Aug. 1863. He was graduated from Yale in 1843, and accompanied Frémont as observer of latitude and longitude in the latter's transcontinental journey. From 1845 until his death he was stationed at the Washington observatory as professor of mathematics in the United States navy. He made important investigations regarding comets, was at two different periods editor of the 'Astronomical Journal,' and was a member of the National Academy of Sciences.

Hubbard, Leonidas, Jr., American journalist, writer, and explorer: b. Waldron, Mich., 12 July 1872; d. Labrador 18 Oct. 1903. He was a teacher in the public school at Angola, Mich., while still in his teens, and early in life showed keen interest in writing, exploration, and athletics. Graduated from University of Michigan in 1897. He once began reportorial work in Ann Arbor, and later on the Detroit *Evening News*. He came to New York in the summer of 18[illegible] and attached himself to the staff of the *Daily News*, but early in 1902 became associate editor of 'Outing,' in which work he was much interested. He conceived the idea of exploring into the wilds of Labrador, and 20 June 1903, accompanied by Dillon Wallace, a New York lawyer, and George Elson, a Cree Indian guide, he left New York, going by steamer from Saint Johns, N. B., to Rigolette, a Hudson Bay trading post on the Grand River. From this point Hubbard and his friends traveled by canoe and on foot, mapping correctly for the first time Grand Lake; then penetrating the interior in a westerly and northwesterly direction, mapping the course of the Beaver River from its source to the point where it flows into the southeast bay of Lake Michikamau; and locating and mapping several large lakes in the interior. The party penetrated some 250 mile further into new territory than any previous expedition. Notes on the geology and general observation of the topography of the country were also made. Among Mr. Hubbard's most noted writings are: 'The Moonshiner at Home' (1902); 'Barataria' (1902); 'Children of the Bush' (1903); and 'Where Romance Lingers' (1904).

Hubbard, Oliver Payson, American physician: b. Pomfret, Conn., 31 March 1809; d. New York 9 March 1900. Graduated from Yale in 1828, he was assistant to Silliman the elder in the laboratory there in 1831–6, and aided Goodyear in experiments connected with the vulcanizing of India rubber. In 1836–60 he was professor of chemistry, pharmacy, mineralogy, and geology at Dartmouth, in 1866–71 lectured on those subjects, and from 1871 until his retirement as professor emeritus in 1883 was professor of chemistry and pharmacy. He was a founder of the American Association of Geologists and Naturalists in 1841, and its secretary in 1844. He contributed to the 'American Journal of Science,' and published 'A History of Dartmouth Medical College' (1880), etc.

Hubbard, Richard William, American artist: b. Middletown, Conn., 15 Oct. 1810. He was educated at Yale, set up his studio in New York, was elected to the National Academy in 1858, and painted numerous American landscrapes, such as: 'Mansfield Mountain at Sunset'; 'Showery Day, Lake George'; 'Glimpse of the Adirondacks'; and 'Lake Cazenovia.'

Hubbard, William, American colonial clergyman and historian: b. Tendring, Essex, England, 1621; d. Ipswich, Mass., 14 Sept. 1704. He was graduated at Harvard College in 1642, and was ordained about 1656 as minister at Ipswich, where he continued during the remainder of his life. He is the author of 'A narrative of the

Troubles with the Indians from 1607 to 1677, with a Discourse' (1677), the map accompanying which is supposed to be the first executed in America. He left in manuscript a 'General History of New England,' for which the colony paid him £50, and which has been consulted with advantage by Mather, Hutchinson, Holmes, and other American historians and annalists. It was published by the Massachusetts Historical Society in 1815.

Hubbardton, hŭb'ard-tŏn, Vt., town in Rutland County; 13 miles from Castleton, its nearest railroad station. It is in an agricultural region, and has but little manufacturing; its raw products are sent direct to the markets. On 7 July 1777 a battle took place here between the Americans under Colonels Francis and Warner, and a British and Hessian force under Generals Riedesel and Fraser, in which the British were successful. The Americans, the rear-guard of Gen. St. Clair's army, who were retreating from Ticonderoga, lost in killed, wounded, and prisoners 324 men; and the British loss was 183 men. A monument in memory of the American soldiers who were killed in this battle occupies a prominent position. Pop. 500.

Huber, Johannes, German philosopher and theologian: b. Munich 18 Aug. 1830; d. there 19 March 1879. He was educated at the University of Munich, became professor of philosophy there in 1859, and was one of the leaders of the Old Catholic party and an active opponent of the Ultramontanes. He vigorously attacked the definition of the dogma of papal infallibility. Among his works were 'Studies' (1867); 'Das Papsttum und der Staat' (1870); 'Der Jesuitenarden' (1873); and 'Zur Philosophie der Astronomie' (1877).

Huber, Victor Aimé, German publicist and author: b. Stuttgart 10 March 1800; d. Wernigerode 19 July 1869. Educated at Würzburg and Göttingen, he became professor of the history of literature and of modern history at Rostock in 1833, of the languages of western Europe at Marburg in 1836, and at Berlin in 1843. He retired in 1850. Huber was one of the most profound of German scholars in the Spanish language and literature. Among his publications were: 'Die Geschichte des Cid' (1829); 'Crónica del Cid' (1844); and 'Skizzen aus Spanien' (1825–35).

Hubert de Burgh, English statesman: d. London 12 May 1243. He held office under Richard Cœur de Lion, and was made castellan of Falaise by King John, with whom he sided in the struggle with the barons, though advising the granting of Magna Charta. In the year of Runnymede (1215) he was made justiciar (chief-justice) of England. On 24 Aug. 1217 he won a distinguished victory over a French fleet bringing reinforcements to the army besieging Dover Castle; the treaty of Lambeth was concluded (11 September) and the enemy evacuated England. After 1219 he was co-regent with Langton, archbishop of Canterbury, for Henry III. He vigorously opposed the foreigners who were endeavoring to obtain control of the government, and sought to end the exactions of the clergy. In 1232 he was dismissed, owing largely to his failures in the conflict with the Welsh, and thereafter he had no part in the government.

Hubert, hū'bėrt (Fr. ü-bār), Saint, apostle of Ardennes, the patron of huntsmen; d. about 727. Legend says that he was a keen hunter, and that being once engaged in the chase on Good Friday, in the forest of Ardennes, a stag appeared to him having a shining crucifix between its antlers, and he heard a warning voice. He was converted, entered the church, and became bishop of Maestricht and Liège. He worked many miracles, and his body, at first deposited in the church of St. Peter at Liège, was in 817 conveyed to the Benedictine convent of Andain, in the Ardennes, which received the name St. Hubert's of Ardennes. The day of the saint is 3 November, and was formerly celebrated at many courts by a solemn chase.

Hübner, Joseph Alexander, COUNT, Austrian diplomat: b. Vienna 26 Nov. 1811; d. there 30 July 1892. He was educated at Vienna, and, having entered the service of the government, became in 1849 minister at Paris, and in 1865–8 was ambassador at Rome. In 1879 he became a member of the clerical-conservative wing in the upper house of the Reichsrat. Among his published works are: 'Sixte-Quint-D'après des Correspondances Diplomatiques Inédites' (1870, new ed. 1883); 'Ein Spaziergang um die Welt' (1872, 7th ed. 1891); and 'Durch das Britische Reich' (1886, 2d ed. 1891).

Hübner, Julius, German painter: b. Oels, Silesia, 27 Jan. 1806; d. Loschwitz, Saxony, 7 Nov. 1882. He studied at the Berlin Academy and was also a pupil of Schadow at Berlin and Düsseldorf. In 1841 he became professor in the Dresden Academy of Arts. He was an historical painter of the Düsseldorf School, his works including 'Disputation between Luther and Eck' and 'Charles V. at Saint Just.'

Hübnerite, a native tungstate of manganese, $MnWO_4$. It always contains some ferrous iron and as its percentage increases it graduates toward wolframite (q.v.), which it often much resembles, but from which it is distinguished by its brown color and pleochroism. It occurs in monoclinic crystals, often bladed and deeply striated. It has easy pinacoidal cleavage, is brittle, has a hardness of 5 to 5.5 and is very heavy, its specific gravity being 7.2 to 7.5. Its lustre is sub-metallic or resinous, and its streak yellowish-brown or greenish-gray. It occurs in considerable quantities near Silverton, Colo., in New Mexico, Nevada, Arizona, and elsewhere.

Huck'leberry, a name of uncertain derivation applied to a variety of shrubs, especially to species of the genus *Gaylussacia*, and to those belonging to the order *Vacciniaceæ* and the genus *Vaccinium*. The principal species are found mainly in the northern hemisphere, throughout North America, Northern Britain, and Europe. The fruit of *Vaccinium* is a many-sided berry with four or five cells. *V. Pennsylvanicum* is a small plant about six inches in height. Other species range widely in size, *V. corymbosum* sometimes attaining a height of nearly 10 feet. In many places in the United States huckleberries are a valuable product, the fields in which they grow are preserved, and the berries are secured either for household use or for profitable marketing.

Huckleberry Finn, The Adventures of, a story by Samuel L. Clemens ("Mark Twain"), published in 1884. It is a sequel to, and follows the fortunes of, the leading characters of the same author's 'Tom Sawyer.' In this book the author not only preserves to us a valuable record of a rapidly disappearing social order, but throws light upon some questions of moment to the student of history.

Hudibras, hū'dĭ-brăs, Sir, the hero of a famous satirical poem by Samuel Butler (q.v.), published 1663–78.

Hud'son, H. Lindsay, "Harry Lindsay," English novelist: b. Belfast, Ireland, 10 April 1858. He has been a journalist and schoolmaster by turns, and among his writings published under the signature "Harry Lindsay" are 'Methodist Idylls' (1897); 'An Up-to-Date Parson' (1899); 'Judah Pyecroft: Puritan' (1902).

Hudson, Henry, English navigator. The time and place of his birth appear to be lost. We only know that he had earned, perhaps by the time he was 40, sufficient reputation as a bold and skilful navigator to be placed in command of the ship Half Moon of Amsterdam. Early in 1609 he made a contract with a party of Dutch merchants to act as captain of their private exploring expedition, and in the written agreement between them he was described as "Henry Hudson, Englishman." This settles the honor of his birth country, though nothing more. At that time the one great commercial demand was for a shorter and better, all-sea trade route to the Far East. It was known that there was land to the west of Europe and it was believed that a passage could be found through these lands directly westward to the East. It is clear that Hudson believed that the western route was the most promising and, no doubt, he suggested it to his employers, but they evidently had more faith in a sea passage north and then east, round Europe and Asia to China. Thus it happened this English sea captain sailed from the Dutch port of Amsterdam in the small ship "Half Moon bound for China by the way of the North Cape. The ship's company of Dutch and English was fortunate in having as mate one Robert Juet (perhaps also of England), and the mate could read and write. Juet kept the ship's log, and in this log book on the first page are these words: "On Saturday, the five and twentieth of March, 1609, after the old account (style), we set sayl from Amsterdam, and by the seven and twentieth day we were down at the Texel; and by twelve of the clock we were off the land, it being east of us two leages off."

Once "off the land" the ship was free to go where the captain pleased and it certainly did not please the crew to face the arctic cold of the attempted voyage round Europe. Solid pack ice and the open mutiny of the crew decided Hudson to turn back and he steered south — and west. It is evident that he felt free to carry out his own plans and reach China by another route. His owners' plans had failed and, while his plan might fail, his success would justify his action. Hudson's decision was almost as bold as that of Columbus for, while he had, no doubt, some knowledge of the lands to the west, he evidently had no conception of the shape or size of North America nor of the width of the Pacific.

The Half Moon was a slow sailer, and four months passed before she made the land along the eastern coast of what is now the United States. The log book described the land as "low white sandy ground" — exactly describing all the shore line south of Sandy Hook. The book might also have described parts of Long Island or Cape Cod and it is clear it did not describe the coast of Maine, and it is more than probable the first land mentioned in the book was south of Sandy Hook for, on reaching the land and finding no passage westward, Hudson steered "northeast by north" until, about two weeks later, he came to a great bay. The log book, which does not give the name of the month, and which must have been September, says, "And from that lake or bay the land lyeth north by east, and we had a great streame out of the bay." The Half Moon had found the "great stream" described by Verrazano, and with the flood tide sailed into New York Bay and headed for the Narrows and, as the log book says, "came to three great rivers." And it continues: "So wee stood along to the northmost, thinking to have gone into it." The Half Moon was off Manhattan. It was true Verrazano, in 1524, had entered New York Bay and left a record of a high hill and a great bay out of which flowed a large river, but Verrazano had not the courage to pass the Narrows, except in a small boat. Other explorers may have looked into the bay. The Half Moon was the first ship to pass up the "great stream" and to Hudson belonged the entire honor of discovering and exploring the river that now bears his name.

The pages of Juet's journal tell nothing of Hudson's own hopes, fears and anticipations. Yet, it is fair to think that Juet's enthusiasm over the beauty and value of the great valley was shared by his captain and that the ship's log was, in a sense, a reflex of Hudson's own views. There is no hint of Hudson's belief that he could reach China by this route, yet it is reasonable to suppose he entered New York Bay in the hope that the "great stream" would lead through the land to the Pacific. The great size of the bay and river and the fact that the tide flowed far into the land and that for the first few days' sail the water remained salt, no doubt encouraged him to keep on through this most promising opening in the land. Favored by "fairer weather" and a favorable breeze he steered northerly over the wide salt arm of the sea until the apparent strait became a river and the sea water became fresh. At the Highlands all hope of a road to China must have faded away. Still, he would sail on, push through the mountains and see what manner of country lay beyond.

The items of the log book plainly show that Hudson, after passing the Highlands, began to recognize the transcendent importance of his discovery. He had found a new land of surpassing beauty and fertility and everywhere clothed in splendid forests. Hudson clearly recognized the commercial value of his discovery, for the log book enumerates all the potential wealth of the river and valley in fish, game, lumber, fruits, vegetables, grains and peltry. It even mentions the fact that Hudson, while the ship was at anchor somewhere near the present city of Hudson, sent the ship's carpenter ashore to fashion a new forearm out of one of the primeval trees — the first bit of lumbering done by white men in the valley.

Hudson seems to have decided, after reaching the upper river and sailing to a point opposite the Catskills, that the best way to mollify his owners on his return would be to report as fully as possible the potential wealth he had discovered and he sent a boat up the river to explore the country. The boat party appears to have been absent several days, for they rowed up stream about nine leagues or perhaps beyond Albany where, as the log book says, the boat found "it bee at an end for shipping to goe in — with but seven foot water and unconstant soundings." Meanwhile Hudson evidently traded with the Indians for peltry, no doubt regarding the furs as something that would demonstrate to his merchant owners the value of his discovery.

Three weeks after the Half Moon entered "the great streame" she again passed Sandy Hook and steered away for Amsterdam. There is no record of the return voyage nor is there any record of Hudson's report to the merchants of Amsterdam, yet it is evident that his story and perhaps the exhibit of peltry created a tremendous sensation in the commercial cities of Holland. Hudson appears not to have cared much about this side of the affair. He seems to have considered his voyage a failure. He had tried to reach China and failed, and wished to sail again, but the merchants seem to have been wholly occupied in fitting out new ships under more commercial captains and would not listen to him. At last, after some delay, he did secure a second ship and set forth once more to find a sea path through America. He appears to have thought there might be a passage round by the north of America and he steered for Baffin's Bay. Once more he found a great passage leading westward into the land, once more a salt water strait seemed to promise success, but it only led to an inland sea. His miserable crew, ignorant, frightened at the arctic cold and gathering ice, rose in mutiny, and putting their great captain in an open boat, with his son, a boy of seven, and some invalid sailors, set them adrift in the vast waters of Hudson Bay and left them there to perish. CHARLES BARNARD,

Lecturer, Board of Education, New York.

Hudson, Henry Norman, American Shakespearian scholar and Episcopal clergyman: b. Cornwall, Vt., 28 Jan. 1814; d. Cambridge, Mass., 16 Jan. 1886. He served as chaplain in the Civil War, was professor of Shakespeare at Boston University, and for a time editor of the 'Churchman.' He published 'Lectures on Shakespeare' (1848); 'Campaign with General Butler' (1865); 'Shakespeare, his Life, Art, and Characters' (4th ed. 1883); 'Essays on Education' (1883). He edited the Harvard and the University edition of Shakespeare.

Hudson, Thomson Jay, American philosophical writer: b. Windham, Ohio, 22 Feb. 1834; d. Detroit, Mich., 1903. After studying law and being admitted to the bar in Cleveland, Ohio, in 1857, he practised three years, was engaged in journalism in Michigan 1860–76, and was principal examiner in the United States Patent Office 1880–93. He has published 'The Law of Psychic Phenomena' (1893); 'A Scientific Demonstration of the Future Life' (1895); 'The Divine Pedigree of Man' (1899); 'Law of Mental Medicine' (1903).

Hudson, William Henry, American educator and critic: b. London, England, 2 May 1863. He was five years private secretary to Herbert Spencer (q.v.) and coming to America was assistant librarian of Cornell University, 1890–2. He has been an assistant professor of English literature at Leland Stanford University from 1892, and has published 'The Church and the Stage' (1886); 'An Introduction to the Philosophy of Herbert Spencer' (1893); 'Studies in Interpretation' (1896); 'Idle Hours in a Library' (1897); 'The Study of English Literature' (1898); 'The Sphinx and Other Poems' (1900); 'The Meaning and Value of Poetry' (1901); 'Life of Sir Walter Scott' (1901); 'Famous Missions of California' (1901); etc.

Hudson or Hudson's Bay, Canada, an extensive bay or inland sea extending between lat. 51° and 64° N., and lon. 77° and 95° W. Its greatest length north to south is about 800 miles, greatest breadth, 600 miles. It is connected with the Atlantic Ocean by Hudson Strait and with the Arctic Ocean by Fox and other channels. Hudson Bay is navigable in summer from the middle of June to the end of October, being obstructed by drift-ice during the rest of the year. There are many islands, reefs and sand banks. The white whale is found in its waters, and there is a considerable summer fishery. Numerous rivers flow into the bay, the chief being the Nelson and Churchill on the east. The shores on the east are high and bold; those on the west are low and level, and much of the land is favorable for stock and dairy farming, while valuable deposits of iron ore, galena, and plumbago exist. With the exception of a few fur trading stations on the west and south coast, there are, however, no settlements.

Hudson, Mass., town, Middlesex County, on the Assabet River, and on the Boston & M. and the Fitchburg R.R.'s; about 17 miles northwest of Worcester. The town is situated in an agricultural region, but it is particularly noted for its manufactures, especially of articles made from leather and rubber. The chief manufactures from rubber are gossamer clothing, webbing, goring, and boots and shoes. Some of the other manufactures are paper and wooden boxes, leather, and leather boots and shoes. The town owns and operates the electric-light plant and the waterworks. Pop. (1900) 5,454.

Hudson, N. Y., city, port of entry, county-seat of Columbia County; on the Hudson River, and on the New York Central & H. R. and the Boston & A. R.R.'s; about 30 miles south of Albany. Area of the city, one square mile. Hudson was settled in 1783 and was called Claverack Landing; but the year following the name was changed to Hudson. In 1785 it was chartered as a city, and in 1790 it was made a port of entry. From the first it was a trading station of importance and a whaling port. After the Revolution a large foreign trade was established, but the commerce of the city was injured by the destruction of its shipping in the War of 1812. The surrounding country is devoted largely to agriculture, and the city has a number of manufacturing establishments. The chief manufactures are foundry products, machinery, knit goods, car-wheels, and creamery products. It has a large sash and blind factory and several small manufacturing establishments. Some of its prominent buildings are the State Volunteer Firemen's Home, the State House of Refuge for Women, an orphanage, hospital, and the city public buildings. The city owns and operates the waterworks. The government is vested in a mayor, who holds office two years, and a city council. Pop. (1900) 9,528.

Hudson, Ohio, town in Summit County, on the Pennsylvania railroad, 20 miles south of Cleveland. This was one of the earliest settled towns on the Ohio Western Reserve, and prior to the Civil War was an abolition stronghold. The Western Reserve College, before its removal to Cleveland, was located here. Pop. (1900) 2,240.

Hudson, Wis., city, county-seat of Saint Croix County; on Lake Saint Croix, an expansion of the Saint Croix River, and on the Chicago, St. P., M. & O. railroad; about 65 miles northwest of Eau Claire and 20 miles east of St. Paul, Minn. The chief manufactures are flour, finished lumber, furniture, railroad cars, machinery, beer, and brooms. The city has a large cold-storage plant and ample facilities for shipping butter, poultry, vegetables, and fruits. It has a large sanatorium. The electric-light plant and the waterworks are owned and operated by the city. Pop. 3,259.

Hudson, the largest river in the State of New York, has its head waters in Hamilton and Essex counties, and flows southwest into Saratoga County, then nearly directly east to Sandy Hill in Washington County, and from this point south through New York Bay into the Atlantic Ocean. It is fed by several of the Adirondack lakes, a number of small streams, and by Schroon River, Batten Kill, Hoosick, Wappingers and Croton from the east, and the Sacondaga, Mohawk, Wallkill, and Esopus Creek from the west. The Mohawk (q.v.), which flows into the Hudson at Cohoes, is the largest tributary; the Rondout enters the Wallkill near the Hudson. The head waters of the Hudson and the sources of several of the streams which flow into the Saint Lawrence are very near each other in the Adirondack Mountains. At Troy, three miles below the mouth of the Mohawk, the Hudson becomes a navigable tidal stream. There is a tidal rise of about one foot at Albany. Above Troy there are a number of rapids and long falls in the river; but below, the navigation is uninterrupted. At one time there were a few obstacles, the largest of which was "Overslaugh", or Castleton Bar, at Castleton. This hindrance to navigation has been almost wholly removed by the Federal and State government. The Catskill Mountains, on the west side, begin about 25 miles below Albany. Lower down are the Highlands, averaging about 1,100 feet in height, which extend along the shore for a distance of about 20 miles. The Highlands of the Hudson are noted for their beautiful scenery. On the west bank are the famous Palisades (q.v.) about 13 miles long, their southern extremity being near Fort Lee, in New Jersey, and the northern extremity near Piermont, New York. This remarkable arrangement of rock rises from near the water's edge, almost perpendicularly, from 350 to 550 feet. Below Verplanck and Stony Point is an expansion in the river the upper part of which is called Haverstraw Bay and the lower part Tappan Sea. Many small islands in the river serve as foundations for lighthouses, or for the erection of dredging platforms. Iona, on which there is now a naval station, Constitution, and Beeren Islands have all figured in history. Below Albany the Hudson is more an estuary or fiord than a river, which accounts for the great depth of water. The area drained by the Hudson above where the Mohawk enters is about 30,000 square miles. The river is noted for its beautiful scenery from the source to the mouth. Along the lower part of its course there are many fine residences, as a large part of the country on both banks from New York to Albany is now a residential section. The Hudson is fittingly called the "Rhine of America."

Hudson River was discovered by Verrazano, an Italian navigator, in 1524; but it was explored by Henry Hudson in 1609. The Indian name for the river was Shatemuc, and the first colonists called it North River, as the Delaware was then called South River. The part of the river west of New York city is still called North River; but it was given the name Hudson in honor of its first explorer. The history of the country since its discovery by Europeans occupies an important place in the history of the United States. The almost unbroken waterway from the Atlantic Ocean through what is now the State of New York, to the Saint Lawrence River, made this an important route for missionaries, traders, and for the armies in the various wars. From the mouth of Lake Champlain to Lake George, across the portage from Lake George to the Hudson, and the Hudson to the ocean, was all disputed territory, and the scene of many a contest of the Revolutionary War. What a change in the map of America if Burgoyne had succeeded in his plan of 1777 "to cut the nation in two" by getting possession of Lake Champlain and the Hudson. See CHAMPLAIN, LAKE; CROWN POINT; HAVERSTRAW; TICONDEROGA.

The river is navigable for ships of the first class for about 117 miles from the ocean. Its whole length is about 300 miles. Before the introduction of railroads, the navigable waters of the Hudson, connecting New York with a large section of country, gave the city great opportunities for development. A canal built along the Mohawk Valley, in 1817–25, connected the Hudson with Lake Erie, and the Champlain Canal completed the water route from the Hudson to Lake Champlain. Later the Erie and the Delaware and Hudson railroads brought the coal of Pennsylvania to the Hudson River for transportation by water to markets in the interior. The New York Central and Hudson River Railroad is on the east side of the river and the West Shore on the west side. In 1807 Robert Fulton made on this river the first successful experiment with steam navigation. The Hudson is now a thoroughfare for an immense amount of freight, and elegant passenger steamers ply daily between New York and Albany. The government has erected and maintains 21 lighthouses and lighted beacons. Navigation ceases in winter because the river is frozen nearly its whole length. The ice crop harvested each winter on that part of the river between Albany and the Highlands is shipped, when navigation opens, chiefly to New York city. Shad fishing is one of the important Hudson River industries. Many of the cities on the Hudson were at first only trading posts or ferry towns, but nearly all have kept pace in development with the rest of the State. The principal cities and towns on the river from north to south are Glens Falls, Sandy Hill, Fort Edward, Mechanicsville, Cohoes, Troy, Albany, Hudson, Catskill, Kingston, Poughkeepsie, Newburg, West Point, Peekskill, Haverstraw, Ossining, Nyack, Tarrytown, and Yonkers. At the mouth of the river are New York and Jersey City, with the suburbs, which are important shipping ports, Hoboken and Weehawken. The only bridge crossing the river between New York and Albany is the one which extends from Poughkeepsie on the east side to Highland on the west. There are 14 public ferries. The use of the water-power of the Hudson as an aid in developing electrical power for the mechanical arts is most important. From Mechanicsville the power of the Hudson is transmitted to the general electric shops of Schenectady. At Spiers Falls, at the foot of Mount McGregor, about forty miles above Albany, there has been constructed a dam, — a stone wall over 1,800 feet long, 100 feet high, and containing 1,800,000 cubic feet of masonry. The Hudson is raised 50 feet above its former river bed, then its waters fall 80 feet, and the power developed is (1904, 30,000 horse-power), transmitted for electrical machinery, to Schenectady, Albany, Troy, Amsterdam, and other places. The electric motors at Spiers Falls get some of their power from the older plant at Mechanicsville, about 20 miles distant. At other points storage plants will be constructed, more power will be developed, the current will be sent at a high pressure to sub-stations at Saratoga, Schenectady, Ballston, Glens Falls, Fort Edward, and Watervliet. This will mean running cars, lighting streets, driving machinery by power developed hundreds of miles away. This power development of the waters of the Hudson combined with development of like power of the waters of the Saint Lawrence at Massena (q.v.), keeps the two rivers, as in early years of our country, of vast importance to the State. Many industries are affected by this great new power, not the least of which are the coal-mining of Pennsylvania and the preservation of the Adirondack forests.

The Hudson occupies an important place in the historical, commercial, and mechanical development of the nation, also in its literary and artistic progress. Washington Irving who lived at "Sunny Side" and was laid to rest in Tarrytown, introduced to the world many of the places along the Hudson. Cro' Nest is associated with Joseph Rodman Drake and his poem, 'Culprit Fay'; West Park and the country around have been practice observation ground for the naturalists John Burroughs and Ernest Ingersoll; Cornwall-on-the-Hudson was the home of N. P. Willis and E. P. Roe. Artists who have received inspiration from Hudson's scenery and history have become sufficiently numerous and their works of importance enough to be called "The Hudson School of Painters." Consult Ingersoll, 'Guide to the Hudson River'; Cooper, article in 'Magazine of American History,' Vol. IV.

Hudson's Bay Company, incorporated 1670, the great fur-trading and later landholding and administrative company of Northwest Canada. It originated in the dissatisfaction of two French Protestant employees of the French fur-trading monopoly at Quebec, Groseilliers and Radisson, with its unwillingness to extend the trade to Hudson Bay, after vainly trying to induce Boston merchants and the French court to take up their scheme for so doing. They gained the ear of a company of London merchants and Prince Rupert, cousin of Charles II., brought a load of furs from the bay, and on 2 May 1670 Rupert and 17 associates received from Charles a charter for "The Governor and Company of Merchants-Adventurers trading into Hudson's Bay." It had the monopoly of the right to trade in the bay or on its coasts, and could expel any one entering the territory without its license; could build forts, send out ships of war and privateers, and declare war and make peace with any non-Christian people. Its capital was £10,500, divided into 34 shares with an extra one for Prince Rupert, and in 1676 it imported some £19,000 worth of furs, sending in return £650 worth of goods to the Indians. The profit was high on the petty capital paid in, but the gross amount was not large for a century. In 1748 the trade was carried on with four ships, and employed about 120 men in all, including the garrisons at its forts. The furs and other imports amounted to over £30,000, the exported goods to £5,000, and the costs of business over £17,000. The average profit was 40 per cent. on capital, but the sum was trivial. Moreover, the company had great losses and tribulations from the French rivalry and assaults, especially in the national wars. The French laid claim to the territory on the strength of a mythical expedition of Jean Bourdon in 1656, and in 1682 and 1686 captured several of the company's forts, the two countries' trading posts shared in the long war ended by the Peace of Ryswick in 1697, captured each others' forts, and the peace yielded Port Nelson to the French, to the great damage of the company. The War of the Spanish succession inflicted frightful hardships on both sides: the company claimed a loss of over £100,000, hundreds of trappers and employees starved to death, and the Indians turned cannibals. The Treaty of Utrecht in 1713 finally resigned all French claim to the Hudson's Bay territory, and thence till the cession of French Canada in 1763, the monopoly gave the company an easy life and good profits, though still on a small scale. But when that cession opened up access to Hudson's Bay from both land and sea, the possibilities of trade were incalculably enlarged. Despite the clandestine rivalry of Montreal traders who intercepted their boats, the gross volume increased manifold, and it was not crippled by the ravages of France in 1782, as part of the war begun in 1778, when they captured and partly ruined the massive stone Fort Prince of Wales at the mouth of Churchill River, and altogether destroyed property valued by the company at half a million pounds. But a much worse rivalry was at hand, organized and powerful: the Northwest Company (q.v.), started on a co-operative plan in 1784 by an association of Scotch merchants in Montreal. The Declaration of Rights having guaranteed free and open trade to all British subjects, this company invaded its rival's territory, and the trade competition for many years merged into actual war. In 1821 they had done each other so much harm that they consolidated, and Parliament in view of the evils of competi-

2. Looking northward from the battery.

tion empowered the crown to issue licenses for the "Indian territories," which was exercised in favor of the new company. Meantime exploration had been steadily enlarging the territory: Samuel Hearne for the old company had reached the Arctic in 1771, Alexander Mackenzie for the new one reached the Pacific in 1793. With the United States, its rivalry for the far Northwest was strenuous and persistent: it planted posts in the Oregon district, repelled settlers, and there was much danger of war till the boundary settlement of 1846 quieted the dispute. In 1849 it secured a grant of Vancouver Island. This was the time of its palmiest growth. In 1846 it had 513 employees and 35 officers, in 1856 it had over 3,000 employees and officers together, with 152 posts. Its trade monopoly expired by limitation in 1859, but there was also a great desire to settle the Northwest Territories, with which the fur-trade and administrative rights of the company were incompatible. The company, liable to be dispossessed by force if it refused to come to terms, agreed in 1869 to transfer its territorial rights to the Dominion of Canada for £300,000 and one twentieth of the lands set out for settlement by the government for the next 50 years. It retained its posts and its rights of trade. The transfer to Canada, and the survey of lands for settlement, was immediately followed by the Riel rebellion (q.v.). The company, despite its lapse of administrative powers, remains the most potent influence for law and order in the unsettled parts, through its relations with the Indians. Consult Bryce, 'History of the Hudson's Bay Company' (1900); Willson, 'The Great Company' (1900); Cawston and Keane, 'Early Chartered Companies' (1896). For the Northwest Company, see also Irving, 'Astoria.'

Hué, hoo-ā', the capital of Anam, on the river Truong, 10 miles from its mouth in the Gulf of Tonking. It is surrounded by Vaubanian fortified walls, five miles in circumference, the internal city being built on a rectangular plan with wide and straight streets. The chief building is the royal palace. Hué is the seat of a French political resident, and at Thuan-an, the port at the river mouth, there is a French garrison. Pop. estimated at 100,000, of whom less than 400 are Europeans.

Huelen, wā'lān, Chilean hero: b. about 1540; d. 1603. He attained the command of the native forces in Araucania, and was for a time successful in repelling the invading Spaniards, whose methods of warfare he copied. He defeated the enemy at Valdivia, near Concepción, and near Bio-Bio, but died at the siege of Osorno.

Hueppe, hüp'pė, **Ferdinand**, German hygienist: b. Heddesdorf, Rhine Province, 24 Aug. 1852. He studied at the Friedrich Wilhelms Institut of Berlin, and in 1890 became professor of hygiene in Prague University (German). His researches in bacteriology and disinfection have been extensive and important. He wrote 'Die Methoden der Bakterienforschung' (1885); 'Naturwissenschaftliche Einführung in die Bakteriologie' (1896); 'Handbuch der Hygiene' (1899), and other works.

Huger, ū-jē', **Benjamin**, American soldier: b. Santee, S. C., 22 Nov. 1805; d. Charleston, S. C., 7 Dec. 1877. He was graduated from West Point, served in the United States army during the Civil War and was brevetted colonel. He resigned his commission in 1861 and entering the Confederate army became a major-general.

Huger, Francis Kinloch, American soldier: b. Charleston, S. C., September 1773; d. there 14 Feb. 1855. He was a nephew of I. Huger (q.v.). His father, Major Benjamin Huger, was killed before the lines of Charleston in 1780. He joined with Dr. Eric Bollman of Philadelphia in a visit to Europe for the purpose of attempting the rescue of Lafayette from the dungeons of Olmütz, his father having been the first to receive that general on his arrival in Georgetown in 1777. The enterprise resulted in their imprisonment for eight months. Huger became a captain in the United States army in 1798, was a colonel in the war of 1812, and served in both branches of the legislature of his State.

Huger, Isaac, American general: b. Limerick Plantation, S. C., 19 March 1742; d. 17 Oct. 1797. He was one of five patriot brothers active in the revolution. Promoted to the rank of brigadier-general in 1777, he took a conspicuous part in the engagements connected with the siege of Savannah in 1778, commanded a force of cavalry at the siege of Charleston in 1780 which was surprised and dispersed by Tarleton, and commanded the Virginia brigade which formed the right wing in the battles of Guilford Court-House, and Hobkirk's Hill.

Huggins, hŭg'ĭnz, Sir **William**, English astronomer: b. London 7 Feb. 1824. In 1852 he was elected a member of the Microscopical Society, and in 1856 erected an observatory at Tulse Hill, in northeastern Surrey. When in 1859 Professor Kirchoff of the University of Heidelberg announced the true interpretation of the dark Fraunhofer lines in the solar spectrum, Huggins at once saw the possibility of using his practical knowledge of chemistry and physics in the service of astronomy. With W. A. Miller, professor of chemistry at King's College, London, he at once set about the task of constructing a star-spectroscope. The two then began the observation of stellar spectra. A full statement of their results was read before the Royal Society in 1864, the essence of the statement being, in Huggins' own words, that the chemistry of the solar system prevails, essentially at least, wherever a star twinkles. In August 1864 Huggins directed his star-spectroscope toward a planetary nebula in Draco, and found its spectrum to be a monochromatic one, thus proving that the nebula consists of a luminous gas. In 1868 he was able to announce to the Royal Society the results of his first measurements of the motion of stars in the line of sight. He began his observations of comet spectra with that of Winnecke's comet in 1868, and in 1868–9 made spectroscopic observations of the solar prominences. About 1876 he resumed his abandoned efforts to photograph stellar spectra, using the gelatine dry plate process then recently introduced, and this time he was completely successful. His photographs of the invisible ultra-violet portions of stellar spectra have proved extremely valuable, providing, for example, the only reliable data for determining the relative ages of the stars. He was elected a fellow of the Royal Society in 1865, and awarded by that body a Royal Medal (1866), the Rumford Medal (1880), and the Copley Medal. He was president of the Royal Astronomical Society in 1876–8. With Lady Huggins he published in 1900 a valuable 'Atlas of Representative Stellar Spectra.'

Hugh Capet, king of France, founder of the Capetian dynasty. See CAPET.

Hughes, hūz, **Ball**, American sculptor: b. London 19 Jan. 1806; d. Boston, Mass., 5 March 1868. He early exhibited a decided taste for modeling, and at 12 years of age made out of wax candle ends a bas-relief copy of a picture representing the wisdom of Solomon, which was afterward cast in silver. He was then placed in the studio of Edward Hodges Bailey, where he remained seven years. At this time he successfully competed for the prize awarded by the Royal Academy, winning the large silver medal for the best copy in bas-relief of the Apollo Belvidere; also the silver medal from the Society of Arts and Sciences for a copy of the Barberini faun, the large silver medal for the best original model from life, and a gold medal for an original composition, "Pandora brought by Mercury to Epimetheus." He emigrated in 1829 to New York, where his first work of importance was a marble statue of Hamilton, for the Merchants Exchange, which was destroyed by fire in 1835. He subsequently removed to Boston, Mass. Among later works of his are the bronze statue of Bowditch at Mount Auburn Cemetery, a bust of Washington Irving, and a statuette of General Warren at Bunker Hill.

Hughes, David Edward, English-American inventor: b. London 16 May 1831; d. there 22 Jan. 1900. When very young came with his parents to the United States. He was educated at Bardstown College, Kentucky, where he was appointed professor of music (1850), and later of natural philosophy. In 1855 he patented his first important invention, that of the well-known printing telegraph which bears his name. It was at once adopted in America, and by 1876 by practically every European country. In 1878 Hughes announced to the Royal Society his invention of the microphone, an ingenious instrument which not only transmits sound, but so magnifies faint sounds as to make them distinctly audible. The microphone is now in universal use in the telephone. Another important invention, that of the induction balance, was completed by Hughes in 1879, and in 1880 he was elected a fellow of the Royal Society.

Hughes, Hugh Price, English Wesleyan clergyman: b. Caermarthen 1847; d. London 17 Nov. 1902. He was educated at University College, London, and the Wesleyan Theological College, Richmond, was appointed to Dover in 1869, and was afterward at Brighton; Stoke-Newington; Mostyn Road, London; Oxford; Brixton Hill; and the West London Mission. From 1885 he was editor of the Methodist 'Times,' and he was also at one time president of the national council of Evangelical free churches. He was prominently identified with reform work in London, and with the Anti-gambling League. Among his writings are: 'Social Christianity' (1889); 'The Atheist Shoemaker' (1889); 'The Philanthropy of God' (1890); and 'Ethical Christianity' (1892).

Hughes, John, American Roman Catholic prelate: b. Annaloghan, County Tyrone, Ireland, 24 June 1797; d. New York 3 Jan. 1864. His parents were poor but made sacrifices to give him the opportunity of acquiring an elementary education; and by his own efforts he continued his studies so that when he came with his parents to America in 1817 he was prepared for college. However, for lack of means he had to defer entering any school, and instead began work as a day laborer, in which occupation he continued for three years, but at 23 entered the Roman Catholic theological seminary, Mount Saint Mary's, Emmittsburg, Md. As a student, his remarkable power of reasoning and his ability in argument attracted attention. He was ordained priest in 1826, and for a time was stationed at Bedford, Pa., from which he was transferred to Philadelphia. Here he had charge of Saint Joseph's parish and later Saint Mary's parish. In 1838 he was consecrated titular bishop of Basileopolis and appointed coadjutor to the bishop of New York. In 1842, after the death of Bishop Du Bois, he was made bishop of New York. In 1850 the diocese of New York became an archdiocese, and on 19 July 1850 he was raised to the dignity of first archbishop of New York, which office he held until his death.

He was an active and effective worker. As a speaker or writer he was ever ready to defend the Church which he represented. When a student at Mount Saint Mary's, he wrote the pamphlet, 'An Answer to Nine Objections against the Catholic Church.' When in Philadelphia, he wrote the replies to Dr. Breckenridge, a Presbyterian clergyman. The articles on both sides are issued in book form, 'Hughes and Breckenridge.' Before asking his priests to collect money to build schools and churches, he had set the example. He collected money for the rebuilding of Mount Saint Mary's after it had been burned. He established St. John's orphan asylum in Philadelphia, and a number of charitable institutions in New York. He settled decisively the "trustee system" question which was agitating New York when he came there; and he defended the Church property against the attacks of the "Knownothing" element. The "school question" was to him all important. One of his first undertakings was to establish a theological seminary at La Fargeville in Jefferson County, N. Y.; the distance from New York caused the abandonment of this plan, and Saint John's College (q.v.) was founded at Fordham instead. In 1858 he laid the corner stone of Saint Patrick's Cathedral. In 1861, during the Civil War, he was sent by the United States government to Europe, to present the cause of the Union, and counteract any adverse sentiment which might exist against the attitude of the North. His diplomatic mission was most successful in France, Italy, and Ireland. Consult: Brann, 'John Hughes,' in the 'Makers of America Series'; Hassard, 'Life of John Hughes'; Sadlier, 'Archbishop Hughes,' in the 'Ave Maria' magazine.

Hughes, Rupert, American author: b. Lancaster, Mo., 31 Jan. 1872. He was graduated from Adelbert College of the Western Reserve University in 1892, was for a time assistant editor of the New York 'Criterion,' and in 1900 entered editorial work in London. In addition to many contributions to periodicals, he wrote: 'The Lakerim Athletic Club' (1898); 'One Dozen from Lakerim' (1899); 'American Composers' (1900); 'Guide-Book to the World of Music' (1901); and, in verse, 'Gyges' Ring' (1901).

Hughes, Thomas, English author: b. Uffington, Berkshire, 20 Oct. 1823; d. Brighton, Sussex, 22 March 1896. He was educated at Rugby and Oxford, later studied law at Lincoln's Inn, was called to the bar of the Inner Temple in 1848, and began practice at once. In 1869 he was appointed queen's counsel, in 1882 county court judge. Throughout his long public career, as advanced Liberal in Parliament (1865–74), as founder with Canon Kingsley and Frederick Maurice of the Christian Socialists, as creator of Rugby, a socialistic community in the mountains of Tennessee (1880), he tried most earnestly to exercise a helpful influence upon English working-people. He early essayed journalism, writing many sketches for the London 'Spectator,'— chiefly accounts of traveling experiences. These sketches served as his apprenticeship in writing, and afterward were collected in book form with the title 'Vacation Rambles' (1895). But authorship was a secondary interest until 'Tom Brown's School Days,' first appearing in 1856, made him famous. This work is largely a presentation of the influence of Dr. Thomas Arnold (q.v.) in the great public school. 'The Scouring of the White Horse' (1858), a spirited account of a vacation trip, had a respectful although less cordial reception. The great success of the first story led him to continue his hero's career with 'Tom Brown at Oxford' (1861), first published serially in 'Macmillan's Magazine.' This second volume, which is much the longer, although often fine and spirited, sometimes waxes prolix, and has never been so popular as the earlier story. At the time of the American Civil War, Hughes was a decided abolitionist, and thus established a friendship with James Russell Lowell. Among other works of his are 'Alfred the Great' (1869); 'Life of Livingston'; 'Memoir of a Brother'; 'Life of Bishop Fraser' (1887).

Hughes, Thomas Patrick, American Protestant Episcopal clergyman: b. Ludlow, England, 26 March 1838. He was educated at Islington College, was ordained priest in 1864, in 1865–85 was missionary and chaplain at Peshawar, Afghanistan, in 1885–9 rector at Lebanon Springs, N. Y., and from 1889 of the Church of the Holy Sepulchre, New York. In 1875–85 he was also examiner in Oriental languages to the British government. Among his writings are: 'Notes on Mohammedanism'; 'The Poems of Abdur Rahman'; 'A Dictionary of Islam'; 'Heroic Lives in Foreign Fields.'

Hugo, hū'gō (Fr. ü'gō), **Victor Marie**, French poet and novelist: b. Besançon 26 Feb. 1802; d. Paris 22 May 1885. Major Hugo, his father, having entered the service of Joseph Bonaparte, king of Italy and afterward of Spain, Victor's earlier years were partly spent in these countries. At the age of 12 he was already writing verses, and in 1823 his first novel, 'Han d'Islande,' appeared, followed in 1825 by 'Bug Jargal.' In 1828 a complete edition of his 'Odes et Ballades' appeared. In these productions Hugo's anti-classical tendencies in style and treatment of his subject had been very visible, but the appearance of his drama, 'Cromwell' (1827), with its celebrated preface, gave the watchword to the anti-classical or romantic school. 'Cromwell' was too long for representation, and it was only in 1830 that 'Hernani,' over which the great contest between Classicists and Romanticists took place, was brought on the stage. Other dramas followed—'Marion Delorme' (1831); 'Le Roi s'amuse' (1832); 'Lucrèce Borgia' (1833); 'Marie Tudor' (1833); 'Angelo' (1835); 'Ruy Blas' (1838); 'Les Burgraves' (1843). During those years he had also published a novel, 'Notre Dame de Paris' (1830), and several volumes of poetry, 'Les Feuilles d'Automne' (1831); 'Les Chants du Crépuscule' (1835); 'Les Voix intérieures' (1837); 'Les Rayons et les Ombres' (1840). The poetry of this period has a melody and grace superior perhaps to any that he afterward wrote, but wants that deep and original sense of life characteristic of his later poems. During the same period he also wrote critical essays on Mirabeau, Voltaire, and a number of articles for the 'Revue de Paris.' In 1841, after having been four times previously rejected, he was elected a member of the French Academy; made shortly afterward a tour in the Rhineland, of which he wrote a brilliant and interesting account in 'Le Rhin' (1842). In 1845 he was made a peer of France by Louis Philippe. The revolution of 1848 threw Hugo into the thick of the political struggle. At first his votes were decidedly Conservative, but afterward whether from suspicion of Napoleon's designs or from other reasons, he became one of the chiefs of the democratic party. After the *coup d'état*, 2 Dec. 1851, he was one of those who kept up the struggle in the streets against Napoleon to the last. He then fled to Brussels, where he published the first of his bitter satires on the founder of the Second Empire, 'Napoléon le Petit.' In August 1852 he went to live in Jersey, and finally settled in Guernsey, where he bought an estate called Hauteville House. In the following year (1853) the famous volume 'Les Châtiments,' a wonderful mixture of satirical invective, lyrical passion, and pathos, appeared. It was in the comparative solitude and quietness of the Channel Islands that he wrote most of the great works of his later years. 'Les Contemplations' (1856); 'La Légende des Siècles,' 1st series (1859); 'Chansons des Rues et des Bois' (1865), and his celebrated series of social novels, 'Les Misérables' (1862); 'Les Travailleurs de la Mer' (1866); and 'L'Homme qui Rit' (1869). In 1870, after the fall of the Empire, Victor Hugo returned to Paris, where he spent his remaining years in occasional attendances at the senate, and in adding to the already long list of his literary works. Among these latest productions may be cited, 'Quatre-Vingt-Treize' (1873); 'L'Art d'être Grand-père' (1877); 'L'Histoire d'un Crime' (1877); 'Le Pape' (1878); 'La Pitié Suprême' (1879); 'Religions et Religion' (1880); 'Les Quatre Vents de l'Esprit' (1881); 'La Légende des Siècles' (last series, 1883); 'Torquemada' (1882). If not the greatest writer that France has produced, certainly he is her greatest poet. But he had grave defects and limitations, the chief being an entire want of humor, a too frequent straining after effect through the abnormal and bizarre, an overweening belief in his own infallibility, and an ever-present conviction that he was a sage, all of whose sayings might be regarded as priceless teachings, to be eagerly caught up by a listening world. An edition of his complete works in 40 vols. appeared at Paris in 1886. The house in which Victor Hugo lived, on the Place des Vosges, has recently been transferred to the city of Paris, and now forms a Victor Hugo Museum, full of interesting relics of the poet. Consult: Swinburne, 'Study of Victor Hugo' (1886); Barbou, 'Victor Hugo et son Temps' (1882); Mabilleau, 'Victor Hugo' (1893); Nichol, 'Victor Hugo, a Sketch of his Life and Work' (1894); Dupuy, 'Victor Hugo, l'Homme et le Poète' (1887); Bire, 'Victor Hugo après 1852' (1894).

Huguenots, hū'gē-nŏts, a term of unknown origin, believed to be derived from a personal name, applied to the Protestants of France during the religious struggles of the 16th and 17th centuries. During the early part of the 16th century the doctrines of Calvin, notwithstanding the opposition of Francis I., spread widely in France. Under his successor Henry II., 1547–59, the Protestant party grew strong, and under Francis II. became a political force headed by the Bourbon family, especially the King of Navarre and the Prince of Condé. At the head of the Catholic party stood the Guises. The contest between the two parties was as much political as religious. The result was that a Huguenot conspiracy headed by Prince Louis of Condé was formed for the purpose of compelling the king to dismiss the Guises and accept the Prince of Condé as regent of the realm. But the plot was betrayed, and many of the Huguenots were executed or imprisoned. In 1560 Francis died, and during the minority of the next king, Charles IX., it was the policy of the queen mother, Catharine de Medici, to encourage the Protestants in the free exercise of their religion in order to curb the Guises. In 1562 an accidental conflict between the followers of the Duke of Guise and some Protestants at a church meeting precipitated a series of religious wars which desolated France almost to the end of the century. Catharine, however, began to fear that Protestantism might become a permanent power in the country, and suddenly making an alliance with the Guises, with their help she projected and carried out the massacre of St. Bartholomew's (q.v.). The Protestants fled to their fortified towns and carried on a war with varying success. On the death of Charles IX., Henry III., a feeble sovereign, found himself compelled to unite with the King of Navarre, head of the house of Bourbon and heir-apparent of the French crown, against the ambitious Guises, who openly aimed at the throne, and had excited the people against him to such a degree that he was on the point of losing the crown. After the assassination of Henry III. the King of Navarre was obliged to maintain a severe struggle for the vacant throne; and not until he had, by the advice of Sully, embraced the Catholic religion (1593), did he enjoy quiet possession of the kingdom as Henry IV. Five years afterward he secured to the Huguenots their civil rights by the Edict of Nantes (q.v.) which confirmed to them the free exercise of their religion, and gave them equal claims with the Catholics to all offices and dignities. They were also left in possession of the fortresses which had been ceded to them for their security. This edict afforded them the means of forming a kind of republic within the kingdom, which Richelieu, who regarded it as a serious obstacle to the growth of the royal power, resolved to crush. The war raged from 1624 to 1629, when Rochelle, after an obstinate defense, fell before the royal troops; the Huguenots had to surrender all their strongholds, although they were still allowed freedom of conscience under the ministries of Richelieu and Mazarin. But under Louis XIV. a new persecution of the Protestants commenced. They were deprived of their civil rights, and bodies of dragoons were sent into the southern provinces to compel the Protestant inhabitants to abjure their faith. The Edict of Nantes was revoked in 1685, and by this act about 50,000 Protestant subjects were driven out of France to other countries. (See HUGUENOTS IN AMERICA.) In the reign of Louis XV. a new edict was issued repressive of Protestantism, but so many voices were raised in favor of toleration that it had to be revoked. The Code Napoléon and later enactments place Protestants in France on an equality with their Catholic compatriots.

Huguenots in America. The French Protestant settlements in the New World divide themselves into two classes: those of choice (or at least with time and opportunity to make choice) and those of necessity. The former extend from the middle of the 16th century down to the capture of New York by the English in 1664; the latter comprise all those dating from the increasing severity of repression that heralded the Dragonnades and the Revocation of the Edict of Nantes to the end. The former were deliberate organized colonizations, of the same stamp as the English and from the same motives; the latter were the desperate and generally hurried resource of crowds of ruined exiles. The former were complete failures, and were soon suppressed, absorbed, or exterminated; the latter sought only life and livelihood and welcomed absorption. The former include the abortive attempts in Brazil and Florida, the earliest settlements in Acadia and Canada, the first settlement of New York, and the settlement of some of the West Indies; the latter include the feeble attempts at settlements in New England, the flood of accessions to the French element in New York, the founding of New Rochelle, the migrations to Pennsylvania, Delaware, and Maryland, the promising but aborted attempt in Virginia and, greatest of all, the tide of immigrants that created South Carolina.

The first attempt at creating a New-World Huguenot asylum and magazine of supplies was undertaken in 1555: Nicholas Durand de Villegagnon (q.v.) pretended to undertake it for Coligny, and settled a colony in Rio Janeiro harbor. But it was half Catholics: Villegagnon was a scamp, persecuted and scattered the Protestants, and finally deserted the colony; and the Portuguese slaughtered it out in 1567. A more honest attempt was made by Jean de Ribault in 1562, at Port Royal, S. C., but failed. In 1564 René de Laudonnière founded a colony on the St. John's in Florida (q.v.), at Fort Caroline; but the next year Pedro Menendez de Avilés butchered the entire settlement. St. Bartholomew and the religious wars intervened; and no further efforts were made till after the accession of Henry of Navarre, who had imbibed the ardor for colonization from Coligny. In 1604, under his commission, Sieur de Monts planted a settlement to be on the basis of perfect religious equality, the first in the New World — at Port Royal, N. S.; French mercantile jealousy had the commission revoked, and it perished; but two years later it was refounded by Poutrincourt, and De Monts and Champlain founded Quebec. In 1613 Sir Samuel Argall (q.v.) destroyed Port Royal, but the French stayed and bands of Protestants came to reinforce them at intervals. A small settlement was made on Newfoundland, but was broken up by the government except for a few who would turn Catholics. The founding of New Amsterdam, usually supposed to be by the Dutch, was in fact by Huguenots under Dutch auspices. The Huguenots — largely French-speaking Walloons — who had crowded into the Netherlands to escape persecutions, had tried to gain permission to found settlements in the English colonies; rebuffed in this, they engaged with the Dutch, and the first shipload of emigrants that came to the future New York were entirely Huguenot, Peter Minuit himself being a Walloon. French families had been there already for years, the first white child born on Manhattan Island being French. For three generations the French element continued to be a highly important factor in the city, and composed much of the business aristocracy; even after the English occupation, all official documents were printed in both Dutch and French as well as English. Of the first shipload of emigrants, a number went up the Hudson and founded Fort Orange (Albany). In 1660 a number of Walloon and Vaudois exiles, who had taken refuge in the Lower Palatinate, settled near Kingston, N. Y.; later, the Vaudois founded New Paltz in the Wallkill Valley. In 1677 a French town was founded at Hackensack, but the fast-breeding Dutch soon swamped it. Small French groups settled in various parts of New Jersey.

Of the second class, the refugee emigration, too scattered and hurried in general to found separate French settlements, the first beginning from the north was at Boston. From 1660 on, small numbers had come from the Channel Islands and Rochelle, but after the Dragonnades 200 or 300 families came over, including some of the most notable names in Boston history. A settlement at Oxford, Mass., was made in 1687, primarily to convert the Nipmuck Indians, but that tribe joined hands with the Canadian tribes in league with the French, and inflicted such horrors on them — one whole summer besieging them in their blockhouse — that the settlement broke up in despair, many of them taking refuge in Milford, Conn. Many small groups settled in Rhode Island; the largest had a miserable history, being defrauded by a New England company organized expressly to sell to innocent foreigners a tract of land to which it had no title. In Connecticut Hartford and Milford received the greatest number. In New York the arrivals strengthened the French element, but soon melted into the general mass. In Pennsylvania, Delaware, and Maryland, many hundreds settled, but as scattered members of the population, and left no outward trace. In Virginia, whose southern climate was congenial to them, the Huguenots had settled in considerable numbers for many years, but in 1690 William III. sent over some 300 Huguenots who had followed him from Holland, and they made a settlement named Monacantown, from an extinct Indian tribe. In 1700, after long negotiations, four shiploads more came over under Marquis de La Muce; about half of them settled at Jamestown, Va., and in South and North Carolina, the rest at Monacantown. Several hundred more came over at different times, and the settlement seemed to have struck enduring roots; but furious religious dissensions broke it in two, and the pastor led part of them to the Trent in North Carolina, whence in fear of Indian massacre they finally went to South Carolina, the Canaan of the Huguenots, settling at Jamestown there. This South Carolina French immigration, due to the latitude and soil fitting their habits, began in 1670 in small numbers. In 1680 the city of Charleston was founded, largely under French auspices; the same year Charles II. sent over about 90 Huguenots to raise wine, oil, and silk. After the Revocation the great tide began to flow in; in 1687 there were four wholly or largely French settlements — Jamestown on the Santee, the "Orange Quarter" on the Cooper, St. John's Berkeley, and Charleston. In 1732 a band of 360 French-Swiss Protestants settled Purysburg on the Savannah; and in 1764 the last French colony was founded — New Bordeaux in Abbeville County. In the intervals there was a steady stream, very large for many years after 1685. Some of the greatest names in Southern history are French, and the entire character and action of the State have been deeply molded by this fiery, impulsive, gallant strain. It is pitiful to record that after all the sacrifice and courage of these exiles, religious persecution forced them to close their churches. All but members of the Church of England were disfranchised in 1706, and the Huguenots were bribed into submission by government support of the churches and having the liturgy translated into French.

The Huguenot settlements in the West Indies — St. Christopher, Martinique, Guadeloupe, and some smaller ones — belong in origin to the former group, that of voluntary colonization; their later history and the flight from them belongs to the latter. They were colonized by a trading company under Richelieu's patronage from 1626 on; there was nominal prohibition of public worship, but actually the law was a dead letter, as there would have been no trade but for the Huguenots; the Walloon Synod of Holland supplied ministers, and the life was one of prosperity and content. Then as the Revocation approached, atrocious penal laws were passed, but still not enforced. But the Revocation changed everything into a scene of misery. The first result was the using of the islands as a penal settlement for the Huguenots of France; the latter were sold into service, sometimes of the worst character, and the horrors of the passage rivaled the worst of the slave-trade. Then the governor-general was ordered to extirpate heresy at all hazard, and threatened a dragonnade if the inhabitants did not recant.

The effect was a general flight; next a stern order from the governor-general to stop or he would carry out the government orders in all their severity, which produced a still greater stampede, assisted by the Catholics themselves. In a few months the islands were half depopulated and their trade nearly ruined. The king then modified his orders; the flight ceased and a few returned; but most of the refugees remained in the English colonies or Bermuda. Several score at least removed to New York, and some of them founded New Rochelle; a few to New England, and the Southern colonies naturally received the largest quota. This immigration had an important effect on the United States trade with the West Indies, as the Huguenot merchants, from their familiarity with the region and their family ties, took the lead in and greatly developed it.

The "dead-line" of the French churches in America, the test of that element's separate existence, is about the middle of the 18th century; beyond that, according to Baird, few existed and fewer kept their language. French instinct was to blend, and of course it was much the best that it should do so. The element was absorbed soon and utterly, but its blood and its ideas have been very valuable to the United States. Consult Baird, 'History of the Huguenot Emigration to America' (1885).

Huichol (wē'chōl) **Indians.** See INDIANS, AMERICAN.

Hull, Edward, Irish geologist: b. Antrim 21 May 1829. As a member of the Geological Survey of Great Britain for 20 years, he geologically mapped a large portion of the central counties of England. In 1869 he became professor of geology at the Royal College of Science, Dublin; and in 1883 commanded an expedition under the auspices of the Palestine Exploration Society to Arabia Petræa and Palestine. Among his important works are: 'The Coal-Fields of Great Britain' (1865); 'Building and Ornamental Stones' (1872); 'A Text-Book of Physiography' (1888); 'Mount Seir, Sinai, and Southern Palestine' (1885); 'Volcanoes, Past and Present' (1892); 'Our Coal Resources at the Close of the 19th Century' (1897).

Hull, Isaac, American commodore: b. Derby, Conn., 9 March 1775; d. Philadelphia 13 Feb. 1843. He commenced his career in the merchant service, and was commissioned as lieutenant in the navy at the commencement of hostilities with France in 1798. In 1800 when first lieutenant of the Constitution, he cut out a French privateer from under a strong battery in the harbor of Port Platte, San Domingo. During the war with Tripoli (1802–5) Hull served with distinction in the squadrons of Commodores Preble and Barron, in command of the schooner Nautilus and brig Argus, participating in the several attacks on the city of Tripoli in July, August, and September 1804, and subsequently co-operating with Gen. Eaton in the capture of the city of Derne. In May 1804, he was promoted to the rank of master commandant, and in April 1806, to that of captain. At the opening of the War of 1812 between the United States and Great Britain he was in command of the frigate Constitution, and in July of that year, while cruising off New York, fell in with a British squadron, which chased the Constitution closely for nearly three days and nights. The wind was light and baffling, but Hull handled his vessel with superior seamanship, and finally escaped without injury; at one time he resorted to a novel and successful expedient; the boats were lowered, and all the spare rope on board was bent to a kedge anchor which was carried out nearly a mile ahead and let go. The ship was warped up to this kedge, which was weighed while another was carried out. In this way she left her pursuers before they discovered the manner in which it was done. After this remarkable escape, Hull went into Boston for a few days, whence he sailed 3 August, and 19 August met the English frigate Guerrière, which after a short conflict he reduced to a complete wreck, and forced the English to surrender. (See CONSTITUTION, THE.) As this was the first naval action of the war, it was regarded as a very important one; Capt. Hull was enthusiastically received, and Congress at its next session presented him with a gold medal. After the war his principal services were in command of the navy yards at Boston and Washington, of the squadrons in the Pacific and Mediterranean, and as a member of the board of navy commissioners.

Hull, William, American soldier: b. Derby, Conn., 24 June 1753; d. Newton, Mass., 29 Nov. 1825. He was graduated at Yale College in 1772, studied law at Litchfield, Conn., and was admitted to the bar in 1775. He entered the army of the Revolution at Cambridge in 1775 as captain of a Connecticut company of volunteers; was promoted to the rank of major in the 8th Massachusetts regiment in 1777, and to that of lieutenant-colonel in 1779. He was in the battles at White Plains, Trenton, Princeton, Stillwater, Saratoga, Monmouth, and Stony Point. His services throughout the war received the approbation of his superior officers, and neither his courage nor patriotism was ever doubted. He was governor of Michigan Territory from 1805 till 1812, when he was appointed as brigadier-general to the command of the northwestern army. He marched his troops to Detroit, heard of the declaration of war, and of the fall of Michilimackinac, which let loose the Indians of the Northwest upon him, crossed into Canada, but found his communications cut off, recrossed, and on the arrival of Gen. Brock surrendered to that officer the post of Detroit and the territory. For this he was tried two years after by a court-martial, and sentenced to be shot. The execution of the sentence was remitted by the President in consideration of his age and Revolutionary services. Historians are now agreed that the difficulties which surrounded Gen. Hull were so great that we need not ascribe his surrender either to treason or to cowardice. In 1824 he published a series of letters in defense of his conduct in this campaign which had a wide circulation. Consult 'Life,' by his daughter, Maria Campbell, and his grandson, James Freeman Clarke (1848).

Hull, Canada, town and county-seat of Ottawa County, Quebec, on the Ottawa River, at the junction of the Gatineau River, opposite the city of Ottawa, and on the Canadian Pacific railway. It is connected with its important neighbor by a fine suspension bridge spanning the Chaudière Falls. Iron mining is carried on in the neighborhood, and the Falls afford immense water-power. Lumbering is the chief industry of the district; and Hull has vast lumber yards, saw- and planing-mills, and manufactories of pulp, paper, matches, pails, woodenware, woolens, axes, etc. It has 5 churches, a college, a convent, many fine residences, and French and English newspapers. The population is chiefly French Canadian. The town has been rebuilt since its almost total destruction by fire, 26 April 1900. Pop. (1901) 13,993.

Hull, Kingston-upon-, England, a large river port, municipal and parliamentary borough, city and county of itself, situated in the East Riding of York, on the north shore of the estuary of the Humber, where it is joined by the Hull, 34 miles east-southeast of York. Its buildings of note are the town-hall, the exchange, the corn exchange, market-hall, post-office, the custom-house, Trinity House, dock offices, public rooms, royal institution (containing the rooms of the Philosophical Society, etc.), art gallery, technical schools, central library, Hymers College, grammar-school, the jail, royal infirmary, borough asylum, hospitals, crematorium, and dispensary. The town possesses three well-laid-out public parks. The industries are varied. There are several ship-building yards, iron-foundries, machine-shops, and steam flour-mills; the other principal branches of industry comprehend seed-crushing, color-making, paper-making, canvas, rope, and cable making, tobacco manufacturing, and oil boiling. Hull ranks as the third port in the kingdom, and has extensive ship accommodation, docks, quays, etc. The principal exports are machinery, coal, metal goods, and woolen and cotton goods, the total value in 1900 being £16,933,078 (besides £5,516,723 of foreign and colonial produce); imports — timber, corn, iron, wool, flax, hemp, tallow, hides, pitch, tar, rosin, bones, etc.; in 1900 £31,168,579. The name of Kingston-upon-Hull was given by Edward I., who erected a fortress, and constituted it a chartered town and port. When Edward III. invaded France in 1359 Hull contributed 16 ships and 470 mariners. During the civil war Hull was besieged unsuccessfully by the Royalists twice. Pop. (1901) 240,618.

Hul'lah, John Pyke, English musical composer: b. Worcester 27 June 1812; d. London 21 Feb. 1884. In 1833 he entered the Royal Academy of Music. His first important composition, an opera entitled 'The Village Coquettes,' of which the words were by Charles Dickens, was successfully produced at St. James' Theatre in 1836. Early in 1841 he opened classes in Exeter Hall for the instruction in vocal music of schoolmasters and the general public, and from 1849 to 1860 continued them in St. Martin's Hall, built for him by his friends and supporters. His classes were remarkably successful despite much adverse criticism of his method of teaching. In 1858 he succeeded Horsley as organist at the Charterhouse, and in 1872 received the appointment of musical inspector of training schools for the United Kingdom. He conducted the Philharmonic concerts at Edinburgh 1866–7, and those of the Royal Academy of Music 1870–3. He also held professorships in King's College, Queen's College, and Bedford College. Hullah's best-known compositions are songs, of which several, such as 'The Sands of Dee,' 'Three Fishers,' 'The Storm,' and 'O that We Two Were Maying,' have become very popular. He issued many excellent collections of songs and other musical pieces, among which are: 'Part Music,' in three series (1842–5); 'Vocal Scores' (1846 onward); 'School Songs' (1851); 'Sea Songs'; 'Singer's Library of Concerted Music' (1859); and 'Song Book' (1866). Dr. Hullah was the author of the following among other works on the history and theory of music: 'Grammar of Vocal Music' (1843); 'On Vocal Music' (1849); 'Grammar of Musical Harmony' (1852); 'The History of Modern Music' (1862); 'Grammar of Counterpoint' (1864); 'Music in the House' (1877). See the 'Life' by his wife (1886).

Hulme, Frederick Edward, English botanist: b. Hanley, Staffordshire, 1841. He has long been prominent as a writer upon natural history, art, heraldry, etc., and among his numerous works are: 'Plant Form' (1868); 'Familiar Wild Flowers' (7 vols. 1878–1902); 'Art Instruction in England' (1882); 'History, Principles and Practice of Symbolism in Art' (1891); 'History, Principles and Practice of Heraldry' (1892); 'Cryptography' (1898); 'History of the Flags of the World' (1897).

Humaita, oo-mä-ē'tä, Paraguay, town and fort; on the Paraguay River, near the mouth of the Paraná River; in the southwestern part of the republic. Its situation made its possession of importance during the war of the "Triple Alliance." It withstood a siege for a whole year, the attacking forces being Argentine and Brazil soldiers, but finally, in 1868, surrendered. At the close of the war, in 1870, the fortifications were destroyed. It is surrounded by a fertile agricultural country. There is but little local manufacturing, but there is an extensive trade in coffee, sugar, cotton, tobacco, hides, and live stock. Pop. 4,000.

Humane Association, American, a consolidation of various societies, formed at Cleveland, Ohio, in 1877, becoming a national organization for the prevention of cruelty to animals and children. The initial work of the society was to regulate the abuses in cattle-transportation by the railroads, and to secure the passage of State laws looking to this end. It offered a prize of $5,000 for the best model of a cattle car that would make possible the feeding, watering and resting of cattle in transit, and many improved cattle cars were brought into use. See Animals, Cruelty to; Children, Society for the Prevention of Cruelty to.

Humane Society, Royal, formed in London, in 1774, for the purpose of resuscitating those who had been immersed in water and were apparently drowned. At the present time it distributes rewards, consisting of medals, clasps, testimonials, and sums of money to those who save or attempt to save life from drowning. Also "all cases of exceptional bravery in rescuing or attempting to rescue persons from asphyxia in mines, wells, blast-furnaces, or in sewers where foul gas may endanger life, are recognizable by the society." It likewise gives prizes for swimming to the pupils of public schools and of training-ships.

Hu'manists, the name assumed at the revival of learning by those who looked upon the cultivation of classical literature as the most valuable instrument of education, in opposition to those who clung to the ancient methods of the Scholastics. In their modes of thought also the tendency of the humanists was to exalt paganism at the expense of Christianity. In the 18th century the name became a word of reproach for those who showed a blind zeal for the classics as the sole educational subject, opposing the Philanthropists, who asserted the value of mathematics, science, modern languages, and history.

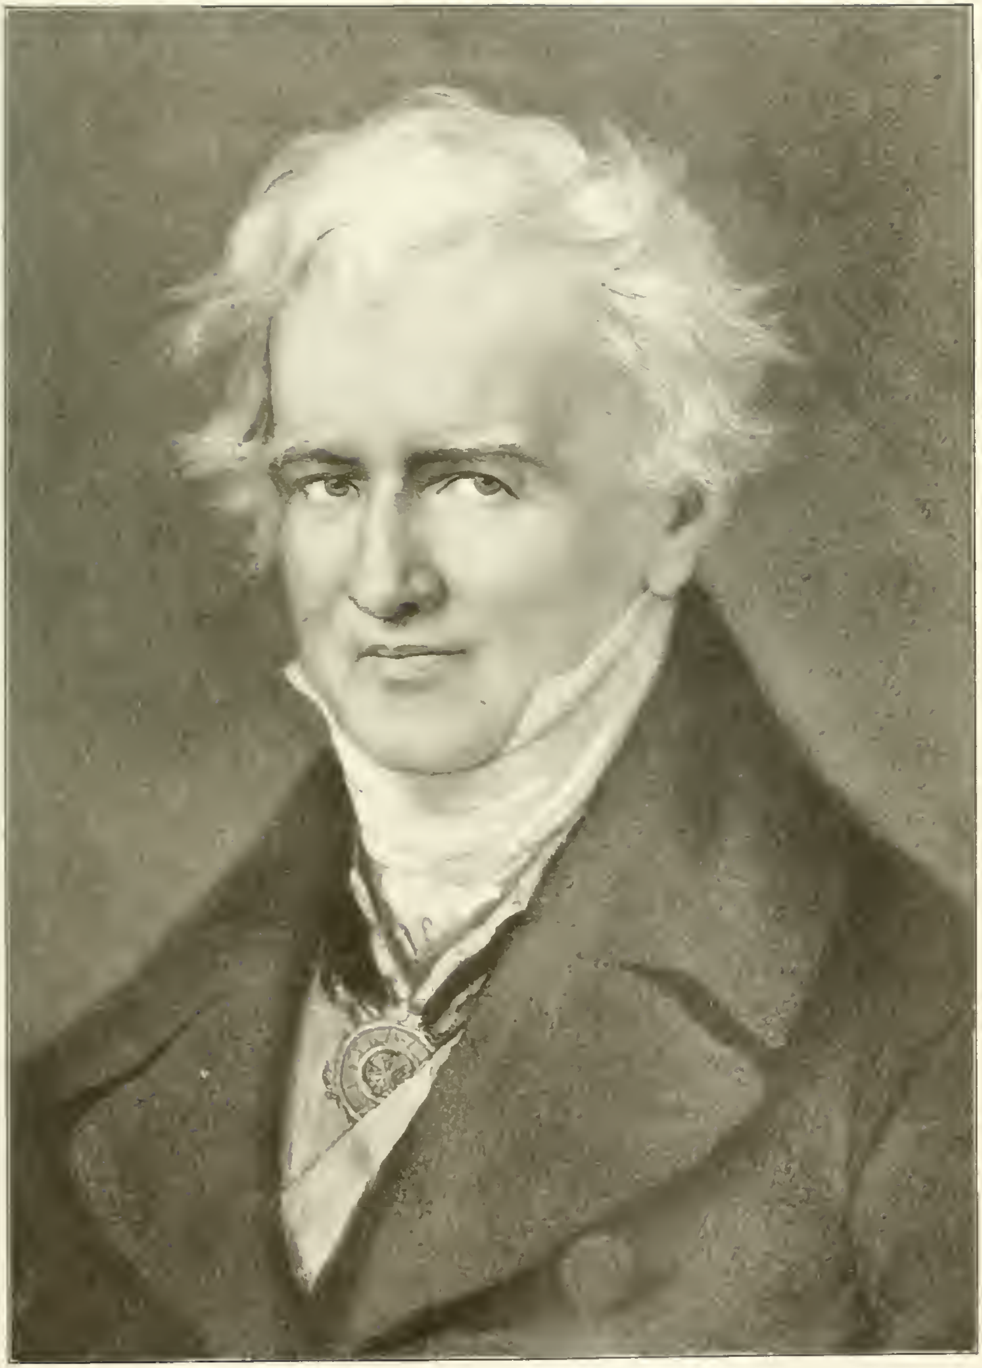
Humanita'rians, a term applied to the various classes of anti-Trinitarians, who regard Christ as a mere man. The earliest known author of the purely humanitarian theory is Theodotus of Byzantium, who lived in the second century. A contemporary of his, Artemon, taught the same doctrine, and asserted that such had been the universal belief of Christians up till the beginning of the 3d century. See UNITARIANISM.

Hum'bert I., RANIERI CARLO EMANUELE GIOVANNI MARIA FERDINANDO EUGENIO, king of Italy: b. Turin 14 March 1844; d. Monza, near Milan, 29 July 1900. He was eldest son of Victor Emmanuel II. and Queen Marie Adelaide, daughter of the Archduke Regnier of Austria. He took part as a youth in the war of independence, and in 1866 was in command of a division at Custozza. On 22 April 1868 he married his cousin, Princess Margherita of Savoy, daughter of the Duke of Genoa. On the death of his father he succeeded to the throne of Italy 9 Jan. 1878 as Humbert I. During his reign he carefully regarded constitutional limitations, and directing his choice of prime-ministers according to parliamentary conditions, selected but one, Rudini, from the Conservatives. In foreign policy he was evidently desirous of an active part in European affairs. In 1891 was concluded the "Triple Alliance" with Germany and Austria, a compact which necessitated the maintenance of a large army and navy, and the oppressive taxation of an already burdened country. Humbert also believed in colonial expansion, which he inaugurated by the occupying of Massowah, on the Red Sea. The Italian troops suffered reverses in 1887 and 1888, when they were defeated by the Mahdi, and 1 March 1896 when they lost the battle of Adowa to the Abyssinians. Humbert's attitude toward the Vatican was one of firmness, respecting all guarantees to the Pope, but insisting on the permanence of the Italian possession of Rome. His private munificence — it is said that he expended not less than $500,000 yearly in benefactions — and his personal interest and courage in the rescue work after the earthquake at Ischia (28 July 1883), and in visits to Busca and Naples during the cholera epidemic (1884), made him greatly respected by the Italians, to whom he was known as "Humbert the Good." He was thoroughly a soldier and eager in the interests of the army. Two unsuccessful attempts were made upon his life, one at Naples 17 Nov. 1878 by Passanante, a fanatic, and another near Rome 22 April 1897 by Acciarito, an anarchist. On 29 July 1900 he was shot and killed at Monza, near Milan, by the anarchist Bresci. See ITALY, *History.*

Humbert Swindle, The, one of the most daring and extensive frauds on record, perpetrated by a Mme. Humbert of Paris with the aid of various accomplices. It was alleged by Mme. Humbert that a certain Robert Henry Crawford, American millionaire, had left to her his fortune of $20,000,000. A subsequent will divided the estate between her younger sister, Marie Daurignac, and Henry and Robert Crawford, nephews of the testator, while a third document bound the heirs to the preservation of the title-deeds and securities, and placed these in the keeping of M. and Mme. Humbert until Marie should attain her majority. Without examination the alleged title-deeds and securities were deposited and sealed in a safe by the authorities. On this wholly fictitious basis Mme. Humbert netted about $10,000,000, while the amount of notes in the form of original loans and renewals equaled $140,000,000. The fraud was discovered, and the Humberts sentenced 22 Aug. 1902 to five years' imprisonment but were released 13 Sept. 1906.

Humble-bee. See BUMBLEBEE.

Humboldt, hŭm'bōlt (Ger. hoom'bōlt), **Friedrich Heinrich Alexander,** BARON VON, German traveler and naturalist: b. Berlin 14 Sept. 1769; d. there 6 May 1859. His father was chamberlain to the king of Prussia. He studied at the universities of Frankfort-on-the-Oder, Berlin, and Göttingen, and in 1790 traveled along the Rhine to Holland, France, and England. This journey gave rise to his 'Observations on the Basalt on the Rhine,' published in 1793. In 1791 he studied mining and botany at the mining school in Freiberg, where his acquirements, his attractive and instructive conversation, his wit, and goodness of heart gained him universal esteem and affection. In 1792 he was appointed assessor in the mining and smelting department, and soon afterward removed to Baireuth, as overseer of the mines in Franconia. Here he introduced many improvements, among which was the establishment of the mining school at Steben; he likewise made valuable galvanic experiments, the results of which were published in 1796, in two volumes. But in 1797 he gave up this office from a desire to travel. Owing to the disturbed state of the Continent, however, it was not easy for him to carry out his project. For some time he resided in various parts of Germany, particularly at Jena, where he became intimately acquainted with Goethe and Schiller. In 1797 he went, in company with his brother, Karl Wilhelm, a Prussian minister of state, to Paris, where he became acquainted with Aimé Bonpland, a pupil of the medical school and botanic garden in Paris. He then went to Madrid, and having obtained permission from the crown to travel through the Spanish colonies in America, immediately sent for his friend Bonpland, and sailed with him from Corunna. They landed at Teneriffe, where they ascended to the crater in Pico, in order to analyze the atmospheric air, and to make geological observations. In July they arrived at Cumana in South America. For five years they were occupied incessantly in traveling through tracts of the earth rich in all that could interest the scientific observer, and till then never scientifically described. They explored the regions of South America watered by the Orinoco and the upper part of the Rio Negro, fully tracing the connection between the Orinoco and the Amazon; then returned to the coast and sailed



FRIEDRICH HEINRICH ALEXANDER VON HUMBOLDT.

for Cuba, where they remained some months. Leaving Cuba in 1801, they returned to the South American continent, sailed up the Magdalena as far as they could, pursued their route by land to Popayan and Quito, and thence as far south as Lima, crossing the Andes no fewer than five times in the course of their journey, and, besides other mountain ascents, climbing Chimborazo (23 June 1802) to an elevation of 19,300 feet, being the highest point of the Andes then reached by man; from Lima they sailed to Guayaquil, and thence to Acapulco, Mexico (January 1803). Some months were spent in examining the city of Mexico and the surrounding country, and in a visit to the United States; and in January 1804, they set sail for Europe, taking Cuba again on their way. On 3 Aug. 1804, they arrived at Bordeaux, bringing with them, as the result of their labors, an immense mass of fresh knowledge in geography, geology, climatology, meteorology, botany, zoology, and every branch of natural science, as well as in ethnology and political statistics. Humboldt selected Paris as his residence, no other city offering so many aids to scientific study, or having so many distinguished savants, and remained there till March 1805, arranging his collections and manuscripts, and experimenting with Gay-Lussac, in the laboratory of the polytechnic school, on the chemical elements of the atmosphere. He was accompanied by Gay-Lussac, who exerted a lasting influence on his chemical studies, in a visit to Rome and Naples, and also by Von Buch on his return through Switzerland to Berlin, where, after an absence of nine years, he arrived in November 1805. As the condition of Germany made it impracticable to publish there his large scientific works, he was permitted by King Frederick William III., as one of the eight foreign members of the French Academy of Sciences, to remain in Paris, which was his residence, excepting brief periods of absence, from 1808 to 1827. There appeared his 'Voyage aux Régions équinoxiales du Nouveau Continent' (with Atlas, 1809–25; German edition, Stuttgart 1825–32; new edition, edited by Hauff, four vols., 1859–60). When in 1810 his elder brother resigned the direction of educational affairs in Prussia to become ambassador at Vienna, the former post was urged upon Humboldt by Hardenberg; but he declined it, preferring his independence. He had also already decided upon a second scientific expedition, through Upper India, the region of the Himalaya, and Tibet, in preparation for which he was diligently learning the Persian language. The political events between the Peace of Paris and the Congress of Aix-la-Chapelle gave him occasion for several excursions. He went to England in the suite of the King of Prussia in 1814; again in company with Arago, when his brother was appointed ambassador to London; and again in 1818 with Valenciennes from Paris to London, and from London to Aix-la-Chapelle, where the king and Hardenberg wished to have him near them during the congress. He also accompanied the king to the Congress of Verona, and thence to Rome and Naples; and in 1827, at the solicitation of the monarch, gave up his residence in Paris, and returned by way of London and Hamburg to Berlin, where in the following winter he delivered a series of public lectures on the cosmos. Under the patronage of the Czar Nicholas he undertook in 1829 an expedition to northern Asia, to explore the Ural and Altai Mountains, the Chinese Dsoungaria, and the Caspian Sea. In this expedition he was accompanied by Ehrenberg and Gustav Rose. Their course lay through Moscow, Kazan, and the ruins of Old Bulghari to Ekaterinburg, the gold mines of the Ural, the platinum mines of Nijni Taghilsk, Bogoslovsk, Verhoturye, and Tobolsk, to Barnaul, Schlangenberg, and Ustkamengorsk, in the Altai region, and thence to the Chinese frontier. From the snow-covered Altai Mountains the travelers turned toward the southern part of the Ural range, and traversed the great steppe of Ischim, passed through Petropavlovsk, Omsk, Miask, the salt lake of Ilmen, Zlatousk, Taganay, Orenburg, Uralsk (the principal seat of the Uralian Cossacks), Saratov Dubovka, Tzaritzin, and the Moravian settlement of Sarepta, to Astrakhan and the Caspian Sea. They visited the Kalmuck chief Sered Jaab, and returned by Voronesh, Tula, and Moscow. The entire journey of over 10,000 miles was made in nine months; its results are given in Rose's 'Mineralogischgeognostische Reise nach dem Ural, Altai und dem Kaspischen Meere' (1837–42); and Humboldt's 'Asie Centrale, Recherches sur les Chaines de Montagnes et la Climatologie comparée.' It extended the knowledge of telluric magnetism, since in consequence of it the Russian Imperial Academy established a series of magnetic and meteorological stations from St. Petersburg to Peking, which was followed, on Humboldt's application to the Duke of Sussex, by the establishment of similar stations in the southern hemisphere by the British government. The convulsions of 1830 gave a more political direction to Humboldt's activity for several years. On the news of the French revolution, and the accession of Louis Philippe, he was selected to convey to Paris the Prussian recognition of the new monarch, and to send political advices to Berlin. The latter office fell to him again in 1834–5, and he was called upon to fulfil it five times in the 12 following years, residing four or five months in Paris on each mission. To this period belongs the publication of his 'Examen critique de la Géographie du Nouveau Continent' (1835–8). He accompanied the king of Prussia in visits to Denmark, England, etc. (1841–5), and resided for several months in Paris in 1847–8, from which time he lived in Prussia, usually in Berlin, occupying a high position at the court until his death. His last great work, 'Cosmos' (1845–58), has been unanimously recognized as one of the most valuable contributions to science ever published. It explains the physical universe according to its dependencies and relations, grasps nature as a whole, moved and animated by internal forces, and by a comprehensive description shows the unity which prevails amid its variety. It has been translated into all languages in which a book of science is required, and has been without an equal in giving an impulse to natural studies. See Bruhns, 'Alexander von Humboldt, eine Wissenschaftliche Biographie' (Eng. trans., 1873); Klenke, 'Alexander von Humboldt, ein biographisches Denkmal' (1859).

Humboldt, Karl Wilhelm, Baron von, German statesman and philologist, brother of the preceding: b. Potsdam 22 June 1767; d. Tegel near Spandau, 8 April 1835. He studied law at Berlin, at Frankfort-on-the-Oder, and at Göttingen, and at the same time devoted equal attention to antiquities, æsthetics, and the philosophy of Kant. In 1789–90 he lived in Erfurt and Weimar, where a friendship commenced with Schiller, continued without interruption till the poet's death. A valuable memorial of his friendship with Schiller is the correspondence between them (Briefwechsel zwischen Schiller und Wilhelm von Humboldt, 1830). In 1801, at the request of the Prussian government, he accepted the situation of ministerial resident at Rome. From 1806–8 he was here minister plenipotentiary, but, having been called from Rome to fill the office of minister of the interior in connection with ecclestiastical and educational matters, had a most important share in the educational progress, which Prussia has since made: more especially is the erection of the Berlin University to be ascribed to him. He exchanged this situation in 1810 for that of extraordinary ambassador and minister plenipotentiary to Vienna. He took an active part during the armistice of 1813 in the peace congress at Prague: in 1814 at the Congress of Chatillon, and the conclusion of the first Paris peace: in 1815 at the Congress of Vienna; and in 1816 at Frankfort-on-the-Main, in all matters connected with the German diet. He was afterward appointed ambassador to London, and in 1818 attended the Congress of Aix-la-Chapelle. In 1819 he was an active member of the Prussian ministry, but sent in his resignation the same year, in favor of a freer and more constitutional system. His collected works (1841–52), include poems, essays on subjects of taste, and in particular numerous valuable disquisitions in regard to the origin and progress of language.

Humboldt, a river which has its rise in the northeastern part of the State of Nevada, flows west and southwest, a distance of about 350 miles into Humboldt Lake, in the eastern part of the State. The stream is narrow, the waters saline, and the whole course is through a barren region, destitute of large trees and but few shrubs, except a few clusters of willows. The fields are covered with sage brush. The only east and west pass through the mountains of Nevada is the valley of the Humboldt. The Central Pacific railroad, in its course through the State, follows this river. Humboldt Lake has no outlet; but the waters evaporate so rapidly that sometimes its bed is dry, but when the water is high it overflows the banks. A dam built a few years ago prevents the overflow from falling in Carson Sink.

Hume, David, Scottish historian and metaphysician: b. Edinburgh 27 April 1711; d. there 25 Aug. 1776. He appears to have entered the University of Edinburgh at 12, and to have left at 14 or 15 without taking a degree. He began the study of law, but abandoned it in order to devote himself to the 'pursuits of philosophy and learning." His first work, the 'Treatise of Human Nature,' was published partly in 1739 and partly in 1740; the books entitled 'Of the Understanding' and 'Of the Passions' appearing in the former, and that entitled 'Of Morals' in the latter year.

The 'Treatise of Human Nature' is the final and most complete exposition of the fundamental principles of the old school of empirical philosophy,— the school to which belonged Bacon, Locke, and Berkeley. According to Hume, the contents of the mind are embraced in the term 'perceptions.' Perceptions consist of sensuous impressions and ideas. Ideas are merely images of sensuous impressions. Knowledge is the cognition of the relation between two perceptions. There is no necessary connection between cause and effect. The idea of cause depends on the habit of the mind which expects the event that usually follows another. Mind is but a series or succession of isolated impressions and ideas. As knowledge is dependent on experience derived through the senses, and as the senses frequently deceive, one can have no absolute knowledge of things, but only of one's impression of them. Hence, to give the conclusion later arrived at in the famous 'Essay on Miracles,' a miracle even if genuine is incapable of proof.

The 'Treatise of Human Nature' is clear, forcible, and untechnical. Its most striking characteristics are its spontaneity and individuality. Hume owed little to academic training, and wrote his earlier works at a distance from centres of learning, without access to large libraries. The literary beauties of the 'Treatise,' however, are marred by its structural defects. It is a series of brilliant fragments rather than a well-rounded whole, and is concerned more with criticism of metaphysical opinions from the point of view of Hume's theory of knowledge than with the construction of a complete system of philosophy.

In 1741 appeared the first volume of the 'Essays, Moral and Political,' the second volume coming out in the following year. These, with some additions and omissions, were republished in 1748 under the expanded title, 'Essays, Moral, Political, and Literary,' which has been retained in the many subsequent editions. Hume's essays are models of their kind, full of sparkle, interest, and animation. Hume accompanied General Sinclair in 1746 and 1747 in his expedition against France and in a military embassy to Vienna and Turin. He now published a recasting of his 'Treatise upon Human Nature,' under the title 'An Inquiry Concerning the Human Understanding' (1747). In 1752 he published his 'Political Discourses,' which were well received, and his 'Inquiry Concerning the Principles of Morals.' The same year he obtained the appointment of librarian of the Advocates' Library at Edinburgh, and began to write his 'History of England,' of which the first volume appeared in 1754. It was, like most of the succeeding volumes, severely attacked both for its religious and political tendencies; but, in spite of adverse criticism, after its completion in 1761, was recognized as a standard work. Its merits are chiefly clearness and force of narrative and philosophical breadth of view in the judgment of men and events. In 1763 he accepted an invitation from the Earl of Hertford, then proceeding as ambassador to Paris, to accompany him, and was enthusiastically received by Parisian circles in his character of philosopher and historian. After the departure of Lord Hertford in 1756, he remained as *chargé d'affaires*, and returned to England in 1766, bringing with him Rousseau, for whom he procured a pension and a retreat in Derbyshire. But the morbid sensitivity of Rousseau brought about a disagreement which put an end to the friendship. In 1767 Hume was appointed under-secretary of state, a post which he held till 1769. As a philosopher, in which quality his reputation is perhaps greatest, Hume's acute skeptical intellect did great service by directing research to the precise character of the fundamental conceptions on which our knowledge and our beliefs are based. His acute negative criticism of these conceptions (for example, his reduction of the ideas of personal identity, conscience, causality, to mere effects of association) compelled philosophy either to come to a dead halt or to find, as Kant did, a new and profounder view of the nature of human reason. See Burton, 'Life and Correspondence of David Hume' (1840); Jodl, 'David Humes Lehre von der Erkenntnis' (1871); Gizyck, 'Die Ethik David Humes' (1878); Huxley, 'Hume' (1879); Knight (1886), and Hume, 'My Own Life.'

Hume, Fergus, English novelist: b. 24 July 1862. He was educated at the University of Otago, New Zealand, became a barrister, and in 1888 removed to London. His first long work, 'The Mystery of a Hansom Cab,' published in Melbourne (1887), and later in London, achieved a phenomenal circulation. Later publications are: 'The Piccadilly Puzzle' (1889); 'Miss Mephistopheles' (1890); 'A Creature of Night' (1891); 'An Island of Fantasy' (1894); 'The Bishop's Secret' (1900); 'The Turnpike House' (1902); 'The Mandarin's Fan' (1904).

Hume, Martin Andrew Sharp, English historian: b. London 8 Dec. 1847. He was educated in Madrid and was attached to the Turkish army 1878–9. He is editor of Spanish State Papers in the Public Record Office and examiner of Spanish in the University of London, and has published: 'Chronicle of Henry VIII.' (1889); 'Courtships of Queen Elizabeth' (1896); 'The Year after the Armada' (1896); 'Sir Walter Raleigh' (1897); 'Philip II. of Spain' (1897); 'The Great Lord Burghley' (1898); 'Spain: Its Greatness and Decay' (1898); 'Modern Spain' (1899); 'History of the Spanish People' (1901); 'Treason and Plot' (1901); 'The Love Affairs of Mary, Queen of Scots' (1903).

Humidity. See RAINFALL.

Hum'mel, Abraham H., American lawyer: b. Boston, Mass., 27 July 1849. He went to New York city in his youth, was educated in the public schools there and entered the law office of William F. Howe as an office boy. He early showed an unusual aptitude for the law, was admitted to the bar of New York in 1870, and subsequently was admitted to practice in the United States courts. In 1870 he founded the law firm of Howe & Hummel, of which he has been ever since a member, and has attained distinction as a divorce lawyer, in theatrical litigation, and important will contests. He represents nearly every important theatre in the United States, many prominent theatrical managers, and leading American and European actors. He is counsel in the United States for the Société des Auteurs Français — organized at Paris, France, for the purpose of protecting all foreign plays produced in the United States and elsewhere.

Hummel, hoom'mĕl, **Karl,** German landscape painter: b. Weimar 31 Aug. 1821. In 1841 he studied painting with Preller. His more idealistic pictures belong to the earlier part of his career, and his later work consists largely of German landscapes. Among his most noted works are: 'The Gardens of Armida' (1888); 'Keller Lake in Holstein' (1884); 'Wooded Landscape near Michaelstein' (1888).

Humming-birds, a family of small birds, the *Trochilidæ*, closely allied to the swifts, peculiar to America and almost exclusively tropical. They are distinguished by small size, iridescent plumage, long slender bill and the peculiar form of the tongue, which consists of a double tube tapering and separating at the tip into two externally lacerated sheaths, which contain the extensile portion. "The horns of the hyoid apparatus are greatly elongated, and pass round and over the back of the head, meeting near the top, and thence stretching in an ample groove to terminate in front of the eyes. This arrangement, analogous to that found in woodpeckers, allows the tongue to be suddenly protruded to a considerable distance, and withdrawn again in an instant." This is a modification of parts adapted to food-getting habits, and is accompanied by others equally characteristic. Humming-birds feed almost entirely upon minute living insects, especially those which gather about flowers and loiter in the corollas, feeding upon the nectar; or dwell on the leaves and bark of plants and trees. Such honey as may be taken with them seems to be gratefully accepted, but the birds do not seek for, nor "suck" the nectar from flowers, as has been popularly supposed. They will dart from a perch and capture an insect like a flycatcher, but ordinarily they obtain them by poising upon their wings about leaves and in front of tree-trunks, picking up morsels, not with the mandibles, but with the tongue; and still more frequently by searching flowers. As it is in the deep, tubular, sweet corollas of trumpet-creepers, orchids, and similar great blossoms of tropical shrubs and vines that insects most abound so there does the humming-bird find its richest hunting-ground; and the long curved beaks of most species have been developed in the constant effort to penetrate to the nectarous depths of these deep blossoms; in truth, the head and half the tiny body may often be pushed into the flower, and in so doing gather and dispense pollen from flower to flower, so that humming-birds are important if not exclusive agents in the cross-fertilization of certain large-flowered plants. This method of obtaining food requires the power of sustaining themselves in the air in a fixed position while they explore leaves or blossoms, since no perch is available for their feet, which are small and weak at best. Hence humming-birds have developed lightness of body coupled with extraordinary muscularity and extent of wings, which in most species reach far beyond the root of the tail. These long narrow wings are operated by pectoral muscles which proportionately exceed in size those of any other bird,— even those of the chimney-swifts; and these huge muscles actuate remarkable short wing-bones, so that extreme rapidity of movement is possible, but it is accompanied by a loss of that power secured by the relatively longer alar bones of other birds. By this apparatus the humming-birds are able to beat the air with a rapidity which enables them to stand still, or to dart and dodge in pursuit of some agile insect, or in escaping danger, with a speed which defies human sight to trace; the moving wings at such times, indeed, appear only as a misty halo about the body of the bird, and make a loud humming noise. Most species have very long bills — frequently exceeding, and sometimes twice as long as the head; but some have short, owl-like beaks, with which they pierce the base of such flowers as are too deep for them.

A characteristic of humming-birds is that flashing beauty of plumage which long ago led to calling them the gems of the air, and is due mainly to the quality of the feathers, upon the surface of which are small scales that reflect the light in prismatic hues, giving an iridescent or metallic sheen to certain parts, especially the throat (gorget), comparable only to the shards of some beetles. Such brilliance, however, belongs only to the males, the females being uniformly more plainly dressed, though still highly colored. In many species, also, the males are further adorned with fanciful crests, mustaches, tufts, pendants of the chin and throat, "puffs" upon the legs, and especially with ornamental developments of the tail-feathers; and these they seem to take great delight in displaying for the admiration of the female, and the exasperation of rivals. They are extremely pugnacious, especially in the nuptial season, when constant and bitter fighting occurs, and their courage is so great that neither sex has any hesitation in attacking any bird which offends them or comes too near the nest,— even hawks and crows often flee ignominiously before the impetuous onslaughts of these little furies. On the other hand no bird is more fearless of man and easily tamed.

The nests of humming-birds are small cups of downy materials, sometimes resting upon the limb of a tree (as is the method with the common ruby-throat of the eastern United States; sometimes fastened in a crotch of a bush or of large leaves; or fastened to the tip of a pendant leaf, or in a bunch of hanging moss or foliage. The materials are adapted to the place in color and appearance, and further concealment is gained by coating the structure with lichens, or bits of bark, or with cone-scales, as is the habit of the familiar Calliope hummer of California, which nests in pine trees. The eggs of all species are only two in number, and purely white.

The family is exclusively American, and is represented from Labrador and southern Alaska to Patagonia; but the more vagrant species are few, and withdraw in winter toward the equator. About 125 genera with some 500 species, are recognized by ornithologists. Nine tenths of them belong to the Amazon and Orinoco valleys, or to the lowlands of Central America; yet some species habitually spend the summer on high mountains. The variety decreases northward, but nearly 20 species reach the boundary of the United States, and several are regularly present in summer west of the great plains, as far north as southern Alaska. One species wanders over the whole country, and is abundant in the Eastern States. This is the ruby-throat (*Trochilus colubris*). It is about 3½ inches long. The whole upper part, sides under the wings, tail coverts, and two middle feathers of the tail, are rich golden green; the tail is forked, and, as well as the wings, of a deep brownish purple; the bill and eyes black; but what constitutes their chief ornament is the splendor of the feathers on the throat of the male, which are ruby-red, and gleam like a great jewel. The females and immature young lack this gorget.

I and II (Edinburgh 1833); Lesson, 'Histoire Naturelle des Colubris' (1830); Gould, 'Monograph of the Trochilidæ' (5 vols. 1850–9); Mulsant and Verreaux, 'Histoire Naturelle des Oiseaux-Mouches ou Colubris' (4 vols. 1876); Ridgway, 'The Humming-birds' (Am. Rept. U. S. National Museum for 1890 (Washington 1892).

Ernest Ingersoll.

Hu'mor, a fluid of the living body, of which Hippocrates enumerated four, namely, blood, phlegm, yellow bile, and black bile. These were considered to be the principal seats of disease in man. In modern medicine humor is a term generally applied to the thinner fluids, whether natural or morbid, limpid, serous or sanious, such as the humors of the eye or the watery matter in a blister of the skin caused by heat, etc.

Hump'back Salmon, Whitefish, etc., several kinds of fishes are said to be "humpbacked" because of an unusually raised dorsal outline. The humpback salmon of the Pacific coast is a commonly known, but little valued species (*Oncorhynchus gorbuscha*), whose flesh is styled in market "pink" salmon. (See Salmon.) The common whitefish (q.v.) is known locally as humpback or bowback; and the curious razor-backed sucker (*Xyrauchen cypho*), is locally called the humpback.

Humpback Whale, one of the baleen whales or rorquals (q.v.) of the genus *Megaptera*, characterized by a low hump in place of the inconspicuous dorsal fin and a tuberculous head. The genus is world-wide, and an undetermined number of species exist, of which the best known is the northern *M. longimanus*, the specific name referring to the elongated pectoral fin, with which the animal beats the water, itself and often its playmates. These whales reach 50 or 60 feet in length, and go about in small schools. See Whale.

Humped Cattle. See Indian Humped Cattle.

Humperdinck, Engelbert, ĕng'ĕl bĕrt hoom'pĕr-dink, German composer: b. Siegburg, near Bonn, 1 Sept. 1854; after studying music at Cologne and elsewhere he taught in the conservatoriums of Barcelona and Cologne, and was musical adviser to a publishing firm in Mainz. Wagner asked him to assist in the production of the latter's only symphony; and he prepared and coached the first cast of 'Parsifal' at Baireuth (1882). He subsequently became famous as the author of the phenomenally successful children's musical fairy play, 'Hänsel und Gretel' (1894); followed by 'Schneewittchen' (The Snow Maiden) and 'The Royal Children.'

HUMMINGBIRDS

1. Double-crested (T. cornutus). 2. Ruby-throat (Trochilus colubris). 3. White-collared (T. melivorus) 4. Tufted-neck (T. ornatus). 5. Delande's (T. delandii). 6. Cora's (T. cora). 7. Golden-green (T. prasina). 8. Vieillot's (T. chalybeus). 9. Evening (T. vesper). 10. Avocet-billed (T. avocetta). 11. Curve-bill (T. curvirostris). 12. Harlequin (T. multicolor). 13. Natterer's (T. scutatus).

Humphrey, hŭm'frĭ, **Charles Frederick,** American soldier: b. New York. He served in the 5th artillery in the Civil War, became 1st lieutenant of the 4th artillery in 1868, was transferred to the quartermaster's department in 1879 as assistant-quartermaster with captain's rank, and in 1897 attained the post of deputy quartermaster-general with grade of lieutenant-colonel. In 1898 he entered the volunteer service, participated in the Cuban expedition, and was promoted brigadier-general of volunteers. In 1899–1900 he was chief-quartermaster of the division of Cuba, in 1900 of the United States China relief expedition. In 1903 he was appointed quartermaster-general, United States army, with rank of brigadier-general.

Humphrey, Heman, American Congregational clergyman and college president: b. West Simsbury, Conn., 26 March 1779; d. Pittsfield, Mass., 3 April 1861. He was graduated from Yale in 1805, was pastor of the Congregational church at Fairfield, Conn., 1807–17, and of that at Pittsfield, Mass., 1817–23 while from 1823 to 1845 he was president of Amherst College. He published several works, including a popular 'Tour in France, Great Britain, and Belgium,' but is best known by a famous pamphlet called 'Parallel Between Intemperance and the Slave Trade.' See Tyler, 'History of Amherst College.'

Humphreys, hŭm'frĭz. **Alexander Combie,** American engineer: b. Edinburgh, Scotland, 1851. He entered business in New York in 1866; in 1877–81 studied at Stevens Institute of Technology (Hoboken, N. J.). He then held various posts first in a lighting, and then in a gas improvement, company, in 1892 became connected with a gas company of London, and in 1894 established a branch business in New York. During this time he did much to improve the manufacture of commercial water-gas. In 1902 he was elected president of Stevens Institute.

Humphreys, Andrew Atkinson, American soldier: b. Philadelphia, Pa., 2 Nov. 1810; d. Washington, D. C., 27 Dec. 1883. He was graduated at West Point 1831, receiving a commission in the artillery. Resigning in 1836 he was associated with Major Hartman Bache as a civil engineer in government work. He re-entered the army in 1838, and was engaged in several government surveys. In the Civil War he was topographical engineer to the Army of the Potomac. In 1862 he was made brigadier-general and commanded the Fifth corps of the Army of the Potomac at the battles of Fredericksburg and Chancellorsville. He commanded a division in the battle of Gettysburg and earned promotion to a major-generalship in the volunteer forces. He commanded the Second corps of the Army of the Potomac in the campaign which closed with Lee's surrender. After his services at Sailor's Creek, he was brevetted major-general in the regular army and was subsequently placed in command of the engineer corps with the regular rank of brigadier-general. He has written: 'The Virginia Campaigns of 1864 and 1865' (1882); 'From Gettysbury to the Rapidan' (1882).

Humphreys, David, American poet: b. Derby, Conn., 1753; d. New Haven 21 Feb. 1818. He was educated at Yale, entered the army at the beginning of the Revolutionary War, and in 1780 became a colonel and aide-de-camp to Gen. Washington. In 1784 he accompanied Jefferson to Europe as secretary of legation, in 1786 was elected to the legislature of Connecticut, and was soon associated with the "Hartford Wits," Hopkins, Trumbull, and Barlow, in the composition of the 'Anarchiad,' being thus one of "the four bards with Scripture names" satirized in London. He was minister to Lisbon 1791–7, minister plenipotentiary to Spain in 1797–1802, and on his return imported from Spain 100 merino sheep, the first introduced into the United States, and engaged in the manufacture of woolens. He held command of the Connecticut militia in the War of 1812. His principal poems are: an 'Address to the Armies of the United States' (1772); 'On the Happiness of America'; a tragedy, entitled the 'Widow of Malabar,' translated from the French of Le Mierre; and 'On Agriculture.' His 'Miscellaneous Works' (1790 and 1804) contain beside his poems 'An Essay upon the Life of Gen. Israel Putnam,' and several orations and other prose compositions.

Humphreys, Frank Landon, American Protestant Episcopal clergyman: b. Auburn, N. Y., 16 June 1868. He was educated at Columbia and Oxford universities. He was precentor and minister in charge of the Cathedral of the Incarnation, Garden City, L. I., 1885–90, and is now canon in the Cathedral of St. John the Divine, New York. Among his writings are: 'The Evolution of Church Music' (1896); 'The Mystery of the Passion' (1898); 'Men of Understanding' (1897); 'Christmas Carols and Caroling' (1900); and 'Clerical Education' (1896).

Humphreys, Joshua, American shipbuilder: b. 1751; d. 1838. He was the first builder of war vessels for the American colonists, and is therefore often called the "father of the American navy." Among the ships constructed by him were the Chesapeake, Congress, United States, Constellation, and the famous Constitution.

Hundred Years' War, the name given to the prolonged struggle between France and England which began in 1337 and ended in 1453. Among the chief of the immediate causes of the war was Edward III.'s claim to the French throne, but the keen rivalry of the two nations rendered conflict inevitable. It lasted during the reigns of five English kings, from Edward III. to Henry VI., and of five French kings, from Philip VI. to Charles VII., ending in the expulsion of the English from France.

Hu'neker, James Gibbons, American musical and dramatic critic: b. Philadelphia 31 Jan. 1859. In Paris he was a pupil of Barili, Ritter, and Dontreleau, and subsequently became an instructor in piano at the National Conservatory of New York. He was musical and dramatic critic of the New York *Recorder* in 1891–5, and of the *Morning Advertiser* in 1895–7. Subsequently he was musical editor, and from 1902 dramatic editor of the New York *Sun*. Among his writings are 'Mezzotints in Modern Music,' essays (1899); 'Chopin, as Man and Musician' (1900), an interesting study; and 'Melomaniacs' (1902), clever but often extravagant stories satirizing the musical profession.

Hungarian Language and Literature. See HUNGARY.

Hungary (Hungarian, Magyar-Ország, «Land of the Magyars»), a kingdom in the southeast of Europe, forming with Austria (q.v.), the Austro-Hungarian monarchy. It includes, in its widest acceptation, Hungary proper, Transylvania on the east, Slavonia and Austrian Croatia on the southwest, extending in this direction so far as to comprise a strip of coast on the Adriatic Sea, together with the former military frontiers, a long strip of territory on the southern borders. Total area, 125,039 square miles, with a population (1900) of 19,254,599. The capital is Budapest. In a more restricted sense Hungary proper is limited to the territory encircled from the east round the north to the northwest by the Carpathian Mountains; bounded west by the river March and some offsets of the Noric Alps; southwest by the Drave; south and southeast by the Danube and the Transylvanian Alps (a continuation of the Carpathian range); with an area of 109,007 square miles, and a population (1900) of 16,721,574. Hungary proper may be considered as a large basin surrounded by mountains on every side except the south; but even there the natural boundaries of this geographical basin are completed at no great distance from the frontier by the highlands of Croatia, Bosnia, and Servia, that meet those of Wallachia and Transylvania at the «Iron Gate», a pass formed by the abrupt divisions of the mountains on either side of the Danube, which there forms a celebrated rapid. From that point the Carpathians proceed by various ranges at first east, but afterward successively northwest and southwest. Several of their summits rise to between 8,000 and 9,000 feet above the sea. The Carpathians are richly wooded in many parts, and their branches are interspersed with numerous romantic and fertile valleys. On the west the Leitha Mountains, a spur of the Alps separating Hungary from Styria and Austria, progressively decline toward the Danube. The Bakonywald (Bakony Forest), another Alpine spur, upward of 2,000 feet in height, and clothed with dense forests of oak, beech, and other trees, intersects the southwest region of Hungary in a northeast direction to near Waitzen, where the Danube bends south, and with the Matra Mountains, beyond that river, divides Central Hungary into a greater and a smaller plain, respectively about 21,000 and 4,000 square miles in extent. The Danube and Theiss rivers traverse the south half of the country in parallel streams about 60 miles apart, the former previously flowing from the west, and the latter from the east or northeast to near the latitude of the capital. Near Eszek, in Slavonia, the Danube, met by the Drave, turns suddenly again to the east, and forms all the rest of the south frontier of Hungary, receiving in this part of its course the Theiss and several minor affluents. The March, Waag, Neutra, Gran, and Ipoli, in Upper Hungary, flow to the Danube from the north; the Bodrog, Schajo, Hernad, and Zagyva, flowing from the same direction, unite with the Thesis; and the Szamos, Körös, Maros, etc., join that river from the east. The Poprad, in the north, flows into Galicia, and is tributary to the Vistula, it being the only Hungarian river not belonging to the basin of the Danube. The Drave forms the southwest frontier on the side of Croatia and Slavonia, and is joined in Hungary by the Mur from Styria. Excepting these two, the Raab, which joins the Danube near the town of its name, is the only river of much magnitude in the southwest quarter of the country; but in that division of Hungary are its two principal lakes, on either side of the Bakonywald—Balaton, in the great plain, and the Neusiedler-See (Hungarian, *Fertö Tava*), close to the border of Austria. In the Carpathians are several smaller lakes, between 4,000 and 5,000 feet above the sea. In the lower courses of the Danube and Theiss are extensive marshes and swamps, especially along the Theiss. The total area of the morasses in Hungary has been estimated at 1,500,000 acres, or upward of 2,300 square miles; within the 19th century enough marsh-land was drained to furnish subsistence for 500,000 inhabitants. Mineral springs are numerous; the most celebrated are those which form the baths of Mahadia in the Banat. Among the minerals are gold, silver, copper, iron, lead, zinc, cobalt, antimony, sulphur, arsenic, salt, soda, saltpeter, alum, vitriol, marble, coals, peat; among the precious stones the opal and chalcedony are remarkably beautiful.

Hungary, including Transylvania, used to yield nearly a half of all the gold annually obtained in Europe. Its principal localities are Kremnitz, Chemnitz, and other places in the north, and Nagy Banya on the Transylvanian frontiers. Silver is found in independent localities, though more frequently in connection with the gold. They are sometimes found pure, but generally in combination with copper. Mining is not yet carried on to a great extent; but the production of coal and iron is rapidly increasing. Hungary is one of the healthiest countries in Europe. Owing to the variety of its surface it possesses a great diversity of climate, which, combined with the fertility of the soil, abundantly supplies her with natural productions.

The Hungarian has a natural inclination to agriculture and the breeding of cattle. Both are however, still in a backward state, though making rapid advances. But the inexhaustible fertility of nature supplies every deficiency of industry and skill, and Hungary is now one of the chief corn-growing countries of Europe, much wheat and flour being exported. Hungarian wheat is well known for its excellent quality. All kinds of grain, a species of maize, rice, kitchen vegetables, and garden plants of every description, melons (which are cultivated in open fields), Turkish pepper, fruits (particularly plums, for the sake of the brandy prepared from them, called *Slivovitza*), wines of different kinds, wood, gall-nuts, potash, tobacco, hemp, flax, hops, saffron, woad, madder, sumach, cotton, and rhubarb are among the products of Hungary.

Many improvements are made by individual proprietors, and Hungary has a large number of technical institutes in which students are thoroughly trained in agriculture. Next to France, Hungary is the chief wine-producing country of Europe, both as regards the quantity and the variety of the product. The annual produce of Hungary and the connected territories is estimated at between 26,000,000 and 27,000,000 eimers, of about 15 gallons each. The finest variety is the Tokay, which is produced in the Hegyallya, in the county of Zemplin.

Horses, cattle, sheep, hogs, game (in the north bears), poultry, fish (among which the sturgeon and salmon, *Salmo dantex,* are the principal), bees, and silkworms are among the productions of the animal kingdom.

The principal artisans are tanners, furriers, manufacturers of *tschism* (cordovan boots), lace-makers, harness-makers, makers of wooden wares, of straw-plait work, etc. There are few extensive manufactures in Hungary. There are numerous iron and steel works, some iron-foundries, tin-plate and wire works; also potteries, glass manufactories, sugar-refineries and beet-root sugar works, soap-works, tallow, stearine, and wax-candle works; soda, saltpeter, and potash works, and brandy distilleries. Trade is almost exclusively in the hands of the Germans, Greeks and Jews. Internal commerce is promoted by the railways and rivers, the Temes and Francis canals (the former 75, the latter 60½ miles long), the fairs (which amount to 2,000), and the complete absence of tolls. The railways in 1901 had a total length of 10,794 miles, 4,876 miles being state lines; 3,439 worked by the state, and the rest private commercial lines. The total length of navigable rivers and canals in the monarchy is over 3,000 miles. The Danube is the most important highway of traffic, but the foreign trade by it is comparatively small. Inland navigation and roads are given careful attention.

The great number of distinct races with entirely different habits which is found in Hungary is remarkable. According to the census of 1900 on the basis of language, the races inhabiting Hungary including Croatia and Slavonia were divided as follows:

Magyars	8,679,014
Rumanians	2,785,265
Germans	2,114,423
Slovaks	2,008,744
Croatians	1,667,377
Servians	1,045,550
Ruthenians	427,825
Various	526,401
	19,254,599

The Magyars, who are the dominant race, are located for the most part in the centre of the kingdom. They are high-spirited, brave, warlike and generous, and, according to travelers, more sincere than their Servian and Wallachian neighbors; impatience of control, pride, indolence, and ignorance are their besetting faults. Their general deportment is serious; and in many respects they resemble the Turks, who followed them out of Asia, and belong to the same great family of mankind. The Magyar costume is remarkable for its picturesque elegance. Most of the Hungarian nobles are Magyars; and it is by this section of the population that the constitutional form of government and municipal institutions have been mainly, if not wholly, upheld. The Slovaks are among the people apparently the earliest settled in Hungary; they inhabit the northwest, and are similar in race, customs, and language to the adjacent Moravians, to whose extensive empire they belonged before the Magyar conquest. The Ruthenians or Rusniaks dwell beneath the north and northeastern Carpathians. The Rumanians (Wallachians) occupy a tolerably wide tract of country on both sides of the west and north boundaries of Transylvania. They are far behind the Slovaks, and, indeed, nearly all the other nations of Hungary, in education and civilization. They appear to be the descendants of Italian colonists, placed in Dacia during the Roman dominion there, and have been accordingly called Daco-Romans — an epithet to which their classic features, easy manners, language, and antique costume seem to give them a claim. They call themselves *Romouni;* and speak a dialect of Latin, but they write it with the Cyrillian or Russian character. In this last particular they unite with their Servian neighbors inhabiting the Banat on their southwest. The Croats people nearly all Slavonia and Croatia, and stretch into seven of the counties of Hungary proper as far as the county of Pesth. The Wends (Vandals) inhabit two counties of Hungary proper as far as the county Theresianopel, and a few other parts of the Banat; the Montenegrins a part of the county Temes; and the Armenians portions of three of the eastern counties. The Germans appear, in the first instance, to have emigrated into the country during or before the 7th century, subsequently to which many successive immigrations took place, especially under Geysa, king of Hungary, who ascended the throne 1141 A.D. and who established large numbers of German colonists from Franconia, Thuringia, and Alsace in several of the northern counties, and in Transylvania. They speedily became dispersed in detached settlements over all Hungary; and early in the 13th century Pesth was described as a «large and rich German town.» In the 18th century other Teutonic immigrants, with some French refugees, settled in the kingdom. The Germans are marked by their industry and thrifty condition, but also, it is said, by their litigious and avaricious propensities. They people the greater part of the western frontier, from Presburg and around the shores of Lake Neusiedler south nearly to the limit of Croatia; elsewhere they are most numerous in the county of Zips, the mining districts, the Banat, and especially in the towns, where they compose the bulk of the trading population.

With regard to popular education, attendance in elementary schools is compulsory from the completion of the sixth year (in Croatia and Slavonia the seventh) till the completion of the twelfth, and also in continuation-schools up to the age of 15. Every parish or commune is also bound to maintain an infant school. The great bulk of the schools are supported by the denominations. Besides gymnasiums and real-schools there are numerous technical schools for arts and industries of all kinds. There are universities at Budapest, Klausenburg, and Agram, attended by over 6,000 students. Over two thirds of the periodicals issued are in the Magyar language. The various religious bodies have long enjoyed equal rights in Hungary and Transylvania.

The civil population according to religion, on the basis of the census of 1900, comprised Roman Catholics 9,846,533, over 51 per cent; Greek Catholics 1,843,634; Greek Oriental 2,799,846; Evangelical Augsburg, 1,280,070; Evangelical Helvetian 2,423,818; Unitarians 68,005; Jews, 846,254; others 14,180.

The Roman Catholic clergy are powerful by reason of their large landed property, and the influence they possess over the appointments to many offices. There are three Roman Catholic archbishops and 17 suffragan bishops, with a Greek (United) Catholic archbishop and five suffragan bishops. Among the Protestants, laymen and clergymen united manage the affairs of the different congregations under the direction of superintendents. Lutherans and Calvinists have each four superintendents in Hungary and one in Transylvania.

A sketch of the Hungarian constitution has already been given in the article AUSTRIA. Hungary is divided into counties and districts, according to a very old division of the country. These have the right to administer their own internal affairs. At the head of each is an *Obergespann* (or lord-lieutenant) and two *Vice gespanne*. There are three county courts in civil cases, according to the importance of the subject in question, consisting either of a judge with a jury, or of the vice-officer of the county with a judge and jury, or of the supreme tribunal of the county (*Sedes Judicaria, Sedria*), which also revises the decisions of the two other courts and of the seignorial courts. The courts of appellate jurisdiction are the Royal Table (which, however, in several cases has original jurisdiction) and the Table of the Seven. The former sits in Budapest and the latter in Agram. They are both comprised under the name of *Curia Regia,* the sentences of which have the force of law in case there is no positive law.

History.— The nations which occupied parts of Hungary before its conquest by the Magyars were the Dacians, Bastarnæ, Illyrians, Pannonians, Sarmatians, Vandals, Bulgarians, Jazyges, Alans, Huns, Marcomanni, Longobards, etc. The Romans held the southwest part of the country under the name of Pannonia, while the southeast belonged to their province of Dacia. Various Slavic tribes, together with Wallachians, Bulgarians, and Germans, were the chief occupants at the time of the Magyar invasion. The Magyars, a warlike people of Turanian race, had made various migrations, and long dwelt in the vicinity of the Caucasian Mountains, and afterward in the region between the Don and the Dniester, before they approached and crossed the Carpathians (about 887) under the lead of Almos, one of their seven chiefs (*vezér*), and elected head (*fejedelem*) or duke. Arpád, the son of Almos, conquered the whole of Hungary and Transylvania, organized the government, and also made various expeditions beyond the limits of these countries. These incursions were extended under his son Zoltán (907–46) and grandson Taksony (946–72), as far as the German Ocean, the south of France and Italy, and the Black Sea. These formidable enemies were first defeated by Henry I., the German emperor, at Merseburg in 933; they then invaded Franconia in 937, and Saxony in 938, were defeated at Stederburg, and also on the river Ohre. Their last incursion into Bavaria (954 and 955) terminated with their complete overthrow on the Lech, where Otho I., king of the Germans, conquered them. They gradually learned from the Slavonians and Germans whom they conquered, and from the prisoners whom they had taken in their incursions, the arts of peace, agriculture, and manufactures. The hospitality of Geysa (972–97), and the religious zeal of Sarolta his wife, did much to attract strangers from different countries and of all classes into Hungary. The Hungarians violently opposed the introduction of Christianity, and Geysa was obliged to leave the extension of it to his son Stephen (997–1038), who finally prevailed by the assistance of Latin monks and German knights. King Stephen granted a constitution, the principal features of which were never lost, but the unsettled state of the succession to the crown, and the consequent interference of neighboring princes and of the Roman court in the domestic concerns of Hungary, long retarded the prosperity of the country. The religious zeal and bravery of St. Ladislaus (1077–95),) and the energy and prudence of Coloman (1095–1114), shine amid the darkness of this period.

The introduction of German colonists from Flanders and Alsace into Zips and Transylvania by Geysa II. (1141–61) had an important influence on those districts. In 1186 Hungary became connected with France by the second marriage of Béla with Margaret, sister to Henry, king of France, and widow of Henry, king of England, who introduced French elegance at the Hungarian court. The reforms of Béla IV. (1235–70) were interrupted by the invasions of the Mongols (1241), and the kingdom was in a most deplorable condition. With Andrew III. (1290–1301) the male line of the Arpád dynasty became extinct, and the royal dignity became purely elective. Charles Robert of Anjou, by his mother a descendant of the extinct dynasty, was the first elected (1309). The reign of his descendant Sigismund (1387–1437) is interesting from the invasion by the Turks (1391) and the war with the Hussites. From their first appearance the Turks constantly disturbed the tranquillity of Hungary, which served as a bulwark to the rest of Europe. The death of Ladislaus I., in the unfortunate battle of Varna (1444) is to be regretted, as the plan of the hero John Huniades, for driving the Turks from Europe, failed through the coldness of the Christian courts and the intrigues of his enemies.

Matthias Corvinus (1458–90), son of Huniades, held the reins of government with a firm hand, and gained the love and confidence of the nation, notwithstanding the severe measures which he was often compelled to adopt.

During the reigns of Ladislaus II. (1490–1516) and Louis II. (1516–26) the ambition and rapacity of the optimates, headed by Stephen Zapolya, and afterward by his son John, excited domestic troubles and caused an insurrection of the peasants, which was only suppressed by the severest measures (1514), while they destroyed the foreign influence of the kingdom. The battle of Mohács (1526), in which Louis II. lost his life, and which for 160 years made a great part of Hungary a Turkish province, was the natural consequence of this state of things. The rest of the country was in dispute between the rivals Ferdinand of Austria and John Zapolya. The contest was decided by the Protestants, who, fearing the persecution of Zapolya, declared for Ferdinand. Their adherence gave him the superiority, and Zapolya was compelled to rest satisfied with the possession of Transylvania and some counties of Upper Hungary; but this division of the kingdom caused continual disputes with the descendants of Zapolya, instigated by the Turks and the French, gave rise to civil commotions, which were quieted by the treaties of Vienna with Stephen Botskay (1606), of Nikelsburg with Gabriel Bethlen (1622), and of Lintz with George Rakoczy (1645). These circumstances delayed the expulsion of the Turks, in which Leopold I. finally succeeded so far that he took Buda (1686), and by the Peace of Carlowitz (1699) recovered the rest of Hungary (except the Banat) and Transylvania.

The Congress of Passarowitz (1718) restored the Banat to Hungary, and the Peace of Belgrade (1739) terminated hostilities with the Porte for a long time. Charles VI. (1711–40) by the pragmatic sanction secured the inheritance of the Hungarian crown to the female descendants of the house of Hapsburg, and improved the administration of the kingdom by giving the royal chancery and the vice-regal office an organization better suited to the age. He also formed a standing army for Hungary, and established the military contribution for its support. Joseph II. (1780–90), one of the greatest sovereigns of his age, was influenced by the best intentions in the changes which he undertook in the Hungarian constitution; but his zeal made him forget the necessity of proceeding gradually in such reforms, and the nation, far from entering into his views, opposed them.

The subsequent history of Hungary — the adoption of the Magyar language in its diet; the resistance against the encroachments of Austria; the heroic struggles for independence, and the noble work of Batthyani, Deak, Kossuth, and Klauzal, along these lines; the disastrous war of 1848 and the reduction of Hungary to the position of an Austrian crown-land; its rehabilitation to independence in 1867 and the constitution of the dual Austro-Hungarian Empire, are described under AUSTRIA. See paragraphs *Austria under the House of Hapsburg-Lorraine*, and *Recent Politics*.

Hungarian Language.— The language of the Magyars, as spoken and written at present in Hungary, is a phenomenon in philology, disclosing rich stores for the philosophical historian and philologist. It is classed in the Ugric branch of the northern division of the Turanian family of languages, and as such is most closely allied to the Ostiak, Vogulic, and Mordvinic, though it is also nearly akin to the Finnish and the Turkish. Differing from all the cultivated languages of Europe in internal structure and external form, the Hungarian nevertheless was obliged to express with the Roman alphabet, adopted with Christianity, all the Asiatic shades of sounds. The alphabet contains the following 26 simple and 6 compound sounds, pronounced as in Italian, except where otherwise marked:— 8 vowels: *a* (like *a* in what, swallow), *e* (=*é* French), *i* and *y*, *o*, *u*, *ö* (= French *eu* or German *ö*), *ü* (French *u*); 18 consonants: *b*, *d*, *f*, *g*, hard *h* (German), *j* (German), *k*, *l*, *m*, *n*, *p*, *r*, *s* (English *sh*), *t*, *v* (also *w*), *z* (French), *sz* (English *s*), *zs* (or *ś*, French *j*); 4 compounds with *y*: *gy* (pronounced *dy*, *gyar*, factory, pronounced *dyar*, in one syllable), *ly* (French liquid sound as in *fille*), *ny* (French and Italian *gn*), *ty*; and two compound sibilants: *cs* (written also *ch* and *ts* = English *tch*), and *cz* (English *ts*). If we add the long vowels, marked with the acute accent, *á*, *í*, *ó*, *ő* (long *ö*), *ú*, *ű* (long *ü*), we have 38 sounds in all, besides *x*, which is used in foreign names. The Hungarian has adopted a good many Slavic, Latin, German, Greek, and other foreign words; but it still retains the essential characteristics of its grammar and phonology. As in the other Turanian languages the root is never obscured in words, whatever changes they undergo. Determining or modifying syllables are placed at the end, and have a double form, always taking a different vowel when attached to a sharp-vowel root from what they have when attached to a flat-vowel root. This is a general characteristic of the Turanian languages. These suffixes represent the case-endings of nouns and the conjugations of verbs in other languages, and are very numerous. Hungarian is destitute of diphthongs. At the beginning of a syllable the Hungarian never allows more than one consonant; in foreign words which begin with two consonants, the consonants are made to go with different syllables by putting a vowel before them (for example, of *schola* they make *iskola*), or a vowel is put between (as from *král* they make *király*). In common with the other languages allied to it, it has no distinction of sex whatever. Family names are considered as adjectives, from which they mostly originated, and hence are put before the baptismal name; for instance, Bátori Gábor (Gabriel Bátori), as if it were the Batorish Gabor, the Gabor of the Batori family. The beautiful proportion between vowels and consonants, the accurate shadowing and full articulation which every syllable requires (the Hungarian suffers no mute vowels), and the fixed succession of vowels, give to the Hungarian language a character of masculine harmony, in which it will bear a comparison with any other. The richness and expressiveness of its various forms give it great energy; the regularity of its inflections and compositions, in which it is to be compared with the Sanskrit, makes it clear and distinct, and its infinite power of composition gives it the means of increasing its stores beyond almost any western language.

Hungarian Literature.— The preference given to Latin over the national language, not only in the church, but in judicial proceedings, legal documents, and forms prevailed until past the middle of the 19th century. The use of a dead language in common life, as well as on all scientific subjects, could neither be advantageous to the language itself, to the general improvement of the people, nor to the national literature. Despite these disadvantages, some buds of literature from time to time unfolded themselves, and native genius, notwithstanding its chains, would sometimes attain distinction. Though with the introduction of Christianity into Hungary the Latin language acquired the ascendency in the church, in schools, and public affairs; yet Hungarian was used in commerce, in the camp, and even the resolutions of the diet were first drawn up in Hungarian. When the missionaries addressed the people in Latin an interpreter was usually present; and there are several relics of poetry, sacred eloquence, and state papers extant in Hungarian. A new impulse was given to this language on the accession of the house of Anjou to the throne of Hungary. The Latin was indeed still the language of church and state; but the Hungarian became the language of the court. Documents were drawn up in Hungarian, and the Hungarian oath, in the Corpus Juris Hungaricæ, dates from this time. The Holy Scriptures were translated into Hungarian; in the imperial library, Vienna, there is a manuscript translation of 1832; and several other translations were published. In 1465 Janus Pannonius wrote a Hungarian grammar, which is lost. The 16th century was favorable to Hungarian literature, through the religious disputes in the country, the sacred, martial, and popular songs, as well as by the histories written and published for the people, and the multiplied translations of the Bible. It then reached a degree of perfection which it retained until the latter part of the 18th century. Among writers of ballads or metrical tales belonging to the 16th century may be mentioned Tinódi, Kákonyi, Tsanádi, Valkai, Tserényi, Szegedi, Iliésfalvi, Fazékas, Balassa, etc. A higher aim was manifested by the epic poems of Count Niklas Zrinyi (1652), Ladislaus Lissthi (1653), Christopher Paskó (1663), Count Stephen Koháry (1699), and in particular the numerous and excellent productions of Stephen von Gyöngyösi (1664–1734), as well as the lyric poems of Rimai, Balassa, Benitzky, etc. In 1653 an encyclopædia of all the sciences, and in 1656 a work on logic, were drawn up in the Hungarian language by John Tsere (Apátzai). A large number of grammars and dictionaries were printed from the 16th century to the 18th. But the hopes of the further development of Hungarian literature were not realized; a Latin period again succeeded, from 1700 to 1780, during which time numerous and finished works were composed in Latin by Hungarian writers. In 1721 a Latin newspaper was established, and the state calendar, which commenced in 1726, was regularly published in Latin. In 1781 the first Hungarian newspaper was printed in Presburg.

After Joseph II. died (1790) many violent yet bloodless changes were made in the Hungarian constitution, and several laws were passed in favor of the Hungarian language. It was required to be used in all public proceedings. Courses of lectures were delivered in Hungarian in some of the schools, and it was taught in all of them. Several periodicals were established, Hungarian theatres erected in Buda and Pesth, many works were written both in poetry and prose. The modern period of Hungarian literature may be said to date from the time of Joseph II. The epic poem of Arpád was written by Andrew Horváth, and published at Pesth in 1830. The brothers Alexander and Charles Kisfaludy acquired a great and deserved reputation as poets and dramatists, and did much toward developing the national language and literature. The latter (who died in 1830) may be looked upon as the founder of the modern drama in Hungary. The most celebrated works of the former are his lyrical masterpiece, 'Himfy Szerelmei' (Himfy's Love, 1807), his 'Regék a Magyar elöidöből' (Tales of the Early Hungarian Times), and his historical tragedies, which were partly modeled on those of Schiller. The development of the Hungarian literature owes much to the influence of the periodical press, which spread abroad a taste for literature at the same time as it intensified the sentiment of nationality among the people. In this department the name of Kossuth deserves honorable mention. Previous to the troubles of 1848–9, which checked for a time the natural growth of the literature, almost every species of composition was successfully practised. Works on politics and narratives of travel were written by Eötvös, Szechényi, Szalay, Szemere, etc.; on history by Stephen and Michael Horváth, Szalay and Jaszay; on philology by Fogarassy and Bloch; works on the exact sciences, however, were confined to translations from the German, French, and English. Novels and romances were written by Baron Jósika, Eötvös, Kemény, Kuthy, Nagy, Pálffy, etc., which, though of no great originality, showed considerable artistic skill, and helped to diffuse a more correct style. The dramatic pieces of Eötvös, Obernyik, Vörösmarty, and the prolific Szigligeti — who for a long time had almost the exclusive possession of the national stage — have greater value and originality. It is in poetry, strictly so called, however, that modern Hungarian literature shines. Many of the poems (songs, ballads, etc.) of Czuczor, Vörösmarty, Bajza, Garay, Bachot, Szász, Erdélyi, Kerény, and others, are among the finest things that modern literature has produced. In this field the palm must be awarded to Alexander Petöfi, who completely freed Hungarian poetry from its dependence on foreign models and subjects, and inspired it with a life drawn fresh from nature and national feeling; and who, in artistic skill and masterly handling of his mother tongue, ranks as a model. Tompa, Hiador, Lisznyai, and others, have copied him with more or less success. The collection of ancient Hungarian national poetry, compiled and edited by John Erdélyi, at the instance of the Kisfaludy Society (three vols., Pesth, 1845–7), contributed greatly toward bringing back the modern poetry to nature and originality, and to impress upon it the stamp of nationality. The ill success of the revolutionary struggle seemed for a time to have dealt a heavy blow to the progress of Hungarian literature, the most gifted writers having either fallen in battle (as Petöfi), or been imprisoned or banished. Time, however, opened the prisons and brought back the exiles; to the writers already mentioned others were added, and an active literary life again began. The greatest recent Hungarian poet is John Arany, who surpasses even Petöfi in artistic feeling, and whose national epic, 'Toldi,' is looked upon as a masterpiece. Baron Jósika holds the first place among the novelists; Jokai, Kuthy, Berczy, Pálffy, Miksrath, and Dobzsa are also favorite fiction writers. Narratives of travel have been written by Count Andrassy, Ladislaus Magyar, Vámbéry, etc.; on politics by Esengery, Szalay, Pákh, and Eötvös. National history has attracted much attention; and besides the works of Szalay and Horváth, we should mention Teleki's 'Age of Hunyad,' Jászay's 'Hungary after the Battle of Mohács,' Salomon's 'The Rule of the Turks in Hungary,' etc. Many excellent translations of modern foreign works have been made, some of which, such as Esengery's translation of Macaulay's 'History of England,' and Somssich's translation of Guizot's 'Histoire de la Révolution d'Angleterre,' rival the originals in style. The best works on Hungarian literature are those of Toldy, some of which have been translated into German.

Hunger. See Appetite; Digestion; Fasting; Food.

Hungerford, hŭng'gėr-fōrd, **Margaret Hamilton Wolfe Argles** («The Duchess»), Irish novelist: b. Ross, Ireland; d. Bandon, County Cork, 24 Jan. 1897. She was the daughter of a vicar choral of Cork Cathedral and the death of her first husband, Edward Argles, left her with a young family to support, whereupon she took to writing novels, using the pseudonym «The Duchess.» Later she was married to T. H. Hungerford. Her more than 30 novels were widely popular both in America and England and without possessing a large amount of literary value are cleverly written, entertaining fictions. Among them may be cited: 'Phyllis' (1877); 'Molly Bawn' (1878); 'Airy Fairy Lillian' (1879); 'Beauty's Daughters' (1880); 'Mrs. Geoffrey' (1881); 'Portia' (1882); 'O Tender Dolores' (1885); 'Green Pastures and Gray Grief' (1886); 'A Modern Circe' (1887); 'The Duchess' (1887); 'Undercurrents' (1888); 'Hon. Mrs. Vereker' (1888).

Hunk'ers (supposably from Dutch *honk*, «post» or «station;» «stick-in-the-muds»), in American politics, at present a contemptuous nickname, like «moss-backs,» for the unprogressive elements of a party, which detest change. Originally, a name given about 1844 to the section of the New York State Democrats which opposed new issues: the points for which it then stood, however, had become party tenets from about 1835. Thence till 1840 the Hunker faction was in opposition to the Locofoco wing (q.v.) which opposed bank charters; but was obliged to yield in 1838. From 1840 to 1846 they oposed the Radicals, who wished a revised State constitution, elective judges, and cessation of State canal building. Thence till 1852 they opposed the Barnburners (q.v.), who, at first separately and then in alliance with the Free-Soil Party (q.v.), fought the national Democratic Party for recognition of its State power. After the election of Pierce in 1852, it divided into «hards» and «softs»; the first under Daniel S. Dickinson opposed the administration, the second under William L. Marcy supported it. The former made up the bulk of the «War Democrats» after 1861. Besides those named, Horatio Seymour is the best remembered Hunker leader; while the opposition has the familiar names of Martin Van Buren, Silas Wright, and John A. Dix, besides others remembered by the older generation.

Hunneus, ûn-nā'ŭs, **George**, Chilean statesman: b. Santiago, Chile, 1831. He was graduated at the university of his native town in 1857, and became professor of political economy and jurisprudence at the same institution the following year. Montt, president of Chile, drove him out of the country on account of his liberal opinions, which he found carried into actuality in the government of the United States, where he spent his time of banishment. He was recalled to his native land in 1861, was elected to the House of Representatives and became its speaker. He was also appointed secretary of public instruction and is now rector of Santiago University, while holding from time to time high positions in the Chilean administration.

Hun'newell, James Frothingham, American bibliographer, and historical writer: b. Charlestown, Mass., 3 July 1832. He has written: 'Historical Monuments of France' (1884); 'The Imperial Island: England's Chronicle in Stone' (1886); 'A Century of Town Life' (1886); 'The Lands of Scott' (1871).

Huns, a people who make their appearance in authentic history about 375 A.D. Ethnologists identify them with a Mongolian people of Northern Asia, who invaded the Chinese Empire about 200 B.C., and after various migrations entered Europe. They appear afterward to have sided with the Goths of Mœsia against the Romans, and sometimes in alliance with the emperors, who purchased their services, and sometimes in hostility with them, they continued to extend their dominion along the Danube until the time of Attila (434), their greatest leader, whose reign constitutes the best-known period of their history. See Attila.

Hunt, Helen. See Jackson, Helen Fiske Hunt.

Hunt, Henry Jackson, American soldier: b. Detroit, Mich., 14 Sept. 1819; d. Washington, D. C., 11 Feb. 1899. He was graduated from West Point in 1839, receiving a commission in the artillery. He saw service in the Canadian rebellion 1837-8; afterwards in the Mexican War. In General Scott's advance on the city of Mexico he distinguished himself as officer of the artillery at Contreras (18 Aug. 1847) and Churubusco (20 Aug. 1847) and subsequently received the brevet rank of major for his gallantry. In 1856 he was placed on the board engaged in revising the system of light artillery tactics. At the outbreak of the Civil War he was stationed at Fort Pickens, Fla., 1861, and the same year commanded the artillery at the battle of Bull Run, and in the defense of Washington. He subsequently organized and commanded the reserve artillery of the Army of the Potomac. As commander of artillery he was present at the battle of Malvern Hill (1 July 1862) and he also took part in the battle of South Mountain. He was brevetted brigadier-general of volunteers in 1862, and was present at the battles of Antietam, Fredericksburg, Chancellorsville, Gettysburg, served in the Wilderness campaign and at the end of the war retired from his position with the rank of brigadier-general in the United States army. In 1866 he received the commission of colonel in the reorganized army, and in 1883 became governor of the National Soldiers' Home at Washington. Among his writings are: 'Instruction for Field Artillery' (1860); 'Battles and Leaders of the Civil War'; 'The Battle of Gettysburg.'

Hunt, James Henry Leigh, English journalist, essayist, and critic: b. Southgate, Middlesex, England 19 Oct. 1784; d. Putney, near London, 28 Aug. 1859. He was the youngest of a large family of children, and was descended on the one side from Tory cavaliers of West Indian adoption, and on the other from American Quakers of Irish extraction. From his father, an improvident and engaging clergyman of convivial habits and of lax doctrines, Hunt seems to have inherited his optimism of temperament, his liberal views, and his courage of conviction; from his mother, a passionate love of nature and of books. From birth a delicate child, he early developed hypochondriacal tendencies that never left him. The years from 1791 to 1799 were spent at Christ's Hospital, and were his only formal preparation for a literary life. In 1801 his father published 'Juvenilia,' a collection of Hunt's poems written from the age of 12 to 17. They show wide reading and some fluency in versification, but are mostly poor imitations. From 1803 to 1805 he worked in his brother Stephen's law office and, at the same time, began his long career as a journalist with contributions to *The Traveller*, *The News*, and other papers. His theatrical criticisms were reprinted separately in 1807.

His next position was in the office of the Secretary of War, resigned in 1808 in order to start his political journal, *The Examiner*, in its far-reaching effects the most significant step of his career. With his brother John as publisher, he continued editor until 1821. *The Examiner* was a departure from the standards of contemporary journalism in its combination of the news-giving quality of the daily sheets with the essay style of the weeklies (Fox-Bourne, 'English Newspapers'). Discussion of politics was its chief object. The liberal policy and boldness of attack of the editor caused one charge of libel by the Tory government to follow closely upon the heels of another. The third resulted in prosecution and conviction for applying to the Prince Regent, afterwards George IV., the phrase, "a fat Adonis of fifty." The two brothers were sentenced to imprisonment of two years, dating from 15 Feb. 1813, in separate prisons, and a fine of £1,000 to be divided between them. They rejected offers from the government to remit the punishment on condition that *The Examiner* should change its attitude, and served the full sentence. Hunt's finances, which up to this time had been good, became greatly involved during his incarceration. Not until 1844 was he free from want. His health suffered greatly from the long confinement. *The Reflector* (1810-12) had much the same political and literary character as *The Examiner*. The chief measures for which Hunt labored through these journals were Catholic Emancipation, reform of Parliamentary representation, liberty of the Press, reduction and equalization of taxes, greater discretion in increasing the public debt, education of the poor and amelioration of their sufferings, cessation of child labor, abolition of the slave trade, reform of military discipline, and of prison conditions, and of criminal and civil laws. After Hunt's release from prison, he was never again so active in political matters.

In 1809 Hunt married Marianne Kent. She was an invalid the greater part of her life; consequently, the 'hugger-mugger' condition of domestic affairs which so greatly distressed the Carlyles. Curiously enough, Hunt was allowed to continue *The Examiner* while in prison. During that time, he republished from *The Reflector* his 'Feast of the Poets,' a wholesale satire on contemporary poets in the manner of Suckling's 'Session of the Poets.' It antagonized the literary world, as *The Examiner* had done the political, and played a large part in creating the antagonism of *Blackwood's* and the *Quarterly* towards Hunt, which resulted in the creation and the long and bitter persecution of the so-called Cockney School. The 'Descent of Liberty' appeared in 1815. The 'Story of Rimini' (1816), also written in prison, was the most important of Hunt's poems up to that time, and brought him into immediate notoriety. For its influence on his contemporaries, particularly Keats, in the use of idiomatic language, and in the revival of the free, heroic couplet, it is the most important of Hunt's poems. It was at once denounced as most pernicious and immoral by the *Quarterly* and *Blackwood's*. 'Foliage' (1818) contains some of Hunt's best epistles and sonnets. 'Hero and Leander,' and 'Bacchus and Ariadne' appeared jointly in 1819, and a translation of Tasso's 'Amyntas' in 1820. His prose style of this period reached its best expression in *The Indicator*, in essays of the occasional and personal type. They are distinguished by a unique charm and tenderness, by delicate humor and keen observation.

During Hunt's imprisonment he had made the acquaintance of Byron, Shelley, Moore, and Lamb. The friendship with Keats probably did not begin until the winter of 1816. In the case of Shelley, it was the beginning of a wonderful friendship that involved personal sympathy and public defence with his pen on the part of Hunt, and much financial aid on the part of Shelley. It was through the latter that Byron, in 1821, invited Hunt to Italy to undertake the management of *The Liberal*, an ultra-political-literary journal, suddenly abandoned after a few months of unsuccessful running. The failure of the project led to Byron's desertion of Hunt and his family in a foreign land, and Hunt's revenge in 1828 in the shape of 'Lord Byron and Some of his Contemporaries,' an error which Hunt later greatly deplored. During the stay in Italy, he edited the *Literary Examiner*, wrote 'Ultra Crepidarius,' a satire on William Gifford, translated the 'Bacchus in Tuscany' of Redi, and contributed the 'Wishing-Papers' to *The Examiner*. He returned to England in 1825 in great poverty. From this time on his work consisted of editing numerous magazines: *The Companion* (1828), *Chat of the Week* (1830), *The Tatler* (1830-1832), *Leigh Hunt's London Magazine* (1834-1835), *Monthly Repository* (1837-1838), *Leigh Hunt's Journal* (1850-1851), unsuccessful because of the great impracticability of the schemes and the monotony of one chief contributor; of contributing to an incredible number of other magazines; of publishing reprints from previously edited journals and collected editions of his 'poetical works'; of selections from other writers made with running comment or introductory essays, as 'Imagination and Fancy' (1844), 'Wit and Humor' (1846), 'Stories from the Italian Poets' (1846), of guide books, as 'The Town' (1848), and 'The Old Court Suburb' (1855). His only novel, 'Sir Ralph Esher,' appeared in 1832. 'The Legend of Florence' was produced at Covent Garden in 1840. His 'Autobiography' was published in 1850, and in a revised form in 1859; the 'Correspondence' posthumously in 1862.

Hunt's best prose work is to be found in his 'Autobiography' and in his essays of the kind already mentioned as having appeared first in *The Indicator*. Carlyle said of the former, "except it be Boswell's of Johnson, I do not know where we have such a picture drawn of a human life as in these volumes." Though less of a poet than an essayist, some of his short poems are exquisite, notably the famous 'Abou Ben Adhem,' 'Mohammed,' 'Jaffar,' 'The Nile,' 'On a Lock of Milton's Hair,' 'Paganini,' and others. As a translator, some of his work is admirable. Hunt's powers of criticism and of selection will not be fully recognized until scattered notes and buried prefaces are collected. He had an inborn love of poetry and all beautiful things. His insight was most remarkable of all in the appreciation of his contemporaries. His personal quality was as rare as his opportunity. He had a personal ascendency, a strange fascination born of the sympathy and chivalry, the sweetness and joyousness of his nature. Barry Cornwall said that he was "compact of all the spicy winds that blow."

Bibliography.—Hunt's works have never been collected and as a whole are difficult of access. His poems and essays, except in small selections and cheap editions, are out of print. The best edition of the former is that edited by S. Adams Lee (Boston 1857); of the latter *The Indicator* and *Companion* (2 vols., London 1834). Scribner publishes in a uniform edition some of the most popular of his works. Consult also: R. B. Johnson, 'Leigh Hunt' (1896); Cosmo Monkhouse, 'Life of Leigh Hunt' (1893); Clarke, 'Recollections of Writers' (1878); Trelawney, 'Recollections of the Last Days of Shelley and Byron' (1858). Frequent references to Hunt are to be found in the writings of Byron, Shelley, Keats, Carlyle, Dickens, Lamb, William Hazlitt and Alexander Ireland. Excellent bibliographies of Hunt's works are to be found in Ireland's 'Lists of the Writings of William Hazlitt and Leigh Hunt' (1868); Monkhouse's 'Life of Leigh Hunt' mentioned above, and in R. B. Johnson's 'Essays and Poems of Leigh Hunt' (Temple Library, 1891).

BARNETTE MILLER,
Instructor in English in Vassar College.

Hunt, Richard Morris, American architect: b. Brattleboro, Vt., 31 Oct. 1828; d. Newport, R. I., 31 July 1895. He began the study of architecture in Europe at an early age, attended the Ecole des Beaux-Arts in Paris, traveled in Germany, Italy, Asia, and Egypt, and under his former teacher, Lefuel, was clerk of the works on the buildings that were erected to connect the Tuileries with the Louvre. In 1855 he returned to the United States and proceeded to signalize himself by a remarkable series of noble architectural creations, such as the Capitol extension at Washington, the Lenox Library, New York, the Yorktown Monument, Va., etc. He also designed the pedestal for Bartholdi's colossal statue of 'Liberty Enlightening the World' on Bedloe's Island, New York harbor. Some of the finest private houses in the country were built by him on a truly palatial scale of magnificence, such as that of W. K. Vanderbilt in New York; the country house of George Vanderbilt at Biltmore, N. C.; the so-called 'Marble House' and the 'Breakers' at Newport. He was one of the founders and president of the Institute of Architects. Through his artistic and structural faculty he exercised a profound influence over American architecture.

Hunt, Theodore Whitefield, American Presbyterian clergyman and educator: b. Metuchen, N. J., 19 Feb. 1844. He was graduated from Princeton 1865 and from Princeton Theological Seminary 18[illegible]), was instructor in English at Princeton 1868–71 and has been professor of English there from 1872. He has published 'The Principles of Written Discourse' (1884); 'English Prose and Prose Writers' (1887); 'Studies in Literature and Style' (1890); 'Ethical Teachings in Old English Authors' (1892); etc.

Hunt, Thomas Sterry, American chemist and geologist: b. Norwich, Conn., 5 Sept. 1826; d. New York 12 Feb. 1892. In 1845 he became an assistant to the elder Silliman at Yale College; was chemist and mineralogist to the Canadian Geological Survey 1847–72, professor of chemistry at Laval University 1856–62, and at McGill University 1862–68, and professor of geology in the Massachusetts Institute of Technology 1872–8. In 1859 he invented the green ink with which greenbacks (q.v.) are printed. He was made an officer of the Legion of Honor in 1867, Fellow of the Royal Society in 1859, and was president of the Royal Society of Canada in 1884. Among his published books are 'Chemical and Geological Essays'; 'New Basis for Chemistry'; etc.

Hunt, William Henry, American lawyer: b. New Orleans, La., 5 Nov. 1857. He was educated at Yale, became attorney-general of Montana in 1884; and held various public offices there after Montana became a State. He was for a time United States agent before the Chilean Claims Commission, but resigned that post in 1900 to become secretary of Porto Rico, and in July 1901 succeeded Charles H. Allen as governor of that island. On 1 July 1904 he was succeeded by Gov. Winthrop and since then has been United States district judge for Montana.

Hunt, William Holman, English Pre-Raphaelite painter: b. London 2 April 1827. He entered the schools of the Royal Academy in 1845, and next year exhibited his first picture, 'Hark!' representing a child holding a watch to her ear. About 1848 Hunt, D. G. Rossetti, and J. E. Millais formed the Pre-Raphaelite Brotherhood, afterward enlarged by the admission of other painters and writers, and which attained a position of great influence through the eloquent support of Ruskin. Each of the three founders exhibited in 1849 a picture painted in strict accordance with the principles of the Brotherhood. Hunt's picture represented 'Rienzi Vowing to Obtain Justice for the Death of his Younger Brother Slain in a Skirmish between the Colonna and Orsini Factions,' and was exhibited at the Royal Academy. The exhibition of 1854 included two of his greatest pictures, one of them the well-known 'Light of the World.' Both it and 'The Awakening Conscience' are characterized by the careful draughtsmanship and attention to detail which form notable features of the best Pre-Raphaelite work, but their full meaning is far from clear to the average spectator. In 1854 Mr. Hunt went to Palestine in order to obtain a living acquaintance with the scenes of the Biblical stories, and the first fruits of his study of Eastern life was 'The Scapegoat' (1856), one of his most original and most poetical works; but much finer is his 'Finding of the Saviour in the Temple,' exhibited in 1860. Among subsequent works of Hunt's are: 'A Street Scene in Cairo—the

Lantern-Maker's Courtship' (1861): 'Portrait of D. G. Rossetti' (1850); 'Fairlight Downs' (1858): 'The After-Glow in Egypt' (1865), "that modern masterpiece of technical art"; 'Isabella, or the Pot of Basil' (1868), based on the well-known story from Boccaccio utilized by Keats, and in respect of coloring, the finest of the artist's works; 'The Shadow of Death' (1873), showing a prevision of the Crucifixion in the carpenter shop where Jesus is working beside his mother; 'The Triumph of the Innocents' (1885), one of his masterpieces; 'Christ among the Doctors' (1860). See biography by Farrar and Meynell (1893); Williamson, 'Life of Holman Hunt.'

Hunt'er, David, American soldier: b. Washington, D. C., 21 July 1802; d. there 2 Feb. 1886. He was graduated at West Point in 1822, became captain in 1833, and resigning from the army in 1836 settled in Chicago. He, however, re-entered the army in 1842 as paymaster with the rank of major, and in May 1861 was appointed brigadier-general of volunteers, and a few months later major-general. He recruited and organized in South Carolina the first negro regiment in the Union army. He defeated the Confederates at Piedmont, 5 June 1864, and was chairman of the military commission which tried the conspirators engaged in the assassination of President Lincoln. He was brevetted major-general United States army, 13 March 1865, and retired on account of age in 1886.

Hunter, John, British surgeon and physiologist: b. Long Calderwood, Lanarkshire, 13 Feb. 1728; d. London 16 Oct. 1793. He was a younger brother of William Hunter (q.v.) In 1749 and 1750 he studied surgical pathology at Chelsea Hospital, London, and already began to make original observations, which his subsequent experience confirmed. In 1751 he attended St. Bartholomew's Hospital and in 1754 entered as a surgeon pupil at St. George's Hospital. In 1754 or 1755 he was admitted to a partnership in his brother's school of anatomy, and continued to lecture there till 1759. He served as staff-surgeon in France and Portugal 1760–3, and then returned to London and commenced practice as a surgeon. In 1767 he received an unexpected proof of the high estimation in which he was held by men of science in being elected a member of the Royal Society, and in 1768 he was appointed surgeon to St. George's Hospital. His investigations at this time extended over every branch of natural history, particularly pathology, comparative anatomy, and physiology, to which he devoted his entire leisure time. In 1790 he was appointed inspector-general of hospitals and surgeon-general to the army. Hunter left at his death a museum which he had built for himself, and filled with upward of 10,000 preparations illustrative of the departments of science to which his attention had been devoted. It was afterward purchased by government, and presented to the Royal College of Surgeons. In addition to papers contributed to the 'Transactions' of learned societies, his leading works are the 'Natural History of the Human Teeth' (1771); 'Treatise on the Venereal Disease' (1786); 'Observations on Certain Parts of the Animal Economy' (1786); 'Treatise on the Blood, Inflammation, and Gun-shot Wounds' (1794).

Hunter, Robert Mercer Taliaferro, American statesman: b. Essex County, Va., 21 April 1809; d. 18 July 1887. He was graduated at the University of Virginia, and, choosing the law for his profession, commenced practice in 1830. He soon began to take an active part in politics and at 24 was elected to the house of delegates, where he remained until 1837, when he was elected to Congress. In the discussions growing out of the commercial convulsion of that year, he at once took his stand on the side of the administration in favor of the independent treasury bill, and in his first speech developed those principles of free trade to which he consistently adhered throughout his public career. In the succeeding Congress he was elected to the speakership; and at the close of his term of service, the usual vote of thanks was passed without a dissenting voice, in a House of Representatives strongly marked by partisan bitterness. At the election in the spring of 1843 for members of the 28th Congress, Hunter was defeated by a small majority, mainly on account of his adherence to that clause of the independent treasury scheme requiring all dues to the government to be paid in specie. At the next congressional election in 1845, he was successful. In 1846 Hunter, in common with other southern representatives, resisted the application of the Wilmot Proviso. He voted for all the measures necessary to prosecute the war to a just and honorable conclusion, but altogether opposed the project, favored by some, of incorporating the whole of the Mexican states into our political system. During the winter of 1846–7 he was chosen by the legislature of Virginia to the United States Senate, and took his seat in December 1847, remaining there until 1861. He was active in framing the tariff act of 1857 and after leaving the Senate became the Confederate secretary of state. At a later period he was a Confederate senator and in 1865 commissioner of peace. He became treasurer of Virginia in 1877 and retired from public life in 1880.

Hunter, William, British anatomist: b. Long Calderwood 23 May 1718; d. London 30 March 1783. After studying at Glasgow University 1732–7, and subsequently medicine at Edinburgh, he went to London in 1741, and in 1746 received the appointment of lecturer on anatomy to a society of naval surgeons. In 1747 he became a member of the College of Surgeons, and practised surgery and midwifery, but at length confined himself entirely to that branch, and was appointed accoucheur to the British Lying-in Hospital. In the first volume of 'Observations and Inquiries,' published by the Medical Society in 1757, appeared Hunter's 'History of an Aneurism of the Aorta.' In 1762 he published 'Medical Commentaries,' and in 1764 was appointed physician-extraordinary to the queen. Hunter was elected a fellow of the Royal Society in 1767; and in 1768, on the establishment of the Royal Academy of Arts, he was appointed professor of anatomy. He was made a foreign associate of the Royal Medical Society at Paris in 1780, and of the Royal Academy of Sciences in 1782. The most elaborate of his publications, the 'Anatomy of the Human Gravid Uterus,' appeared in 1774. In 1770 he purchased and completed a house and theatre, in which he constituted a splendid museum At first he only contemplated a collection of preparations in human and comparative anatomy, but added a collection of shells, corals, and other objects of natural history, paintings and ancient coins and medals. He bequeathed the whole of his splendid museum, valued at £150,000, to the University of Glasgow, with the sum of £8,000 in cash to be expended in an appropriate building for its reception, and a further sum of £500 per annum to bear the charges of its preservation.

Hunter, Sir William Wilson, English statistician and author: b. Glasgow 15 July 1840; d. 1900. He was educated at the University of Glasgow and foreign universities, and appointed to the Bengal Civil Service in 1862. As director-general of statistics he made a statistical survey of India, the results of which are embodied in the well-known 'Imperial Gazetteer of India' (1881; 1885-7). He also published 'Annals of Rural Bengal' (1868; 5th ed. 1872), continued in 'Orissa' (1872); 'The Life of the Marquess of Dalhousie'; 'A Dictionary of the Non-Aryan Languages of India and High Asia'; 'Brief History of the Indian Peoples,' which has been translated into five languages, and was editor of the series of biographies known as 'The Rulers of India.' He was knighted in 1887.

Hunting, the sport or recreation of pursuing game, is a very ancient amusement. Alexander the Great is said to have paid a large sum of money for a treatise on hunting by Aristotle. The true sportsman rarely kills game for any other purpose than eating. The hunting of large game, as bear, deer, tigers, lions, leopards, etc., will be found treated under the titles by which they are described. In Europe the various methods of shooting game are known as open shooting, covert shooting, river and pond shooting, and salt-water wild fowl shooting. Deer-stalking (q.v.) and wild-boar hunting are favorite amusements of royalty in Europe; in India boar-hunting is commonly known as "pig-sticking." See Fox Hunting; Game Laws; Game Preserves, etc. Consult Dodge, 'Hunting Grounds of the Great West' (1877); Gasper, 'The Complete Sportsman' (1893); Mills, 'The Sportsman's Library'; Long, 'American Wild-Fowl Shooting' (1874); Murphy, 'American Game Bird Shooting' (1892); Pringle, 'Twenty Years' Snipe Shooting' (1899); Ramsford, 'Hunting' (1896); Roosevelt, 'Big Game Hunting' (1899); Ward, 'Records of Big Game' (1896).

Hunting-dog. See Hyena-dog.

Hunting Leopard. See Cheeta.

Hun'tingdon, Selina Shirley, Countess of, English religious leader: b. 24 Aug. 1707; d. 17 June 1791. She was married in 1728, to the Earl of Huntingdon and on his death in 1746 became very devout, appointing the famous George Whitefield (q.v.) her private chaplain. Adopting the principles of the Methodists, she was long considered, owing to her rank and fortune, as the head of the Calvinistic Methodists, her followers being known as the "Countess of Huntingdon's Connection." She founded a College at Trevecca in Wales, for the education of ministers, built some 64 chapels, and contributed liberally to the support of the clergy.

Huntingdon, Pa., borough, county-seat of Huntingdon County; on the Juniata River, and on the Pennsylvania railroad; about 200 miles west of Philadelphia. Where Huntingdon is located was once a famous council ground for the Indians of the central part of Pennsylvania. It was first settled by white people in 1760, and was chartered in 1796. The country around is a fertile agricultural region, with valuable mineral deposits and quite extensive forests. The chief manufactures are boilers, machinery, radiators, sewer pipe, flour, furniture, stationery, knit goods, and stoves. The trade is in the manufactures, and grain and fruits. Huntingdon is the seat of the State Industrial School, and of Juniata College, an institution opened in 1876 under the auspices of the German Baptist Brethren. The original charter is still in force and provides for a chief burgess, who holds office three years, and a council. Pop. (1900) 6,053.

Huntingdon's Disease, hereditary chorea. Chorea, or St. Vitus' dance, sometimes attacks adults, most frequently pregnant women. In such cases it is hard to distinguish from locomotor ataxia. The offspring of adults thus affected are likely to have congenital or hereditary chorea.

Hun'tington, Collis Potter, American capitalist: b. Harwinton, Conn., 22 Oct. 1821; d. Pine Knot Camp, near Lake Raquette, N. Y., 13 Aug. 1900. He worked on his father's farm, until his 14th year. In his 16th year he procured credit in New York for $3,000 worth of clocks, and peddled them through the South and West. He shipped goods to California in 1848; followed them in person in 1849 and began to make his fortune in the hardware business. In 1860 he matured a plan for a transcontinental railroad in conjunction with Leland Stanford, Charles Crocker, and Mark Hopkins. The Central Pacific was finished in 1869. This was the crowning achievement of his life, and at his death the railroad system known as the Southern Pacific, of whose managing board he was president, comprised 26 corporations, with more than 9,000 miles of tracks and 5,000 miles of steamship line. He was one of the largest landholders in the country and his fortune was estimated at $35,000,000. He built a granite church, to the memory of his mother, in his native town; gave C. W. Peale's portrait of Washington to the New York Metropolitan Museum; a library and reading-room to Westchester, N. Y., materially aided in building and equipping Hampton (Va.) Normal Agricultural Institute; and gave $50,000 for the endowment of Tuskegee (Ala.) Normal and Industrial Institute.

Huntington, Daniel, American painter: b. New York 14 Oct. 1816; d. there 18 April 1906. He was educated at Hamilton College, where he made the acquaintance of Charles L. Elliott, from whom he received a decided bias for his art. In 1835 he entered the studio of Professor Morse, president of the National Academy of Design, and soon after produced the 'Bar-room Politician'; 'A Toper Asleep,' besides some landscapes and portraits. In 1839 he went to Europe and in Florence painted the 'Sibyl' and the 'Florentine Girl.' Removing to Rome soon after, he painted the 'Shepherd Boy of the Campagna,' and 'Early Christian Prisoners,' both of which were purchased by New York collectors. He became a member of the National Academy in 1840 and was its president in 1862 and 1869, and continuously from 1877 to 1899. He devoted himself mainly to portraits and among portraits by him of well known people are those of Presidents Lincoln and Van Buren, and of Sir Charles Eastlake. His noted 'Mercy's Dream' is now in the Corcoran Gallery at Washington.

Huntington, Frederic Dan, American Protestant Episcopal bishop: b. Hadley, Mass., 28 May 1819; d. Hadley, Mass., 11 July 1904. He was graduated at Amherst in 1839, and studied three years in the divinity school of Cambridge. In 1842 he was ordained pastor of the South Congregational (Unitarian) church in Boston, which he left in 1855 to become Plummer professor of Christian morals at Harvard. In 1860 he resigned and took orders in the Episcopal Church, founding Emmanuel Church, Boston, and serving as its rector 1861–9. In April 1869 he was consecrated bishop of Central New York. He has published: 'Sermons for the People' (1856); 'Christ in the Christian Year'; 'Helps to a Holy Lent' (1872); 'The Gospel and the People'; etc.

Huntington, Jedidiah Vincent, American author, brother of Daniel Huntington (q.v.): b. New York 20 Jan. 1815; d. Pau, France, 10 March 1862. He was educated as a physician, but in 1839 entered the Episcopal ministry, officiating for a short time as rector of an Episcopal church in Middlebury, Vt. In 1849 he became a Roman Catholic. His published works are: 'Poems' (1843); 'Lady Alice, or the New Una,' a novel (1849), which is the most popular of his works; 'Alban' (1850); 'The Forest,' a sequel to 'Alban' (1852); etc.

Huntington, Samuel, American jurist: one of the signers of the Declaration of Independence: b. Windham, Conn., 3 July 1732; d. Norwich, Conn., 5 Jan. 1796. He was educated to the law, and previous to 1775 held the offices of king's attorney and associate justice of the superior court of Connecticut. In January 1776 he entered the Continental Congress as a delegate from his native State. In September 1779 he succeeded John Jay as president of Congress, and discharged the functions of that office until July 1780, when he resumed his seat on the Connecticut bench. He served again in Congress from May to June, 1783, and in the succeeding year was appointed chief justice of the superior court of Connecticut. In 1785 he was elected lieutenant-governor of Connecticut, and in 1786 he succeeded Roger Griswold as governor, to which office he was annually re-elected until his death.

Huntington, William Reed, American Episcopal clergyman: b. Lowell, Mass., 20 Sept. 1838. After graduation from Harvard in 1859 he took orders in the Episcopal Church, was assistant at Emmanuel Church, Boston, 1861–2, rector of All Saints, Worcester, Mass., 1862–3, and since 1883 has been rector of Grace Church, New York. He has long been prominent in the councils of the Episcopal Church and is an acknowledged leader of the Low Broad Church school of thought.

Huntington, Ind., city, county-seat of Huntington County: on the Little River, and on the Chicago & E. and the Wabash R.R.'s; about 20 miles southwest of Fort Wayne and 70 miles southeast of South Bend. It was settled in 1834, incorporated as a town in 1834, and received its charter in 1873. The city has excellent water power. Its chief manufactures are bicycles, boots and shoes, pianos, plows, barrels, lime, and cement. It has railroad shops, and wood-working factories. The trade, in addition to the manufactures, is in coal and lime from the coal fields and lime-kilns nearby, and agricultural products. It is the seat of the United Brethren College. The public library has about 12,000 volumes. The city owns and operates the electric-light plant and the water-works. Pop. (1900) 9,491.

Huntington, N. Y., town in Suffolk County on Long Island. It is on Long Island Sound and on the Long Island Railroad. Huntington originally included the village of Babylon and other adjoining places. As first laid out, the area was 150 square miles. The first settlement was made in 1653, and the first deed of land given to actual settlers was made on 2 April 1653, on behalf of the Matinecock tribe of Indians, and conveying to the whites six square miles between Cold Spring and Northport. The consideration paid was six coats, six kettles, six hatchets, six "howes," six shirts, 10 knives, six fathoms of wampum, 30 "muxes," and 30 needles. Additional lands were purchased in 1656–8. The early settlers were nearly all Puritans from England. The inhabitants of Huntington were among the first of the colonists to protest against "taxation without representation." From the first agriculture was the chief occupation; but trade with the West Indies began at an early date. In 1675 Thomas Fleet was listed as owning 40 vessels. Whales were often caught along the south coast. Nathan Hale (q.v.) was captured in Huntington. The place of capture is marked by a boulder, a shaft, and a drinking fountain. The town celebrated its 250th anniversary on 4 July 1903. The chief manufactures are pottery, brick, and dairy products. Large market gardens are in parts of the town, but much of it is a favorite residential suburb of New York. Pop. (1900) 9,483.

Huntington, W. Va., city, the capital of Cabell County, on the Ohio River, just below the confluence of the Guyandotte River, 18 miles above Ironton, 52 miles west of Charleston and on the Chesapeake & O., the Guyandotte Valley, and the Ohio River R.R.'s. The city, named after the late Collis P. Huntington, was founded and incorporated in 1871. It is an important commercial and industrial centre, has steamship communication with all the important river ports, and among its industrial establishments are the car manufacturing shops of the Chesapeake & Ohio railroad, foundry and machine shops, lumber and planing mills, manufactures of woodwork, paints, glass, stoves, bricks, and ice, bottling and meat-packing establishments, etc. The city is regularly laid out, has electric lights and street railways, two national banks, and is noted for its educational establishments which include Marshall College (the State Normal School), the Douglas High School for colored students, and a Carnegie library. The West Virginia Asylum for Incurables is situated here. Pop. (1890) 10,108; (1900) 11,923.

Huntsville, Ala., city and county-seat of Madison County, on the Nashville, C. & St. L. and the Southern R.R.'s; 96 miles due north of Birmingham; 97 miles due west of Chattanooga; 125 miles south of Nashville, and 210 miles east of Memphis. The city is located in the heart of the famous Tennessee Valley, and is surrounded by a large and fertile agricultural, cotton, fruit, and stock-raising country, making it the most important commercial centre of this entire valley territory. In manufacturing it is fast reaching a position among the most important in the south. As a cotton manufacturing point it is to-day without a rival in all this section, and in spindles leads the South, and is second only to Lowell, Mass. Its nine cotton mills have 203,000 spindles, with 4,374 looms, the annual product of which amounts to $4,775,000. Besides these, Huntsville has machine and foundry shops, cottonseed-oil mills, hoop and heading factory, fibre factory, spoke and handle factories, saw and planing mills, brick plants, gas and electric plants, electric car lines, paid fire department, waterworks owned and operated by the city and supplied from a magnificent spring of purest water with a daily capacity of 2,400,000 gallons. The first settler here was John Hunt, a Virginian, and a soldier of the Revolution, who came to the "Big Spring" in 1805, built his cabin, the first, near by, and in 1806 went back to Tennessee and brought his family, having lived in that State before coming to Alabama. In 1811 the town was incorporated by the Territorial Legislature as "Huntsville." The first State constitutional convention sat here and framed the first constitution of the State, the convention convening 5 July 1819. The first legislature sat here and assembled on the first Monday in August 1820, and this was the first capital of Alabama. The city is well supplied with a number of private schools, and an excellent public city school with a new modern building erected at a cost of $25,000. Four miles north of the city is located the "Alabama Agricultural and Mechanical College for Negroes." The government of the city, under a new charter of 1897, is composed of a mayor and board of aldermen of eight, and it controls all of the city's affairs, including the waterworks. Pop. 16,000.

Benjamin Powel Hunt.

Hunts'ville, Mo., city, county-seat of Randolph County; on the Wabash railroad; 130 miles northwest of Saint Louis and 145 miles northeast of Kansas City. It is situated in an agricultural and coal-mining region. Its principal industrial establishments are flour mills, machinery shops, rake and stacker factory. Its trade is chiefly in agricultural and mining implements, live stock, and farm products. Pop. (1900) 1,805.

Huntsville, Texas, city, county-seat of Walker County; on the International & G. N. railroad; about 200 miles southeast of Austin and 68 miles north of Houston. The first settlement was made about 1835. It is in a fertile agricultural region in which cotton is one of the large crops. The chief manufactures are cotton goods, cottonseed oil, cigars, steam-engines, foundry-products agricultural implements, furniture, ice, corn meal, and wagons. Here are the home and grave of Sam Houston, which are of historic interest; the main State Penitentiary, and the Sam Houston State Normal School are located in this city. Huntsville has an extensive trade in cotton. Pop. (1890) 1,509; (1900) 2,484.

Hurlbut, hėrl'bŭt, **Stephen Augustus,** American soldier and politician: b. Charleston, S. C., 29 Nov. 1815; d. Lima, Peru, 27 March 1882. He was admitted to the bar in 1837 and removing to Illinois became prominent in State politics, being a member of the Illinois Legislature 1859, 1861, and 1868. At the opening of the Civil War he became a brigadier-general of volunteers, and he commanded a corps in the expedition to Meridian in 1864. He was United States minister to the United States of Colombia, 1869–73; Republican member of Congress from Illinois, 1873–7; and United States minister to Peru.

Hur'ley, Wis., town, capital of Iron County, on the Montreal River, at the State boundary, opposite Ironwood, Mich. It is 49 miles by rail east by south of Ashland, on the Chicago & N. W., the Milwaukee, L. S. & W., and the Wisconsin C. R.R.'s. It is in a rich iron mining district and has saw-mills and considerable lumbering interests. Pop. (1900) 1,823.

Huron, hū'rŏn, an Indian tribe. See Wyandot; Indians, American.

Huron, S. Dak., city, county-seat of Beadle County; on the Chicago & N. W. and the Great N. R.R.'s; about 115 miles northwest of Yankton. It is situated in an agricultural and stock-raising region, where there is a large acreage of wheat and from which many cattle are shipped annually to market. Its manufactures are flour, bricks, dairy products, carriages, and wagons; and it has the Chicago & Northwestern railroad repair-shops, and grain elevators. Pop. (1900) 2,793.

Huron, Lake, one of the Great Lakes on the boundary between the United States and Canada. Canada is on the north and east, Canada and Michigan on the south, and Michigan on the west. It receives the waters of Lake Superior through the Saint Mary's River, and the waters of Lake Michigan through Straits of Mackinac, and discharges its waters through Saint Clair River into Lake Saint Clair (q.v.). Its general direction is northwest and southeast. Its length is about 250 miles, its average width about 155 miles, and its area, 22,322 square miles. This area includes Georgian Bay and North Channel. It is 581 feet above the sea, the same as Lake Michigan, 21 feet below the level of Lake Superior. The depth of the waters beyond the land shelf is from 200 to 750 feet; and along the coast, from 20 to 60 feet. The waters of the whole lake are remarkably clear, and in the northern part cold. In summer the temperature of the surface varies from 52° to 58° and of the bottom from 42° to 52°.

The chief arm of the Lake on the east coast is Georgian Bay, which indents Ontario; and on the west, Saginaw Bay, in Michigan. Other indentations on the west coast are Thunder, Presque Isle, and Hammond bays. A number of short streams flow into the lake from Michigan, the largest of which are Thunder Bay, Au Sable, and Black rivers. The Lake receives from Canada a large amount of water from lakes Nipissing, Simcoe, Muskoka, and several other small bodies which discharge their waters through short rivers into Georgian Bay.

There are no large islands in the main body of the Lake, but on the north and northeast shores are a number of small islands, composed chiefly of glacial deposits and limestone. Grand Manitoulin and Cockburn islands, together with several small islands, belong to Canada. Drummond, Mackinac, and Bois Blanc islands belong to the United States. The long group of islands in the northeast are separated from the mainland of Ontario by North Channel. The greater part of the shore line is low and at one time the country on the west was well-wooded. Regular terraces showing different water levels, deposits of fine sand and clay containing fresh-water shells, extend inland fully 20 miles and at heights above the Lake to 100 and 200 feet. These wide beaches show that at one time this Lake, as the other Lakes, must have been much larger than at present. The area of the whole basin of the Lake, including the surface of the water, is about 74,000 square miles. Some picturesque cliffs along the southeastern coast rise to a height from 80 to 150 feet. The harbors are nearly all protected by breakwaters. The chief ports on the west coast are Cheboygan, Alpena, Tawas City, Bay City (at the head of Saginaw Bay), and Sandbeach. Mackinaw and Saint Ignace, at the entrance to the Straits of Mackinac, are important ports. A railroad line from Detroit to Mackinaw is almost parallel with the west coast. There is an abundance of fish in this Lake, one kind, the whitefish, is most important.

Violent storms, to which the Lake is subject, make navigation dangerous. During the summer months, from the first of May to December, there are but few storms. Lake Huron as a factor in commercial enterprises is most important: it is one of the great waterways of the world, and the shipping on its waters is growing in amount and importance. The great bulk of the iron ore from the Lake Superior district is now brought to the Cleveland and Pittsburg districts: the wheat and flour from the Northwest comes east, and nearly all are carried over Lake Huron; and a large proportion of the products of the east which are sent to the Northwest pass over this same Lake. The Saint Mary's Falls Canal or "The Sault Canal," has been the means of greatly increasing the travel and traffic on Lake Huron.

As early as the 17th century this Lake was crossed by the French missionary, Père Marquette, who, in 1668, established a mission at Sault Sainte Marie, Saint Mary's Falls. In 1673 he was in charge of the mission at Mackinaw, from which place, on 17 May 1673, he departed with Joliet and others in search of the "Big River." For amount of tonnage see GREAT LAKES.

Huronian Series, the name (now largely abandoned) first given by Sir William Logan to a series of strata lying in the vicinity of Lake Huron. They are about 18,000 feet thick, and consist chiefly of quartzite with great masses of greenish chloritic schist, sometimes containing pebbles derived from the Laurentian rocks. No organic remains have yet been found in them, and limestones are rare. They are believed to be of Lower Cambrian age, and lie unconformably on the Laurentians. They occupy the same relative position as the upper parts of the Archæan rocks of Great Britain.

Hurricane. See CYCLONE; STORMS; TORNADO; TYPHOONS.

Hurst, hėrst, **Hal**, English artist: b. London 25 Aug. 1865. He started on his artistic career by drawing eviction scenes in Ireland. He emigrated to the United States, and joined the staff of the Philadelphia *Press;* afterward at New York, Paris, and London he contributed to various journals and periodicals. He became a painter, studying at the Art League in New York and under Julian at Paris. Among his paintings are 'The Siren' (1896); 'The Capture' (1898); and 'The First Court of Henry VII.'

Hurst, John Fletcher, American Methodist bishop: b. near Salem, Md., 17 Aug. 1834; d. Washington, D. C., 4 May 1903. He was graduated from Dickinson College, Carlisle, Pa., in 1854, studied theology in Halle and Heidelberg, Germany, and after holding pastorates in New Jersey and Staten Island became bishop in 1880, and chancellor of the American University in 1891. He was one of the leading men in his denomination and of much prominence as a writer. Among his many works may be cited: 'Literature of Theology'; 'History of Rationalism' (1865); 'Martyr to the Tract Cause' (1873); 'Life and Literature in the Fatherland' (1874); 'Outline of Church History' (1875); 'Our Theological Century' (1876); 'Bibliotheca Theologica' (1883); 'Short Histories of the Church' (1888–90); 'Short History of the Christian Church'; 'Indika: the Country and People of India and Ceylon' (1891); 'History of the Christian Church' (1897); translations of theological works and histories; etc.

Husband and Wife. See LAW OF HUSBAND AND WIFE.

Husbandry, Patrons of. See GRANGERS.

Huskisson, hŭs'kĭ-sŏn, **William**, English statesman and financier: b. Birch-Moreton, Worcestershire, 11 March 1770; d. 15 Sept. 1830. He was sent to Paris in 1783 to study medicine. In 1789 he became an enthusiastic sympathizer with the French Revolution, was present at the taking of the Bastille, and joined the Club of 1789, instituted the following year. He made a speech at the club against the proposed creation of paper money, and withdrew from it when the assembly decreed the issue of assignats. His views of the Revolution afterward underwent a change. In 1790 he was appointed secretary to the British ambassador; and when the ambassador was recalled in 1792 he returned to England, and in 1795 he became under-secretary for war and the colonies. In 1796 he was elected member of Parliament for Morpeth. He resigned in 1801, and returned in 1804. In Pitt's administration formed in this year he became secretary of the treasury, and during the Whig ministry that succeeded Pitt's death was an active member of the opposition. In 1807 he resumed his post as secretary of the treasury, which he resigned in 1809. In 1823 he was elected M.P. for Liverpool, and appointed president of the board of trade, and treasurer of the navy. In 1827 he became secretary of state for the colonies. He was killed at the opening of the Liverpool and Manchester railway 15 Sept. 1830. He seldom spoke in Parliament except on commercial or financial subjects, on which he was an authority. He also anticipated Peel in his advocacy of a free-trade policy. A collective edition of his speeches appeared in 1831.

Huss, Henry Holden, American composer: b. Newark, N. J., 21 June 1861. In 1882 he entered the Munich Conservatory, Germany, and studied music, in theory and practice, under Rheinberger, Giehrl, and Abel. In 1885 he settled in New York, where he has had a successful career as composer, performer, and teacher. He has composed 'Cleopatra's Death,' a scene for soprano and orchestra, as well as songs, anthems, and charming chamber music.

Huss, or Hus, John, Bohemian religious heresiarch: b. Husinec, Southern Bohemia, about 1369; d. Constance, Switzerland, 6 July 1415. He studied at the University of Prague and in 1398 began to lecture on theology and philosophy. In 1401 he was made dean of the faculty of philosophy, and was made rector of the university (1400). Since 391 he had been acquainted with the writings of Wickliffe, and his denunciations of the indulgences, of masses for the dead, of auricular confession, etc., alarmed Archbishop Stynko of Prague, who had 200 volumes of Wickliffe's writings burned (1410) in the archiepiscopal palace, and the preaching of his doctrines in Bohemia prohibited. Huss appealed to the Pope John XXIII., who summoned him to appear at Bologna. Huss refused to appear and was in consequence excommunicated, and Prague threatened with an interdict as long as Huss should remain in it. Wenceslaus, the king, alarmed by this menace, thought to bring about peace; and at his demand, Huss made an orthodox profession of faith in 1411. But the quarrel broke out again when Huss and his friend Jerome publicly condemned the papal indulgences granted for the crusade against Ladislaus of Naples. Huss was again excommunicated and Prague interdicted. He now retired to Husinec to the protection of his feudal lord and here he wrote his books 'On the Six Errors' and 'On the Church,' in which he attacks transubstantiation, the belief in the papal primacy and the saints, the efficacy of the absolution of a vicious priest, unconditional obedience to earthly rulers, and makes the Scriptures the only rule of matters of religion. In the meantime the Council of Constance had convened in 1413. Huss was summoned to this council to render an account of his doctrines. The emperor Sigismund granted him a safe conduct to the council. After several examinations of his doctrines, and his persistent refusal to retract the points which were regarded as heretical, he was sentenced to death and burned 6 July 1415.

Husted, James William, American politician: b. 1833; d. Peekskill, N. Y., 25 Sept. 1892. He was graduated at Yale in 1854, studied law, and in 1869 was elected to the New York Assembly. He was re-elected 15 times, and was chosen speaker in 1874, 1876, 1878, 1886, and 1887. He also served in such varied capacities as superintendent of public schools, deputy superintendent of insurance, harbor master, deputy captain of the port of New York, judge-advocate of the Seventh brigade, and major-general of the Fifth Division, National Guard.

Hutcheson, hŭch'ĕ-sŏn, **Francis,** Irish philosopher: b. Drumalig, Ireland, 8 Aug. 1694; d. Dublin 8 Aug. 1746. He was educated at the University of Glasgow, taught in Dublin 1717–29, and in 1729 became professor of philosophy at Glasgow. In 1725 the first edition of his celebrated 'Inquiry into the Ideas of Beauty and Virtue' appeared without his name. In 1728 he published his 'Treatise on the Passions,' often reprinted, and admired even by those who dispute the soundness of its philosophy. In 1775 was published from his MSS. a 'System of Moral Philosophy.' The philosophy of Hutcheson is based primarily on that of Locke. His particular theory of conscience as a distinct sense was attacked by Richard Price in a celebrated work, 'Principal Questions and Difficulties in Morals.' The views of Hutcheson and Price are reviewed in Jouffroy's 'Cours de Droit Naturel.' Hutcheson was a writer of considerable originality, and justly regarded as the precursor of Reid, and the founder of the Scottish school in philosophy. An admirable résumé of his works is contained in Cousin's 'Philosophie Ecossaise.'

Hutch'ins, Thomas, American geographer: b. Monmouth, N. J., 1730; d. Pittsburg, Pa., 28 April 1789. In early life he enlisted in the English army, and saw active service in the French and Indian war. He was in England in 1779, and was arrested in London, and thrown into prison as an advocate of American independence. He escaped to France, from which country he sailed to America, and joined the Continental army and was appointed geographer-general by Gen. Greene. Among his published works are: 'Topographical Description of Virginia, Pennsylvania, Maryland, and North Carolina' (1778); 'History, Narrative and Topographical Description of Louisiana and Western Florida' (1784).

Hutch'inson, Anne, American religious leader, the founder of the Antinomian party in the New England colonies: b. Lincolnshire, England, about 1590; d. Westchester County, N. Y., August 1643. She was the daughter of a Lincolnshire clergyman. In England she was interested in the preaching of John Cotton and her brother-in-law John Wheelwright, and it was her desire to enjoy the ministry of the former which induced her to follow him to New England. She arrived in Boston with her husband, 18 Sept. 1634, was admitted a member of the Boston church 2 November, and rapidly acquired esteem and influence. She instituted meetings of the women of the church to discuss sermons and doctrines, in which, with a ready wit, bold spirit, and imposing familiarity with the Scripture, she gave prominence to peculiar speculations which even on her voyage had attracted the attention and caused the displeasure of her fellow passengers. Such were the tenets that the person of the Holy Spirit dwells in every believer, and that the inward revelations of the Spirit, the conscious judgments of the mind, are of paramount authority. She had been two years in the country before the strife between her supporters and her opponents broke out into public action. Among her partisans were the young governor Vane, Cotton, Wheelwright, and the whole Boston church with the exception of five members, one of whom was the associate pastor, Wilson, while the country clergy and churches were generally united against her. "The dispute," says Bancroft, "infused its spirit into everything; it interfered with the levy of troops for the Pequot war; it influenced the respect shown to the magistrates, the distribution of town lots, the assessment of rates; and at last the continued existence of the two opposing parties was considered inconsistent with the public peace." The peculiar tenets of Mrs. Hutchinson were among the 82 opinions condemned as erroneous by the ecclesiastical synod at Newtown 30 Aug. 1637; and in November she was summoned before the general court, and after a trial of two days sentenced, with some of her associates, to banishment from the territory of Massachusetts, but was allowed to remain during the winter at a private house in Roxbury. She joined the larger number of her friends, who, led by John Clarke and William Coddington, had been welcomed by Roger Williams to his vicinity, and had obtained through his influence from the chief of the Narragansetts the island of Aquidneck, subsequently called Rhode Island. There a body politic was formed on democratic principles, in which no one was to be "accounted a delinquent for doctrine." The church in Boston, from which she had been excommunicated, vainly sent a deputation of "four men of a lovely and winning spirit" to the island with the hope of reclaiming her. After the death of her husband in 1642 she removed with her surviving family into the territory of the Dutch, probably from apprehensions that Rhode Island might not be a safe place of refuge from the encroachments of Massachusetts. The precise locality where she settled has been a matter of dispute, but according to the latest authorities it was near Hell Gate, Westchester County, N. Y. The Indians and the Dutch were then at war, and in an invasion of the settlement by the former her house was attacked and set on fire, and herself and all her family, excepting one child who was carried captive, perished either by the flames or by the weapons of the savages.

Hutchinson, Horatio Gordon, English golfer: b. 16 May 1869. He was educated at Charterhouse School, London, and graduated with classical honors in the University of Oxford. He was golf champion in England 1886–7. He has published 'Hints on Golf'; 'Golf' (in Badminton Library); 'Creatures of Circumstance'; 'Peter Steele the Cricketer'; 'My Wife's Politics'; 'Cricketing Laws and Stories'; 'The Book of Golf and Golfers' (1899); 'Little Lady Mary' (1900); 'Dreams and Their Meanings'; 'A Friend of Nelson' (1902).

Hutchinson, John, Puritan English soldier: b. Nottinghamshire 1617; d. Sandown castle, Kent, 11 Sept. 1664. Being of a religious turn of mind, he devoted much time to the study of divinity, from which his attention was soon diverted by the serious political questions which agitated the kingdom. A careful investigation of the matters at issue between the king and the parliament satisfied him of the justice of the latter's cause, and after the commencement of the civil war he declared for the parliament and was appointed governor of Nottingham castle, which he held until the close of the war. He afterward represented Nottingham in parliament, and, as a member of the high court of judiciary appointed for the trial of the king concurred in the sentence pronounced on him. The subsequent course of Cromwell, however, met with the disapproval of Hutchinson. At the restoration he was comprehended in the general act of amnesty, but was subsequently arrested on a suspicion of treasonable conspiracy, and after a detention of ten months in the Tower was removed to Sandown castle, where he died of fever.

Hutchinson, John, English philosopher; founder of a mystical school of philosophy and theology: b. Spennithorne, Yorkshire, 1674; d. 28 Aug. 1737. In 1724 appeared the first part of his 'Moses' Principia,' in which he disputed the Newtonian theory of gravitation. In the second part (1727) he continued his criticisms of Newton, and maintained on Biblical authority the doctrine of a *plenum* in opposition to that of a *vacuum*. From this time one or more of his uncouthly written volumes, containing a sort of cabalistic interpretation of the Hebrew Scriptures, appeared annually. His leading idea is that the Scriptures contain the elements of all rational philosophy as well as of general religion. The Hebrew language has not only its literal but its typical sense, every root of it being significant of hidden meanings. With this elastic principle of exegesis he deduces a system from which the occult powers of attraction, gravitation, magnetism, and electricity are excluded, but according to which the whole mechanism of the heavens is the result of the agency of fire, light, and spirit, the three material elements which were set to work in the beginning, and which typify the three persons of the Trinity.

Hutchinson, Thomas, American colonial governor: b. Boston 9 Sept. 1711; d. Brompton, near London, 3 June 1780 He was the son of a merchant of Boston who was long a member of the council, and graduated at Harvard College in 1727. He represented Boston for 10 years in the general court, of which he was for three years speaker; became judge of probate in 1752, was a councillor from 1749 to 1766, lieutenant-governor from 1758 to 1771, and appointed chief justice in 1760, thus holding four high offices at one time. In the disputes which led to the Revolution he sided with the British government. His brother-in-law, Andrew Oliver, was appointed distributor of stamps under the law which was to go into effect 1 Nov, 1765, but was compelled by mobs to resign the office before that time. The mansion of Hutchinson was also twice attacked in consequence of a report that he had written letters in favor of the act, and on the second occasion (Aug. 26), when the rioters were maddened by liquor, his house was sacked, the furniture burned in bonfires in the street, and many manuscripts relating to the history of the province, which he had been 30 years in collecting and which could not be replaced, were lost. The inhabitants of the town on the following day in public meeting voted their abhorrence of the proceedings; but though many of the actors were well-known, no one was punished. He, however, received compensation for his losses. When in 1769 Gov. Bernard was transferred to Virginia, the government of Massachusetts fell to Hutchinson. The popular excitement had already been increased by the arrival of the British troops, and after the so-called Boston massacre a committee of citizens, headed by Samuel Adams, obliged him to consent to the removal of the regiments. The popular indignation against Hutchinson became so great that he at last obtained leave of absence and sailed for England 1 June 1773. The privy council investigated his official acts, and decided in favor of "his honor, integrity, and conduct," which decision was approved by the king. He was rewarded with a pension. He published 'History of the Colony of Massachusetts Bay, from the First Settlement Thereof, in 1628, until the Year 1750' (2 vols., 1760–7, vol. 3, 1828); 'Brief State of the Claim of the Colonies' (1764); 'Collection of Original Papers Relative to the History of the Colony of Massachusetts Bay' (1869). His diary and letters appeared (1804–6). The sober judgment of later times has reversed the prejudiced accusations of his American contemporaries and he is now seen to have been a conscientious man, zealous in the performance of duty but sorely perplexed between the claims of loyalty to the king and his natural inclinations in favor of the colony. See Hosmer, 'Life of Thomas Hutchinson' (1896); Fiske, 'Historical Essays, Vol. I.' (1902).

Hutchinson, Kan., city and county-seat of Reno County; on the Arkansas river, and on the Atchison, T. & S. F., the Chicago, R. I. & P., the Hutchinson & S. and the Missouri P. R.Rs.; 40 miles west of Wichita. The city has one of the largest salt interests in the world, producing about 6,000 barrels per day. It is also an important meat packing and shipping centre; and has manufactures of lumber, machinery, boilers, etc., and the railroad shops of the Hutchinson & Southern railroad. It has a public library, high school, state reformatory, electric lights, a national bank, and an assessed property valuation of $1,500.000. Pop. (1900) 9.376.

Hutch'ison, John, English sculptor: b. Edinburgh, Scotland, 1832. He served his apprenticeship in his native town at the trade of wood carving. Meanwhile he attended an art school, visited Rome and chose as his profession that of a sculptor. He exhibited in the London Royal Academy for the first time in 1862. He is best known for his statues of Robert Bruce and John Knox, and his busts of Norman McLeod, Queen Victoria, and the Prince Consort, as well as for the four figures he contributed to Scott's monument at Edinburgh (Baron Bradwardine, Hal-o'-the-Wynd, the Glee Maiden, Flora MacIver. Among his imaginative works are 'Greek Torch Racer'; 'Roman Dancing Girl.'

Hut'son, Charles Woodward, American educator: b. McPhersonville, S. C., 23 Sept. 1840. He was graduated from South Carolina College in 1860; served in the Confederate army, 1861–5; was professor of Greek in Louisiana State University, 1869–81; of modern languages in the University of Mississippi, 1881–9, and of English and history in the Texas Agricultural and Mechanical College from 1893. He has published 'Out of a Besieged City' (1887); 'The Beginning of Civilization' (1888); 'French Literature' (1889); 'The Story of Language' (1897).

Hutten, hoot'tĕn, **Philip von,** German adventurer; cousin of Ulrich von Hutten (q.v.): b. Birkenfeld about 1490; d. Venezuela 1546. In 1528 the Emperor Charles V. made a grant of the province of Venezuela to the Welsers, a firm of Augsburg merchants; and Hutten sailed with one of the companies sent out by them. He accompanied the viceroy, Georg Hohemut, in a journey (1536–8), in which they reached the headwaters of the Rio Japura, near the equator. In 1541 he set out in search of the Golden City. After several years of wandering, harassed by the natives and weakened by hunger and fever, he and his followers came on a large city, the capital of the Omaguas, in the country north of the Amazons; where they were routed by the Indians, and Hutten himself severely wounded. He led those of his followers who survived back to Coro in 1546, where Juan de Caravajal had in the meantime usurped the office of viceroy; and by him Hutten and his lieutenant, Bartel Welser, were seized and beheaded. Eight years later the Welsers' grant was taken from them, and the German rule in Venezuela was concluded. Hutten left an account of his journeyings which was published under the title 'Zeitung aus Indien' (1765). See Von Langegg, 'El Dorado' (1888).

Hutten, Ulrich von, ool'rĭн fōn, German knight, distinguished for his poems and satires, and for the influence which his writings exercised upon the Reformation: b. Steckelberg on the Main 21 April 1488; d. Ufnau, an island in the Lake of Zürich, 23 Aug. 1523. His father placed him at Fulda, in order to educate him for a monk. The monastic school there was one of the most famous in all Germany, and he received an excellent education. Here he lost his faith and the declared enemy of Christianity fled to Erfurt in 1504, where he became intimately acquainted with several scholars and poets. In 1511 he went to Wittenberg, where he published a work on versification. Ulrich, duke of Würtemberg, having murdered a cousin of Hutten, Hutten gave free course to his indignation in poems, letters, and addresses, which made him known throughout Germany. He distinguished himself no less in the Reuchlinian controversy with the Dominican Hogstraaten in Cologne.

Hutten severely criticized the monastic life, and was so much the enemy of the clergy, that by his edition of Laurentius Valla, 'De falso credita et ementita Donatione Constantini,' he declared war upon the Church and prepared the way for Luther. In 1518 he entered the service of Albert, archbishop of Mayence, and made several official journeys to Paris. He also accompanied the archbishop to the diet at Augsburg, where Luther held his well-known discussion with Cajetan, and Hutten, in a Demosthenic oration, urged the German princes to a war against the Turks. He took the field with the Swabian League in 1519, against his hereditary enemy, Ulrich of Würtemberg, and then retired to the solitude of his paternal castle of Steckelberg, to engage anew in the controversy with the monks. Here he published work after work, violently assailing the Church, the clergy and the state. Leaving Steckelberg in 1822 he went first to Basel and thence to Zürich, where he died. He was a savage and violent controversialist during his life and was unsparing in the vehemence of his invective.

Hutton, hŭt'n, **Charles**, English mathematician: b. Newcastle-upon-Tyne 14 Aug. 1737; d. 27 Jan. 1823. The destruction of the old bridge at Newcastle having attracted his attention to the subject of the construction and properties of arches, he was led to the production of a small work on the 'Principles of Bridges' (1772), which laid the foundation of his future fame. He was in 1773 appointed professor of mathematics at Woolwich Academy, elected a fellow of the Royal Society in 1774, and in 1785 published his 'Mathematical Tables,' preceded by an introduction, tracing the progress and improvement of logarithms from the date of their discovery. Later works were: 'Tracts, Mathematical and Philosophical' (1786); 'Elements of Conic Sections'; 'Mathematical and Philosophical Dictionary' (1795–6); 'Course of Mathematics' (1798–1811).

Hutton, Frederick Remsen, American mechanical engineer: b. New York 28 May 1853. He was graduated from Columbia in 1853 and is professor of mechanical engineering there. He has published: 'Mechanical Engineering of Power Plants' (1897); 'Heat and Heat Engines' (1899); 'Machine Tools.'

Hutton, James, Scottish geologist: b. Edinburgh 3 June 1726; d. there 26 March 1797. He studied medicine at Paris and Leyden, but on his return (1754) devoted himself to agricultural pursuits and to chemistry, from which he was led to mineralogy and geology. In 1768 he removed to Edinburgh, and there spent his time in scientific investigations. He published 'A Theory of the Earth' (1795) and 'A Theory of Rain' (1784); 'Dissertations in Natural Philosophy' (1792); 'Considerations on the Nature of Coal and Culm' (1777); and other works. See HUTTONIAN THEORY.

Hutton, Laurence, American editor and critic: b. New York 8 Aug. 1843; d. Princeton, N. J., 10 June 1904. He was privately educated, for some time devoted himself to the study of literature and to foreign travel, in the early 70's became a dramatic critic, and began contributions to periodicals of many sorts. From 1886 to 1898 he was literary editor of 'Harper's Magazine,' and subsequently he became lecturer in English literature at Princeton University. He was a well-known collector, possessing among various things a famous series of death-masks of historical personages. He was also an organizer and founder of the Authors' Club, and of the American Copyright League. Among his numerous writings were: 'Plays and Players' (1875); 'Literary Landmarks' (1885–1903), etc.

Hutton, Richard Holt, English essayist and journalist: b. Leeds 2 June 1826; d. Twickenham 7 Sept. 1897. The son of a Unitarian clergyman, he was educated at University College, London, and in Germany, for the Unitarian ministry, but, coming under the influence of F. D. Maurice, he entered the English Church. In 1861 he became editor of the 'Spectator,' which owed its prominence largely to him. Hutton's best work is in the critical 'Essays, Theological and Literary' (1871), and 'Essays on Some Modern Guides of English Thought' (1887), and in the biography of Sir Walter Scott in the 'English Men of Letters' (1878).

Hutton, William Holden, English Anglican clergyman and historian: b. Gate Burton, Lincolnshire, 24 May 1860. He was educated at Oxford where he was select preacher 1898–1900 and Bampton lecturer for 1903. He has published 'The Misrule of Henry III.'; 'Simon De Montfort'; 'St. Thomas of Canterbury'; 'William Laud'; 'Sir Thomas More'; 'Short History of the Church in Great Britain'; 'Constantinople'; etc.

Huttonian Theory, a view of geological processes first published by James Hutton (q.v.) in 1788, in his 'Theory of the Earth,' and developed in 1795. He was the first to distinguish between cosmogony and geology, believing the latter to be in no way concerned with "questions as to the origin of things." His view was that the upraised land of the globe must be worn away by atmospheric influences and the débris be finally deposited in the bed in the sea, where it is consolidated under great pressure; it is then forced upward by subterranean heat, acting with an expansive power, and thereby split and cracked, the fissures at the same time filling with molten mineral matter; and so the process goes on. Hutton was the precursor of Sir Charles Lyell, whose views were essentially the same, and who procured for them large acceptance among geologists. See UNIFORMITARIANISM.

Huxley, hŭks'lĭ, **Thomas Henry**, English biologist: b. Ealing, Middlesex, England, 4 May 1825; d. Eastbourne, Sussex, 29 June 1895. When he was 12 or 13, he wished to become a mechanical engineer; but a medical brother-in-law (Dr. Salt) took him in hand, and he commenced at this early age the study of medicine. Eventually he went to Charing Cross Hospital, and passed the first M. B. examination of the University of London. Stern necessity compelled him, as soon as his medical course was over, to seek at once, even before he was of age, some post or employment. At the suggestion of a fellow student, Huxley in 1846 applied for admission to the medical service of the navy, was admitted, and was in attendance at the naval hospital at Haslar. The next year he was appointed assistant-surgeon of the Rattlesnake, which was sent on an exploring and surveying cruise in the seas on the east and northeast of Australia. The voyage lasted four years, and gave Huxley an opportunity of gaining an almost unrivaled knowledge of marine zoology. Various papers on this subject were contributed by him to the Linnæan and the Royal Society (one of them gaining a medal from the latter body, of which he was elected a member in 1851), and a further result of his investigations was the important work published in 1859, entitled 'The Oceanic Hydrozoa.'

The Rattlesnake returned to England at the end of the year 1850 and Huxley found that the scientific papers he had sent home had already made him famous. By the aid of those who valued the promise given by his published work, he was allowed by the admiralty for

THOMAS HENRY HUXLEY.

three years to draw pay as a navy surgeon whilst devoting himself to the working up of the results of his observations when at sea. In 1854 he was appointed lecturer or professor of natural history in the Royal School of Mines, a post long combined with that of naturalist to the geological survey. In 1855 he was appointed Fullerian professor of physiology to the Royal Institution, and delivered four courses of lectures in as many years; while he was also an examiner for seven years to the University of London. The posts of Croonian lecturer to the Royal Society and Hunterian professor in the College of Surgeons were likewise filled by him.

There is no doubt that Huxley was fortunate to obtain at 27 a post, worth nearly a thousand a year, in London, and unburdened with any excessive duties. He had to give during winter (October to end of February) a course of lectures on five days of the week, and attend in his study at the Museum in Jermyn Street, but had not the cares of a laboratory. He carried out his researches alone, and consequently was able to arrange the employment of his day in his own way. He wrote largely for the press upon such topics as belonged to his branch of science; lectured frequently in other places besides Jermyn Street; and took an active and important part in various government commissions, to which his official position rendered it proper that he should be appointed. His lectures to workingmen, in 1860, on the 'Relation of Man to the Lower Animals,' gave rise to much discussion, and led him to treat the subject in his 'Evidence as to Man's Place in Nature' (1863). By this time the Darwinian theory had given rise to much excited controversy, and Huxley's thorough-going Darwinism brought many a bitter attack upon him. In 1862 he was appointed by government to assist in inquiring into the effects of the acts regarding trawling for herring; and his labors and advice had much influence in determining the course of fishery legislation and administration. In 1870 his name became more prominent than ever on the publication of his collection of papers entitled 'Lay Sermons, Essays, and Reviews,' which met with fierce denunciation in many quarters. In this year he presided over the Liverpool meeting of the British Association, and was also elected a member of the first London School Board. In 1872 he was elected Lord Rector of Aberdeen University; in 1875–6 lectured on natural history in Edinburgh University.

In 1883 Huxley received the crowning honor of his life, being elected president of the Royal Society. But ill health soon compelled him to give up his official work. In 1885 he retired from his professorship, from his fishery post, and from the presidency of the Royal Society, and confined himself to such work as he could perform in his study at Eastbourne (where in 1890 he built himself a house), or in the Engadine, where he usually spent the summer.

He produced between 1885 and his death in 1895 a large series of brilliant and interesting essays, especially on the relation of science to Hebrew and Christian tradition, and on the evolution of theology and of ethics. During this period he was president of the Marine Biological Association, in the founding of which he took an active part, and in 1892 was made a member of the Privy Council.

In 1888 Huxley received the Copley medal of the Royal Society, and in 1894 the Darwin medal. Huxley was one of the first scientists of his time; his chief and most valuable work was in the direction of the popularization of science, particularly of the Darwinian theory; he was active also in lines of social and political reform, and in the development and organization of scientific education. His works include 'Oceanic Hydrozoa' (1859); 'Evidence as to Man's Place in Nature' (1863); 'Elementary Physiology' (1866); 'Anatomy of Vertebrated Animals' (1871); 'Elementary Biology' (with Dr. H. N. Martin); 'Anatomy of Invertebrated Animals' (1877); 'Physiography' (1877); 'Hume' (1878); 'The Crayfish' (1880); and numerous essays and addresses on scientific and sociological subjects. Consult: the 'Life,' by Mitchell; 'Life and Letters,' by L. Huxley; and Clodd, 'Thomas Henry Huxley.'

Huygens, hoi'gĕns or hī'gĕnz, **Christian**, Dutch mathematician and physicist: b. The Hague 1629; d. there 8 June 1695. He studied at Leyden, and at Breda, where he went through a course of civil law from 1646–8. Among his most important contributions to science are his investigations on the oscillations of the pendulum, and his 'System of Saturn,' in which he first proved that the ring completely surrounds the planet, and determined the inclination of its plane to that of the ecliptic. In 1690 he published important treatises on light and on weight. His 'Traité de la Lumière' was founded on the undulation theory, but in consequence of the prevalence of the Newtonian theory was long neglected till later researches established its credit.

Huygens' Principle. See Light.

Huysmans, hīs-măns, **Jorris Karl**, French novelist: b. Paris 5 Feb. 1848; d. 12 May 1907. He studied law and entered the French civil service, but abandoned it for literature. At first a pronounced realist, he turned to idealism and even mysticism. His first work was 'Pack on Back'; then followed 'Martha' (1876); 'The Vatard Sisters' (1879); 'The Ménage' (1881); 'Down There' (Lá-bas) (1889).

Hwang or **Hoang-ho**, hwăng'hō, or **Yellow River**, China, a large river which rises in the mountains of north Tibet, in the Koko-Nor territory, about lat. 34° 30′ N., and lon. 97° 30′ E. It derives its name from the vast quantities of yellow mud continually carried down by its waters. After a winding course, north, east, and south, of about 2,600 miles, it flows since 1853 into the Gulf of Pe-chi-li, prior to that year its outlet being in the Yellow Sea. It is a turbulent, turbid, and impracticable stream, but little used for navigation and subject to disastrous floods, to prevent which and the former frequent changes in its bed and outlet, great expense is incurred maintaining artificial embankments.

Hy'acinth (1) A genus (*Hyacinthus*) of lilies with corolla-like, bell-shaped, six-cleft perianth, six stamens fixed in the tube of the perianth, and dry capsular fruit. The Oriental hyacinth (*H. orientalis*), one of the chief favorites of florists' flowers, is a native of Asia Minor, Syria, and Persia. It is now naturalized in some parts of the south of Europe. It has broad linear leaves, and a scape with a raceme of many flowers pointing in all directions. The flowers in cultivation exhibit great variety of color, chiefly blue, purple, and white. They are very beautiful and very fragrant. The fragrance is strongest about or after 11 o'clock at night. Among cultivated hyacinths are many with double flowers. The hyacinth has been cultivated from a remote period. It was introduced into Europe, probably by the Dutch, about the beginning of the 16th century. The grape-hyacinth is a somewhat different plant of the genus *Muscari*, of which *M. racemosum* is common in gardens. (2) See ZIRCON.

Hyacinthe, Père, pār ē-ā-sānt. See LOYSON, CHARLES.

Hyænodon, hī-en'ō-dŏn, a genus of primitive carnivorous mammals (creodonts), fossil in the upper Eocene and lower Miocene rocks of Europe and the western United States, of which several species are known by well preserved skeletons. The skull was relatively very large and long, with great canines and strong hyena-like molars, but the brain-cavity was very small. The feet were fully five-toed, had powerful claws, and the animal, which must have somewhat resembled a small, cat-like bear, was partly plantigrade. The remains of *H. cruentus* are numerous in the White River beds of North Dakota.

Hyams, Henry Michael, American lawyer and politician: b. Charleston, S. C., 1805; d. 1875. In 1828 he went to New Orleans, studied law, and after 15 years of country practice in Alexandria, La., resumed his residence in New Orleans, where his investments in landed property made him wealthy. In politics he was originally an old line Whig, but on the outbreak of Know-Nothingism joined the Democratic party. In 1855 he was elected to the State Senate; in 1859 he was chosen lieutenant-governor; the first Israelite to hold such an honor in the United States. He was devoted to the Southern cause, sent his sons to fight in the Confederate army, and after the war found his large fortune vanished. Prepared to begin life anew, he resumed the practice of law until his death.

Hyatt, Alpheus, American naturalist: b. Washington 5 April 1838; d. Cambridge, Mass., 15 Jan. 1902. He was graduated from the Lawrence Scientific School at Harvard in 1862, then entered the army and served during the war in the 47th Massachusetts regiment, being promoted to the rank of captain. After leaving the army, he resumed his studies under the instruction of Agassiz, and later studied abroad. In 1867 he went to Salem, where he was one of the founders of the Peabody Academy of Sciences and one of the curators of the Essex Institute. In 1870 he was made custodian of the collections of the Boston Society of Natural History, becoming curator in 1881. He was also connected with Boston University, was manager of the Teacher's School of Science, had charge of a laboratory of natural history founded by the Women's Educational Society at Annisquam, and was for several years professor of zoology and palæontology at the Massachusetts Institute of Technology. In his later life he had charge of invertebrate fossils in the Museum of Comparative Zoology at Cambridge. He was a member of the American Academy of Arts and Sciences, of the National Academy of Sciences, and of the American Society of Naturalists. He was one of the founders of the last mentioned society and its first president (1883); he was also one of the founders and editors of the 'American Naturalist.' His most distinctive work was the investigation of the development of the fossil *Cephalopoda* and of the fossil and semi-fossil *Planorbis* on Steinheim Lake, Germany, from which investigations he deduced laws of growth very important to the evolutionary theory. His works include 'Observations on Polyzoa' (1866); 'Fossil Cephalopods of the Museum of Comparative Zoology' (1872); 'Revision of North American Poriferæ' (1875–7), the only work on North American commercial sponges; 'Genesis of Tertiary Species of Planorbis at Steinheim' (1880); 'Genera of Fossil Cephalopoda' (1883); 'Larval Theory of the Origin of Cellular Tissue' (1884); 'Genesis of the Aretidæ' (1889); 'Bioplastology and the Related Branches of Biologic Research' (1893); 'Phylogeny of an Acquired Characteristic' (1894); 'Cephalopoda' (1900).

Hy'att, John Wesley, American inventor: b. Starkey, N. Y., 28 Nov. 1837. After an education in the common schools he became a printer and then an inventor. He perfected a composition billiard ball (1865), secured a "bonsilene" compound (1878), a water-purifying system, and a method of dissolving pyroxylin. He has secured about 200 patents for his inventions.

Hybridity, the crossing of two individuals of distinct species. The result of the intercrossing of species is a hybrid, for example, the mule, which is the result of breeding the horse with the ass. As the mule is invariably sterile, the infertility has always been supposed to be a test of species. But this is not an invariable rule, as not a few so-called "good" species have been crossed with one another. It may be set down as a general proposition that the difficulty of crossing increases the more distant the systematic relationship of the species experimented with. Also these difficulties are, says Hertwig, by no means directly proportional to the systematic divergence of the species.

Nature tends to keep species separate, in the higher animals, as well as among insects, etc.; mating is usually prevented by the structure of the parts concerned with sexual union; also the principle of preferential mating comes into play among mammals as well as insects, as often between males and females, even of closely allied species, or varieties. When there is no structural differences there may exist an aversion which prevents any union of the sexes.

Artificial Hybridization.— Many experiments have recently been made on the lower marine animals in which the eggs are fertilized in the sea without sexual union, by placing the eggs of starfish and sea-urchins, etc., in a watch-glass and adding the sperm of the males, thus securing artificial fertilization. In this way hybrids have been obtained from species belonging to quite different genera, while it has been found that in some cases closely related species will not cross. For example, among the sea-urchins the spermatozoa of *Strongylocentrotus lividus* readily fertilize the eggs of a species of Echinus, but only rarely those of the more closely allied *Sphærechinus granularis.* Hybrids have been obtained from different genera of fishes, as those between the salmon and brown trout. It appears that salmon eggs have been fertilized by trout sperm, but not trout eggs by salmon sperm. According to Hertwig eggs have been fertilized by sperm belonging to species of different families, orders, and possibly classes. For example, the eggs of a flounder (*Pleuronectes platessa*) and of *Labrus rupestris* have been fertilized by the sperm of the cod; frog's eggs (*Rana arvalis*) by sperm of a triton, and even, it is said, the eggs of a starfish by milt from a sea-urchin; in such cases, however, the hybrids die during or at the close of segmentation of the yolk.

Fertility of Hybrids.— While the mule and many other hybrids are sterile, there are some known exceptions. Hybrids of hares and rabbits have continued fruitful for generations, and also hybrids obtained from the wild buck and she-goat, from the Chinese goose (*Anser cygnoides*) and the common goose (*A. domesticus*); from *Salmo salvelinus* and *S. fontinalis; Cyprinus carpio* and *Carassius vulgaris,* as well as between the two silkworm moths, *Philosamia cynthia* and *P. ricini,* the Arrhindy worm. In this country Caton has hybridized the common Virginian deer with the Ceylon deer and the Acapulco deer, and states that the hybrids seemed perfectly healthy and prolific. Ewart states that the Indian buffalo and the American bison produce fertile hybrids with the European wild ox.

In the human species it is a well-established fact that marriages between remote varieties or races tend to sterility, while crossing between allied races are fertile, and such unions are most beneficial. Thus the most mixed white races are the most fertile and vigorous. Ewart thinks that as there are no definite limits between species and varieties, there can be "no fundamental difference between a hybrid and a cross, nor yet any *a priori* reason why any given hybrid should be sterile, or any given cross fertile." He also states that sterility has in some cases been slowly acquired, in others abruptly, but how it has been acquired is not known.

As the result of breeding thousands of moths Standfuss states that in no case observed by him has the female of a true hybrid been shown to be fertile. On the other hand, the occurrence of undoubted cases of fertility in male hybrids has been proved by crossing the male hybrids with the females of both parent species.

Ewart's Experiments with crossing the Zebra and Horse, and the Wild Ass and Horse. — A Burchell's zebra stallion, "Matopo," became the father of nine zebra hybrids by mares of various sizes and breeds. The hybrids exhibited a curious blending of characters, which seemed to have been derived partly from their actual and partly from their remote ancestors; some of the hybrids strongly suggest their zebra sire, others their respective dams, "but even the most zebra-like in form are utterly unlike their sire in their markings."

According to 'Nature,' August 1903, he succeeded in 1902 in securing a male wild ass (kiang) from Central Asia and a couple of Mongolian pony mares, one a yellow dun and the other a chestnut. The wild ass was mated with the dun Mongol mare, a brownish-yellow Exmoor pony, and a bay Shetland-Welsh pony. The kiang hybrid in its long legs, slender joints and speed took after its kiang parent. The mane and tail "are exactly what one would expect in a mule." This kiang hybrid also differs from the wild horse (Przewalsky's horse) in not neighing like a horse. The result is to prove that the wild horse is not a kiang-pony male, but a "good" species. Also in accordance with Mendel's law (see under HEREDITY) the kiang proved to be dominant, the Exmoor pony recessive.

Hybridity in Plants.— The method of hybridizing hermaphroditic flowers is to cut away their stamens before they are ripe, and then enclose the flower in a paper bag. After the stigma has ripened the pollen is placed on it, the bag is again tied over the flower and not removed until the seed begins to form. Great advantages and improvements have resulted from hybridizing plants, chief among which are many new varieties of cultivated plants, increased size and vigor, hardiness, or adaptation to warmer climates, and increased resistance to disease, as well as increase in odor of flowers and the quality and flavor of fruits.

Thus far the cause of infertility in animals is unknown, but botanists attribute the frequent sterility of plants to the imperfect formation of the pollen. Standfuss' experiments with moths agree with Focke's statement as to the great variability of the offspring resulting from the crossing of a plant hybrid with one of the parent species. In plants, as discovered by Mendel, the proportion of the pure races is constantly increasing in the successive generations descended from a hybrid. Malformations and sports are much more frequent, especially in the floral organs in hybrids, than in individuals of a pure descent. Double flowers appear to be formed especially easily in hybrids. Recent experiments and results in the study of hybridity show how intimately the subject bears on heredity (q.v.) and the origin of species.

Consult: Bailey, 'Plant Breeding' (New York 1896); De Vries, 'Die Mutationstheorie' (Leipsic 1901–3); Bateson, 'Mendel's Principles of Heredity' (Cambridge, England, 1902) contains a bibliography of the subject.

ALPHEUS S. PACKARD,
Late Professor of Zoology, Brown University.

Hydatid, hī'dā-tĭd. See BLADDERWORM; TAPEWORM.

Hyde, Edward, British colonial governor in America: b. England about 1650; d. North Carolina 8 Aug. 1712. In 1710 he arrived as governor of the Albemarle district of North Carolina province. The provincial governor, by whom he was to be commissioned, was dead, and Thomas Carey, formerly a deputy-governor, had undertaken an armed insurrection. Hyde, at the request of the better class of the population, took office as governor, and, assisted by Spottswood, governor of Virginia, crushed the revolt. Not long after massacres by the North Carolina Indians compelled him to seek aid from Virginia and South Carolina.

Hyde, Edward Wyllys, American mathematician: b. Saginaw, Mich., 17 Oct. 1843. He was graduated from the civil engineering school of Cornell University in 1872, was instructor in civil engineering there in 1871–3, assistant professor of mathematics in the University of Cincinnati in 1875–8, and professor from 1878. Besides extensive contributions to mathematical journals, he wrote: 'Skew Arches' (1875); 'Directional Calculus' (1890); 'A Portion of Higher Mathematics' (1896).

Hyde, William Dewitt, American college president: b. Winchendon, Mass., 23 Sept. 1858. He was graduated from Phillips Exeter Academy in 1875, from Harvard in 1879, and studied theology at Union and Andover. After completing his theological studies he was pastor for a time at Paterson, N. J. In 1885 he became president of Bowdoin College; at that time he was the youngest college president in the United States, and was not widely known. He has since won a high reputation as a scholar and an able executive, the college having grown largely in numbers and resources during his administration. He has written 'Practical Ethics' (1892); 'Social Theology' (1895); 'Practical Idealism' (1897); 'The Evolution of a College Student' (1898); 'God's Education of Man' (1899); 'The Cult of Optimism' (1900).

Hyde Park, London, a park in the West End, adjoining Kensington Gardens. It derived its name from having been the manor of the Hyde belonging to the Abbey of Westminster, and contains nearly 400 acres. It was opened to the public shortly after the Restoration in 1660, and abounds with fine trees and pleasing scenery. The sheet of water called the Serpentine River was made between 1730 and 1733 by order of Queen Caroline. It is much frequented in summer for bathing, and during frosts for skating. Other attractive features of the park are the fashionable drive, bridle path, and promenade of Rotten Row, the Ladies' Mile, and Marble Arch.

Hyde Park, Mass., town in Norfolk County; on the Neponset River, and on the New York, N. H. & H. railroad; about four miles southwest of Boston. The town contains four small villages. It was incorporated as a town in 1868. The chief manufactures are rubber goods, paper, morocco, cotton and woolen goods, curled hair, chemicals, dyestuffs, looms, and machinery. It is a residential suburb for many of the Boston business men. It has good schools and a free library which contains about 14,200 volumes. Pop. (1890) 10,193; (1900) 13,244.

Hyde Park, Vt., village in the town of Hyde Park; county-seat of Lamoille County; on the Lamoille River and on the Boston & M. railroad; about 31 miles northeast of Burlington and 23 miles north of Montpelier. The stone-quarries nearby are a source of industrial wealth. The manufactures are flour, lumber, dairy products, and leather. Pop. village (1900) town, 1,472.

Hyder Ali, hī'dėr ā'lē, Indian Mohammedan prince: b. Bangalore about 1728; d. Chittore, 7 Dec. 1782. Having deposed Kandih Rao, he was chosen rajah of Mysore in 1762, and he so greatly extended his dominions, that in 1766 they contained 84,000 square miles, and afforded an immense revenue. His reign was passed in wars with the English and with the Mahrattas. A treaty which he made with the East India Company in 1769, was violated in 1780, and, forming an alliance with the Mahrattas, he obtained the services of French officers, and took Arcot on the 31st October of the same year. He was defeated by Sir Eyre Coote, 1 June 1781. He was succeeded by his son Tippoo Saib (q.v.).

Hyderabad, hī-dėr-a-băd', or **Haidarabad,** hī-da-ra-băd', India. (1) One of the largest native states occupying the greater part of the Deccan plateau of southern India, in possession of the Nizam, a Mohammedan prince, and frequently called the NIZAM'S DOMINIONS. It is bounded north by Berar, northeast by the central provinces, southeast by Madras, and west by Bombay. Area, 82,698 square miles; pop. (1901) 11,141,142. The chief rivers are the Godavery in the north and the Kistnah in the south. The soil generally is fertile but poorly cultivated; the principal crops are rice, wheat, maize, sugarcane, tobacco, cotton, and fruits. Indigo is manufactured, and the forests yield valuable timber; there are coal and iron deposits as yet little exploited, and diamonds and other gems are found. The ruler belongs to the dynasty founded by Asaf Jah, a distinguished soldier, whom the Emperor Aurungzebe made viceroy of the Deccan in 1713 with the title of Nizam or Regulator.

(2) HYDERABAD, the capital, is on the Musi River, at an elevation of 1,672 feet above the sea, about 400 miles in a direct line southeast of Bombay, with which it is connected by rail. It is wall-girt, and its chief buildings are the extensive nondescript palace of the Nizam, the handsome British Residency, the Charshinar, or Four Minarets, built about 1590 as a Mohammedan college, but now used for warehouses; and the Jumma Musjid or cathedral mosque, a reproduction of that at Mecca. Pop. (1901) 448,466. (3) HYDERABAD, the capital of a district of Sindh, British India, on the east bank of the Indus, is a well fortified town connected by rail with Karachi, 105 miles to the southwest. Pop. (1901) 69,378.

Hy'dra, a minute fresh-water polyp, living on the stems and underside of submerged leaves. The body is a club or vase-shaped sac, the mouth at the upper end surrounded by a crown of from five to eight long tentacles armed with lasso or nettling cells buried in the skin. The hydra feeds on minute crustacea, etc., which become paralyzed when swimming in contact with the arms of the hydra, thus being easily drawn by the creature into its stomach. The body is very retractile, and the hydra can slowly move from one place to another, by detaching the end of the body. The sexual cells are, during the reproduction season, developed in the skin, appearing as circular swellings, one (male) just below the tentacles, the other mass, corresponding to the ovary of higher animals, farther down the body. The hydra is famous from its power of regenerating parts of its body. Trembley in 1744 experimented upon this animal; he cut them in two, also into slices, and found that each bit became a new hydra, finally he turned one inside out, the stomach-lining becoming the skin, this experiment having recently been successfully repeated. This is due to the lack of differentiation in the tissues and organs of the body, there being no distinct nervous, or circulatory system, the hydra being the most generalized member of its class, except the Protohydra, which has no tentacles.

Hydrangea, hī-drăn'jē-a, a genus of shrubby plants of the order *Saxifragaceæ,* with about 30 species indigenous to eastern Asia and temperate America. They have large simple leaves and very large cymes of flowers, the outer ones being infertile. The *H. vulgaris* grows on the Alleghanies, and in other parts of the United States. *H. nivea,* a more ornamental shrub, is most abundant in the region of the southern Alleghanies, but is found as far north as Pennsylvania. The *H. quercifolia,* distinguished by its lobate leaves, inhabits the country bordering on the Gulf of Mexico. The best-known species is *H. hortensis,* the Japan rose. The fruit is a multilocular capsule.

Hy'drants. See Valves and Hydrants.

Hydras'tis, an herb, the rhizome and rootlets of which are used as a bitter stomachic tonic and a tonic to the uterus in various diseases. In poisonous doses it stops the heart-action.

Hy'drate, in chemistry, a compound containing one or more molecules of the radical «hydroxyl» (OH). In these compounds, the water may be considered as playing the part of an acid, and the compounds themselves are entirely analogous to salts. Thus water, H_2O, combines with sodium oxid, Na_2O, according to the equation $Na_2O + H_2O = 2NaOH$; the reaction being accompanied by the liberation of considerable heat. The sodium hydrate (NaOH) that is produced is quite a different substance from the simple oxid, Na_2O, and it cannot be resolved into Na_2O and water by the action of heat alone. In organic chemistry hydrates are met with very frequently. The large and exceedingly important class of substances collectively known as the alcohols, for example, are hydrates of organic radicals. (See Alcohol.)

The word «hydrate» is also used in a less definite manner, to signify any compound which contains water, or from which water can be expelled by the action of heat. Thus salts or minerals which are associated with water of crystallization are said to be «hydrated.» When an aqueous solution of a salt, containing an excess of the salt in the free state, is cooled until it freezes, a mechanical mixture of ice and of the precipitated salt is obtained, which is known as a «cryohydrate,» although it is not a definite chemical compound.

Hydraulic (hī-drâ'lĭc) Cement. See Cement.

Hydraulic Crane. See Hoisting Apparatus.

Hydraulic Engine, or Hydraulic Motor, an engine or motor driven by water under pressure. The water is admitted at a high pressure at the beginning of the stroke, and exhausted at a low pressure at the end of the stroke, thus giving a reciprocating motion to the plunger. The velocity of the piston has to be kept low to avoid injurious shocks in suddenly bringing the column of water to rest. Working under greater pressure than steam-engines — 700 pounds to the square inch is not an uncommon pressure — the hydraulic pressure engine can be built much smaller than an equivalent steam-engine. An additional advantage of the hydraulic engine for intermittent work is the comparative ease with which it may be started or stopped; hence it is commonly used for capstans, winches, cranes, and drawbridges. Single action in the hydraulic engine avoids shock at dead centres; and the three-cylinder single-acting form is in common use, since the three cranks make the turning force uniform and make it possible to start the engine from any position. Another form, of very recent development, is the turbine (q.v.).

Hydraulic Engineering, that branch of civil engineering which deals with the application to the use and convenience of man of the natural laws governing liquids. A liquid is a substance appreciable to the senses of sight and touch, and the particles composing which are incompressible and offer no resistance to interchange of position from any external force applied to them. The typical liquid is water, and the generic term hydraulics, used to denote the science and practice of handling liquids, is derived from a Greek word which means «pertaining to water.» There are three distinct sets of laws or principles of science which have to be considered: hydrostatics, which relates to liquids at rest; hydraulics, which relates to liquids in motion; and hydrodynamics or hydromechanics, which relates to the mechanical effects produced upon other substances by liquids when acted upon by external forces.

The science of hydraulics is entirely modern. There is no evidence, either traditional or documentary, that the principles governing the action of liquids either at rest or in motion were studied and formulated at all prior to the days of Archimedes, 2,200 years ago. A few of the facts of both hydrostatics and hydraulics were established experimentally, so that aqueducts to convey water long distances were built by the Romans, and possibly before them by the Phœnicians and the Greeks; but no record remains of any elucidation of principles or formulation of laws. After the destruction of Rome in 475 A.D. even what had been known seems to have been lost for more than 1,000 years. As late as 1630 Galileo said that the laws governing the motions of the stars were better understood than those controlling the movement of water on the earth.

Hydrostatics.— It was Galileo who discovered and formulated the important law of hydrostatics that the pressure exerted by a column of fluid on any square unit of the surface which confines it is equal to the weight of a column of one unit square and of the height of the surface of the liquid above the point at which the pressure is measured, no matter whether the horizontal area of the column at that point is greater or less than at other points in its height. If the confining walls of the column are horizontal at any point, or if they are inclined to the perpendicular, the pressure of the liquid at that point is the same, whether upward or downward, as it is laterally against a vertical wall, and the wall at that point must be of such thickness that it will resist that pressure.

Where the pressure is upward the resisting force of the wall is increased by its own weight, and where the pressure is downward the resisting force is diminished by the weight of the wall itself. It is essential therefore to the stability of a wall which is surrounded by a liquid mass that the adjacent liquid should be excluded from passing under the wall so as to permit of an upward pressure which would tend to lift the wall from its base.

In all mechanical problems there are three units of comparison needed: the units of time, of distance, and of weight. The unit of time in modern science is the second, or $\frac{1}{86400}$ part of the average day. The unit of distance which is generally used in England and America is the foot, which is subdivided into twelfths, called inches, or into thousandths, while the unit of weight is the pound, which is arbitrarily fixed by law. In France and Germany the unit of distance is the metre, which is supposed to be one ten-millionth part of the distance from the pole to the equator, and is 3.28 feet long, and is subdivided into thousandths, while the unit of weight is the gram or cubic centimetre, which is the $\frac{1}{1000000}$ part of the weight of a cubic metre of pure water. Efforts are making by scientists to secure the universal adoption of the metric system of measures and weights, but in the English-speaking countries the foot and the pound are the only standards generally used and understood. In hydraulic science the basic hydrostatic facts are that a cubic foot of pure water weighs 62.417 pounds, and that to exert a pressure of one pound on every square inch of surface a column of water must be 2.307 feet high.

Hydraulics.— The instant that an orifice is made in the barrier confining a volume of liquid the particles of the liquid begin to move in the direction of the orifice. The theoretical velocity with which they issue from the orifice was discovered in 1644 by Torricelli, a pupil of Galileo, to be equal to that acquired by a cubic unit of the liquid in falling through the height between the surface of the liquid and the orifice. It was not until 1738 that Bernoulli formulated the fundamental expression for the acceleration of gravity, $v=\sqrt{2gh}$, in which v represents the speed per second of time, h represents the distance of the orifice below the surface of the liquid, and g is a quantity determined by experiment to be the velocity acquired by any body in falling freely in a vacuum, from a state of rest, in one second of time. Taking the foot as the unit of distance, $g=32.16$ and $\sqrt{2g}=8.020$, while if the metre is the unit, $g=9.80$ and $\sqrt{2g}=4.427$.

The students of hydraulic problems soon discovered that the conditions under which the movements of fluid take place modify materially the theoretical results obtained from the formulæ based on the laws of gravitation only. For 260 years they have been striving by a combination of reasoning and experimentation to formulate the laws which govern the movements of water under varying conditions of form and character of material composing the enclosing channels in which the movements occur. The value of v, as found to exist in practice, is only a fractional part of the theoretical value, and is designated by the expression $v=c\sqrt{2gh}$, in which c is a numerical coefficient which varies with the form of the orifice or channel through which the water passes, and with the character of the material through which the orifice is made. The reason of this is that the particles of the liquid which are in contact with the restraining solid material are retarded in their fall by the solid, and they in turn retard the next adjacent particles of fluid, the amount of retardation decreasing as the distance from the immovable solid increases. This retarding effect varies also with the roughness of the limiting solid, and with the velocity at which the initial movement, due entirely to the force of gravity, takes place. The quantity of water discharged is equal to the product of the velocity by the area of the orifice or $q=ac\sqrt{2gh}$. The value of c under the most favorable conditions has been found from numerous carefully conducted experiments to be about 0.60, or in other words, only about 60 per cent of the amount of water which the theoretical calculation of the velocity due to the head indicates as possible to be passed through an orifice in the side or bottom of a vessel or reservoir containing a mass of water, can be actually so passed. After passing the orifice of entry to a long channel, a new set of conditions is encountered in conveying water for long distances, as in a pipe or open canal. Gravity is the impelling force as before, and to ensure flow there must be a difference of elevation between the extremities of the channel, but the retarding forces are numerous, consisting of variations in the slope of the channel, in the proportion which the length of the wetted perimeter of the channel bears to the area of the waterway, and in the irregularity of the surface over which the water flows.

The fundamental formula for the velocity of the flow in channels of all kinds which is now accepted was suggested by Chézy in 1775 and is

$$v=c\sqrt{rs}$$

in which v represents the mean velocity of the fluid, r represents the hydraulic radius, as it is termed, or the area of waterway divided by the length of the wetted boundary of the channel, and s represents the slope of the surface, or the difference of elevation of the two ends of any section of channel, divided by the length of the section. The value of c is determined by experiments on the discharge of channels of different forms, materials, and dimensions. It is purely experimental. In the last 100 years numerous carefully conducted series of observations have been made by hydraulicians with the object of determining an exact mathematical expression for this coefficient under different conditions. The formula which so far seems to approach most nearly to the obtaining of a definite result is that proposed by Kutter, a German scientist, about 1868, in which the dominant element is a variable quantity designated as n, the value of which depends solely on the degree of irregularity in the wet surface bounding the cross section of the channel. In applying this formula to any channel the engineer must assume that value for n which has been determined by experiment to belong to a channel most nearly approaching in roughness the one under consideration, and from this he will be able to deduce with a very considerable degree of accuracy the value of c, and use this to determine the velocity and discharge.

Hydrodynamics or Hydromechanics.— These are terms applied to the science which treats of the dynamic effect produced upon other substances by the arrest of the movement of fluids coming in contact with them. A stationary column of water exerts a pressure only; a moving column exerts a dynamic pressure proportional to the velocity with which the mass is moving. If an obstacle is interposed to water flowing in a channel of any kind, the force exerted by the water in removing that obstacle can be utilized in such a way as to produce a mechanical energy or work. The simplest form of this is the undershot wheel, where the pressure of the water flowing in a stream causes vanes or paddles attached to a shaft to revolve the shaft, and from this, by mechanical appliances, the circular motion can be directly utilized to exert energy either by revolving or reciprocating movement of machines. The breast-wheel and the overshot wheel utilize the power generated by a fall or head of water of from one half to two thirds of the diameter of the wheel. The turbine wheel invented in France by Fourneyron in 1833 revolutionized water-power engineering, utilizing as it does nearly the entire energy of any great head or fall of water by discharging the fluid from a pipe against revolving vanes so shaped as to afford the greatest resistance to the attacking current and the least to the discharging current. When the impulse of movement of machines. When the impulse of the moving liquid, which is that due to the product of its weight by its velocity, is at right angles to the interposing surface, it is equal to double the pressure exerted by the fluid in a state of rest. As the angle between the current and surface becomes oblique the pressure diminishes. The same rule holds good with reference to submerged surfaces exposed to the impact of waves and currents in deep water, so that the hydrodynamic forces present to the naval architect, as well as to the hydraulic engineer, innumerable problems delicate and difficult of solution.

Hydraulic Engineering.— The improvement of natural watercourses on the face of the earth is the most ancient and the most extensive of the works which have called for the exercise of hydraulic engineering. The remains of works for restraining the flood-waters of rivers, antedating all historical records, have been discovered in Egypt and China. In countries where the rainfall is so distributed throughout the year that alternate periods of extreme wetness and drought of long continuance occur, the retention of the excess of water in the wet season and its gradual delivery for irrigation purposes during the season of drought was extensively carried on at an early date. In Egypt, 2,320 years before the Christian era, Lake Mœris was constructed as a storage reservoir for retaining the waters of the Nile, and the prosperity of that country has ever since depended upon the maintenance and progressive improvement of its system of irrigation. The earlier works, while remarkable for their extent and magnitude, were not characterized by any particular skill in design or economy in construction. During the latter part of the 19th century and since the beginning of the present, under the control of French engineers, some very fine examples of dams and irrigation canals have been constructed. The Assuan dam is 90 feet high at the deepest point of the valley it crosses; 6,400 feet long, of granite, founded on solid rock; and it impounds water for the irrigation of 2,500 square miles of land 350 miles farther down the stream, where another dam, 48 feet high and 3,030 feet long, diverts the water on to the lands to be benefited.

In India, from very early ages, irrigation has been practised on an extensive scale, and enormous reservoirs were constructed for the storage of water at least as far back as 500 B.C. There are about 90,000 such reservoirs or their remains which were constructed before the British occupation of India, and 2,000 were built by English engineers in the last half of the 19th century. In Italy about 4,000,000 acres of land are under irrigation, and it is to the Italian engineers of the 18th century that hydraulic engineering is largely indebted for the elucidation of principles and the application of the same to practice so as to produce the greatest efficiency at the least expense.

For the successful conduct of irrigation works there is needed not only a knowledge of the laws of hydraulics, but also a thorough study of the meteorological conditions which have prevailed in the region under consideration for a long series of years, and likewise of the topography and geology of the region.

In the United States the importance of this has been fully recognized only within the last 20 years; but during that period the general government has devoted a good deal of attention to the subject, and has caused surveys, both topographical and geological, to be made of the arid region lying west of the 100th meridian of longitude; while a series of measurements of the rainfall and the run-off of the streams is being instituted, which will furnish the engineer with data necessary to an intelligent designing of irrigation works. This will undoubtedly prove of great benefit, inasmuch as not more than 7 per cent of the 70,000,000 acres in the United States susceptible and in need of irrigation are now supplied with it. In the works so far constructed are seen numerous efforts at improvement in design and methods of construction, some of which have not yet stood the test of time long enough to determine whether they will be effective. The careful observations which have been made and are still being made have resulted in a decided advance in knowledge of hydraulic principles.

In passing to the consideration of the next oldest class of hydraulic works, that for the regulation of rivers to protect and reclaim the riparian lands, the questions to be considered by the hydraulic engineer are materially changed. Large storage reservoirs are needed as in irrigation projects, but their capacity and arrangement with reference to the fluctuations of the natural flow of the stream must be very different. The channels, too, for the conveyance of the water are differently proportioned, and are likely to be required to be constructed of different material. In irrigation canals a low velocity of flow is desirable to avoid abrasions of the banks, and the sizes of the channel are proportioned to convey definite quantities of water steadily. In river regulation the channels must be designed to carry constantly varying quantities of water at different speeds of current, and the banks must be fortified against injury from sudden fluctuations of level in the water surface and from abrasion by floating material or accretion by deposit. The construction of levees or embankments along the banks of a river and parallel to its current is the earliest and simplest of the methods of river improvement; but it is only within the last 200 years that this has been reduced to a science, and the most effective and economical methods of design and construction formulated. If the stream improved is of sufficient size to be navigable, the conditions of the problem are again changed. The course of the channel in places may have to be altered to avoid rapids of too steep descent for passage of boats, and a sufficient depth of water must be maintained at all times and in all places for boats of definite dimensions and draft. Where such artificial channels are necessary it is important that they should be so proportioned that the passage of the largest boat at the maximum permissible speed should not create a wave which would injure the banks or retard the progress of the boat.

River improvements of this class led to the construction of entirely new artificial channels or canals connecting different navigable streams or bodies of water. There are some very ancient examples of such structures. The Royal Canal of Babylon was built 650 B.C., and about 102 B.C. the Fossa Mariana, connecting the River Rhone and the Mediterranean Sea, was built. In the 8th century was built the Grand Canal of China, about 650 miles long, utilizing several canalized rivers on its way, and thus creating an inland navigation system of 1,000 miles. On this canal there were several inclined planes, up and down which loaded boats were passed from one level to another. Locks were first invented in 1439 by Philip Visconti, an Italian engineer. Prior to this time there was but one method of overcoming differences of elevation in navigable channels which had been constructed so as to afford long and nearly level stretches on which boats could pass in either direction, with approximately the same motive power, and with sudden changes of elevation at the ends of such levels. That method was the transhipment of cargoes, the Chinese method of inclined planes not being economical in the then state of the mechanic arts. Between 1750 and 1830, however, a number of inclined planes were built in England and America in cases where the lift of locks was so great as to necessitate a great wastage of water and loss of time. Since 1876 several vertical lifts have been constructed where very great heights had to be overcome, compressed air being the power medium. The invention of locks gave a great impetus to canal construction, and all over Europe large systems of internal navigation were constructed. Indeed the improvement of river channels was neglected for a long time, and canals were built parallel to rivers, and the opinion was expressed by an eminent English engineer, near the end of the 18th century, that "rivers were created for the purpose of feeding canals."

During the first half of the 19th century about 3,000 miles of canals were constructed in the United States. Much experience in hydraulic construction was thus had, and many improvements in methods of construction were introduced; but there cannot be said to have been much advance in hydraulic science in this direction. In the matter of river improvement, however, the work done by the United States government on the Mississippi, and the records kept of the results attained, were of great scientific value, and enabled the Mississippi River Commission of 1879 to formulate the principles which should be observed in the regulation of large rivers of that class. Both in Europe and America during the last 30 years there has been great advance made in careful observation of the phenomena of rainfall, evaporation, seepage, and infiltration as affecting the run-off of rivers and the fluctuations in their flow at different seasons of the year and for periods of years. The action of flowing water on different materials and modes of construction has been also observed more systematically than ever before, with the result of a decided advance in hydraulic science and its practical application to the economical and effective improvement of river regulation in the interest of water transportation.

The question of the regulation of smaller non-navigable streams, so as to prevent injury to the territory along them from escaping floods, has of late been receiving attention. It is considered by some engineers that it will be practicable, by the construction of large storage reservoirs with restricted outlets, so to restrain the discharge at points along the course of a stream that sudden and great floods may be prevented. Experience has not yet proved the practicability of such an automatic regulation of the flow, but there is little question that before long efforts will be made to accomplish this object, or at any rate to acquire data from which a practicable scheme may be devised.

It is in the application of hydraulic science to the comfort and convenience of the individual rather than of the community that the most striking progress has been made during the last few generations. The fostering of agriculture and the improvement of means of transportation of heavy freights are of benefit to the public at large, but the furnishing of pure and wholesome water for household consumption in large quantities and at reasonable cost affects the health, the comfort, and the general condition of the individual directly. There are remains of structures which were evidently designed to supply water to large communities in the oldest partly civilized nations, but these are of crude design and display evidences of lack of knowledge of hydraulic principles. The Romans, about 500 B.C., built numerous aqueducts to convey water from distant sources, not only to the Imperial City itself, but also to the larger cities in their provinces; but for several hundred years after the fall of the Roman empire there did not appear to have been any works built for supplying water to communities. It was not until 1582 that London was furnished with water by Peter Morrys, who pumped it from the Thames and supplied a portion of the city. The grant under which he did so is still held by his successors.

There has been steady progress in the art of supplying water to towns during the last 300 years and now the questions which the hydraulic engineer is required to consider in the design and construction of any waterworks embrace a great variety of subjects. It is necessary to consider:

1. The quantity of water likely to be needed. There is not yet any consensus of opinion among engineers on this point, the estimates varying from 100 to 150 gallons per day for each resident of the district to be supplied, at the expiration of 20 years from the inauguration of the supply. The prospective population is estimated from the records of the past growth of the district and the growth of districts of similar character of occupation.

2. The possible sources whence the required quantity of water can be obtained.

3. The character of the water obtainable from each source, as regards its chemical constituents, in order to judge of its economical as well as its sanitary value. It sometimes happens that a water otherwise acceptable is so charged with certain chemicals that the amount of soap required for washing with it is greatly in excess of that required by another water more difficult to procure, so much so that the cost to individual consumers for its constant use will be greater than the cost to the community of the introduction of the other supply.

4. The character of the water biologically; the number and nature of the organisms which are found in it. This is most important from the sanitary point of view. The identification of certain organisms as pathogenic or disease-producing is of recent origin; it marks a decided advance in sanitary science and is of great interest to the hydraulic engineer, since it is found that the removal of the injurious organisms from water can be effected by filtration, and it is the engineer's function to design or construct works for filtration through sand or other material which experiment proves to be adapted to the purpose.

5. The quantity of water obtainable from each source which appears generally suitable, the area of the watershed, the amount of annual rainfall upon it, the distribution of the rainfall through the year, the geological and topographical features of the surface, the range of temperature of the air, and the amount of evaporation must all be taken into consideration. Whenever the minimum rate of daily run-off from the watershed exceeds the maximum daily consumption to be provided for, reservoirs must be constructed to retain the stream-water in times of excessive flow, and deliver the excess gradually as required. The location of such reservoirs requires a thorough acquaintance with the topography of the district, and their construction demands a high order of both theoretic and practical acquaintance with the action of water on various materials and with the form and method of their collocation. The construction of dams of earth and masonry has been the subject of careful study within the last few years, and the general principles have been pretty well established: but there still remain a number of unsettled problems due largely to the progress of the mechanical arts and the introduction of new modes of construction. Just how far, for instance, combinations of metal and masonry, which assure strength with a reduction in amount of material and cost, can be depended upon for durability under the action of water in motion, can only be learned after the lapse of more time from the introduction of this class of construction.

6. The means of conveying the water from the source to the point where it is to be used. The conditions of this problem are unlike those which are encountered in rivers, or in canals for either irrigation or navigation. A nearly uniform quantity of water must be continuously carried a long distance at as great a velocity as is consistent with safety and economy. It must be protected from loss by evaporation and by leakage of the channels, and protected from pollution on its route. These conditions are best fulfilled by an enclosed conduit or pipe of masonry or metal, with a smooth interior surface, laid on a uniform grade so that there will not be any upward pressure tending to lift the covering of the conduit. The relations between different values of n, which can be obtained by using different classes of material and of construction, and values of c, obtainable by using different grades and alignments, have been for more than 30 years the subject of carefully conducted experiments by scientists, and it is the function of the hydraulic engineer to apply to the special case he has in hand the use of the materials which are available and the mode of construction practicable in the case, in accordance with the latest results of scientific research. Up to the present time the best form and material for large conduits seem to be masonry conduits of horseshoe form, with smoothly plastered interior surface; or steel-plate circular pipes with as few irregularities caused by rivet-heads as possible, laid on uniform grades, which will ensure a velocity of two miles per hour in the water flowing in the conduit.

7. On reaching the point of distribution an entirely different set of conditions is encountered. The water heretofore concentrated in large masses has to be distributed over a wide area in a great number of small pipes in which orifices are opened and shut at irregular intervals of time, these pipes, moreover, being under a great head of water producing a pressure of 50 to 100 pounds per square inch, and consequently a high velocity of efflux from any orifice. The problem to be solved is so to arrange the connections and sizes of these pipes that, under the ordinary conditions of use, the pressure in the pipes will not be materially altered at any time, and a constant supply may be kept up in the entire system. As illustrating the magnitude and complication of the distribution system in a large city, the conditions existing on Manhattan Island alone, in the city of New York, may be cited. There were there, in 1900, an area of 12,576 acres, 682 miles of pipes for the delivery of water, with 130,000 taps or orifices from which water is drawn at irregular intervals. The development of such a system as this involves the exercise of not only theoretical knowledge of the principles governing the flow of water under all conditions, but also a thorough acquaintance with materials of construction and the methods of using them to produce the best results at the least expenditure.

An interesting and important branch of hydraulic engineering is that which deals with larger masses of water than any of those so far considered. The water of the ocean, when agitated by the winds and by terrestrial forces not thoroughly comprehended as yet, exerts a dynamic force which must sometimes be restrained and sometimes guided so as to produce results in a desired direction. Along the seacoasts of all countries there are places where the conformation of the shore and the nature of the contiguous lands render the creation of harbors desirable, but where the tidal waves and littoral currents come in conflict in such a way as to make the approach from the sea dangerous to vessels. To lessen the destructive effects of the great masses of water in motion, impelled by either the wind or the tidal currents, breakwaters or piers of stone projecting from the shore are built with good results. The massiveness which such structures are required to possess may be judged from the fact that it has been learned that the foundation for a breakwater must extend out to where there is from 18 to 20 feet of water at low tide; that the height of the waves by which it is likely to be assailed may be from 10 to 20 feet; and that the impact of the wave on the opposing structure may be as high as 6,000 pounds to the square foot. In the open sea it is not likely that waves as high as this are formed, or that the force exerted by them is nearly as great, but the problem of the form and resisting power of the hull of ships has to be considered from the standpoint of the dynamic effect of the water which is impelled by the wind and waves against the hull, as well as the resistance offered by the water to the passage of the hull through it.

The problem of the resistance of the water to a vessel passing through it enters into the consideration of the navigation of canals and inland waters as much or possibly even more than it does into ocean navigation. The more rapidly a vessel passes through a small channel, the greater is the work to be done in the displacement of the bulk of water occupied by the hull. The displaced water is prevented from flowing off by the adjacent banks and shallow bottom, and the pressure required to propel the boat is so increased that it is found that a greater velocity than three miles per hour is not economical.

Hydromechanics, as already stated, relates to the mechanical effects which may be produced by utilizing the force exerted by water in motion to generate power. In hydraulic works, distinctively so called, the effort is constantly made to diminish the mechanical effect of the moving water so as to avoid injury to surfaces and substances unprepared to resist it. In hydrodynamic works the effort is made to concentrate all the power obtainable from the moving water and transmit it to machines which do effective work. The difficulty of transmitting the power long distances without great loss has hindered utilization in many cases where a great head of water is available in some out-of-the-way spot, but recent improvements in electrical transmission have made such water-powers available for use, and many developments of hydraulic generation of electricity have been made, while others are now in course of construction. The utilization of Niagara Falls is a prominent instance of work of this class, and the latest installation in progress there is noteworthy for its boldness and promise of economical effectiveness, the head on the turbine wheels being obtained by sinking a vertical shaft on the shore a short distance above the falls and discharging the water through a tunnel run under the bed of the river to the precipice behind the Horseshoe Fall.

In the present state of hydraulic science more attention is being paid than ever before to the obtaining of closely accurate results of experiments conducted by skilled observers, in which the aid of electricity is used to register all phenomena in a manner never possible heretofore. Great as the advances have been during the last 25 or 30 years, equal or greater progress in the elucidation and practical application of principles may be expected within the next quarter of a century.

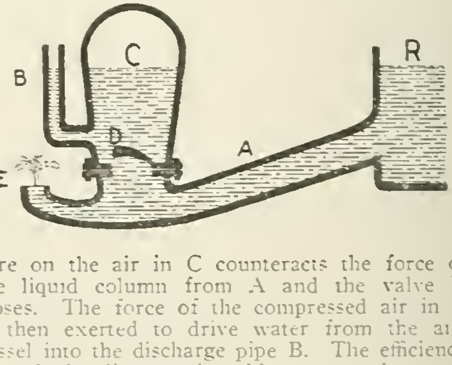
Hydraulic Ram, a machine for raising water, the force being a greater body of water at a lower level. It consists primarily of two pipes, one, A, leading from the reservoir, spring, pond or other source of supply into C, an air-vessel, the opening being by a valve D; and the other pipe, B, leading out of this air-vessel. In the pipe A, or an extension of it is a ball valve E, smaller than the inside of the pipe. This ball valve E is forced shut by the free flow through A; the growing pressure forces D the valve into the air-vessel open; and the water flows into C the air-vessel and, to a less degree because of the smaller diameter of the pipe, into the discharge pipe B. The greater pres-



sure on the air in C counteracts the force of the liquid column from A and the valve D closes. The force of the compressed air in C is then exerted to drive water from the air-vessel into the discharge pipe B. The efficiency of a hydraulic ram is seldom more than two thirds, so that 150 units of water falling 15 feet will lift 15 units only 100 feet, instead of 150 feet, as it theoretically should. The ram was invented in 1797 by Montgolfier and is commonly used where there is no regular water-works but a plentiful supply of water.

Hydraulics, the branch of mechanics dealing with liquid flow in pipes and channels. The particles of fluids flow over each other with less friction than over solid substances; and as each particle is under the influence of gravitation no quantity of homogeneous fluid having its surface free can be in a state of rest unless every part of the surface is level. When water flows in a current, as in rivers, it is in consequence of the inclination of the channel, but all such motion is affected by the form of the channel and the friction of its sides. Experimental investigation gives various coefficients, whereby the resistance to the flow of water in pipes or channels can be calculated. As water in descending follows the same laws as other falling bodies its motion is accelerated; in rivers, however, the velocity and quantity discharged at different depths is not as the square roots of those depths, the friction against the bottom diminishing the rapidity of the flow. But the law of the proportionality of the velocity of discharge to the square root of the depth applies, however, to the spouting of water through jets. Thus, if a hole be made in the side of a vessel of water, the water at this orifice, which before was only pressed by the simple weight of the perpendicular column above it, will be pressed by the same force as if the water were a solid body descending from the surface to the orifice.

Machines to raise water may be divided into four classes. Machines in which water is lifted in vessels by the application of some mechanical force to them were the earliest hydraulic engines; a type is the Persian wheel, a large vertical wheel, turned by animal power or by running water, and having buckets attached to the rim, and moving in a reservoir of water. The buckets are filled at the bottom and emptied at the top, so that the water is raised a height equal to the diameter of the wheel. The common dredges for rivers and harbors are modifications of this kind of machine. The Archimedian screw, the screw-pump and the bucket-engine or chain-pump are all on the same principle. The chain-pump usually consists of a succession of long links of metal rods revolving like an endless rope over two wheels, one under water. On this chain, between each joint, is fixed a flat piece of wood or metal, usually square, supported and kept in place by the projecting arms of the wheels; the wheel not under water is turned by a winch, which causes the whole chain to move, one side of it passing upwards, while the other side is continually descending in the same direction. The ascending side of the chain is made to pass through a box or pipe, one end of which is immersed in the water, the other end nearly reaching the upper wheel; this box corresponds in shape with the size of the plates, which fit pretty closely and form the pump. The succession of plates passing upward through the trunk forms a succession of cavities which are filled with water and are constantly discharged at the top. This pump will only work in deep water, and cannot drain a reservoir to the bottom; but it has the advantage of not becoming choked with sand or weeds. If the top and bottom wheels of this machine be retained, while the tube or trunk is taken away, and a number of small boxes or buckets be attached to the chain instead of the plates the machine then becomes a bucket-engine, which is only another form of the Persian wheel already described.

In the next class, more commonly called pumps, the water is raised by the pressure of the atmosphere. These act by removing the air from the surface of the water, which may thus be raised to the height of about 32 feet. Whenever it becomes necessary to raise water to greater heights, the third class of machines, or those which act by pressure on the water, are employed. The common suction-pump consists of a hollow cylinder A, of wood or metal, which contains a piston B, stuffed so as to move up or down in the cylinder easily, and yet be air-tight: to this piston there is attached a rod which reaches at least to the top of the cylinder when the piston is at the bottom. In the piston there is a valve C, and at the bottom of the cylinder there is another valve D also rising upwards, which covers the orifice of a tube fixed to the bottom of the cylinder, and reaching to the well from whence the water is to be drawn. This tube is commonly called the suction-tube, and the cylinder the body of the pump. When the piston is at the bottom of the cylinder there can be no air, or very little between it and the valve D. But the air in the cylinder being very much rarefied, the pressure of the valve D on the water at the bottom will be much less than that of the external atmosphere on the surface of the water in the well; therefore the water will be pressed up the pump

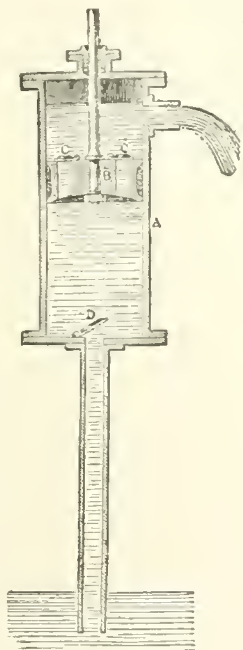


Fig. 1.—Suction Pump.

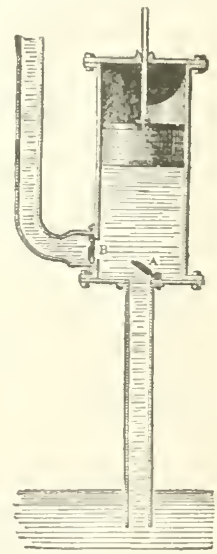

Fig. 2.—Forcing Pump.

to a height not exceeding 32 feet. As the valves shut downward, the water is prevented from returning. The quantity of water discharged in a given time is determined by considering that at each stroke of the piston a quantity is discharged equal to a cylinder whose base is the area of a cross section of the body of the pump, and height the play of the piston. Thus if the diameter of the cylinder of the pump be 4 inches, and the play of the piston 3 feet, then by mensuration we have to find the content of a cylinder 4 inches diameter and 3 feet high, the area of the cross section of the cylinder will be .08733 square feet; hence $.08733 \times 3 = .26199$ the content of the cylinder in cubic feet and the quantity of cubic feet of water discharged by one stroke of the piston.

The lifting-pump, like the suction-pump, has two valves and a piston, both opening upwards; but the valve in the cylinder, instead of being placed at the bottom of the cylinder, is placed in the body of it, and at the height where the water is intended to be delivered. The bottom of the pump is thrust into the well a considerable way, and when the piston is at the bottom as its valve opens upwards, there will be no obstruction to the water rising in the cylinder to the height which it is in the well, for water will always endeavor to come to a level. Now when the piston is drawn up the valve in it will shut, the water in the cylinder will be lifted, the valve in the barrel will be opened, and the water will pass through it, and cannot return as the valve opens upward; another stroke of the piston repeats the same process, and in this way the water is raised from the well. But the height to which it may be raised is not in this, as in the suction pump, limited to 32 feet. To ascertain the force necessary to work this pump, we are to consider that the piston lifts a column of water whose base is the area of the piston, and height the distance between the level of the water in the well and the spout at which the water is delivered.

The forcing-pump constitutes the third class. It can raise water to any height. The piston of this pump has no valve, but there is a valve at the bottom of the cylinder, as is shown at A. In the side of the cylinder, and immediately above the valve A, there is another valve B opening outward into a tube, which is bent upward to the height at which the water is to be delivered. When the piston is raised the valve in the bottom of the pump opens, and a vacuum being produced, the water is pressed up into the pump on the principle of the suction-pump. But when the piston is pressed down the valve A at the bottom shuts, and the valve B at the side which leads into the ejection-pipe opens, and the water is forced up the tube. When the piston is raised again the valve B shuts and the valve A opens. In this form the discharge is not continuous. To make it so an air-vessel is fastened to the top of the eduction pipe. The air-vessel is a box, with a valve opening upwards into it and covering the top of the pipe. A tube is fastened into the top of the box, and reaches nearly to the bottom; it rises out of the box, and is furnished with a stop-cock. If the stop-cock be shut, and the water be sent by the action of the pump into the air-vessel, it cannot return because of the shutting of the valve at the bottom of the box; and because of the space occupied by the water, the air in the box is condensed, and will consequently exert a proportionate pressure on the water in the air-vessel, and force it up through the tube. The stream of water issuing will therefore be continuous, the pressure being continuous.

The fourth class of hydraulic machines for raising water consists of such engines as act either by the weight of a portion of the water which they have to raise, or of any other water that can be used for such purpose, or by its centrifugal force, momentum, or other natural powers. The centrifugal pump consists of a drum or wheel containing a series of curved vanes; this wheel is encased in a circularly-shaped casing, gradually enlarging toward the outlet. The wheel with its vanes being rapidly rotated causes the water to be impelled outward into the casing and ultimately discharged from the outlet. This machine is very similar in form to the vortex-wheel or turbine, the direction of flow of the water being, however, in the reverse direction.

An ingenious form of pump called the *pulsometer* has lately been devised and extensively employed. It consists essentially of a double chamber, having a ball-valve at top, and clack-valves at bottom. Steam is admitted to one of the chambers and presses out the water contained there. Condensation then taking place a vacuum is formed, and the ball falls over and closes the opening through which the steam entered, and water flows up through the clack-valves and again fills the chamber. The steam in the meantime acts upon the water contained in the adjoining chamber. Condensation then taking place there the ball falls back to that side, and the operations go on alternately, the result being a steady stream of water sucked into one chamber after another, and then forced out and upward by the steam pressure. The water is drawn into the machine from the centre. To the fourth class also belongs the hydraulic ram (q.v.).

Water-wheels are either vertical or horizontal. The former class is undershot, overshot, or breast-wheel, as the water is fed to it from below, above or at the middle of the wheel.

The undershot wheel, the oldest form, acts chiefly by the momentum of the water, the weight of the water being scarcely called into action, and so can be used where there is a great supply of water always in motion. It is the cheapest of all water-wheels, and is more applicable to rivers in their natural state than any other form of the wheel; it is also useful in tide-currents, where the water sets in opposite directions at different times, because it receives the impulse equally well on either side of its floats. In the overshot wheel the circumference is furnished with a series of buckets, into which the water is delivered from above. The buckets on one side being erect, will be loaded with water, and the wheel will be thus set in motion; the mouths of the loaded buckets being thus turned downwards by the revolution of the wheel, will be emptied, while the empty buckets are successively brought under the stream by the same motion and filled. The breast-wheel differs from this in receiving the water a little below the level of the axle, and in having floats instead of buckets. In these two wheels the weight of the water is used as well as its momentum, and a much greater power is therefore produced with a less supply of water than is necessary for the undershot wheel. In order to permit these wheels to work with freedom, and to the greatest advantage, it is necessary that the back or tail water, which is discharged from the bottom of the wheel, should have an uninterrupted passage off; otherwise it accumulates and forms a resistance to the float-boards.

Turbines or horizontal water-wheels are very suitable for high falls of water, as the action of such wheels depends upon the impulse of the water and not upon its direct weight as in the overshot wheel. Turbines have been divided into three classes: parallel-flow, where the water is supplied and discharged vertically; outward-flow, where the water acts from the centre outward; and inward-flow, where the water acts from the outside, the currents flowing inward toward the centre. In all cases the greatest efficiency is obtained when the water acts upon the blades of the wheel without causing a shock, and leaves the wheel without having any whirling motion. See HYDRODYNAMICS; HYDROSTATICS.

Hy'drazine, or Di-Amidogen, a substance having the formula N_2H_4 (or $H_2N.NH_2$), obtained (together with oxalic acid, $H_2C_2O_4$,) by heating an aqueous solution of the complicated substance known as triazoacetic acid $(C_3H_3N_6)_3(COOH)_3$. It is a gas with a peculiar penetrating odor, but the properties of the pure substance are imperfectly known, on account of the avidity with which it combines with water to form the hydrate, $N_2H_4.H_2O$, and the consequent difficulty of isolating it. Hydrazine is a powerful base, combining with acids to produce numerous definite crystalline salts. Among these the sulphate, $N_2H_4.H_2SO_4$, and the two hydrochlorids, $N_2H_4.2HCl$ and $N_2H_4.HCl$, are important. The hydrate may be prepared by boiling the sulphate with a solution of caustic soda. It is a fuming liquid, somewhat oily in appearance, and boiling at 245° F. The hydrate reduces cold ammoniacal solutions of silver nitrate, and also reduces Fehling's solution. It attacks glass, cork and india rubber, but may be kept in silver vessels.

(2) The substances derived from hydrazine by replacing one or more of its hydrogen atoms by compound radicals are also called "hydrazines." If only one hydrogen atom is replaced the hydrazine is said to be "primary." If two hydrogen atoms are replaced, the hydrazine is said to be "secondary." The radical which replaces the hydrogen may belong to the fatty series, or to the aromatic series. One or more of the hydrogen atoms may also be replaced by a metal, such as sodium. The most important of the organic hydrazines is phenyl hydrazine, in which one of the hydrogen atoms is replaced by the aromatic radical phenyl, C_6H_5. This substance, which has the formula $(C_6H_5)HN.NH_2$, is an oily liquid, which solidifies to monoclinic tablets at 73° F. It mixes with alcohol, ether, benzene and chloroform, but hardly at all with water. It reduces Fehling's solution in the cold, and is very poisonous. A secondary hydrazine is "symmetrical" when the two substituted radicals are attached to different nitrogen atoms; it is "unsymmetrical" if they are attached to the same nitrogen atom. Thus $(C_6H_5)HN.NH(C_2H_5)$ is the symmetrical secondary hydrazine of phenyl (C_6H_5) and ethyl (C_2H_5), while $(C_6H_5)(C_2H_5)N.NH_2$ is the unsymmetrical secondary hydrazine of the same radicals.

Hy'dride, a chemical substance consisting of hydrogen combined with a metal, or some simple or compound metallic base.

Hydriod'ic Acid, an acid composed of hydrogen in combination with iodine, and having the formula HI. Hydriodic acid is analogous to the more familiar hydrochloric acid, both in its chemical structure and in its general properties. It may be prepared by the direct union of hydrogen and iodine at a red heat. A more convenient method, however, consists in passing sulphuretted hydrogen gas (H_2S) through water in which a little pulverized iodine is suspended. The reaction is $H_2S + 2I = 2HI + S$. Fresh supplies of iodine are added from time to time, and the liberated sulphur is finally removed by agitation and filtration, the sulphuretted hydrogen remaining in solution being also removed by the application of a gentle heat. The aqueous solution so prepared possesses strongly acid properties, and combines with bases to form salts called iodides. From it, or by other methods that are given in the larger treatises on chemistry, pure hydriodic acid, free from water, may be prepared. The pure acid is a colorless gas, with an odor similar to that of hydrochloric acid gas. It has a density about 63 times as great as that of hydrogen, and at a temperature of 32° F. it condenses to a liquid when subjected to a pressure of four atmospheres; the liquid so obtained freezing to a solid mass at about 67° F. below zero. The specific heat of the gas, at ordinary temperatures, is about 0.055 (at constant pressure), and the ratio of its specific heat at constant pressure to its specific heat at constant volume is 1.397. It dissolves freely in water, the specific gravity of a saturated aqueous solution, at 32° F., being about 2.00. The aqueous solution is colorless when pure, but it is slowly decomposed by sunlight, becoming dark from the liberation of iodine.

Hydriodic Ether (more correctly known as "iodide of ethyl"), a heavy, colorless liquid with a sharp, pungent taste and a penetrating ethereal odor, obtained by acting upon pure ethyl alcohol ($C_2H_5.OH$) by iodine, in presence of phosphorus. It has the formula C_2H_5I, boils at 162° F. (under ordinary atmospheric pressure), and has a specific gravity of about 1.946. When not quite pure it becomes brownish upon exposure to light, from the liberation of iodine. In chemistry, hydriodic ether (or ethyl iodide) is largely used as a fundamental substance in the preparation of the various other compounds of ethyl.

Hydrobro'mic Acid, or Hydrogen Bromide, a compound having the formula HBr, and analogous in its general properties to hydrochloric and hydriodic acids. Hydrogen and bromide do not combine directly, even in strong sunlight; but when hydrogen that is charged with bromine vapor is burned, hydrobromic acid and water are formed. Hydrogen and bromine may also be made to combine by electric sparks, or by passing the mixed gases over hot platinum. The most convenient way of preparing the acid, however, is by the action of bromine upon water, in the presence of phosphorus, the reaction being $4H_2O + 5Br + P = 5HBr + H_3PO_4$. Phosphoric acid, it will be seen, is formed at the same time; but the two are easily separated by heat. Pure hydrobromic acid, when free from water, is a colorless gas, having a density about 39.1 times as great as that of hydrogen. Under ordinary atmospheric pressure it condenses into a liquid at 99° F. below zero, and at a slightly lower temperature it crystallizes. It dissolves freely in water, a saturated solution, at 32° F., having a specific gravity of 1.78. A concentrated aqueous solution of hydrobromic acid fumes strongly in the air, but does not decompose. Hydrobromic acid is a powerful acid, forming, with metallic bases and with organic radicals, definite salts called "bromides." The bromides of the alkalies are greatly used in medicine as sedatives. Bromide of silver is also extensively used in photography, in the manufacture of sensitive dry-plates.

Hydrocar'bons, compounds consisting solely of carbon and hydrogen. They are exceedingly numerous, and many of them occur in nature, both in petroleum, asphaltum, and other similar minerals, and in the essential oils of plants. The hydrocarbons can be broadly divided into two general classes, according to the way in which the carbon atoms that they contain are connected to one another. In the fatty series, the atoms are all connected in open chains, while in the aromatic series the carbon atoms are connected with one another in such a manner as to form closed rings. (See FATTY COMPOUNDS and AROMATIC COMPOUNDS.) As a class, the hydrocarbons are insoluble in water: they cannot be saponified; and they are neutral, and do not combine with acids to form salts.

The classification of the hydrocarbons is as yet incomplete; but the greater number of those that are known can be included in one or another of the following groups:

1. The *Paraffins*, having the general formula C_nH_{2n-2}. The lowest member of this series is methane, or marsh gas, CH_4, and many other members of the series are known, each containing one carbon atom and two hydrogen atoms more than its immediate predecessor. (See PARAFFINS.)

2. The *Olefines*, having the general formula C_nH_{2n}. Ethylene, C_2H_4, is the simplest member of this series.

3. The *Acetylene* series, having the general formula C_nH_{2n-2}. Acetylene gas, C_2H_2, is the simplest representative of this series.

The foregoing all belong to the fatty subdivision. To them we may add:

4. The *Benzene* series, having the general formula C_nH_{2n-6}, and

5. The *Terpenes*, a class of substances having the general formula $C_{10}H_{16}$. Both of these latter series belong to the aromatic subdivision of the general hydrocarbon group.

The known hydrocarbons having any one general formula may be ranged in a series, whose members exhibit a sort of regular progression in their properties. For example, the first eight members of the normal paraffin group may be arranged as follows:

		Boiling point.
Methane	CH_4	(Gaseous)
Ethane	C_2H_6	"
Propane	C_3H_8	"
Butane	C_4H_{10}	34° F.
Pentane	C_5H_{12}	100° F.
Hexane	C_7H_{16}	158° F.
Heptane	C_6H_{14}	210° F.
Octane	C_8H_{18}	255° F.

A series of this sort is said to be «homologous.»

The paraffins are said to be «normal» when they contain but two methyl groups, (CH_3). Thus normal propane, C_3H_8, has the constitutional formula $CH_3.CH_2.CH_3$; and it is not possible to arrange its atoms in any other way. In proceeding from this hydrocarbon to the next in the same series (that is, butane, C_4H_{10},) we may substitute the methyl group, CH_3, for a hydrogen atom in the CH_2 of the propane, or for a hydrogen atom in one of the CH_3 groups. Hence we may have either of the two following constitutional formulas for the hydrocarbon butane:

$$
\begin{array}{c}
CH_3 - CH - CH_3 \\
| \\
CH_3
\end{array}
$$

or

$$CH_3 - CH_2 - CH_2 - CH_3.$$

The latter compound, which contains only two CH_3 groups, is called «normal butane»; while the former, which contains three such groups, is known as «isobutane.» Two butanes, each having the empirical formula C_4H_{10}, are therefore possible, and both are actually known. When we pass to the higher members of the paraffin group we find that a far greater number of isomeric forms can exist, according to the way in which the new CH_3 group is introduced, in generating the new hydrocarbon from the one next below it in the general series. Thus octane, C_8H_{18}, can exist in 18 different isomeric forms, and tridecane, $C_{13}H_{28}$, in no less than 802.

Hydrochlo'ric Acid, an important compound of hydrogen and chlorine, which under the names «spirit of salt» and «muriatic acid,» has been known in aqueous solution from very early times. It has the chemical formula HCl, and may be formed by exposing a mixture of equal volumes of hydrogen and chlorine to diffuse daylight, the combination taking place quietly under these circumstances, but explosively under the influence of direct sunlight. A more convenient and usual method of preparing hydrochloric acid is by treating common salt («sodium chlorid,» NaCl) with strong sulphuric acid (H_2SO_4). The reaction is as follows: $NaCl + H_2SO_4 = HNaSO_4 + HCl$. Pure hydrochloric acid is a colorless gas, 1.269 times as heavy as an equal volume of air at the same temperature and pressure. At a temperature of 50° F. it condenses, under a pressure of 40 atmospheres, to a colorless liquid, which boils, under ordinary atmospheric pressure, at 171° F. below zero, and solidifies at a temperature about 6° below the boiling point. The specific heat of the gas at constant pressure (compared with water) is about 0.19; and the ratio of its specific heat at constant pressure to its specific heat at constant volume, at ordinary temperatures, is 1.389. Hydrochloric acid gas was first prepared, in an approximately pure state, by Priestley, in 1774; but it was believed to be an oxid of a new element (provisionally called «murium») until Davy, in 1810, showed that it is a compound of hydrogen and chlorine.

Hydrochloric acid gas is exceedingly soluble in water. If a dry glass flask, which is completely filled with the dry gaseous acid, be brought mouth downward under water, and the stopper is then removed, solution takes place with such extreme rapidity that the water is often drawn into the flask suddenly enough to break it. By passing a stream of the gaseous acid into water, an aqueous solution may be prepared which has a specific gravity, when saturated, of 1.21. The commercial acid is commonly known, to the present day, as «muriatic acid.» Large quantities of it are obtained as a by-product in the manufacture of sodium carbonate from common salt; but the acid so produced is not entirely pure, and the traces of iron and other impurities that are present give it a yellowish tinge. Aqueous hydrochloric acid is largely used in the laboratory, and also in the arts in the manufacture of a great variety of substances.

Hydrochloric acid combines with metallic bases to form salts which are known as «chlorids.» Common salt (chlorid of sodium, NaCl) is the most familiar and the most abundant example, in nature, of this class of substances. The chlorids of silver, gold, mercury, barium, aluminum, platinum, and ammonia are also important, and are described under MERCURY, ALUMINUM, etc.

Hydrocyan'ic Acid, or **Prussic Acid,** an exceedingly poisonous substance, discovered by Scheele in 1782. It has the chemical formula HCN, and may be formed by passing a series of electric sparks through a mixture of nitrogen and acetylene (q.v.). The reaction in this case is $2N + C_2H_2 = 2HCN$. The pure acid is more conveniently prepared by passing sulphuretted hydrogen gas, H_2S, over dry mercuric cyanide, $Hg(CN)_2$, hydrocyanic acid and mercuric sulphid being formed, according to the equation $Hg(CN)_2 + H_2S = 2HCN + HgS$. As thus prepared, hydrocyanic acid is a volatile liquid, boiling at 80° F. and freezing at 5° F., and possessing a peculiar smell of bitter almonds. It is so intensely poisonous that a single drop of the anhydrous acid produces instant death when swallowed, and its vapor, even when mixed with considerable quantities of air, is also exceedingly poisonous. It mixes readily with water, ether, and alcohol. Although it is called an acid, and forms salts that are known as «cyanides,» it is very weak in its acid properties. It does not redden litmus paper, and its salts are readily decomposed by other acids.

Among the more important compounds of hydrocyanic acid are potassium cyanide and mercuric cyanide. Potassium cyanide, KCN, may be formed by passing nitrogen gas over a white-hot mixture of charcoal and potassium carbonate, the reaction being:

$$K_2CO_3 + 2N + 4C = 2KCN + 3CO.$$

It is more conveniently prepared, however, by strongly heating potassium ferrocyanide (see below), which breaks up into potassium cyanide, carbide of iron, and free nitrogen. Potassium cyanide is a white salt, soluble in water and in alcohol, and exceedingly poisonous. It is much used in electroplating as a solvent for gold and silver, and also in the extraction of gold from certain ores by the process known as «cyaniding.» It melts without decomposition, and in the molten state it is a powerful reducing agent. For this reason it is often used as a flux in welding, and in other metallurgical operations.

Mercuric cyanide, which is also very poisonous, is used in medicine, and is prepared by dissolving mercuric oxid in an aqueous solution of hydrocyanic acid.

Allied to hydrocyanic acid are two other acids, known respectively as «ferrocyanic acid,» $H_8Fe_2(C_3N_3)_4$, and «ferricyanic acid,» $H_6Fe_2(C_3N_3)_4$, which are not of any importance in the arts in the free state, but whose potassium salts are much used. Potassium ferrocyanide, or yellow prussiate of potash, $K_8Fe_2(C_3N_3)_4 + 6H_2O$, is prepared on a large scale by heating a mixture of nitrogenous organic matter and caustic potash, and treating the mass with freshly prepared ferrous carbonate. Crude cyanide of potassium is formed in the first instance, and this combines with the ferrous carbonate to form the yellow prussiate of potash and potassium carbonate, from which the yellow prussiate may be obtained in large crystals, by evaporation. When pure, the yellow prussiate is not poisonous. It is used, in the arts, as a source of Prussian blue, and also for the manufacture of potassium cyanide, which is liberated when the yellow prussiate is strongly heated.

Potassium ferricyanide, or red prussiate of potash, $K_6Fe_2(C_3N_3)_4$, is prepared by passing chlorine gas through a solution of the yellow prussiate, two molecules of potassium being thereby abstracted from it, with the formation of potassium chlorid as a secondary product. The red prussiate is used in the manufacture of sensitive paper for making blue-prints.

Hydro-ferricyanic (fĕr-ō-sī-ăn'ĭk) **Acid,** and **Hydro-ferrocyanic Acid.** See HYDROCYANIC ACID.

Hydrocele, hī'drō-sēl, a collection of serous fluid forming tumors around the testicle or spermatic cord. During fœtal life the testicle pushes the peritoneum before it as it descends from the abdomen into the scrotum. Along the spermatic cord the sac is usually obliterated, but if it is not it may become distended with fluid. The pouch of the peritoneum normally remains alongside of the testicle, and is called the tunica vaginalis. Distentions of these pouches may be congenital, but ordinarily they begin after maturity and probably are due to some fault in the blood-vessels, allowing the escape of the serum. Symptoms are due to the weight of the tumor, and the only danger lies in the possibility of the injury and rupture of the sac. Aspiration of the fluid, followed by the injection of a few drops of carbolic acid, may accomplish a cure, but partial removal of the sac may be necessary.

Hydrodynamics (ὕδωρ, water; δύναμις, force), or *Hydromechanics*, is that part of Dynamics which treats of the motion or rest of fluids under the action of forces. A perfect fluid is defined as a body whose parts are perfectly free to move under the action of the smallest forces, or otherwise, as a body such that the reactions between any two portions of it are normal to the surface separating them. If there is any tangential drag tending to prevent the one portion of the substance from slipping past the other, the fluid is said to be *viscous*. A perfect fluid is an abstraction, like the material particle or the rigid body, but many of the ordinary fluids, like water, alcohol, air, and other gases, are so slightly viscous that for many purposes they may be considered as perfect. The normal reaction, which alone we suppose to be present, is called the *pressure*, and is measured by the limit of the ratio of the force exerted on an element of surface to the area of the element, when both diminish without limit. The usual gravitational unit of pressure is the pound-weight per square inch, the usual scientific, absolute unit (see MECHANICS), is the dyne per square centimeter. The pressure of the atmosphere may be considered as equal to one million dynes per square centimeter.

The fundamental theorem of hydrodynamics is that the pressure on an element of surface is independent of the direction of the normal to the surface. This may be proved by considering the equilibrium of a small tetrahedron $ABCD$, Fig. 1, and resolving the forces on its

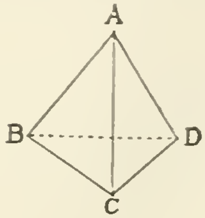

FIG. 1.

faces in the direction BD. The pressure being normal, the forces on ABD, BCD have no component along BD, while if the pressures on ABC, ACD, and the areas of those sides are respectively p_1, p_2, S_1, S_2, their normals n_1, n_2, we have for equilibrium $p_1S_1 \cos (n_1, BD) = p_2S_2 \cos (n_2, BD)$. But $S_1 \cos (n_1, BD)$, $S_2 \cos (n_2, BD)$ are the projections of the areas on a plane perpendicular to BD, which are equal, therefore $p_1 = p_2$. If there are other forces applied to the fluid besides the pressure, such, for instance, as its weight, these will be proportional to the volume of the tetrahedron, and when its size is diminished indefinitely, the volume vanishes to the third order of small quantities, and may thus be neglected in comparison with the area, which is of the second order, so that the result is not affected.

HYDROSTATICS.—We will first consider hydrostatics, or that part of our subject which deals with fluids at rest. Suppose that the fluid is subject to the action of forces whose components along the coordinate axes are equal to X, Y, Z per unit of mass. These we call bodily forces. Now consider the equilibrium of an infinitesimal rectangular parallelopiped, Fig. 2, whose edges, parallel to the coordinate axes, have lengths dx, dy, dz. Suppose

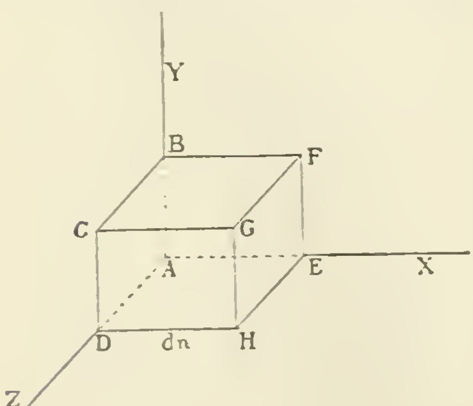

FIG. 2.

that the mean value of the pressure on the side $ABCD$, which is at a distance x from the origin, is p, then the X-component of the force on this side is $p\,dy\,dz$. On the side $EFGH$, which lies at a distance dx farther from the origin, the mean pressure will be $p + \frac{\partial p}{\partial x}dx$, and the component on the face $EFGH$, acting on the parallelopiped, being in the opposite direction will be $-\left(p + \frac{\partial p}{\partial x}dx\right)dy\,dz$. Now if the density of the fluid is ρ, the amount of matter in the parallelopiped, being the product of the density and volume, will be $\rho\,dx\,dy\,dz$, and the force exerted upon it in the X-direction will be $X\rho\,dx\,dy\,dz$. We must therefore have for equilibrium

$$p\,dy\,dz - \left(p + \frac{\partial p}{\partial x}dx\right)dy\,dz + \rho X\,dx\,dy\,dz = 0,$$

and passing to the limit by decreasing the dimensions, p will be the pressure at any point, and dividing by $dx\,dy\,dz$, we have

$$\rho X = \frac{\partial p}{\partial x}.$$

In a similar manner we have

$$\rho Y = \frac{\partial p}{\partial y}, \qquad (1)$$
$$\rho Z = \frac{\partial p}{\partial z}.$$

Thus the fluid can be in equilibrium only under the influence of bodily forces such that the components of the bodily forces, multiplied by the density, are the derivatives of the same function of the coordinates. Now there is in general a physical relation between the pressure of a fluid and the density at any point. If we put

$$P = \int \frac{dp}{\rho}, \quad \frac{dP}{dp} = \frac{1}{\rho},$$

we have

$$\frac{\partial P}{\partial x} = \frac{dP}{dp}\frac{\partial p}{\partial x} = \frac{1}{\rho}\frac{\partial p}{\partial x}, \quad \frac{\partial P}{\partial y} = \frac{dP}{dp}\frac{\partial p}{\partial y} = \frac{1}{\rho}\frac{\partial p}{\partial y},$$
$$\frac{\partial P}{\partial z} = \frac{dP}{dp}\frac{\partial p}{\partial z} = \frac{1}{\rho}\frac{\partial p}{\partial z},$$

and our equations (1) become

$$(2) \qquad X = \frac{\partial P}{\partial x}, \quad Y = \frac{\partial P}{\partial y}, \quad Z = \frac{\partial P}{\partial z}.$$

Now this is the condition that the bodily forces are *conservative* (see MECHANICS). In that case the potential energy for unit mass is called the *potential* of the forces, and will be denoted by V. Thus we shall have $P = -V + \text{const.}$, and $dV = -dP = -\frac{dp}{\rho}$. If two fluids of different densities are in contact, we have at their common surface

$$-dp = \rho_1 dV = \rho_2 dV,$$

so that

$$(\rho_1 - \rho_2)\,dV = 0,$$

and since $\rho_1 - \rho_2$ is not zero we must have $dV = 0$, $dp = 0$. Consequently the surface of separation is a surface of constant potential and constant pressure. In the case of gravity we have, if the Z-axis is measured vertically upward, $V = gz$, so that the surfaces of constant V are horizontal planes, and a surface where water is in contact with the atmosphere must be a horizontal plane, or level surface, the pressure being the constant atmospheric pressure. If we suppose the fluid to be incompressible, we have ρ constant, $P = p/\rho$,

$$(3)\qquad \frac{p}{\rho} = -V + \text{const.} = -gz + \text{const.},$$

$$(4)\qquad p = -g\rho z + \text{const.},$$

so that, if we neglect the atmospheric pressure, and count the depth from the plane $z = 0$, we have the fundamental theorem for heavy liquids, namely, that the pressure is proportional to the depth. This may be proved experimentally by placing a well-fitting plate under a tube, Fig. 3, communicating with a

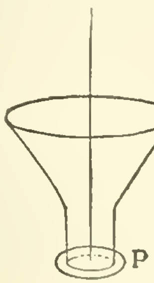

FIG. 3.

vessel of any shape, and holding the plate up by a wire hung from a balance, while water is poured in above. The weight required to hold the plate up is found to be independent of the shape of the vessel, and to depend only on the depth and the area of the plate. The vase and plate may also be immersed in liquid, while, instead of liquid within, weights are placed on the plate; the weight supported will then be proportional to the depth.

Consider now a gas, or compressible fluid, satisfying the law of Boyle and Mariotte,

$$p = a\rho.$$

Accordingly,

$$(5)\qquad P = \int \frac{dp}{\rho} = \int \frac{a\,d\rho}{\rho} = a \log \rho + \text{const.},$$

and

$$(6)\qquad V = gz = c - a \log \rho,$$

$$(7)\qquad \rho = \rho_0 c^{-\frac{gz}{a}}.$$

Thus as we ascend to heights in arithmetical progression the density decreases in geometrical progression, becoming zero at an infinite height. From equation (7) the barometric formula is obtained by which heights are found from barometer readings. The law of Boyle assumes constant temperature. It is, however, more likely that the temperature varies in accordance with what is called convective equilibrium, so that if a portion of air is hotter than the stratum in which it lies it will rise, and, cooling and expanding, will eventually find a layer of the same density and temperature as its own. The principles of thermodynamics give us the relation between pressure and temperature when the rarefaction is adiabatic, that is, when no heat is lost or gained by the air,

$$p = b\rho^{\kappa},$$

where κ is a constant for the gas, whose value is about 1.4. We then have

$$(8)\qquad V = gz = -\int b\kappa\rho^{\kappa-2}d\rho = c - \frac{b\kappa\rho^{\kappa-1}}{\kappa - 1}.$$

Since $\kappa > 1$, ρ diminishes as z increases, and is equal to zero when $gz = c$, so that on this hypothesis the atmosphere has an upper limit.

Let us now consider the equilibrium of a solid body floating in a liquid. If we consider the body removed and the space that it occupied filled with water, since this water is in equilibrium, its weight is borne up by the pressure of the surrounding water, the effect of which is accordingly to apply to each portion of the water in question an upward force just equal to its weight. Now just the same forces must be the resultant of the pressures on the solid when it is substituted for the displaced water, so that it is borne up by a force equal to the weight of the displaced water. This is the Principle of Archimedes. Since the resultant of the weight of all the displaced water is a single force applied at its center of mass, the resultant upward thrust on the floating body is applied at a point coinciding with the center of mass of the displaced water. This point is called the *center of buoyancy* of the body. If the body is to be in equilibrium, according to the principles of statics of a rigid body, its weight must be equal to that of the displaced body, and its center of mass and center of buoyancy must be in the same vertical line. If the first condition is satisfied, but not the second, the body will float, but will be subject to a turning couple.

Suppose the body floats without being wholly immersed. A plane which cuts off from the body a volume equal to the volume of water having an equal weight is called a *plane of flotation*, and if we draw all such planes they will envelop a surface called the *surface of flotation*. For every plane of flotation there will be a center of buoyancy, and the locus of all these points is called the *surface of buoyancy*. Suppose the floating body is displaced from its position of equilibrium by rotation through a small angle $\delta\theta$ about an axis OX through O, Fig. 4, and let WL, $W'L'$ be the original and

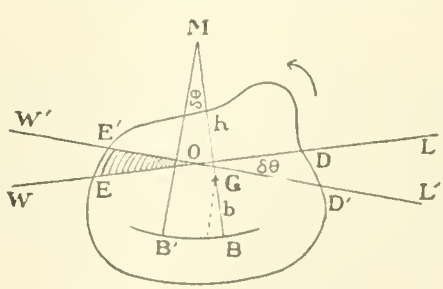

FIG. 4.

final planes of flotation. By turning the figure until either is horizontal both positions of the body may be shown. Let B be the original center of buoyancy, G the center of mass of the floating body. Then if B were the center of buoyancy in the second position, the body would be acted on by the couple of which either arm would be the weight $W=mg$, and the arm the horizontal projection of BG, $b\delta\theta$, where $b=BG$. The moment of the couple tending to further displace the body will then be $Wb\delta\theta$. But this is not the only couple, for the immersed part is not the same as before, the volume of the wedge EOE' having become immersed, giving rise to an upward thrust, and the wedge DOD' having emerged and lost its buoyancy, both these causes giving rise to a turning moment in the same direction, and opposite to that previously found. Since the volume under water is to be the same in both positions, the volume of the wedges of immersion and emersion must be equal. Since the wedges are infinitely thin, the thickness at any point x, y in the plane of flotation is $z=y\delta\theta$. The condition for equality of volumes is then

$$(9)\qquad \iint z\,dxdy=\delta\theta\iint y\,dxdy=0,$$

the integral being taken over the plane of flotation. This will be the case if the axis passes through the center of mass of the area of flotation. The thrust on any element of volume $d\tau=zdxdy$ being $g\rho d\tau$, the moment about the X-axis will be

$$(10)\qquad L'=\iiint g\rho y\,d\tau=g\rho\delta\theta\iint y^2dxdy$$
$$=g\rho\delta\theta S\kappa_x^2,$$

where κ_x is the square root of the mean of the squares of the distances of the elements from the X-axis, or the so-called radius of gyration of the area of flotation about the X-axis, and S is the area of flotation. In like manner the moment about the Y-axis is

$$(11)\qquad M'=-\iiint g\rho x\,d\tau=-g\rho\delta\theta\iint xy\,dxdy.$$

There are always two axes at right angles to each other, called *principal axes*, for which the integral above vanishes, and for such an axis a displacement about it gives rise only to a couple about that axis. Subtracting this couple L' from the one previously found we obtain for the magnitude of the *righting couple*

$$(12)\qquad L=g\delta\theta(\rho S\kappa_x^2-mb).$$

It is evident that in moving the point of application of the thrust from the center of mass of one wedge to that of the other, the center of buoyancy will be moved in a parallel direction, so that, in the limit, this direction being that of the plane of flotation, the line BB' will be parallel to that plane, or the tangent to the surface of buoyancy is parallel to the corresponding plane of flotation. It is also evident that the body is under the same forces that it would be if the surface of buoyancy were material and rested on a horizontal plane, for the reaction would be vertical and equal to the weight of the body.

If B' be the new center of buoyancy, and we draw verticals from B and B', they will be normals to the surface of buoyancy and will intersect at M, the center of curvature of the section of the surface of buoyancy. This point is called the *metacenter*, and its distance h_x above G the *metacentric height*. Evidently for stable equilibrium, or a positive righting couple, M must be above G. The arm of the couple being the horizontal projection of MG is equal to $h_x\delta\theta$ and we have $L=mgh_x\delta\theta$. Inserting this in equation (12) we obtain for the metacentric height

$$(13)\qquad mh_x=\rho S\kappa_x^2-mb,$$

and dividing by m and writing $V=m/\rho$ for the volume of displaced liquid,

$$(14)\qquad h_x=\frac{S\kappa_x^2}{V}-b.$$

The equilibrium is stable or unstable according as this is positive or negative.

For the displacement about the Y-axis we have in like manner a couple proportional to the angle of displacement, with a new metacentric height,

$$(15)\qquad h_y=\frac{S\kappa_y^2}{V}-b,$$

where κ_y is the radius of gyration about the Y-axis. It is evident that the metacentric height is greater for a displacement about the shorter principal axis of the plane of flotation. Thus it is easier to roll a ship than to tip it endwise. The above theorems concerning the surfaces of flotation and buoyancy are due to Dupin.

If the floating body is totally submerged, like a submarine boat, only the first moment $mgb\delta\theta$ comes into play, S being zero, and the center of buoyancy becomes the metacenter. The stability is in this case only secured by placing the center of gravity low.

Hydrokinematics.—We will now consider the motions possible to a fluid, without regard to the forces causing them. Let the velocity at a point be the vector q, with components u, v, w, and let us consider the quantity of fluid entering or leaving any closed surface in the unit of time. The amount of fluid which crosses the element of surface dS, Fig. 5,

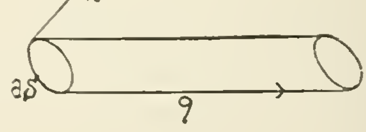

Fig. 5.

with a velocity q would in unit time, if q were constant, fill a prism on the base dS with a slant height q. If n is the normal to dS, the volume of this prism is $dSq\cos(qn)$, and the mass of fluid in it $dS\rho q\cos(qn)$, or using the formula for the projection of q on n (see Mechanics, equation (12)),

$$dS\rho q_n=dS\rho\{u\cos(nx)+v\cos(ny)+w\cos(nz)\}.$$

Consequently if we consider any closed surface, whose outward normal is n, we have for the whole outflow in unit time the surface integral

$$(16)\qquad \Phi=\iint\rho q_n dS=\iint\rho[u\cos(nx)$$
$$+v\cos(ny)+w\cos(nz)]dS.$$

But we may find a different expression for the same quantity, by considering the elements of volume. Consider the parallelopiped of Fig. 2, and let u be the mean velocity on the side $ABCD$, $u+\frac{\partial u}{\partial x}dx$ on the opposite side $EFGH$. Then the inflow on the first side will be $\rho u dy dz$, while the outflow through the second will be $\left\{\rho u+\frac{\partial(\rho u)}{\partial x}dx\right\}dydz$. The total outflow will thus be

$$\frac{\partial(\rho u)}{\partial x}dxdydz.$$

In a similar manner we find the outflow through the two remaining pairs of sides to depend on the other two components. From the whole surface we accordingly have the outflow

$$\left\{\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}\right\}dxdydz,$$

and for the outflow per unit volume we have

$$(17)\qquad \frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}.$$

On account of this kinematical interpretation, if we have any vector F, whose components X, Y, Z are functions of the coordinates of a point, the expression

$$(18)\qquad \frac{\partial X}{\partial x}+\frac{\partial Y}{\partial y}+\frac{\partial Z}{\partial z}$$

is called the *divergence* of the vector, and will be abbreviated div F. Summing up the outflow for all the elements of volume inside the surface S, it is evident that the volume integral thus found must be equal to the surface integral Φ. Thus we have

$$(19)\quad \iint \rho\{u\cos(nx)+v\cos(ny)+w\cos(nz)\}dS$$
$$=\iiint\left\{\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}\right\}dxdydz.$$

This may be taken as a kinematical proof of the *Divergence Theorem*, due to Gauss and Green, in which, for any vector function which is continuous and has a definite value at every point in the volume within S,

$$(20)\quad \iint\{X\cos(nx)+Y\cos(ny)+Z\cos(nz)\}dS$$
$$=\iiint\left\{\frac{\partial X}{\partial x}+\frac{\partial Y}{\partial y}+\frac{\partial Z}{\partial z}\right\}dxdydz,$$

or in more abbreviated notation,

$$(20)\qquad \iint F_n dS=\iiint \operatorname{div} F\cdot d\tau.$$

The surface-integral in (20) is called the *flux* of the vector F through the surface S. If we have any continuously distributed vector-function F, that is, one whose components X, Y, Z are continuous functions of the point x, y, z, we may draw curves having the property that at every point on a curve its tangent has the direction of the vector F. The differential equations of these curves are

$$\frac{dx}{X}=\frac{dy}{Y}=\frac{dz}{Z}=\frac{ds}{F},$$

and the curves are called *lines* of the vector F. For instance, lines of the vector q are called *lines of flow*. If we draw all the lines of the vector passing through a closed contour, we shall obtain a tubular surface called a *tube* of the vector, Fig. 6.

If the fluid is incompressible, as much fluid must flow out from as into any volume, so

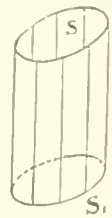

FIG. 6.

that the total outflow is zero. The density is then constant, and we have, dividing (17) by ρ,

$$(21)\qquad \operatorname{div} q=\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}=0.$$

A vector whose divergence is zero is said to be *solenoidal* ($\sigma\omega\lambda\dot{\eta}\nu$, a tube), for its tubes have the property that the flux across a cap, or portion of a surface bounded by the tube, is the same wherever the surface be drawn. Analytically, applying the divergence theorem to the portion of space bounded by a portion of such a tube and two caps forming ends, since along the sides of the tube the normal component vanishes that portion of the flux in (20) is zero. Accordingly the flux through both ends is zero, or the flux out through one is equal to that in through the other. Or, looking in the direction of the vector-lines, the flux across any cap is the same. If we consider a tube of infinitesimal cross-section, and S is the area of a right section, since the flux is FS, which is constant for the tube, the magnitude of the vector F is inversely proportional to the area of the cross-section.

If the liquid is not incompressible the total outward flux is equal to the time-rate of decrease of the mass inside the surface, S, so that, the mass in an element of volume $d\tau = dxdydz$ being $\rho d\tau$, we have

$$(22)\qquad -\frac{\partial m}{\partial t}=-\frac{\partial}{\partial t}\iiint\rho d\tau=\iint\rho q_n dS$$
$$=\iiint\operatorname{div}(\rho q)d\tau$$

Now since the volume over which we integrate is independent of the time, we may differentiate under the integral sign; also, both integrals being taken over the same volume, we may combine them into one,

$$(23)\qquad \iiint\left\{\frac{\partial\rho}{\partial t}+\operatorname{div}(\rho q)\right\}d\tau=0.$$

This equality holding for any volume whatever, the integrand must vanish, so that we have

$$(24)\qquad \frac{\partial\rho}{\partial t}+\frac{\partial(\rho u)}{\partial x}+\frac{\partial(\rho v)}{\partial y}+\frac{\partial(\rho w)}{\partial z}=0.$$

This is the so-called *equation of continuity*, the term arising from the continuity of existence of mass, none being created or destroyed, but being conveyed without change from place to place.

Beside the surface- and volume-integrals dealt with above, we need to consider certain line-integrals. If we resolve the vector q along the direction of the tangent to a curve running from A to B, and multiply by the length of the arc ds, and integrate from A to B along the curve, the line-integral

$$(25)\qquad \int_A^B q_s ds = \int_A^B (u dx + v dy + w dz)$$

is called the *circulation* along the curve. If we describe the curve in the reverse direction, the integral changes sign. If the curve is a closed one, we shall prove the line-integral to be equal to a certain surface-integral over any surface S which has the contour in question as a boundary. Suppose first the contour is a plane curve and the surface is a plane. Let us divide the area up into infinitesimal rectangles by lines parallel to the axes of X and Y, Fig. 7. If we then find the circulation

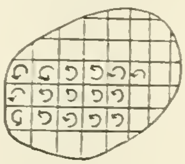

FIG. 7.

around each of the rectangles in the same direction, we shall have gone around all the sides common to two adjacent rectangles twice in opposite directions, so that those parts of the circulation will have destroyed each other, and there will remain only those parts which belong to the original contour. Accordingly the integral around the contour is equal to the sum of all these around the infinitesimal rectangular contours. Consider one of these, $ABCD$, Fig. 8. Along AC the

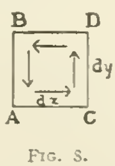

FIG. 8.

tangential component is u, and the contribution to the integral $u dx$. Along BD the value of u is $u+\frac{\partial u}{\partial y}dy$, and since we are going in the opposite direction the contribution to the integral is $-\left(u+\frac{\partial u}{\partial y}dy\right)dx$. Along AB the tangential component is v, and, since we are moving from B to A, the contribution to the integral is $-v dy$. Along CD the tangential component is $v+\frac{\partial v}{\partial x}dx$ and the contribution $\left(v+\frac{\partial v}{\partial x}dx\right)dy$. Adding these four we have

$$\left(\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y}\right)dx\,dy,$$

and summing for all the rectangles,

$$(26)\qquad \int q_s ds = \int\int\left(\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y}\right)dx\,dy,$$

which is a particular case of our theorem.

If the contour is not a plane curve, so that the surface S is not plane, let us by drawing a series of planes parallel to one of the coordinate planes divide it into infinitesimal strips, Fig. 9, and then by drawing planes alternately

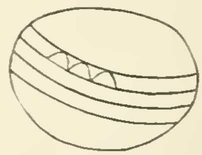

FIG. 9.

parallel to the two other coordinate planes divide each strip into infinitesimal triangles each having one side parallel to each coordinate plane. As before, the sum of the circulations around all the triangles is equal to the circulation around the contour. Let us consider one of these triangles, BCD, Fig. 10, and let A

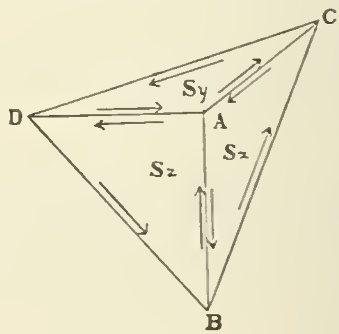

FIG. 10.

be the point from which lines drawn parallel to the coordinate axes will pass through B, C, D. Again, circulation around BCD is equivalent to the sum of the circulations around the triangles ABC, ACD, ADB, the projections of BCD parallel to the coordinate planes. Let the areas of these four triangles be respectively dS, $dS_x = dS\cos(nx)$, $dS_y = dS\cos(ny)$, $dS_z = dS\cos(nz)$, n being the normal to S. Then we have, applying (26) to the three contours,

$$\int_{ABCA} q_s ds = \left(\frac{\partial w}{\partial y}-\frac{\partial v}{\partial z}\right)dS_x,$$

$$\int_{ACDA} q_s ds = \left(\frac{\partial u}{\partial z}-\frac{\partial w}{\partial x}\right)dS_y,$$

$$\int_{ADBA} q_s ds = \left(\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y}\right)dS_z,$$

and consequently

$$\int_{BCDB} q_s ds = \left\{\left(\frac{\partial w}{\partial y}-\frac{\partial v}{\partial z}\right)\cos(nx)\right.$$

$$\left.+\left(\frac{\partial u}{\partial z}-\frac{\partial w}{\partial x}\right)\cos(ny)+\left(\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y}\right)\cos(nz)\right\}dS$$

Summing up for all the infinitesimal triangles, we find the surface-integral over the surface S to be equal to the circulation around the contour.

$$(27)\quad \int (u\,dx + v\,dy + w\,dz) =$$

$$\iint \left\{ \left(\frac{\partial w}{\partial y} - \frac{\partial v}{\partial z}\right)\cos(nx) + \left(\frac{\partial u}{\partial z} - \frac{\partial w}{\partial x}\right)\cos(ny) + \left(\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}\right)\cos(nz)\right\} dS.$$

This is known as Stokes's theorem.

If we define a vector ω with the components ξ, η, ζ,

$$(28)\quad \begin{aligned} 2\xi &= \frac{\partial w}{\partial y} - \frac{\partial v}{\partial z}, \\ 2\eta &= \frac{\partial u}{\partial z} - \frac{\partial w}{\partial x}, \\ 2\zeta &= \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}, \end{aligned}$$

we have the integrand in the surface-integral in (27),

$$2[\xi \cos(nx) + \eta \cos(ny) + \zeta \cos(nz)] = 2\omega_n,$$

as the component of 2ω normal to the surface S. The vector 2ω is called the *curl* of q, for the reason that if the lines of the vector «curl» about in any region, so that the tangential component along a closed curve always has the same sign, the surface-integral, and hence the curl, cannot vanish. We may write Stokes's theorem in the abbreviated form

$$(27)\quad \int q_s ds = \iint (\text{curl } q)_n dS.$$

As an example of the kinematical significance of the curl, let us consider a portion of fluid which revolves like a rigid body about the Z-axis We then have $u = -ay$, $v = ax$, where a is a constant representing the angular velocity. We thus have

$$2\zeta = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} = 2a.$$

Or applying Stokes's theorem to a circle with center on the axis of rotation, since $q = ar$,

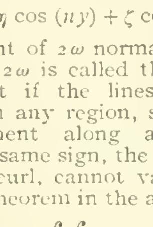

Fig. 11.

the line-integral is $2\pi r \cdot q = 2\pi r^2 a$, which is equal to the area of the circle multiplied by $2a$, which must represent the curl. Thus we

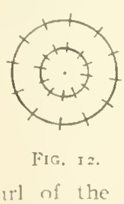

Fig. 12.

find that the curl of the velocity is twice the angular velocity with which an element of fluid is revolving. On this account the vector ω has received the name of *vorticity*, and fluid moving so that ω is not zero is said to move vortically. As the difference between vortical and non-vortical motion is very important, we may illustrate it as follows: It is possible that fluid may circulate in a region either vortically or non-vortically. Suppose that the fluid is filled with short straws represented by the short lines in Figs. 11 and 12; if, as the fluid moves about, these all remain parallel to their original direction, the flow is non-vortical, Fig 11; if they turn, the flow is vortical, Fig. 12. Thus it is impossible to tell by merely looking at a diagram of stream-lines whether the flow is vortical or not.

It will be shown later that the divergence and curl of a vector function are characteristic of it, and that if they are known everywhere the complete nature of the vector is known. They are quite independent of each other, as is illustrated in Fig. 13, which shows re-

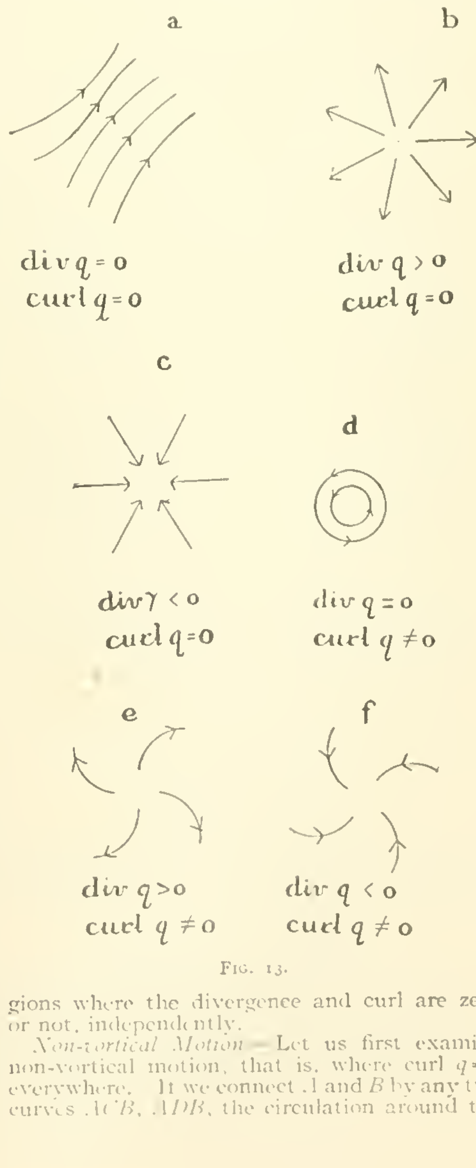

Fig. 13.

gions where the divergence and curl are zero or not, independently.

Non-vortical Motion.—Let us first examine non-vortical motion, that is, where curl $q = 0$ everywhere. If we connect A and B by any two curves ACB, ADB, the circulation around the closed path $ACBDA$ will be zero, hence the circulation from A to B will be the same by either path. Thus the circulation does not depend on the path, but only on the position of its ends, so that we have

$$(29)\qquad \int_A^B q_s ds = \phi_B - \phi_A,$$

which necessitates

$$q_s ds = u dx + v dy + w dz = d\phi = \frac{\partial\phi}{\partial x}dx + \frac{\partial\phi}{\partial y}dy + \frac{\partial\phi}{\partial z}dz,$$

and therefore

$$(30)\qquad u = \frac{\partial\phi}{\partial x},\quad v = \frac{\partial\phi}{\partial y},\quad w = \frac{\partial\phi}{\partial z}.$$

The function ϕ is called the *velocity-potential.* The direction of the velocity q is everywhere normal to the equipotential surfaces $\phi = \text{const.}$, for if we move along the equipotential we have

$$d\phi = u dx + v dy + w dz = 0,$$

which is the condition that the vectors u, v, w, the velocity, and dx, dy, dz, the displacement, are perpendicular. According to the relation $q_s ds = d\phi$, we have the component of velocity in any direction $q_s = \frac{\partial\phi}{\partial s}$, equal to the space-rate of variation of potential in that direction; and since the velocity itself is equal to the rate of change of ϕ in the direction of the normal to the surface $\phi = \text{const.}$, a vector related to a function ϕ by the relations (30) is called the *gradient* of the function. A vector which is thus derived from a potential function is called a *lamellar* vector.

As an example of lamellar flow, let us take the case in which the velocity is directed radially outwards from a given point a, b, c with a value depending on the distance $r = \sqrt{(x-a)^2 + (y-b)^2 + (z-c)^2}$ from that point, $q = f(r)$. The equipotential surfaces are concentric spheres, and we easily find the potential to be $\phi = \int f(r)dr$. For, since the direction cosines of r are $\cos(rx) = \frac{x-a}{r}$, $\cos(ry) = \frac{y-b}{r}$, $\cos(rz) = \frac{z-c}{r}$, we have the components of the velocity,

$$\begin{aligned} u &= f(r)\frac{x-a}{r} = \frac{d\phi}{dr}\frac{\partial r}{\partial x} = \frac{\partial\phi}{\partial x},\\ (30)\qquad v &= f(r)\frac{y-b}{r} = \frac{d\phi}{dr}\frac{\partial r}{\partial y} = \frac{\partial\phi}{\partial y},\\ w &= f(r)\frac{z-c}{r} = \frac{d\phi}{dr}\frac{\partial r}{\partial z} = \frac{\partial\phi}{\partial z}.\end{aligned}$$

The flux out through any of the concentric spheres is $M = 4\pi r^2 q$, so that if the fluid is incompressible we must have

$$(31)\qquad q = \frac{M}{4\pi r^2},\quad \phi = -\frac{M}{4\pi r},$$

where M is constant. The vector q is then solenoidal as well as lamellar, and the equation of continuity becomes

$$(32)\quad \operatorname{div} q = \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = \frac{\partial^2\phi}{\partial x^2} + \frac{\partial^2\phi}{\partial y^2} + \frac{\partial^2\phi}{\partial z^2} = 0.$$

This equation for ϕ is known as Laplace's equation, and the sum of the three partial derivatives of second order, which will be abbreviated as $\Delta\phi$, is called the *Laplacian* of q. Obviously the above flow cannot extend as far as $r = 0$, for there the velocity would be infinite. Suppose that in a small region of volume τ at the center liquid is being created just fast enough to supply the outflow, so that the volume M is created per unit of time. Such a region is called a *source*, and the whole system of flow is called a *squirt*. The quantity M is called the *strength* of the source, and the strength per unit of volume $M/\tau = \sigma$ the *source-density*. If we have several sources, and add their potentials, the resultant velocity will be obtained as the gradient of the sum. Thus a complicated vector-field may be represented by its potential function. The sources may be continuously distributed through a portion of space, then σ, the source-density, will be a function of the position of the point, and the total strength will be

$$(33)\qquad M = \iiint \sigma d\tau,$$

while the total potential will be

$$(34)\qquad \phi = -\frac{1}{4\pi}\iiint \frac{\sigma d\tau}{r},$$

where r represents the distance from the element $d\tau$ to the point where ϕ is calculated. The total flux through any closed surface will be

$$(35)\quad \iint q_n dS = \iint \frac{\partial\phi}{\partial n}dS = \iint (\text{grad }\phi)_n dS,$$

or by the divergence theorem,

$$(36)\quad \iint q_n dS = \iiint \operatorname{div} q \cdot d\tau = \iiint \Delta\phi \cdot d\tau = \iint (\text{grad }\phi)_n dS.$$

Since this flux must be equal to the strength of all the sources within the surface of integration, we must have

$$(37)\qquad \iiint \Delta\phi \cdot d\tau = \iiint \sigma d\tau.$$

Now as this equality holds for any volume whatsoever, the integrands must be equal; accordingly we have

$$(38)\qquad \Delta\phi = \sigma,$$

as a consequence of equation (34). The equation (38) is called Poisson's equation. We may also prove the converse, namely, that if σ is given as a function of the point, the integral of equation (38) is given by (34). This is done by means of Green's theorem.

In the divergence theorem (20) let us put for the vector F the value $U \cdot \text{grad } V$, where U and V are two functions, both of which, with their derivatives, are finite, singly-valued, and continuous in the region of integration. Then we have

$$X = U\frac{\partial V}{\partial x},\quad Y = U\frac{\partial V}{\partial y},\quad Z = U\frac{\partial V}{\partial z},$$

$$\frac{\partial X}{\partial x} + \frac{\partial Y}{\partial y} + \frac{\partial Z}{\partial z} = U\Delta V + \frac{\partial U}{\partial x}\frac{\partial V}{\partial x} + \frac{\partial U}{\partial y}\frac{\partial V}{\partial y} + \frac{\partial U}{\partial z}\frac{\partial V}{\partial z},$$

$$(39)\quad \iint F_n dS = \iint U(\text{grad } V)_n dS$$

$$= \iint U \frac{\partial V}{\partial n} dS$$

$$= \iiint \left\{ U \Delta V + \frac{\partial U}{\partial x}\frac{\partial V}{\partial x} + \frac{\partial U}{\partial y}\frac{\partial V}{\partial y} + \frac{\partial U}{\partial z}\frac{\partial V}{\partial z} \right\} d\tau.$$

Interchanging the functions U and V and subtracting from (39), we have

$$(40)\quad \iint \left\{ U \frac{\partial V}{\partial n} - V \frac{\partial U}{\partial n} \right\} dS$$

$$= \iiint \left\{ U \Delta V - V \Delta U \right\} d\tau.$$

The equations (39) and (40) are known as Green's Theorem. Let us apply it to two functions, one of which, U, is the reciprocal distance from a fixed point P, $U = 1/r$. Let us apply the theorem to the whole extent of space, bounded by the infinite sphere, with the exception of a portion bounded by a small sphere with center at P, which we exclude, on account of the infinite value of U at P. We must thus take the surface-integrals over the large and small spheres, the normals being in each case drawn away from the volume considered, or out in the first case, in in the second. Since the direction of the normal coincides with that of the radius of the sphere,

$$\frac{\partial(1/r)}{\partial n} = \pm \frac{\partial(1/r)}{\partial r} = \mp \frac{1}{r^2},$$

in the two cases respectively, while $dS = r^2 d\omega$, where $d\omega$ is the element of area of a sphere of radius unity, cut out by a cone of vertex P, having as base the element dS. Accordingly on either sphere

$$(41)\quad \iint V \frac{\partial(1/r)}{\partial n} dS = \mp \iint V d\omega,$$

and if V vanishes at $r = \infty$, the integral over the infinite sphere vanishes. If we now let the radius of the small sphere diminish without limit, the value of V to be taken is the value at P, so that

$$(42)\quad -\iint V \frac{\partial(1/r)}{\partial n} dS = -V_P \iint d\omega = -4\pi V_P.$$

On the other hand the surface-integral

$$\iint \frac{1}{r}\frac{\partial V}{\partial n} dS = r \iint \frac{\partial V}{\partial n} d\omega,$$

over the spheres vanishes for $r = \infty$, on account of the vanishing of $\frac{\partial V}{\partial n}$ to the second order, and for the small sphere in the limit, on account of the factor r. As for the volume-integrals we have seen in (31), (32), that any multiple of $1/r$ satisfies Laplace's equation, hence $\Delta(1/r) = 0$, so that finally

$$(43)\quad V_P = -\frac{1}{4\pi} \iiint \frac{\Delta V}{r} d\tau,$$

the integral being taken over all space. But this is the required theorem, the converse of (38).

Solutions of Laplace's equation can be found for the case of uniplanar flow, where the velocity is parallel to a given plane, and independent of the coordinate perpendicular thereto. A plane diagram then represents the flow. If the given plane is that of X, Y, Laplace's equation becomes

$$(44)\quad \frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0.$$

An infinite number of solutions are furnished us by the method of functions of a complex variable $x + iy$, where i is the imaginary defined by $i^2 = -1$.

If now we take any function $w = f(z)$ of the combination $z = x + iy$, on arranging it in powers of x, iy, all even powers of i will be real, all odd ones real multiples of i; accordingly w will be of the form $\phi + i\psi$, where ϕ, ψ are real functions of the two real variables x, y. Differentiating partially,

$$\frac{\partial w}{\partial x} = f'(z)\frac{\partial z}{\partial x} = f'(z), \quad \frac{\partial w}{\partial y} = f'(z)\frac{\partial z}{\partial y} = if'z = i\frac{\partial w}{\partial x},$$

$$\frac{\partial w}{\partial y} = \frac{\partial \phi}{\partial y} + i\frac{\partial \psi}{\partial y} = i\frac{\partial w}{\partial x} = i\frac{\partial \phi}{\partial x} - \frac{\partial \psi}{\partial x},$$

and equating real and imaginary parts,

$$(45)\quad \frac{\partial \phi}{\partial x} = \frac{\partial \psi}{\partial y}, \quad \frac{\partial \phi}{\partial y} = -\frac{\partial \psi}{\partial x}.$$

Differentiating the first equation by x, the second by y, and adding, we have

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0,$$

and similarly

$$\frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} = 0.$$

Thus either function ϕ or ψ derived from any function of a complex variable gives us a case of uniplanar flow of an incompressible fluid. From the equations (45) we obtain by cross-multiplication

$$(46)\quad \frac{\partial \phi}{\partial x}\frac{\partial \psi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{\partial \psi}{\partial y} = 0,$$

which is the condition that the normals to the family of curves $\phi = \text{const.}$ and those of the family $\psi = \text{const.}$ intersect each other at right angles. Such families are called orthogonal. For instance, the function

$$(47)\quad w = \frac{1}{z} = \frac{1}{x + iy} = \frac{x - iy}{x^2 + y^2}$$

gives

$$(48)\quad \phi = \frac{x}{x^2 + y^2}, \quad \psi = \frac{-y}{x^2 + y^2},$$

and the curves

$$\frac{x}{x^2 + y^2} = \text{const.}, \quad \frac{y}{x^2 + y^2} = \text{const.}$$

are a set of circles tangent to the Y-axis and the X-axis respectively, the two sets intersecting each other at right angles.

The flux across any cylindrical surface whose generator has the length unity parallel to the Z-axis, and which intersects the XY-plane in a curve from A to B, is, if $\rho = 1$,

$$(49)\quad \Phi_{AB}=\int_A^B q_n ds=\int_A^B \frac{\partial\phi}{\partial n}ds$$
$$=\int_A^B \left\{\frac{\partial\phi}{\partial x}\cos(nx)+\frac{\partial\phi}{\partial y}\cos(ny)\right\}ds.$$

But if the normal lies on the right as we go along the curve, Fig. 14,

$$\cos(nx)ds=dy,\quad \cos(ny)ds=-dx.$$

Using these values and equations (45), we have for the flux

$$(50)\quad \Phi_{AB}=\int_A^B \frac{\partial\psi}{\partial x}dx+\frac{\partial\psi}{\partial y}dy=\psi_B-\psi_A,$$

so that the quantity of liquid crossing the surface does not depend on the curve joining

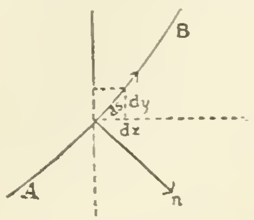

Fig. 14.

AB, but is the same for one as for another, as must be the case if the liquid is incompressible. The function ψ is called the *flux-function*, and since if $\psi_B=\psi_A$, no liquid crosses, it is evident that the curves $\psi=$const. are stream-lines. It is evident from equations (45) that either of the two functions ϕ, ψ may be taken for the velocity-potential, the other being taken for the flux-function. Functions satisfying equations (45) are called *conjugate functions*, and the two states of flow just described are called conjugate. In the case just investigated, the two conjugate flows happened to be identical; this is not generally the case.

For instance, consider the function $w=\log z$, and introducing polar coordinates r, θ,

$$(51)\quad w=\log z=\log(x+iy)$$
$$=\log\{r(\cos\theta+i\sin\theta)\}=\log\{re^{i\theta}\}=\log r+i\theta.$$

Thus we may put

$$(52)\quad \phi=\log r,\quad \psi=\theta,$$

obtaining a radial flow, or uniplanar squirt, with circular equipotentials, or

$$(53)\quad \phi=\theta,\quad \psi=\log r,$$

obtaining a circular flow with radial equipotentials.

Vortex Motion.—Let us now free ourselves from the restriction that the curl of the velocity vanishes. There will then be no velocity-potential in regions where there is curl. Lines whose tangent has everywhere the direction of the vector ω, the vorticity, are called *vortex-lines*, and tubes generated by such lines vortex-tubes, tubes of infinitesimal cross-section being termed vortex-filaments. The fluid within such a tube is called a vortex. Since the curl of any vector is solenoidal, as is seen by differentiating the equations (28) to find the divergence, the vorticity is a solenoidal vector and its tubes have the solenoidal property that the vorticity in any filament is inversely proportional to the area of the cross-section of the filament. The product $S\omega$, which is constant for the filament, is called the strength of the filament. Consequently the vorticity cannot vanish at any point on a tube, nor can the cross-section. The vortex-tubes must accordingly be closed, or end at a free surface of the liquid, as do those vortices formed by an oar at the surface of water.

The properties of vortex-motion were first investigated in an important paper by Helmholtz in 1858. Following him we shall now show that any continuous flow vanishing at infinity may be represented as the sum of a lamellar and a solenoidal part, and that the solenoidal part may be represented as the curl of another vector. Suppose that ϕ be the potential of the lamellar part, Q the vector with components U, V, W, whose curl represents the solenoidal part. Then we assume

$$(54)\quad \begin{aligned} u&=\frac{\partial\phi}{\partial x}+\frac{\partial W}{\partial y}-\frac{\partial V}{\partial z},\\ v&=\frac{\partial\phi}{\partial y}+\frac{\partial U}{\partial z}-\frac{\partial W}{\partial x},\\ w&=\frac{\partial\phi}{\partial z}+\frac{\partial V}{\partial x}-\frac{\partial U}{\partial y}.\end{aligned}$$

Finding the divergence of q we have

$$(55)\quad \operatorname{div} q=\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}=\Delta\phi,$$

since the divergence of the curl vanishes. But by (43) we have

$$\phi=-\frac{1}{4\pi}\iiint\frac{\Delta\phi}{r}d\tau=-\frac{1}{4\pi}\iiint\frac{\operatorname{div} q}{r}d\tau.$$

Since q represents a continuous flow, $\operatorname{div} q$ is finite. Accordingly we find that the lamellar part of the flow is completely determined by the distribution of its divergence.

Secondly, find the curl of q.

$$(56)\quad 2\xi=\frac{\partial w}{\partial y}-\frac{\partial v}{\partial z}=\frac{\partial}{\partial y}\left\{\frac{\partial\phi}{\partial z}+\frac{\partial V}{\partial x}-\frac{\partial U}{\partial y}\right\}$$
$$-\frac{\partial}{\partial z}\left\{\frac{\partial\phi}{\partial y}+\frac{\partial U}{\partial z}-\frac{\partial W}{\partial x}\right\}$$
$$=-\Delta U+\frac{\partial}{\partial x}\left\{\frac{\partial U}{\partial x}+\frac{\partial V}{\partial y}+\frac{\partial W}{\partial z}\right\}.$$

Since the vector Q is as yet undetermined except as to its curl, let us assume it to be solenoidal, which will make the divergence in (56) vanish, giving

$$(57)\quad 2\xi=-\Delta U,\quad 2\eta=-\Delta V,\quad 2\zeta=-\Delta W.$$

As before, we find the integrals of these equations to be

$$(58)\quad U=\frac{1}{2\pi}\iiint\frac{\xi}{r}d\tau,\quad V=\frac{1}{2\pi}\iiint\frac{\eta}{r}d\tau,$$
$$W=\frac{1}{2\pi}\iiint\frac{\zeta}{r}d\tau.$$

The integrals are to be taken over all space, but as any part of space where the vorticity vanishes will contribute nothing to the integrals, we may suppose them restricted to the vortices. Thus we see that the solenoidal part of the flow q, which is due to the vortices, is completely determined by the distribution of curl q. Thus the statement is justified that a continuous vector-function is completely determined by its divergence and curl. Kinematically we may say that any flow is the resultant of squirts and vortices. The vector Q, whose components are formed in the manner of potentials from the components of 2ω, is called the *vector-potential* of 2ω.

Thus the velocity due to a vortex is the curl of the vector-potential of twice the vorticity. We may find this velocity by differentiation. Let us distinguish the point of integration from the point for which the potentials are calculated, and by which we differentiate, by attaching an accent to the coordinates of the former. We have

$$(59)\qquad u=\frac{\partial W}{\partial y}-\frac{\partial V}{\partial z}$$
$$=\frac{1}{2\pi}\left[\frac{\partial}{\partial y}\iiint\frac{\zeta'}{r}d\tau'-\frac{\partial}{\partial z}\iiint\frac{\eta'}{r}d\tau'\right]$$
$$=\frac{1}{2\pi}\iiint\left\{\zeta'\frac{\partial}{\partial y}\left(\frac{1}{r}\right)-\eta'\frac{\partial}{\partial z}\left(\frac{1}{r}\right)\right\}d\tau'.$$

Thus the portions of velocity contributed by the element of the vortex $d\tau'$ are

$$du=\frac{1}{2\pi r^3}\{\zeta'(y'-y)-\eta'(z'-z)\}d\tau',$$
$$(60)\qquad dv=\frac{1}{2\pi r^3}\{\xi'(z'-z)-\zeta'(x'-x)\}d\tau',$$
$$dw=\frac{1}{2\pi r^3}\{\eta'(x'-x)-\xi'(y'-y)\}d\tau'.$$

These are immediately seen to be, aside from the factor $1/2\pi r^3$, the projections of the parallelogram whose sides are the vectors ω', and r the vector from x', y', z' to x, y, z. If dq be the magnitude of the resultant, we accordingly obtain

$$(61)\qquad dq=\frac{\omega'\sin(\omega' r)}{2\pi r^2}d\tau',$$

the direction of dq being perpendicular to both ω' and r, as shown by (60).

Let us take for the element of volume $d\tau'$ a length ds of a vortex-filament of cross-section S. Then $d\tau'=Sds$, and since $S\omega'=\kappa$, the strength of the filament

$$(62)\qquad dq=\frac{\kappa ds\cdot\sin(\omega r)}{2\pi r^2}.$$

The velocity is connected with the vorticity in the same way that the magnetic field due to an electric current is connected with the current-density, equation (62) giving us the magnetic field produced by a current of strength $\kappa/2\pi$.

HYDRODYNAMICS.—We now arrive at the subject of Hydrodynamics proper, in which we take account of the forces that are capable of producing the states of flow that have been previously described. Suppose that the coordinates of a particle are x, y, z, then $u=\frac{dx}{dt}$, $v=\frac{dy}{dt}$, $w=\frac{dz}{dt}$. The principles of dynamics tell us that the product of the mass by the acceleration of any particle is equal to the resultant of all the forces applied to it. Taking the mass contained in the element of volume $d\tau$, and the resultant of the bodily forces and pressures, as found under the treatment of hydrostatics,

$$(63)\qquad \rho d\tau\frac{d^2x}{dt^2}=\rho d\tau\frac{du}{dt}=\left(\rho X-\frac{\partial p}{\partial x}\right)d\tau,$$

from which we obtain the equation with two similar ones,

$$(64)\qquad \frac{du}{dt}=X-\frac{1}{\rho}\frac{\partial p}{\partial x},\quad \frac{dv}{dt}=Y-\frac{1}{\rho}\frac{\partial p}{\partial y},$$
$$\frac{dw}{dt}=Z-\frac{1}{\rho}\frac{\partial p}{\partial z}.$$

By the derivative $\frac{du}{dt}$ is meant the rate of change of velocity of a particular particle as it moves about. If we have any function F of the position of a particular particle, we may write its derivative

$$(65)\qquad \frac{dF}{dt}=\frac{\partial F}{\partial t}+\frac{\partial F}{\partial x}\frac{dx}{dt}+\frac{\partial F}{\partial y}\frac{dy}{dt}+\frac{\partial F}{\partial z}\frac{dz}{dt},$$

where $\partial F/\partial t$ would be the rate of change of the function if the particle were at rest. The derivatives $\frac{dx}{dt}$, $\frac{dy}{dt}$, $\frac{dz}{dt}$ are the velocity-components u, v, w. Accordingly we have

$$(66)\qquad \frac{dF}{dt}=\frac{\partial F}{\partial t}+u\frac{\partial F}{\partial x}+v\frac{\partial F}{\partial y}+w\frac{\partial F}{\partial z}.$$

We call this mode of differentiation *particle differentiation*.

Introducing this terminology, our equations of motion become

$$\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}+w\frac{\partial u}{\partial z}=X-\frac{1}{\rho}\frac{\partial p}{\partial x},$$
$$(67)\qquad \frac{\partial v}{\partial t}+u\frac{\partial v}{\partial x}+v\frac{\partial v}{\partial y}+w\frac{\partial v}{\partial z}=Y-\frac{1}{\rho}\frac{\partial p}{\partial y},$$
$$\frac{\partial w}{\partial t}+u\frac{\partial w}{\partial x}+v\frac{\partial w}{\partial y}+w\frac{\partial w}{\partial z}=Z-\frac{1}{\rho}\frac{\partial p}{\partial z}.$$

These equations are due to Euler. These three equations, with the equation of continuity, (24), and the physical relation between ρ and p furnish five equations for the determination of the five variables u, v, w, ρ, p as functions of x, y, z, t.

Subtracting from both sides of the first of equations (67) the quantity

$$\frac{\partial}{\partial x}\left(\frac{q^2}{2}\right)=\frac{1}{2}\frac{\partial}{\partial x}\{u^2+v^2+w^2\}=u\frac{\partial u}{\partial x}+v\frac{\partial v}{\partial x}+w\frac{\partial w}{\partial x},$$

we obtain

$$(68)\qquad \frac{\partial u}{\partial t}+w\left(\frac{\partial u}{\partial z}-\frac{\partial w}{\partial x}\right)-v\left(\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y}\right)$$
$$=X-\frac{\partial P}{\partial x}-\frac{\partial\left(\frac{q^2}{2}\right)}{\partial x}.$$

If the bodily forces are conservative and derived from a potential V, the right-hand member is the derivative of the quantity $-(V+P+q^2/2)=U$, and inserting the values of ξ, η, ζ,

$$\frac{\partial u}{\partial t}+2(w\eta-v\zeta)=\frac{\partial U}{\partial x},$$
$$(69)\qquad \frac{\partial v}{\partial t}+2(u\zeta-w\xi)=\frac{\partial U}{\partial y},$$
$$\frac{\partial w}{\partial t}+2(v\xi-u\eta)=\frac{\partial U}{\partial z}.$$

If the motion is *steady*, that is, independent of t, the time-derivatives vanish. Then multiplying the equations (69) by dx, dy, dz respectively, adding and integrating along any curve, we obtain on the right the difference between the terminal values of $V+P+q^2/2$. If the curve is either a stream- or vortex-line, that is, if dx, dy, dz are proportional either to u, v, w, or to ξ, η, ζ, the sum on the left will also vanish, so that along a stream-line or a vortex-line we have $V+P+q^2/2=\text{const.}$ If the motion is non-vortical, the left-hand side of (69) vanishes, so that the above sum is constant throughout the fluid. In this case

$$(70)\qquad V+P+\tfrac{1}{2}q^2=\text{const.},$$

this result being called Daniel Bernoulli's theorem.

If the fluid is incompressible, $P=p/\rho$, and if there are no bodily forces $V=0$, so that (70) becomes

$$(71)\qquad \frac{p}{\rho}+\frac{1}{2}q^2=\text{const.}$$

Accordingly where the velocity is small the pressure is large and vice versa. By constricting the tube the velocity is made large and the pressure small. This is the principle of jet exhaust-pumps, like that of Bunsen, the air being sucked in at the narrow part of the jet. The same principle is used in the Venturi water-meter. The horizontal main being reduced in diameter in a certain portion and the difference of pressure at a point in that portion and in the main observed, the velocity is computed. If the pressure at the two cross-sections S_1 and S_2 is p_1, p_2, we have

$$(72)\qquad p_1-p_2=\frac{\rho}{2}(q_2^2-q_1^2).$$

But since the flow is solenoidal, $S_1q_1=S_2q_2$. Combining with (72),

$$(73)\qquad p_1-p_2=\tfrac{1}{2}\rho q_1^2\left\{\left(\frac{S_1}{S_2}\right)^2-1\right\},$$

which determines q_1 in terms of the pressure-difference. The efflux in unit time is $\rho q_1 S_1$.

For the adiabatic expansion of a gas,

$$(74)\qquad P=\frac{b\kappa\rho^{\kappa-1}}{\kappa-1}=\frac{b\kappa}{\kappa-1}\left(\frac{p}{b}\right)^{\frac{\kappa-1}{\kappa}}.$$

We may use Bernoulli's theorem to calculate the efflux of gas from a reservoir. If we consider a point in the reservoir where the pressure is p, so far from the orifice that the air may be considered at rest and if the velocity at the orifice is q and the atmospheric pressure p_0, we have

$$(75)\qquad q^2=2b^{\frac{1}{\kappa}}\frac{\kappa}{\kappa-1}\left\{p^{\frac{\kappa-1}{\kappa}}-p_0^{\frac{\kappa-1}{\kappa}}\right\},$$

which is the usual formula for the efflux of gases.

If the external force be gravity, $V=gz$, and we have for an incompressible fluid,

$$(76)\qquad \frac{p}{\rho}+gz+\tfrac{1}{2}q^2=\text{const.}$$

If we again consider efflux from a reservoir whose upper free surface $z=z_1$ is so large that q is negligible, the pressure being that of the atmosphere, the same above and at the orifice where $z=z_2$, the velocity of efflux is given by

$$\frac{p_0}{\rho}+gz_1=\frac{p_0}{\rho}+gz_2+\tfrac{1}{2}q^2,$$

$$(77)\qquad q^2=2g(z_1-z_2),$$

or the velocity of efflux is that acquired by a body falling freely from a height equal to that of the free surface above the orifice. This is the theorem of Torricelli, one of the oldest on hydrodynamics.

Wave-motion.—The case of uniplanar waves may be dealt with by the method of the complex variable. We shall find that the waves travel with constant velocity a and that it will simplify the problem if we impose upon the whole fluid a horizontal velocity equal and opposite to that of the waves. The waves then stand still, and the motion is *steady*, as in the case of waves about an obstruction in a running river.

Let us consider waves in deep water. At a great depth the vertical motion will disappear, so that

$$u=-a,\quad v=0,\quad \phi=-ax.$$

The function

$$w=-az+Ae^{-ikz}=-a(x+iy)+Ae^{-ik(x+iy)}$$

gives

$$\phi+i\psi=-a(x+iy)+Ae^{ky}(\cos kx-i\sin kx).$$

$$(78)\qquad \phi=-ax+Ae^{ky}\cos kx,$$

$$\psi=-ay-Ae^{ky}\sin kx.$$

When $y=-\infty$ this makes $\phi=-ax$, as required. The free surface of the water being composed of stream-lines is represented by one of the lines $\psi=\text{const.}$, and if we take the origin in the surface its equation is

$$(79)\qquad ay+Ae^{ky}\sin kx=0,$$

which shows that y is a periodic function of x with the wave-length $\lambda=2\pi/k$. The longer the wave-length, that is the smaller k, the more nearly does the exponential reduce to unity and the profile to a curve of sines. The velocity is given by

$$(80)\qquad u=\frac{\partial\phi}{\partial x}=\frac{\partial\psi}{\partial y}=-a-Ake^{ky}\sin kx,$$

$$v=\frac{\partial\phi}{\partial y}=-\frac{\partial\psi}{\partial x}=Ake^{ky}\cos kx,$$

$$(81)\qquad q^2=u^2+v^2=a^2+A^2k^2e^{2ky}+2Ake^{ky}\sin kx.$$

So far we have merely kinematics. The dynamical relation required is that for steady motion,

$$(82)\qquad \frac{p}{\rho}+gy+\tfrac{1}{2}q^2=C.$$

At the surface putting $p=0$ and making use of (79),

$$gy+\tfrac{1}{2}\{a^2+A^2k^2e^{2ky}-2a^2ky\}=C.$$

Since the surface passes through the origin, putting $y=0$,

$$C=\tfrac{1}{2}(a^2+A^2k^2).$$

$$(83)\qquad (g-a^2k)y+\tfrac{1}{2}A^2k^2(e^{2ky}-1)=0.$$

This equation can be only approximately fulfilled, but if the height of the waves is so small in comparison with the wave-length that the square of $2ky$ may be neglected, developing the exponential gives

$$(g-a^2k+A^2k^3)y=0,$$

giving the relation between the velocity and the wave-length.

$$(84)\qquad g-a^2k+A^2k^3=0.$$

If ky is small, the equation of the profile (79) is approximately

$$(85)\qquad y=-\frac{A}{a}\sin kx,$$

so that the height of the waves above the origin is $B = A/a$, inserting which in (84) gives

$$(86)\qquad a^2\left\{\frac{2\pi}{\lambda}\left(1-\frac{4\pi^2B^2}{\lambda^2}\right)\right\}=g.$$

For long waves we accordingly have $a^2 - g\lambda/2\pi$, or the velocity of long waves in deep water is equal to the velocity acquired by a body in falling freely from a height equal to one half the radius of a circle whose circumference is the wave-length.

In order to study the motions of the individual particles of water let us now impress upon the motion given by (80) a uniform velocity a in the X-direction. Equations (80) now give the motion with respect to axes traveling with the waves, so that in order to obtain the motion with respect to fixed axes we have to add a to the u of (80) and replace x by $x - at$, obtaining

$$(87)\qquad \begin{aligned} u &= -Akc^{ky}\sin k(x-at),\\ v &= Akc^{ky}\cos k(x-at).\end{aligned}$$

If the displacement of a particle which when at rest was at x, y is ξ, η, the above values are $\frac{d\xi}{dt}$, $\frac{d\eta}{dt}$, and if we neglect the small change of velocity from x, y to $x+\xi$, $y+\eta$, we may integrate with respec. to the time,

$$(88)\qquad \begin{aligned} \xi &= -Bc^{ky}\cos k(x-at),\\ \eta &= -Be^{ky}\sin k(x-at).\end{aligned}$$

Thus each particle performs a uniform revolution in a vertical circle of radius Bc^{ky} in the time $T=\frac{2\pi}{ka}=\frac{\lambda}{a}$. The rapidity of decrease of the motion as we go below the surface is seen by the fact that at a depth $y = -\lambda$ the amplitude has diminished in the ratio $e^{-2\pi} = .001867$. The form of the wave-profile is shown in Fig. 15, the crests being farther above the

FIG. 15.

level than the troughs are below it. As the height increases the waves become sharper at the crest.

Vortex-motion.—Let us consider the change in circulation along a line that always contains the same particles. We have

$$(89)\qquad \frac{d\phi_{AB}}{dt}=\frac{d}{dt}\int_A^B(udx+vdy+wdz)$$
$$=\int_A^B\left\{\frac{du}{dt}dx+u\frac{d}{dt}(dx)+\frac{dv}{dt}dy+v\frac{d}{dt}(dy)+\frac{dw}{dt}dz+w\frac{d}{dt}(dz)\right\}.$$

Now consider an element ds which at a time later by dt has moved to a position ds', Fig. 16. Since one end has moved in the X-direction a distance udt and the other a distance

$$\left\{u+\frac{\partial u}{\partial x}dx+\frac{\partial u}{\partial y}dy+\frac{\partial u}{\partial z}dz\right\}dt$$

the new value of its X-projection is

$$dx' = x+dx+\left\{u+\frac{\partial u}{\partial x}dx+\frac{\partial u}{\partial y}dy+\frac{\partial u}{\partial z}dz\right\}dt - (x+udt),$$

from which we obtain the derivatives

$$(90)\qquad \begin{aligned} \frac{d}{dt}(dx) &= \frac{dx'-dx}{dt}=\frac{\partial u}{\partial x}dx+\frac{\partial u}{\partial y}dy+\frac{\partial u}{\partial z}dz,\\ \frac{d}{dt}(dy) &= \frac{dy'-dy}{dt}=\frac{\partial v}{\partial x}dx+\frac{\partial v}{\partial y}dy+\frac{\partial v}{\partial z}dz,\\ \frac{d}{dt}(dz) &= \frac{dz'-dz}{dt}=\frac{\partial w}{\partial x}dx+\frac{\partial w}{\partial y}dy+\frac{\partial w}{\partial z}dz.\end{aligned}$$

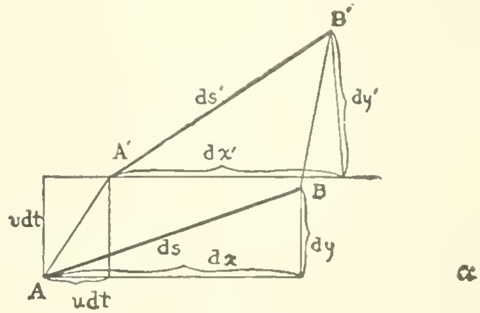

FIG. 16.

But the equations of motion (67) are, in abbreviated form,

$$(91)\qquad \frac{du}{dt}=\frac{\partial(U+q^2/2)}{\partial x},\quad \frac{dv}{dt}=\frac{\partial(U+q^2/2)}{\partial y},\quad \frac{dw}{dt}=\frac{\partial(U+q^2/2)}{\partial z},$$

where $U = -(V+P+q^2/2)$. Accordingly,

$$(92)\qquad \frac{d\phi_{AB}}{dt}=\int_A^B\left\{\frac{\partial(U+q^2/2)}{\partial x}dx+\frac{\partial(U+q^2/2)}{\partial y}dy+\frac{\partial(U+q^2/2)}{\partial z}dz+\left(u\frac{\partial u}{\partial x}+v\frac{\partial v}{\partial x}+w\frac{\partial w}{\partial x}\right)dx\right.$$
$$\left.+\left(u\frac{\partial u}{\partial y}+v\frac{\partial v}{\partial y}+w\frac{\partial w}{\partial y}\right)dy+\left(u\frac{\partial u}{\partial z}+v\frac{\partial v}{\partial z}+w\frac{\partial w}{\partial z}\right)dz\right\}$$
$$=\int_A^B\frac{\partial(U+q^2)}{\partial x}dx+\frac{\partial(U+q^2)}{\partial y}dy+\frac{\partial(U+q^2)}{\partial z}dz$$
$$=(U+q^2)\Big/_A^B,$$

which vanishes for a closed curve. Therefore if the bodily forces are conservative, the circulation around any closed curve moving with the fluid is independent of the time. If the circulation around a closed path is zero at one time, it remains zero, so that if the velocity-potential once exists, it always exists. This theorem is due to Lagrange.

From the equations (69), whose right-hand members are derivatives of the same quantity U, this quantity may be eliminated by differentiation. Differentiating the last equation by y, the second by z, and subtracting,

$$\frac{1}{2}\frac{\partial}{\partial t}\left(\frac{\partial w}{\partial y}-\frac{\partial v}{\partial z}\right)+\xi\frac{\partial v}{\partial y}+v\frac{\partial \xi}{\partial y}-\eta\frac{\partial u}{\partial y}-u\frac{\partial \eta}{\partial y}-\zeta\frac{\partial u}{\partial z}$$
$$-u\frac{\partial \zeta}{\partial z}+\xi\frac{\partial w}{\partial z}+w\frac{\partial \xi}{\partial z}=0,$$

or otherwise,

$$(93)\qquad \frac{\partial\xi}{\partial t}+u\frac{\partial\xi}{\partial x}+v\frac{\partial\xi}{\partial y}+w\frac{\partial\xi}{\partial z}=u\left\{\frac{\partial\xi}{\partial x}+\frac{\partial\eta}{\partial y}+\frac{\partial\zeta}{\partial z}\right\}$$
$$-\xi\left\{\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}\right\}+\xi\frac{\partial u}{\partial x}+\eta\frac{\partial u}{\partial y}+\zeta\frac{\partial u}{\partial z}.$$

On the right the coefficient of u, being the divergence of the vorticity, is zero, while that of ξ is by the equation of continuity equal to $-\frac{d\rho}{\rho\, dt}$, so that equation (93) becomes

$$\frac{d\xi}{dt} = -\frac{\xi}{\rho}\frac{d\rho}{dt} + \xi\frac{\partial u}{\partial x} + \eta\frac{\partial u}{\partial y} + \zeta\frac{\partial u}{\partial z},$$

which may be written, with its two companions,

$$(94)\qquad \begin{aligned} \frac{d}{dt}\left(\frac{\xi}{\rho}\right) &= \frac{\xi}{\rho}\frac{\partial u}{\partial x} + \frac{\eta}{\rho}\frac{\partial u}{\partial y} + \frac{\zeta}{\rho}\frac{\partial u}{\partial z}, \\ \frac{d}{dt}\left(\frac{\eta}{\rho}\right) &= \frac{\xi}{\rho}\frac{\partial v}{\partial x} + \frac{\eta}{\rho}\frac{\partial v}{\partial y} + \frac{\zeta}{\rho}\frac{\partial v}{\partial z}, \\ \frac{d}{dt}\left(\frac{\zeta}{\rho}\right) &= \frac{\xi}{\rho}\frac{\partial w}{\partial x} + \frac{\eta}{\rho}\frac{\partial w}{\partial y} + \frac{\zeta}{\rho}\frac{\partial w}{\partial z}. \end{aligned}$$

Thus the time-derivatives of $\frac{\xi}{\rho}$, $\frac{\eta}{\rho}$, $\frac{\zeta}{\rho}$ for a given particle are homogeneous linear functions of those quantities. By continued differentiation with respect to t and the substitution of the derivatives from these equations, we see that all the time-derivatives are homogeneous linear functions of the quantities themselves. Thus if at any time these quantities are zero, all their derivatives are zero, and developing by Taylor's theorem, we find that the function remains zero for all times. Thus if a particle is once not vortically revolving, it never can acquire such rotation under conservative forces.

Let us now consider two points A and B lying on the same vortex-line at a distance apart $ds = \varepsilon\frac{\omega}{\rho}$, where ε is a small constant. Since the particles lie on the vortex-line we have

$$(95)\qquad \frac{dx}{\xi} = \frac{dy}{\eta} = \frac{dz}{\zeta} = \frac{ds}{\omega} = \frac{\varepsilon}{\rho}.$$

For the difference of velocity at A and B we have

$$(96)\qquad \begin{aligned} u_B - u_A &= \frac{\partial u}{\partial x}dx + \frac{\partial u}{\partial y}dy + \frac{\partial u}{\partial z}dz \\ &= \varepsilon\left\{\frac{\xi}{\rho}\frac{\partial u}{\partial x} + \frac{\eta}{\rho}\frac{\partial u}{\partial y} + \frac{\zeta}{\rho}\frac{\partial u}{\partial z}\right\}, \end{aligned}$$

or, by equations (94),

$$(97)\qquad u_B - u_A = \varepsilon\frac{d}{dt}\left(\frac{\xi}{\rho}\right).$$

Now at an instant later by dt, when the particles are at A' and B',

$$(98)\qquad \begin{aligned} dx' &= dx + (u_B - u_A)dt = \varepsilon\left[\frac{\xi}{\rho} + \frac{d}{dt}\left(\frac{\xi}{\rho}\right)dt\right], \\ dy' &= dy + (v_B - v_A)dt = \varepsilon\left[\frac{\eta}{\rho} + \frac{d}{dt}\left(\frac{\eta}{\rho}\right)dt\right], \\ dz' &= dz + (w_B - w_A)dt = \varepsilon\left[\frac{\zeta}{\rho} + \frac{d}{dt}\left(\frac{\zeta}{\rho}\right)dt\right]. \end{aligned}$$

Therefore the projections of the arc ds' in the new position are proportional to the new values of the components of ω/ρ, as they originally were, so that the particles still lie on a vortex-line. Accordingly a vortex-line is always composed of the same particles of fluid. Also, since the components of ds have changed so as to be always proportional to the components of ω/ρ, if the liquid is incompressible the rotation is proportional to the distance between the particles. And whether ρ vary or not, if S is the cross-section of a vortex-filament, since the mass $\rho S ds$ of a length ds remains constant, so does $S\omega$, the strength of the filament. Accordingly the strength of a vortex-filament is constant, not only at all points in the filament, but at all times, consequently a vortex existing in a perfect fluid is indestructible, however it may move. It is from this remarkable property of vortices discovered by Helmholtz that Lord Kelvin was led to imagine atoms as consisting of vortices in a perfect fluid.

From the kinematical properties of flow due to vortex-motion (62), we see that the velocity at every point of a circular vortex-ring, Fig. 17, due to all the elements of the vortex,

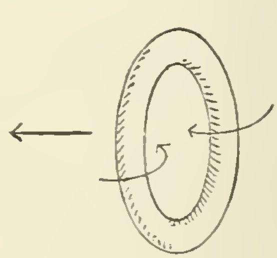

FIG. 17.

is in the same direction perpendicular to the plane of the ring, and in the direction in which the inside of the ring is turning; the ring therefore advances with a constant velocity, as if it were rolling in a tube which it just fits. We may verify this by an experiment due to Professor Tait, where smoke is suddenly forced out through a circular hole in a box provided with an elastic back. The smoky air rolling on the edge of the hole is endowed (by the friction, a *non-conservative* force) with a vortical rotation, and issues as a vortex-ring, which advances with approximately constant velocity for a considerable distance. That it consists always of the same air is seen by the smoke which it carries with it. Such a ring, on striking an edge or obstacle, is not destroyed or cut. Similar experiments can be performed with the rings formed by letting drops of ink fall into water. The loss of velocity finally obtaining in all these cases is due to the viscosity, that is, to non-conservative forces. The treatment of viscosity is beyond the scope of this article.

Hy'drogen (Greek, "producing water," in reference to the fact that in burning in air or oxygen, hydrogen forms water-vapor), a gaseous element, discovered by Cavendish in 1766. It was at first called "inflammable air," the present name being due to Lavoisier. Hydrogen is the lightest known substance, and it also has the smallest known atomic weight. The atomic weight of hydrogen is often taken as unity in stating the relative atomic weights of the different elements (see ATOMIC THEORY), but it is now more usual to assume the atomic weight of oxygen to be precisely 16, which amounts to making the atomic weight of hydrogen 1.0076. According to Regnault's experiments, hydrogen has a density equal to 0.06926 of that of an equal volume of air, at the same temperature and pressure. In absolute measure, the mass of a cubic centimetre of hydrogen, at the freezing point of water and under a pressure of 76 centimetres of mercury at Paris, is 0.00008957 gram, or 0.08957 milligram. Hydrogen has the chemical symbol H, and is one of the most abundant elements known. It occurs in the free state in volcanic gases, and in the sun and in many of the fixed stars. Free hydrogen is also present in the earth's atmosphere in exceedingly small amount. Water (or hydrogen monoxid) is its commonest and most abundant compound, and it is an essential constituent of nearly all organic tissues. Hydrogen may be prepared very easily by many methods. One of the most convenient of these consists in acting upon metallic zinc with dilute sulphuric acid, the reaction in this case being: $Zn + H_2SO_4 = ZnSO_4 + 2H$. Hydrogen is chemically inert towards most of the elements, at ordinary temperatures, but it combines with chlorine when exposed to light,— quietly in diffused daylight, and explosively under the direct action of sunlight. At elevated temperatures it combines with other elements also, and it burns in air (or oxygen) with the development of an intense heat, but with very little light; water being produced as the result of the combustion. Hydrogen has been both liquefied and solidified. Its critical temperature is estimated, by Dewar, to be about 402° F. below zero, and the same authority gives 15 atmospheres as the critical pressure. (See CRITICAL POINT, and GASES, LIQUEFACTION OF.)

Hydrogen combines with oxygen in two proportions. The monoxid, or common water, H_2O, is formed, as already noted, when hydrogen is burned in air or in oxygen. It is also formed in many of the double decompositions that occur in chemistry, as when metallic oxids or hydrates are dissolved in acids. Sodium hydrate, for example, combines with sulphuric acid according to the equation $2NaOH + H_2SO_4 = Na_2SO_4 + 2H_2O$, sodium sulphate and water being formed.

Hydrogen peroxid (or dioxid), H_2O_2, may be prepared by acting upon barium dioxid, BaO_2, with dilute sulphuric acid; the reaction being: $BaO_2 + H_2SO_4 = BaSO_4 + H_2O_2$. The barium sulphate that is formed at the same time is a heavy, insoluble substance, which is easily removed from the solution by filtration, or by settling and subsequent decantation. The aqueous solution of the peroxid may then be concentrated by evaporation over strong sulphuric acid, under the receiver of an air pump. When the water has all evaporated, the pure peroxid remaining behind has a specific gravity of 1.452, and is a colorless, oily liquid, devoid of odor, but having a disagreeable, metallic taste. The peroxid does not freeze, even when cooled to 0° F. At 70° F. it slowly gives off half its oxygen, passing into watbr. At 212° F. this change takes place very rapidly. Owing to the facility with which hydrogen peroxid gives off oxygen, it is used quite largely as a bleaching agent, and also, in surgery, as a disinfectant in the treatment of wounds.

When hydrogen is passed through boiling sulphur, combination takes place, with the formation of hydrogen sulphid, or sulphuretted hydrogen, H_2S. This compound is more conveniently prepared, however, by treating sulphid of iron, FeS, with dilute sulphuric acid, ferrous sulphate ($FeSo_4$) being formed at the same time. The reaction is: $FeS + H_2SO_4 = FeSO_4 + H_2S$. Sulphuretted hydrogen is a gas, devoid of color, but possessing an overpowering odor, suggestive of rotten eggs. It burns with a bluish flame, and is poisonous when inhaled in any considerable quantity, even though largely diluted with air. Under ordinary atmospheric pressure, sulphuretted hydrogen gas condenses, at 80° F. below zero, to a colorless liquid, which freezes to an ice-like solid upon being further cooled to 121° F. below zero. Liquefaction may also be induced at the ordinary temperature of the air by the application of a pressure of from 17 to 20 atmospheres. Sulphuretted hydrogen is an invaluable reagent in the chemical laboratory, where it is greatly used for separating the metals into groups, in inorganic analysis. (See CHEMICAL ANALYSIS.)

With carbon, hydrogen forms a large number of compounds which are collectively known as hydrocarbons (q.v.). With carbon and oxygen, and with carbon, oxygen and nitrogen, hydrogen forms compounds past enumeration. For further information concerning these, consult any treatise on organic chemistry, and also, in this encyclopedia, the articles FATTY COMPOUNDS and AROMATIC COMPOUNDS.

Hydrograph'ic Surveying. See SURVEYING.

Hydrography, hī-drŏg'ra-fĭ (Greek *hydōr* or *hudor,* water, *grapho,* to describe), meaning literally a "description of water." is the name applied to that branch of physical geography which describes the water on the surface of the globe, whether occurring on land, as in springs, rivers, and lakes, or in seas and great oceans. It is sometimes used in a more restricted sense, and confined to a description of the bearings of coasts, of currents, soundings, islands, shoals, etc., with a more immediate view to navigation, and the construction of charts and nautical tables. Henry the Navigator was the first who constructed a tolerably reliable sea-chart, and laid the foundation of hydrography as a science. This was in the 15th century. In France and other countries, institutions specially formed for teaching navigation are called hydrographical schools. The hydrographic office is now an important department of the naval administration, its officers consolidating into available maps the results of the observations sent to them from time to time by those engaged in exploring expeditions, and by navigators from all parts of the world. See SURVEYING.

Hy'drolite. See GMELINITE.

Hydrom'eter, an instrument for determining the specific gravity of fluids. When a solid body floats in a liquid, and displaces a quantity of the liquid, it is supported by the same upward pressure that formerly supported the liquid which it displaces. The weight of the solid body is thus equal to the weight of the liquid that it displaces. Hence, the depth to which

FIG. 1.— Forms of Hydrometer.

the same solid body is immersed in a liquid is greater as the density of the liquid is less, and less as the density of the liquid is greater. And, likewise, the weights required to immerse a given body equally deep in various liquids are inversely proportional to the densities of the liquids. On each of these principles a form of hydrometer is founded. One is called the constant weight hydrometer, the other the constant volume hydrometer. The first, usually made of glass, is shown in Fig. 1. It has a large hollow bulb, and below that a smaller bulb, weighted with mercury, to make the instrument float upright and it is surmounted by a cylindrical glass stem which is graduated, the divisions being usually marked on a piece of paper enclosed within the stem. The depth to which the hydrometer sinks in the liquid gives the density.

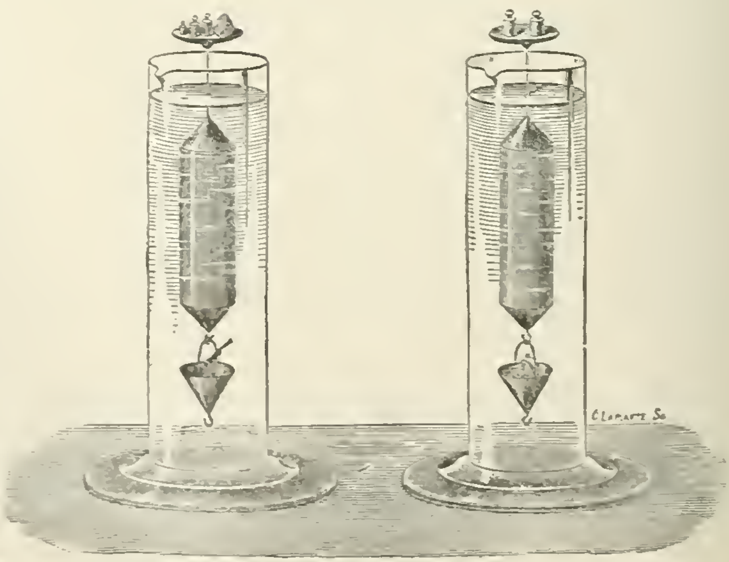

FIG. 2.— Nicholson's Hydrometer.

Of constant volume hydrometers, Nicholson's hydrometer, the best known, possibly, is adapted for determining the specific gravities not only of fluids, but of solids also. It is shown in Fig. 2. It consists of a hollow cylinder of metal, surmounted with a very fine metallic stem, to the top of which there is attached a plate or pan for weights. From the bottom of the metallic cylinder hangs a kind of cup or basket. The whole instrument is weighted so as to float upright. On the fine metallic stem there is a marked point: and by putting weights on the upper pan the hydrometer is always made to sink precisely to the point. If the weight of the instrument itself is known, and also the standard weight, or weight required to sink it to the marked point in distilled water, the calculation of the specific gravity of any liquid from an observation with the instrument is very easy. To determine the specific gravity of solids, the instrument is placed in distilled water and the solid body is put on the upper pan. Weights are then added till the hydrometer sinks to the marked point. But the standard weight of the instrument being known, it is plain that the difference between it and the weights that must be added on the upper pan to the weight of the body whose specific gravity is to be determined must be the weight in air of that body. The body is now transferred to the basket below the instrument, and the weight of the solid in water is similarly determined. From these data the specific gravity of the solid is calculated in the ordinary way. (See SPECIFIC GRAVITY.)

Hydrop'athy, a name for the treatment of diseases by the use of water. This name is now largely superseded by the term hydrotherapy (q.v.).

Hydrophobia (from Greek words meaning "fear of water"), an acute or subacute infectious disease, particularly of canine animals. It is usually communicated by a bite of the afflicted animal, and the contagion, the exact nature of which is unknown, is resident for the most part in the saliva, although it has been found in the peripheral nerves, the pancreas, and the suprarenal gland. It is frequently communicated to man, although the dog, wolf, fox, deer, cat, cow and skunk are the animals most frequently affected: it has been known to occur also in the horse, pig, birds, and other animals. Nine tenths of all the cases are contracted through the bites of rabid dogs. Hydrophobia may be produced, however, by wounds occurring during the dissection of rabid animals; it is said to have been caused by eating the flesh of animals that have died of the disease; and the milk of sucklings, animal and human, is thought to contain the virus. This poison has been found to be active in a dog 44 days buried, and in a rabbit buried 21 days.

In dogs the disease is comparatively common. In 1900 D. E. Salmon, chief of the United States Bureau of Animal Industry, determined that the disease was prevalent throughout the United States, and largely on the increase. The chief symptoms in dogs may be divided into two classes. Dogs suffer from furious rabies, and from dumb rabies. In the former Pasteur thought that the brain was involved; in the latter, the spinal cord. The furious form of the disease shows (1) a period of melancholy or depression; (2) a period of irritation; (3) a period of paralysis. The first varies from a few hours to two days. During this period the anxious and restless dog may also be cross. He hides from his master, obeys sullenly, and changes his position frequently. His appetite may not be at first affected, but it soon fails; he may lick everything in sight, or bite everything within reach, swallowing all sorts of foreign bodies. The period of irritation usually persists three or four days, during which the dog is spasmodically mad; restlessness increases, and the animal has an irresistible impulse to run away. During the running spells dogs may bite at everything in sight; at such times they usually seem fearless, and rarely avoid other dogs or people. If caged, they tear and chew on the bars, even breaking their teeth or fracturing their jaws. The bark is modified into a peculiar howl. During the third or paralytic period the dog is subdued and more sullen; the lower jaw becomes paralyzed and hangs down, saliva dripping from the mouth; the gait is staggering; from the fourth to the eighth day after the onset he dies of paralysis or exhaustion.

In dumb rabies the characteristic second stage may be entirely absent. The most persistent feature of dumb rabies is the dropped lower jaw, the paralysis of the jaw in the later stages preventing the dog from biting. Veterinarians see many cases of dumb rabies in dogs brought to them by owners who think that the trouble is caused by a bone in the throat. Beware of a dog that becomes listless and dull and hides away, is always on the go, prowling about and restless; one that is sullen and walks with his head down like a bear. A dog that scrapes incessantly and tears things up, and one that suddenly becomes excessively fond of its master, desiring to lick his hands and face, should be watched and guarded. A dog that has trouble in swallowing, that seems to have a bone in his throat, or, having wandered away from home, returns covered with dirt, exhausted and miserable, should be put under lock and key.

So far as the water-test is concerned, it is nonsense. The mad dog is often very fond of water; he is thirsty and rushes into water, thrusts his head into it; but he may have great difficulty in swallowing it, the act of swallowing usually bringing about severe convulsions.

In man the disease may go through somewhat similar stages, but the course is greatly modified; males are more likely to be affected than females, the difference in dress and exposure accounting for this; and two fifths of the subjects are below the age of 15. Bites on the face, neck, and hands are thought to be the most liable to develop the disease, and punctured wounds are more dangerous than lacerated wounds because of the difficulty in cleansing them. In man the period of incubation varies widely, from 20 to 60 days is the usual range, but six months may represent an extreme limit. In exceptional instances the period of incubation seems to have been greatly prolonged. The pathological changes recently discovered are found to be extremely characteristic, so that it is now even possible to diagnose rabies in a dog within a reasonable time after his death.

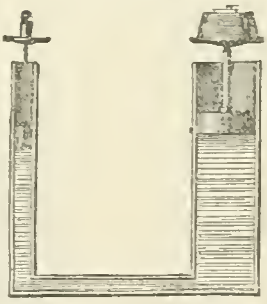
In all cases of suspected hydrophobia it is best not to kill the dog; but if, by accident or design, the death is accomplished the body should at once be sent to the health board authorities for a confirmation of the diagnosis. The characteristic changes, as described by Nélis in 1900, consist in minute alterations in the spinal ganglion cells, especially in a proliferation of the endothelial cells of the ganglionic cell capsule. These changes are considered characteristic of this disease, and are not known to occur in any other affection. The general treatment is both prophylactic and remedial. All stray dogs should be destroyed; or, if they have bitten anyone, they should be imprisoned and watched. It is best to have dogs muzzled or held in leash. In Germany muzzling has entirely eradicated hydrophobia. London in 1889 had 176 cases of hydrophobia. Muzzling was made compulsory, and in 1890 the number of cases of rabies had fallen to 44; in 1891 to 28; and in 1892 to 3. The muzzling was then allowed to lapse, owing partly to the sentimental agitation of many so-called lovers of dumb animals, and the cases of rabies increased, 25 persons dying of the disease in five years, while 174 patients were sent for treatment to the Pasteur Institute.

The direct treatment of the wound causing rabies is important. The poison seems to diffuse slowly, so that, if a ligature is promptly placed about the limb on the body side of the wound, a suction-cup or direct sucking may extract all of the virus. In the non-abraded mouth the virus is not very poisonous. If the wound is deep it is sometimes wise to make immediately a free incision, permitting the flow of blood to wash away the virus, and also allowing a more open surface for the actual cautery. One of the best cauterizing agents to use is strong nitric acid. The after-treatment will depend very largely on the promptness and thoroughness of the first treatment. If there is reason to believe that the early cauterization was ineffectual, the Pasteur method of treatment (see Pasteur, Louis) is advisable. This is a complicated method which was elaborated by Pasteur about 1880. He found that the virus was present in the spinal cord of a rabid animal; that its virulence slowly diminished after the death of the animal; that the virus could be artificially weakened by passing it through a series of monkeys until it was powerless; and that, conversely, this virulence could be restored by inoculating the attenuated virus in a series of rabbits. Thus Pasteur made a weak virus and a strong one at will, and he later produced immunity to the virus by the use of his attenuated material. The final plan that was adopted was to kill a rabbit by means of his strong virus, remove its spinal cord, cut this up into short sections, and dry it for varying periods of time. In this manner he secured a graded series of cord-sections of gradually decreasing virulence. These were emulsified in salt-solution and used to inject into animals or man, the weaker virus being first used and the stronger later. Two methods are now (1903) in vogue — the simpler method, for the less severe bites, in which 19 injections are given in 14 days; and the intensive method, for the severe bites about the neck and face and the large nerve-trunks, in which 28 injections are administered in 21 days. The serum-treatment of the disease is also rapidly becoming a possibility. Two Italian investigators, Tizzoni and Centanni, have made an anti-rabic serum that promises something for the future. For the present, however, the Pasteur method is the most reliable. It is certainly harmless, and is worthy of trial. The results are assuring, and the statistics, to most minds, convincing. It should not be forgotten that there is a false hydrophobia which is of purely hysterical origin, during an attack of which some patients have died. Consult: Bradford, 'Two Lectures on Rabies' ('Lancet,' 3 March 1900); 'Hydrophobia in Germany' ('Hygienische Rundschau,' 7 Nov. 1899); 'Report of Select Committee of the House of Lords on Rabies in Dogs' (Blue Book, 1887); Medical News' (15 Aug. 1903); Sixteenth Annual Report Bureau of Animal Industry (1899). See HYSTERIA.

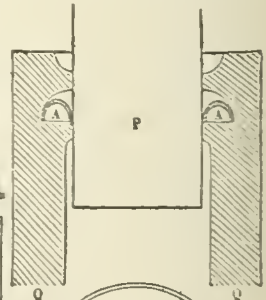
SMITH ELY JELLIFFE, M.D.,
Managing Editor Journal of Nervous and Mental Disease.

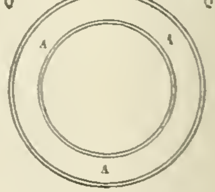
Hydrophytes, plants which grow in water or mud. They may be wholly submerged, completely without roots, and derive their sustenance wholly from the water; or may live amphibiously, rooted in soil and lifting some or all of their leaves into the air, and so differ only in a greater or less degree from land plants. Adaptations of water plants are especially to meet the difficulty of obtaining oxygen and of effecting pollination under water. In plants which grow wholly in or under water, roots, when present, are comparatively small and free from hairs, stems are slender and abound in air-spaces, and leaves are, as a rule, either long and narrow, or else greatly subdivided, so as to expose the greatest possible amount of surface. The cuticle of the leaf, also, is very thin, and lacks several of the structures, such as palisade cells and stomata, always present in aerial leaves. Water therefore enters easily into the tissues of the plant and carries with it a large amount, not only of oxygen, but of dissolved nutriment, so that in any oceanic plants, and plants of ponds and rivers, no roots whatever are developed, and these live practically independent of any connection with the land. The fertilization of submerged cryptogams is effected by the passing of generative elements through the water, but only a few submerged phanerogams make such use of the agency of the water. The pollen of the eel-grass (*Zostera*) has been modified for under-water efficiency. It does not form round grains, but elongated thread-like filaments which have the same specific weight as the water, and hence neither float nor sink, but move about at the level of eel-grass growth until they come in contact with the stigma of some neighboring flower. In the duckweeds and some other submerged plants, the male flowers break loose, rise to the surface and float away like little boats carrying pollen to the female blossoms, which at that time have risen to the surface but sink again as soon as fertilized. The hydrophytes show many examples of exceedingly wide distribution, as might be expected of oceanic plants, but is not so easily explained of those of fresh waters, many genera and species of which, nevertheless, are cosmopolitan.

Hydrostatic Press, a machine, sometimes called Bramah's press, from Joseph Bramah, its presumed inventor, which by the force obtained from water under pressure performs work, especially packing, as of cotton. Two tubes of unequal area are connected, and the whole vessel filled with water. Let the area of the smaller tube be one square inch, and let the piston that closes it be loaded with one pound. A pressure of one pound per square inch will be exerted on every part of the boundary of the fluid. There will thus be a pressure of one pound per square inch put upon the piston that closes the larger tube: and if we suppose the area of the piston to be 16 square inches, it is evident that it must



Principle of the Hydraulic Press.





Cup-leather.

be loaded with 16 pounds in order that the pressure to which it is exposed may be equilibrated. Thus a load of one pound on the smaller piston supports 16 pounds on the larger.

The principle of the hydrostatic press was pointed out by Stevinus; but it was Bramah who, in 1796, by an ingenious contrivance, gave the principle practical application. A Bramah's press, as ordinarily constructed and used to provide immense pressure, is a simple enough contrivance. By means of a small pump water is pumped from a cistern through a small horizontal tube into the space that receives a large piston. The goods to which pressure is to be applied are placed between the plate attached to the large piston and an upper plate that is kept in position by powerful iron rods. The water-tight stuffing of the piston is the great difficulty in the construction of the machine, and it was the invention of a water-tight collar by Bramah that made the use of the press practicable. The diagram shows a section AA of the collar surrounding the piston P. The collar consists of a circle of solid leather, which is stamped by means of a die into the half-ring, of which a section is seen. When pressure is applied the water fills the channel formed by the half-ring, and squeezes the inner side of the ring against the piston, and this takes place with greater force the greater the pressure to which the water is subjected.

Hydrostatics, the part of hydrodynamics that treats of the application of forces to fluids at rest. It is generally divided into two parts, one, hydrostatics proper, which deals with incompressible fluids, or liquids, and the other, which deals with compressible fluids, that is, with gases. The latter part of the subject is commonly called pneumatics.

The property of fluids which distinguishes them from solids, is want of rigidity. A fluid offers no permanent resistance to forces tending to change its shape. The particles of a fluid are mobile; and while in the case of liquids very considerable forces of cohesion are exhibited, yet the particles show great freedom to alter their relative positions, and to pass from place to place within the general mass. A very important property that follows from the nature of fluids is that of the equable transmission of pressure. Suppose a weightless liquid inclosed in a vessel A, which is fitted with a piston P. If pressure is applied to P it will be transmitted in all directions through the liquid. If other openings are made, and if they are fitted with pistons, it is evident that to keep each of these pistons in its place, pressure inward must be applied. The pressure that must be applied to any piston equal in area to the area of P is equal to the pressure on P; and if the area of one of the other pistons is greater or less than the area of P, the pressure required to keep it in its place is proportionately greater than or less than the pressure that is applied to P. This principle, which is the most important in hydrostatics, finds a practical application in the hydrostatic press (q.v.).

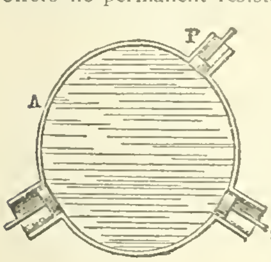


FIG. 1.

In measuring fluid pressure the area exposed to the pressure of the fluid is to be considered. If it were required to calculate the force that must be applied to the rod of one of the pistons in the figure in order to keep the piston in its place, it would be necessary to know the area of the piston and the pressure on it in grams per square centimetre. When the pressure over a given area is not uniform we must then know the law of variation, or at least the average pressure over the whole area, in order to calculate the whole pressure on it; and it will be readily understood that when, in such a case as this, the pressure per unit area at a point is spoken of, it is understood to mean the pressure which would be exerted on unit area were there found a unit of area pressed with a uniform pressure, the same as that at the point in question. Not only is pressure transmitted out to the surface or envelope of the liquid, as is shown in the figure, but within the fluid itself the particles are all pressed together. The pressure is transmitted to every point within the liquid and may be observed to be acting there. When a solid is immersed in the liquid it is pressed at every point of its surface in the direction perpendicular to the surface at that point, and, in the case of the hypothetical weightless liquid, with a pressure equal in amount per unit of the area to that applied from without to the liquid. The pressure about any point in a fluid is equal in all directions, and when any surface is exposed to the pressure, the direction of it is normal to the surface at every point.

In actual fluids, which have weight, it is evident, in the first place, that the lower layers of the fluid sustain more pressure than the upper layers. For whatever pressure the upper layers are exposed to is transmitted to the lower layers; and besides the lower layers have to support the weight of the superincumbent liquid. The most important case to consider is that of liquids having a free surface, that is, a surface exposed to the air. Here the surface itself is level. Otherwise there would be a tangential force which would make it flow down till the level state is reached. In every horizontal layer throughout the liquid the pressure per unit area is the same; and this is the case independently of the shape of any vessel in which the liquid may be contained. The pressure per unit area in any horizontal layer depends only on the height of the free surface of the liquid above the layer considered, and the specific gravity of the liquid; and it is equal to the weight of a column of the liquid of unit sectional area whose height is the height of the free surface. This principle gives rise to remarkable results. Take, for instance, an apparatus consisting of a pair of circular boards connected by a belt of pliable leather (like a pair of bellows), and having a small tube inserted into an opening near the bottom, and from it a tall tube rising perpendicularly. Heavy weights may be put on the upper circular board, and if water be then poured into the upright tube they will be raised up by the pressure from below of the water. For the pressure to which the under side of the circular board is exposed is equal to the weight of a column of water whose section is that of the circular board, and whose height is the difference of the heights of the under surface of the circular

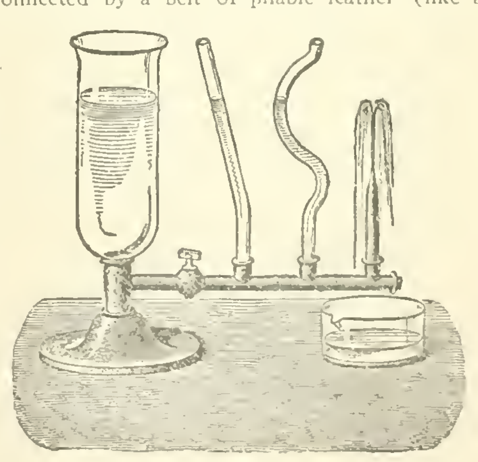

FIG. 2.

board and of the free surface of the water in the small upright tube. When shown in this form the principle here employed is often called the hydrostatic paradox, on account of the very great pressure that a very small quantity of water may be made to give rise to.

It is a well-known principle that liquids tend to find their own level. Thus, in the accompanying figure, showing a series of connected vessels, the liquid is seen to stand at the same height in the principal vessel and in the variously shaped tubes communicating with it, while from the short, narrow mouthed tube it spouts up to nearly the level of the water in the principal vessel.

When a solid is immersed either partially or wholly in a liquid a portion of the liquid is displaced. The solid is at the same time pressed at every point by the liquid, the pressure being always normal to the surface. The upward pressure on the solid is greater than the downward by an amount equivalent to the weight of the liquid displaced by the solid; for if, instead of the solid, the quantity of liquid displaced by it were present, its weight would be upborne by the pressure on every side. These pressures now act on the solid and whether or not the solid floats under their influence, as much of the weight of the solid as corresponds to this pressure is supported by the surrounding fluid. These considerations applied to the phenomenon of floating bodies illustrate the principle just explained; and the experiments that are made for the purpose of determining the specific gravity of bodies heavier than water also depend on that principle. See SPECIFIC GRAVITY.

If a body be immersed in water or other fluid, the resultant of the fluid pressures meets the surface at a point called the centre of pressure, which will coincide with the centre of gravity of the body if the body be horizontal, but will pass below it if the plane of the body is inclined to the fluid's surface.

The conditions of floatage and of stability of a body floating in a liquid are of great importance. A floating body displaces a certain quantity of the liquid, and the weight of the

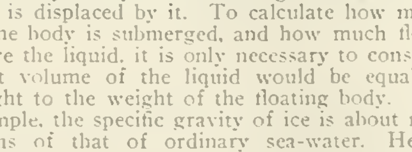

FIG. 3.

solid body is equal to the weight of the liquid that is displaced by it. To calculate how much of the body is submerged, and how much floats above the liquid, it is only necessary to consider what volume of the liquid would be equal in weight to the weight of the floating body. For example, the specific gravity of ice is about nine tenths of that of ordinary sea-water. Hence 9 cubic feet of sea water weigh as much as 10 cubic feet of ice. Thus in an iceberg nine tenths of the ice is under water, and one tenth is above the surface. In ships and other floating bodies the stability depends on the form of the body. A sphere of wood floating in water is indifferent as to position. The slightest force is sufficient to overturn it from any given position or to set it rotating in the water. With a ship or other body that must float with one side upward, the stability is quite as important as the floating power. The accompanying figure illustrates the conditions of stability. When a solid body is slightly displaced from its ordinary position of equilibrium, the forces that act upon it are seen to be twofold. First, there is the force of gravity on the solid acting vertically downward, which, if G be the centre of gravity, may be considered to act downward through that point; and secondly, there is

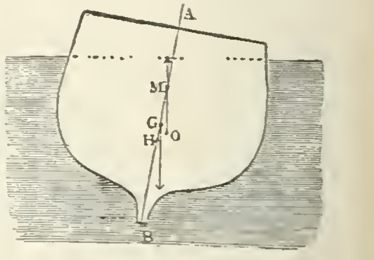

FIG. 4.

the resultant of the upward pressures of the various portions of the liquid, which, if O be the centre of these upward parallel forces, may be considered as equivalent to a single force acting vertically upward through that point. In the figure these two equal parallel forces are seen to form a mechanical couple whose tendency is to right the boat, and bring it back into its ordinary floating position. But if the upward vertical line through O were on the other side of the downward vertical line through G, it is plain that the effect of the couple would be to carry the boat away from the position in which it ought to float; and the boat would thus be unstable.

The metacentre is a point in a floating body of great importance, as its position determines whether the equilibrium is stable or unstable. Let A B in the figure be a line drawn through the points G and H, the centre of gravity of the floating body, and the centre of the figure of liquid displaced when the body is floating with A B vertical. Let the body be then slightly displaced, and let O be the new position of the centre of the figure of the displaced liquid, and let M be the point in which A B is cut by a vertical line through O: M is the metacentre when the displacement from the original position is infinitesimal. If the metacentre is above G then the equilibrium is stable; if it is below G the equilibrium is unstable, and the body being slightly displaced, it tends to fall farther and farther from its position of equilibrium.

Among the instruments and machines founded on the hydrostatic principles here laid down are the barometer, the siphon, the hydrostatic press, and the hydrometer (qq.v.).

Hydrotherapy (Greek, *ὕδωρ*, water, and, *θεραπεία*, cure), a method of treating diseases by the application of hot and cold water, which has come extensively into practice of late years, and is recognized by the medical profession as a very efficient therapeutic agent. The efficacy of water as a hygienic medicine has been recognized from the earliest times. Hippocrates, Celsus, and Galen regarded water as of especial value in the treatment of acute diseases; and during the Middle Ages the same view was advocated by many famous physicians. During the 18th century there was a growing belief in its virtue as a curative agent, though rather in acute than in chronic diseases. Some physicians used water for internal treatment, others for external treatment, but hydrotherapy, as now understood, combines both methods. It was originated by Vincent Priessnitz, a Silesian peasant. When a boy of 13, having sprained his wrist, he applied it to the pump, and afterward bound a wet bandage upon it. As this became dry he rewetted it, and thereby reduced the inflammation, but produced a rash on the surface of the skin. Shortly afterward he crushed his thumb, and applied the wet bandage as before, and again an eruption showed itself. He concluded that the rash was an indication of impurity of blood; and having instituted a series of observations in regard to various wounds and ulcers on the persons of his neighbors, he was led to form a pathological theory, according to which disease is caused by an accumulation of morbific matter, which must be eliminated from the system by cold water applications and the observance of a strict regimen. His views were confirmed by an accident to himself, in which, through a cart running over him, he received some broken ribs and severe contusions, and was given up by the physicians; but on learning their opinion he tore off their bandages, and applied others wet with cold water. He also replaced his ribs by inflating his lungs while pressing his abdomen against the window-sill. Either through or in spite of this treatment Priessnitz recovered and the carrying out of this cold-water theory became the object of his life. In rapid succession he invented the sponge-bath, the wet-sheet packing, the sitz, foot, and arm baths, the douche, the steam-bath, the dripping sheet, the plunge, the dry-blanket packing, and other appliances of the hydropathic system. In 1829 he established, at his native village of Gräfenberg, a range of baths, which speedily grew in reputation, and attracted visitors from all parts of Europe. The Austrian government lent him its patronage, and all the opposition of the medical faculty was unable to stem the popularity of the new system. The original establishment at Gräfenberg soon expanded into an extensive suite of buildings, stretching along the slope of one of the Sudetic Mountains, and resorted to by troops of invalids, who sought to regain health by bathing, exercise, simple diet, and agreeable society. Similar institutions soon sprung up in other parts of Germany, and were at length introduced into England, a hydropathic society having been formed in London in 1842. At the present time hydropathic institutes exist in great number throughout the world, and so universal have hydrotherapeutic procedures become that a large body of quacks thrive on the prestige given to hydrotherapy by regular physicians. The theories of Preissnitz are now known to be fallacious.

The work of Winternitz and his disciples has put the general principles of hydrotherapy on a rational footing; there is little doubt, however, that hydrotherapy, like any other therapeutic agent, may be greatly abused. It is by no means a universal panacea. There are a large number of ways of applying hot and cold water to the body. One enthusiastic advocate has described over 300 separate kinds of application. In general, however, the water may be applied in the shape of tub-baths, ablutions, packs, rain-baths, and douches. These may be divided and subdivided as indicated. *Tub-baths* may be full, half, or local baths, as to the pelvis, the feet, the hands, etc. The full tub-bath is usually given at a temperature of 55° F., unless special indications are to be met. If the patient's reaction is not of the best, the temperature should be about 60° F., and vigorous friction of the skin should be maintained. The time spent should be short, 10 to 20 seconds. The full tub-bath is a strong tonic. In severe illness the tub-bath should be given only by a trained nurse under the physician's orders. Half-baths are taken at a temperature of 60°–75° F. After wetting the face and chest the patient sits in a tub about one third to one half filled with water, sufficient at least to cover the legs and the pelvis. The attendant splashes the cold water over the patient's body, maintaining at the same time a vigorous friction by means of a flesh-brush. The time is from one to five minutes, but the bath should not be continued if the teeth begin to chatter or if there is any evidence of defective reaction, as blueness of the lips, or thin pulse. Local cold baths, such as sitz-baths and foot-baths are very important hydriatric measures. The cold foot-bath, plunging the feet for from one to three minutes in cold running water, is of service in sluggish circulation of the feet, neurasthenia and hysteria. Warm full baths at a temperature of 90°–98° F., for a period of from 5 to 20 minutes are very useful as sedatives to the nervous system, particularly so in insomnia and nervousness from overwork, especially when taken at night. The best effect is obtained if they are taken at the time of retiring and are followed by a brief application of cold water, either in the shape of a half-bath, or a douche. After the bath the patient should wrap up in a linen sheet and a blanket to keep up the dilatation of the blood-vessels of the skin. Perspiration is to be avoided, save in particular instances.

Ablution.— This is one of the simplest of hydriatric measures. It is a valuable skin and nerve tonic, and is particularly adapted for children and women. It consists in the application of water to the body at a temperature of 50°–60° F., from the hollow of the hand, or by means of a bath-glove or wash-cloth. The entire body is gone over, one part after another being systematically treated. One to two minutes' application followed by vigorous rubbing with a coarse towel or flesh brush, is sufficient. Ablution is particularly valuable for reducing temperature, often bringing about quiet, restful sleep in tossing and fretful children.

Affusion.— In this treatment a volume of water from a pitcher or a pail is poured over the entire body, or upon certain parts, the patient sitting or standing erect in a tub or bath. The temperature should be 50°–60° F., and the whole procedure should not consume over 10 or 15 seconds. The reaction is obtained by rubbing. In certain muscular tremors, in neurasthenia, etc., this procedure is of service.

Packs or Compresses.—These may be dry or wet, general or local. The dry and wet packs are applied in the same manner. The patient is placed on a narrow bed or couch with a rubber sheet, a blanket, and a linen sheet beneath him, the blanket and sheet falling on each side of the couch. The sheet is then brought up and, with the arms to the side, wrapped thoroughly about him, the face alone being exposed. The blanket is then wrapped about the patient in a similar manner. Cloths wrung out in cold water may be applied to the head. In a wet pack the sheet is first wrung out in cold water: in the dry pack it is frequently warmed. The object of the application is to bring about free perspiration, and this is the usual result. Hot drinks may be administered freely. The time given to the application will depend largely on the conditions to be met. If reduction of temperature alone is desired, the patient may remain in the pack until the perspiration is free, and he may then be wrapped up in a dry blanket. In certain uræmic states, and in infantile convulsions, a longer period may be necessary. The wet pack is an excellent procedure in the treatment of alcoholic excesses. The initial effect of a cold pack is constriction of the blood-vessels: this is soon followed by a dilatation which continues throughout the application and is the main cause of the free perspiration. The pulse-rate is reduced and the arterial tension falls. The stress of elimination is taken from the kidneys, the amount of blood within the brain diminishes, and sleep is encouraged. In the hot general pack a blanket only is used. This is wrung out in water at 140°–150° F., the temperature at the time of application not being over 105°–108° F. Local packs or compresses are of inestimable service in a variety of conditions. These are usually made of pieces of heavy muslin, canton flannel, or linen, varying in shape according to the site of application. They are wrung out in cold or hot water and applied to the head in headache, to the neck in sore throat, tonsillitis, diphtheria, earache; to the chest in pleurisy, pneumonia, neuralgias; to the heart in rapid overacting heart-action; to the stomach in indigestion; to the joints in sprains, rheumatism and gout; to the abdomen in gastroduodenal catarrh, irritable bladder, catarrhal appendicitis, colitis, peritonitis. Hot applications are particularly serviceable in painful menstruation. Hot water-bags have largely taken the place of hot compresses since they have been made so handy in shape and size and so reasonable in price.

The Douche.— This application is one of the best tonics, but requires special rooms for its use. These are found in the best appointed hydropathic institutes. The douche consists in the application of hot and cold water delivered through a hose. It combines the elements of the water, heat, cold, and force. The regulation of the pressure and temperature is an important feature in the scientific use of the douche.

SMITH ELY JELLIFFE, M. D.,
Instructor in Pharmacology and Therapeutics, Columbia University.

Hydrozo'a, a class of *Cœlenterata* (q.v.) embracing the polyps, all of which bear a general resemblance to *Hydra* (q.v.). There are two alternating generations, that is, (1) the sessile asexual polyp, which (2) gives rise to a jelly fish or medusa. The hydroid polyp is like hydra, a two-layered vase-like sac, with a circle of tentacles around the mouth. This gives off by a budding process a bell-shaped medusa, which is much more highly organized than the polyp, having a well developed digestive and nervous system, and sense-organs (eyes and ears, or otocysts). The *Hydrozoa* are at present divided into seven orders, the most important of which are, besides *Hydraria* represented by hydra; the *Hydrocorallinæ* of which *Millepora* (q.v.) is the type; the *Tubulariæ* comprising *Hydractinia*, *Tubularia*, etc.; the *Campanulari* of which *Campanularia*, *Clytia*, and *Obelia* are examples. Near this group belongs the extinct order of *Graptolites*, which were floating forms living in the Paleozoic seas. The last order (*Siphanophora*) comprises the Portuguese man-of-war (q.v.) and other forms, which are beautiful transparent pelagic animals, very brightly colored and highly specialized.

Hyena, hī-ē'nä, one of a family (*Hyænidæ*) of carnivorous mammals, having relations in structure to the bears, the cats and the civets, familiar in Africa and southern Asia. They are of moderate size, have large, rather short heads, powerful forequarters, feeble and drooping hindquarters and short tails. The eyes are large, and have longitudinal pupils; the ears are long, erect, very open, and directed forwards. The teeth are numerous, massive, tuberculated, and well adapted to aid the muscular jaws crunch the strongest bones, as hyenas are able to do. Hyenas are nocturnal animals which pass the day in solitude in caves or other hiding places, which they quit at night in order to seek their prey in bands. Carrion is a favorite food, and the stench attracts the hyena by night as it does the vulture by day. In some cases they dig up dead bodies and devour them. They also prey on living animals, and flocks of sheep and goats suffer severely from their ravages in some localities. The common or striped hyena (*Hyæna striata*) is a native of Northern Africa and parts of Asia, even eastward to Burma. It is about the size of a large dog, brownish-gray and marked with transverse bands of dark brown on the body, which become oblique on the flanks and legs. The hair upon the line of the back is much thicker and stronger than on any other part, forming a sort of mane, extending from the nape of the neck to the origin of the tail. This species was well known to the ancients, who entertained many absurd notions respecting it, believing that its neck consisted of but one bone; that it changed its sex every year; that it could imitate the human voice, etc. It was formerly supposed that the hyena was untamable, but that it can be completely tamed there is not the shadow of a doubt. The spotted hyena (*H. crocuta*) has a considerable resemblance to the former species, but is larger, and is marked with numerous round blackish-brown spots instead of stripes, nor is the mane so large. This species inhabits many parts of Africa, and used to be peculiarly numerous around the Cape of Good Hope. There is another species, the brown hyena (*H. brunnea*), which differs from the preceding by having stripes on the legs, the rest of the body being of a dark grayish-brown. It also inhabits the south of Africa. An extinct species, the cave hyena, was abundant in England, France, and Germany anterior to the glacial epoch, and has left its remains in many caves of these countries. Though named *H. Spelæa*, it seems practically identical with the existing *H. crocuta*.

The fossil ancestry goes back into the tertiary whence it seems to have sprung from the same stock that gave rise to the viveroids. Consult writers upon nature and sport in Africa and India.

Hyena-dog, an African canine animal (*Lycaon pictus*), which takes its name from its hyena-like appearance in shape and color, and is also called Cape hunting-dog because it hunts in packs. It differs from the typical dogs in having only four toes on both the fore and hind limbs, and in its dental fauna, and it seems to be a comparatively recent immigrant into South Africa, since its bones are found in British caves. It preys upon antelopes, cattle, etc., and was a scourge to the early settlements, when it was more numerous and bold than now.

Hy'giene, broadly, the science and art of preserving health; as currently restricted, not by curing disease but by its prevention, through the removal of its generating causes. As we cannot remove them until they are known or truly inferred, the science advances *pari passu* with that of medicine, and had no general basis till the past century, during which unprecedented progress was made in all branches of medicine, than which none is more important than that of preventive medicine (q.v.). Still, good sense had been applied to it for ages, especially in regions where ignorance was speedy death. The Mosaic laws recognize the three great principles of cleanliness, isolation, and wholesome diet, with a thoroughness that leaves little to be desired. Hence, the Jews were almost immune for many centuries from the plagues which swept away their Christian neighbors: this was one reason why they were often suspected of starting or spreading the plagues. As in most ancient religions, these sanitary principles were part of their religious observances. In the 18th century some elementary ideas of hygiene had become known: the prevention of scurvy by lemon-juice and vegetable diet, of jail-fever by less crowding and more cleanliness, and of smallpox by inoculation, were among the foremost advances. Our new scientific acquaintance with ultimate causes for the first time enables us to make hygiene a true science on a basis of exact knowledge.

The subject naturally divides itself into two main branches, those of environment and of the person; though there are some items which belong to neither, and the two cannot always be separated.

Environment.— This includes (1) climate; (2) private: the site, construction, elevation, warming, water-supply, and purification of dwellings; (3) public: the cleaning of streets, disposal of the dead, prevention of befoulment either by excreta or sputa, and other methods of public sanitation. The third will be dealt with under another title by an expert authority on public health. See SANITARY SCIENCE.

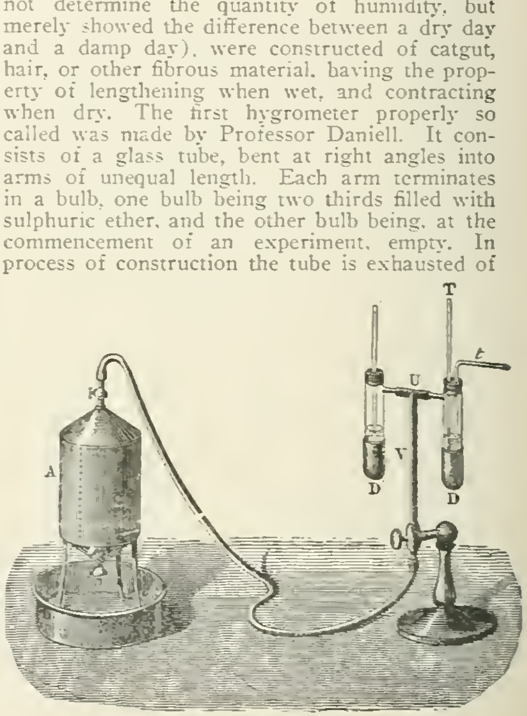
Climatic conditions cannot to any extent be modified: they must be neutralized, when unsanitary, by other conditions pertaining to hygiene. All nations have more or less adapted their habits to their climate, unless acclimated so that they become part of its working: the hours of work or travel, the character of dwellings, the sites selected, the diet found wholesome by experiment, all form part of a hygienic system built up by social experience and tradition. Those unacclimated may have personal advice from predecessors; too often nothing but personal experience can be of any avail, and frequently that is only acquired by fatal results.

The subject of *dwellings* includes a number of considerations. The site, if possible, should not be one where the ground-water is near the surface, or freshets or tides set back the drainage of closets, or where there are great fluctuations in the level of the ground-water, which it is better to have nearer the surface and steady than lower and more unstable. "Made" land in cities is often unhealthy, but tenants cannot in practice exercise much choice; the city authorities should prevent bad results by thorough sewerage with a good fall. The construction most important to have right is the plumbing; including the drains at the bottom: it is a commonplace which need not be dwelt on, that leaking sewer-pipes and clogged drainage mean the infection of a house with disease-laden air. Paint is better than paper for walls, as it can be washed; and old paper should be scraped off before new is laid on. When possible, rooms should be large enough not to need incessant change of air; when not possible, as is usual in cities, plenty of windows and the fullest possibilities of draft should make up; if this, too, is not available, the best systems of artificial ventilation. Unhappily, science is very backward in this class of invention, and small, close, unventilated rooms shorten millions of lives and prematurely break down working power in even the civilized cities of the world. The normal supply should be at least 3,000 cubic feet of air per head each hour, and this largely increased in work or sickness. The volume of consumption and other scrofulous diseases, bronchitis, pneumonia, etc., is directly dependent on foul air, which also increases the virulence of all zymotic diseases. The ventilation of public buildings rests on the same principles, and has the same results. The warming of houses is of great importance, and is generally ill done, with disregard of ventilation. The vast majority of houses in America are grossly overheated even when the air-supply is enough, giving a sensitive skin which "catches cold" as soon as it touches fresh air. Little children especially are literally killed by thousands from overheating and overdressing. The water-supply is a matter of public concern: where there is a flat price, people do not stint themselves. Where there are meters, they often do; but closets should be kept fully flushed at any cost. In country houses, where city water and sewerage are not available, it is not necessary to insist on the frequent cleaning and disinfection of receptacles for excreta. Advice on this point is obtainable gratis from physicians, apothecaries, and others. If the dry methods are carefully used, they have many advantages in healthfulness over the elaborate city systems.

Personal Hygiene.— This has very many divisions: the most obvious are considerations of food, and drink, nerve stimuli, clothing, cleanliness, natural necessities, work and rest, and moral self-control. In the matter of diet, there can be no one rule: "at forty," says the proverb, "one is either a fool or a physician"; and each must use his own experience as a guide to whether meat is a necessity or vegetarianism an advantage, what foods agree with him, whether dry meals give him heartburn or drinking with them impedes digestion, and whether he is eating so much as to make him heavy, impairing his capacity for work and enjoyment. or making his body gross. In general, probably professional and sedentary workers as a class overeat, and would find their minds more alert and their bodies freer from disorders with less gratification of appetite. Nerve stimuli, ranging from tea, coffee, and cocoa, to tobacco, alcoholic drinks, and opium, are hard to frame a general rule upon: they, too, have infinitely varied effects. Cocoa is most of a food; coffee with most is an agreeable stimulant, with many an active nerve-poison, producing heavy headaches and incipient stupor; tea is a real nerve-food on occasion and in small quantity, while taken steadily and largely it is a poison and a very mischievous one; tobacco sparingly used by grown men probably does little harm, and sometimes saves worse things, but should not be used by those under age, nor by those with weak nerves, and is highly injurious in heart disease, Bright's disease, and venereal diseases; alcoholic drinks suggest too many questions for discussion here; narcotics like opium, hashish, etc., as well as chloral and its like, should be used only on a physician's prescription. Clothing, if there is time and means, can be accommodated to changes of weather and occasion so as greatly to advance health; with most, there must be a rough average. Personal cleanliness within limits is a *sine qua non* of reasonable immunity from disease, and with delicate persons, of reasonably good ordinary health; but even this good thing can be irrationally overused and make mischievous. Too frequent hot baths in a northern climate are a great aggravator of lung-diseases, and one great city (Pittsburg) had a marked decrease of pulmonary complaints one winter when the water-supply broke down, and people resorted greatly to dry rubbing. Especially it is possible to use too much soap, and keep the natural oil of the skin washed away. Natural necessities should be attended to more constantly than they are: workmen especially often grudge the time, but the waiting till there is severe pressure often creates dangerous bladder and intestinal complaints. Work, for most, is not under their own control; but to some extent resting is, and the average American perhaps owes more to compulsory public holidays than he is aware. There is more temptation to overwork than to idle, for the average man. Exercise should be taken by the sedentary, even a homespun house-method being preferable to nothing. Grotius preserved his health in prison by whipping a top two hours a day. This should be one of the most rigidly imposed forms of self-control, which in all forms is all-important. Excessive sexuality, either of act or imagination, is simply destructive of will-power as well as bodily fibre; giving way to fits of anger or despondency is almost a recipe for entire nervous wreck. As to laziness, of mind or body, it is one of the worst and most incurable forms of this evil.

The management of children is really personal hygiene, only controlled by another than the subject, the care of the dead belongs to public hygiene; the prevention of disease belongs either to medicine, by the use of drugs like quinine or inoculations, or to house-hygiene as disinfection. The hygiene of the sick-room should be under the direction of the physician.

Hygrom'eter (Gr. «moisture-measure»), a meteorological instrument used to ascertain the quantity of moisture in the air. The first hygrometers, or rather hygroscopes (for they did not determine the quantity of humidity, but merely showed the difference between a dry day and a damp day), were constructed of catgut, hair, or other fibrous material, having the property of lengthening when wet, and contracting when dry. The first hygrometer properly so called was made by Professor Daniell. It consists of a glass tube, bent at right angles into arms of unequal length. Each arm terminates in a bulb, one bulb being two thirds filled with sulphuric ether, and the other bulb being, at the commencement of an experiment, empty. In process of construction the tube is exhausted of



Regnault's Hygrometer.

air, and is thus filled with vapor of ether through its entire length. A thermometer with a bulb immersed in the ether of the lower arm is inserted in the tube to register variation of temperature, and a second thermometer is attached to the stand of the instrument to show the temperature of the outer air. For use one bulb containing the sulphuric ether has a zone of polished gold, and the other bulb a muslin cover. If sulphuric ether be dropped on the latter, as it evaporates the bulb is cooled, and the vapor of ether is condensed within it from the other bulb; the temperature of which rapidly falls owing to evaporation from it. The operation is carried on, ether being dropped on the second bulb as is required, till the temperature of the first is so far reduced that dew from the surrounding air just begins to condense upon it. By means of the thermometer contained in the first bulb the temperature is read off at the instant at which vapor begins to condense, and the dew-point is thus obtained. The hygrometric condition, that is, the ratio between the quantity of moisture that the air actually contains and the quantity which it is capable of containing at the existing temperature is then easily deduced.

Regnault's hygrometer, shown in the above figure, is an important modification of Daniell's instrument. D and D' are two precisely similar cups or thimbles of polished silver; each is surmounted with a similar glass tube into which, by means of a cork, two thermometers are fitted, and the bulbs of the thermometers are covered with ether. Through the cork in one of the tubes a small glass tube *t* passes, and is carried down below the surface of the ether; while a side tube establishes communication with the vertical tube U V which is connected with an aspirator A (or vessel into which air is sucked at the top to supply the place of water which escapes at the bottom). There are no corresponding side tubes connecting the left-hand tube of the hygrometer D′. By means of the aspirator a current of air is drawn through *t*, it therefore bubbles through the ether, causing evaporation and cooling the ether till the dew-point is reached. This is observed with great nicety by means of the silver cap; for the instant the dew commences to deposit, the brilliant polish of the silver is dulled. The temperature of the air is at the same time read off by means of the other thermometer in D′. Regnault's hygrometer, both from its construction and from the use of the aspirator, avoids the too great proximity of the observer, which, from the nature of the experiments, is objectionable.

Mason's dry and wet bulb hygrometer consists of two thermometers arranged side by side as in the figure. The dry bulb gives the temperature of the air at the time of observation; and the other bulb, which is covered with muslin, and kept moist by filaments of cotton carried from it into a small cistern of rain or distilled water, reduces the height of the mercury in its tube in proportion to the capacity of the air for drying, or taking up additional vapor. This instrument does not give the dew-point directly. The difference between the readings of the two thermometers is multiplied by a special factor for every temperature of the dry bulb.

Hyksos, hĭk′sōz, according to the Egyptian annals, a conquering nomadic race from the East, who, under Salatis, their first king, took Memphis, and rendered the whole of Egypt tributary. Their name probably means "foreign kings," the explanation "shepherd kings" being of later origin. The date of their invasion and conquest was about 1700 B.C., of their expulsion about 1600 B.C. The seat of their rule was the strongly garrisoned fortress of Avaris, on the northeastern border of the Delta. They followed Egyptian customs, and their six monarchs took Egyptian names. It seems likely also that a great part of Syria was subject to them. The only detailed account of them in any ancient writer is an unreliable passage of a lost work of Manetho, cited by Josephus in his rejoinder to Apion.

Hymans, Louis, loo-ē ē-mäṅ, Belgian historian, journalist, novelist, and poet: b. Rotterdam 1829; d. Brussels 22 May 1884. He removed to Belgium in boyhood and rose rapidly to distinction as a Liberal journalist. He edited the Belgian 'Star' and the Parliamentary 'Echo' for some years, and was elected to Parliament in 1859. He wrote: 'History of the Marquisate of Anvers' (1848); 'Popular History of Belgium' (1860); 'Political and Parliamentary History of Belgium' (1869–70); two popular novels, 'André Bailly' (1861), and 'The Buvard Family' (1858); and some pleasing poems.

Hy′men, the god of marriage in Grecian mythology. The common legend is that he is the son of Apollo. No marriage took place without his being invoked to sanction it. He is described as having around his brows the flower of marjoram, in his left hand the flame-colored nuptial veil, and in his right the nuptial torch.

Hymenoptera, an order of Hexopoda or insects, considered by many entomologists to be the highest and most perfect expression of the insect type. The metamorphosis is complete and extensive. The larvæ are short, thick grubs, footless except in the saw-flies (*Tenthredinidæ*) and in most cases are carefully nurtured and fed in nests. The pupæ have nearly the form of the perfect insects. The imagos are of compact, highly complex construction, with the three regions well marked except that the first segment of the abdomen is united with the thorax. A considerable part of the large head is occupied by the conspicuous compound eyes besides which there are three ocelli. The jaws or mandibles are conspicuous biting organs, and the remaining mouth-parts usually form more or less of a proboscis with a large ligula or tongue. Although the wings are small they move with great rapidity and sustain the body in rapid and extended flight; there are two pairs (sometimes absent), membranous, veined and transparent. The genital appendages of the females are modified to form a sting or, more rarely, an ovipositor. Marked sexual dimorphism is very frequent especially among the social forms, in which a third class of individual, the worker or neuter, in reality imperfect females, also occurs. Many of the ant communities are still farther polymorphic. The order is one of great extent and exceptional interest, as it includes the ants, bees and wasps, the ichneumon-flies, gall-flies and saw-flies, divided into numerous families. Among the ants and bees are exhibited most remarkable and complex social states, which are described in the articles on these groups. The habits of the numerous species of wasps, and especially the varied architecture of their nests, are of nearly equal interest. A remarkable series of adaptations to special conditions are presented by the parasitic ichneumon flies and their allies, which lay their eggs within the bodies of the larvæ or even in the eggs of other insects, on the substance of which their own larvæ feed. Confining their parasitism to plants, the gall-flies produce by the irritation caused by their eggs or secretions deposited with them in the tissues of leaves, twigs or fruits, the familiar excrescences whose shapes are almost as numerous as the species which produce them. (See GALLS.) Finally, the saw-flies are least typical of the order but stand nearest to the main hexapod stem. Their larvæ have both thoracic and abdominal legs and closely resemble caterpillars; they are vegetarians and many of them are very destructive to plants.

Consult standard works of Entomology (see INSECTS), and the bibliographical list given by L. O. Howard in the appendix to his 'Insect Book' (New York 1902).

Hyndman, hĭnd′man, **Henry Mayers**, English socialist and author: b. London 7 March 1842. He was educated at Trinity College, Cambridge; and entered journalism. He was special correspondent for the *Pall Mall Gazette* in the war of 1866 between France and Italy, and wrote leading articles in favor of free education in the Melbourne 'Argus' in 1869. In

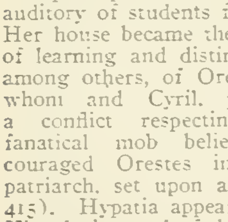
1881 he was one of the founders of the Social Democratic Federation, and has since been active in the Socialist movement, being the acknowledged leader of the Marxian Socialists in England. In 1884 he founded the paper 'Justice,' of which he is editor. His works include 'Historical Basis of Socialism in England' (1883); 'Socialism and Slavery,' a reply to Herbert Spencer; 'The Commercial Crises of the Nineteenth Century' (Social Science Series, 1892); and 'Economics of Socialism' (1896).

Hyne, Charles John Cutliffe, English novelist: b. Bibwry, Gloucestershire, 11 May 1866. He was graduated from Clare College, Cambridge, traveled widely both overland and by sea, and has published several rigorous stories, including: 'The Stronger Hand' (1896); 'The Adventures of Captain Kettle' (1898); 'Through Arctic Lapland' (1898); 'Further Adventures of Captain Kettle' (1899); 'The Filibusters' (1900); and 'Thompson's Progress' (1902).

Hypatia, hī-pā'shī-a, Greek philosopher of the eclectic school, daughter of Theon, a celebrated astronomer and mathematician, who was at the head of the Neo-Platonic school in Alexandria early in the 5th century. Such was her reputation that she became a preceptress in the school of Plotinus at Alexandria, and expounded the principles of his system to a numerous auditory of students from all parts of the East. Her house became the resort of all the persons of learning and distinction in Alexandria, and, among others, of Orestes the Prefect, between whom and Cyril, patriarch of Alexandria, a conflict respecting authority existed. A fanatical mob believing that Hypatia encouraged Orestes in his opposition to the patriarch, set upon and murdered her (March 415). Hypatia appears as the central figure of Kingsley's novel of the name (q.v.) (1853).

Hypatia, a work of historical fiction, by Charles Kingsley (q.v.), named from the principal character, the philosopher Hypatia (q.v.). The book presents a brilliant and stirring though not historically trustworthy picture of the 5th century of the Christian era, against the background of the learned city of Alexandria in Egypt.

Hyper'bola, in geometry, a curve formed by the intersection of a plane with two cones united at their apexes. The intersecting plane has such an inclination to the axis of the upper cone that it produces a similar section of the lower cone; the two branches thus formed are called opposite or conjugate hyperbolas. The two points where the branches approach nearest to each other are called the vertices, the straight line which joins them is called the major or transverse axis, and its middle point the centre of the hyperbola. A line of a certain definite length drawn through the centre and continued both ways at right angles to the major or transverse axis, is called the minor or conjugate axis. When the major axis is produced beyond the vertices two points called foci occur at equal distances from the centre, and the difference of their distances from any one point of the hyperbola is always equal to the major axis. Every line drawn from any part of the hyperbola to one of the foci is called a radius vector. If at one of the vertices a perpendicular to the major axis be erected, so as to be bisected by this axis and made equal in length to the minor axis, and if through the extremities of this perpendicular and the centre of the hyperbola two indefinite straight lines be drawn, these form what are called the asymptotes, which though they lie entirely outside the hyperbola, are always drawing nearer and nearer to it, but never actually reach it. The equation of the hyperbola referred to its centre and axis is $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$



Hyperbola — D B E, G A H, are opposite hyperbolas; F f, foci; C, centre: A B, major or transverse axis; a b, minor or conjugate axis; N C P, a diameter.

Hyperion, hī-pē'rĭ-ŏn, in Greek mythology, a Titan: son of Uranus and Ge, and father of Helios, Selene, and Eos. Homer and later poets apply the name as a patronymic for Helios himself. The attribute of beauty has therefore been connected with the name, as in Shakespeare's comparison of "Hyperion to a satyr."

Hyperion, in astronomy, the name assigned to the 7th satellite of Saturn, discovered in 1848, at the Harvard Observatory by G. P. Bond. It is outside the satellite Titan, whose mass causes perturbations in the orbit of Hyperion, which have proved to be a difficult problem in celestial mechanics, and a unique case in the solar system. They apparently give large eccentricity to Hyperion's orbit, and cause the apparent line of apsides to follow the conjunction points of Titan and Hyperion, in a direction contrary to the usual motion of this line.

Hyperion, a romance, by H. W. Longfellow, published in 1839. It is the tale of a young man in deepest sorrow, wandering from land to land in search of occupation for his mind, and forgetfulness of grief. This motive forms the thread of a story which connects a series of philosophical discourses, and romantic legends and poems. Many of these last are Longfellow's translations of German poems, and have found a place in his collected poems.

Hyperpyrexia, hī-pėr-pĭ-rĕk'sĭ-ạ. See Fever.

Hyperspaces. *Dimensionality.*—In order to make quite intelligible the concept variously denoted by such terms as hyperspace, space of higher dimensions or dimensionality, multidimensional space, *n*-space, *n*-fold or *n*-dimensional space, it is in the first place necessary to explain the meaning of dimensionality and to indicate the way in which the dimensionality, or number of dimensions, of a given space in a given element is determined or ascertained. Because, in order to determine the position of a *point* in a curve or straight line, it is necessary and sufficient to know *one* fact about the point, as, for example, its distance (with algebraic sign) from a fixed point or origin, a line is said to be a *one*-dimensional space of *points*. But instead of the point, we may choose for element of the space (line) a *pair* or a *triplet*, . . . or an *n-set* of points. In such cases, in order to determine the element, *i.e.*, to pick it out or distinguish it from among all others of its kind, it is necessary and sufficient to know two or *three*, . . . or n *independent* facts about it. Hence a line is a *two*- or *three*-, . . . or n-dimensional space of *pairs* or *triplets*, . . . or *n-sets*, of points. In like manner a flat pencil (totality of lines of a plane that have a common point) is a *one*-dimensional space of *lines*, while its dimensionality is 2 in line *pairs*, 3 in *triplets*, and so on. For like reasons a plane is a *two*-dimensional space of *points* or of *lines*. In *circles* its dimensionality is 3, in *conics* 5, in *curves of third order* 9, and so on. It is at once seen that the dimensionality of a given space depends on the entity chosen for primary element, the element, *i.e.*, in terms of which we elect to study and express the properties of the given space. Illustrations abound. A curved surface, as, say, a sphere, regarded as the envelope of (its tangent) planes, is a *two*-dimensional space of *planes*, while, conceived as the assemblage of (its tangent) lines, it is a *three*-dimensional space. The reader will observe that the term space is employed generically to denote any unbounded continuum of geometric entities. The generalization is, however, a natural one, for, for geometric purposes, ordinary space is viewed primarily as an assemblage of elements of one kind or another. To determine the position of a point in ordinary space, three independent data (as the distances of the point from three mutually perpendicular planes of reference) are necessary and sufficient. Ordinary space is, therefore, *three*-dimensional in *points*, and that is what is meant, consciously or unconsciously, when, without specifying the element (point), it is simply said that space is three-dimensional. But tri-dimensionality is in no strict sense a *definitive* property of ordinary space. For some little understood, probably economical, certainly extra-logical, reason, the point recommended itself to primitive man as the element par excellence with which to geometrize, and so it has become traditional and proverbial that our space is essentially, uniquely, characteristically, intrinsically, exclusively three-dimensional. Such, however, it is not. It is indeed *three*-fold in *planes* as in points, but in *lines* it is *four*-dimensional. So, too, it is *four*-fold in *spheres*, but in *circles* its dimensionality is *six*. In general, it is possible by proper choice of element to endow any given space with any prescribed dimensionality however high. Accordingly, if by hyperspace is meant a space of dimensionality greater than 3, the notion is simple and near at hand, we need not go beyond ordinary space to realize it, we detect it in the line, in the plane, in ordinary space, here, there, and yonder. Well, such *is* one of the recognized significations of the term. But it has 'another,' namely, hyperspace usually means a space whose *point* dimensionality is four or more. Now this latter meaning is *logically* and *conceptually* quite consistent with the other, it is indeed a special case of it; but a hyperspace of *points* is difficult or impossible to *picture*, to realize in *visual imagination*, and it is this non-logical circumstance that renders the term hyperspace at once so tantalizing, mysterious, baffling, and fascinating to the non-mathematician. To the mathematician, however, whose activities, so far from being confined within the limits of the visual imagination, lie for the most part quite beyond them, the conception in question offers as such no difficulty whatever, and it has long since established itself among the most approved of orthodox scientific notions.

Definition of Hyperspace of Points.—What, then, is a *hyperspace* of *points?* How is the notion arrived at? And what is its utility? The values of a single continuous variable x are familiarly representable by the points of a right line; the ordered *pairs* of values of two independent variables x_1 and x_2, by the points of a plane; and the ordered triplets of values of three independents x_1, x_2, x_3, by the points of ordinary space. To the analyst with geometric bias or predilection, the suggestion immediately and forcibly presents itself that there *ought* to be a space whose points would serve to represent, as in the preceding cases, all ordered sets of values of n independent variables $x_1, x_2, \ldots, x_n$; and, not finding such a space present to *intuition*, *vision*, or *visual imagination*, he *posits*, or, if you prefer, he *creates*, one in *thought*. This done, it becomes immediately practicable to appropriate the terse, sensuous, stimulating language of geometry to the uses of analysis. Moreover, the hyperspaces serve as boundless playgrounds for the human spirit. They are immeasurable and immeasurably interesting fields for geometric research and exploration. In them light is found for the illumination of many otherwise dark or undiscovered properties of the lower, ordinary, spaces of intuition. By their study, the geometrician discovers how such higher and higher worlds would appear to a vision capable of beholding them.

Another Mode of Generating the Concept.—Another way, and, by virtue of its appeal to the intuition, possibly the best way, of arriving at the notion of hyperspaces of points, is the following: Posit two *points* (spaces of *zero* dimensionality in *points*). These determine a line, a space of dimensionality *one* in points. Next posit a point *outside* the line. The locus of all the points of all the lines determined by the posited point and the points of the given line is a plane, a space of *two* dimensions in *points*. Posit a point *outside* of the plane. The locus of all the points of all the lines (planes) determined by the posited point and the points (lines) of the given plane is a space (like our ordinary space) of *three* dimensions in *points*. Let the process continue. If intuition fail, reflect that in any case it is only a non-essential, extra-logical auxiliary, and hence proceed by positing *conceptually*, in *thought*, a point *outside* of the threefold space S_3, before obtained. The locus of all the points of all the lines (planes, 3-fold spaces) determined by the posited point and the points (lines, planes) of the given S_3 is a space of *four* dimensions in *points*. Obviously the principle of genesis here exemplified admits of endless application and leads directly to the concept of an n-fold space of points.

But we need not suffer ourselves to be dominated by the conception of point. Among possible elements, the point has no *logical* claim to preference or primacy, and the foregoing process is equally available for the generation of the concept of a space n-dimensional in any other element, *e.g.*, the line. Posit two intersecting lines (spaces of *zero* dimensionality in *lines*). These determine a flat pencil, a *one*-fold space, of *lines*. Posit a line *outside* the pencil, *i.e.*, not belonging to it but going through its vertex. The assemblage of all the lines of all the pencils determined by the posited line and the lines of the given pencil is a hyperpencil (sheaf of lines), a *two*-dimensional space of *lines*. Next posit a line outside the sheaf (but cutting all of its lines). So is determined a 3-fold space of lines, the assemblage of lines of which each with the posited line determines a pencil. The next step leads to a 4-fold line space; the next, to a 5-fold line space; and so *in infinitum*.

It is clear that the lower spaces are contained in the higher, as points in lines, lines in planes, etc., or as lines in pencils, pencils in sheaves, etc., etc. It should be noticed, too, that any space S is *zero*-dimensional in such spaces S taken as *elements*. The complete understanding of the geometry of a space of k dimensions demands a study of the like variety of space of $k+1$ dimensions, and so on. In particular the point geometry of ordinary 3-fold point space is quite as much illuminated by that of 4-fold point space as is the point geometry of the plane by that of 3-space.

Coordinates, etc.—In point space of n dimensions the simplest coordinates of the point are the distances $x_1, x_2, \ldots, x_n$ of the point from n mutually perpendicular point spaces of $n-1$ dimensions. These coordinate spaces, taken $n-1$ at a time, determine n coordinate axes. A linear equation $\xi_1 x_1 + \xi_2 x_2 + \ldots + \xi_n x_n + 1 = 0$ defines or represents an $\overline{n-1}$-dimensional space of order *one*, the analogue of the plane in ordinary space. The ξ's are the negative reciprocals of the axal intercepts of the $\overline{n-1}$-space. Holding the x's fixed and letting the ξ's vary, the foregoing equation will represent a point as envelope of its generating $\overline{n-1}$-spaces. Two such equations together define an $\overline{n-2}$-space as their intersection or a straight line as their envelope. Similarly, three such equations serve to represent an $\overline{n-3}$-space as locus of points or a plane as envelope of $\overline{n-1}$-spaces, and so on. A space that is n-fold in points is also n-fold in spaces of $\overline{n-1}$-dimensions. Its dimensionality is $2(n-1)$ alike in lines and in spaces of $n-2$ dimensions. In general, its dimensionality is $p(n-p+1)$ if the point space either of $p-1$ or of $n-p$ dimensions be taken as generating element. Not only, however, do he two last mentioned elements furnish the same dimensionality, but they are indeed reciprocal elements of n-fold point space, for the same system of equations which on proper interpretation defines one of the elements admits of a second (dual) interpretation defining the other. It thus appears that by taking as elements the various simple spaces of less than n dimensions for generating elements of n-fold point space, there arise κ geometries of this space; or, if we regard two reciprocal theories as but two aspects of one geometry, the elements in question yield $n:2$ or $1+(n-1):2$ geometries according as n is even or odd, the element having $(n-1):2$ dimensions being, in case of n odd, its own reciprocal, or *self-reciprocal*, like the line in ordinary space (see LINE GEOMETRY AND ALLIED THEORIES).

Remarks on Four-space.—Thus point space of 4 dimensions is also 4-dimensional in ordinary spaces (say *lineoids*), the point and the lineoid being reciprocal elements. It is 6-dimensional in *lines* and also in *planes*, which are also reciprocal elements of this space. It appears that this space, unlike ordinary space, does not admit of self-reciprocal construction. An equation of degree n in point (lineoid) coordinates x_1, x_2, x_3, x_4 ($\xi_1, \xi_2, \xi_3, \xi_4$) represents a locus (envelope) of *order* (*class*) n. If $n=1$, the locus (envelope) is a lineoid (point). Two linear equations define a plane as locus or a line as envelope; three, if independent, represent a line as locus or a plane as envelope; and four give a point or a lineoid. In general, two planes have, not a line, but only a point in common; reciprocally, two planes are not in general in a same lineoid. A lineoid being determined by four independent points, it appears that two arbitrary lines determine a lineoid. In 4-space a point can pass from the inside to the outside of a (two-dimensional) closed surface, such as an ordinary sphere, without going *through* the surface, just as in ordinary space a point can pass from the inside to the outside of a circle without *crossing* the circumference. Accordingly, in 4-space a 3-fold solid like the human body could be literally seen through, and no ordinary prison-house could confine.

Do hyperspaces exist? Undoubtedly they have *logical* existence, the *concept* of hyperspace being interiorly consistent and available for thought. More mathematics does not demand. The hypothesis of their 'physical' existence, 'natural' science may yet be compelled to employ. Indeed it has been conjectured that certain chemical phenomena (as of the carbon compounds) may be due to greater freedom of motion than ordinary space affords.

Bibliography.—The literature of the geometry (both pure and analytical) of hyperspaces is very extensive. It is, however, chiefly contained in the mathematical journals. All scientific nations have contributed to the subject, the Italians probably more than any other. The best work for the beginner is P. H. Schoute's 'Mehrdimensionale Geometrie' (1902). An excellent explanation, addressed to the non-mathematician, of the concept of 4-space is found in Hermann Schubert's 'Mathematical Essays and Recreations.'

CASSIUS J. KEYSER,
Adrain Professor of Mathematics, Columbia University.

Hyphomyceteæ, hī-fō-mī-sē'tē-ē. See FUNGI.

Hypnotics are agents that induce sleep. They may be mental, physical, or medicinal. Thus certain kinds of music, the human voice, and suggestion may have power to induce sleep, which may also follow from eating, or from a warm bath before retiring. All such simple measures should be used before drugs are resorted to in the treatment of insomnia (q.v.). Hypnotics *per se* may be divided into two broad groups—those that induce sleep by alleviating pain and those that have no pain-relieving character. The latter are pure hypnotics. Combinations of the two are frequently employed in medicine. The pain-relieving drugs all come under the head of analgesics (q.v.). The pure hypnotics may be divided into a number of groups based on their chemical relationship, for in this class of drugs the relation between chemical composition and physiological action is peculiarly close. Alcohol is one of the most prominent of the hypnotics, but while it is extensively used to induce sleep, the practice of taking a "nightcap" cannot be regarded as a safe one. Substituted alcohols, however, yield some of the most widely employed of all hypnotics. Chloral, paraldehyde, amylene hydrate belong to this series, while from chloral as a basis a number of allied hypnotics have been made. These are chloralamide, chloralose, chloretone, urethane, etc. The fundamental action of these is to cause a peaceful sleep without leaving ill after-effects. They all dilate blood-vessels, relieve spasm, and induce sleep. In large doses they depress the heart-action. Another group of hypnotics includes substituted sulphur compounds. The most important of these are sulphonal, trional, and tetronal. They are all closely allied in chemical structure. Sulphonal is the weakest, tetronal the strongest, trional occupies a middle position. In poisonous doses, and even in small doses if long continued, hypnotics of this group cause a form of chronic poisoning in which the red blood-cells are disintegrated. This is shown by the appearance of a cherry-red, or purple-red discoloration in the urine. A third group of hypnotics depends on some form of bromine, as bromides. Sodium bromide, potassium bromide, bromal, bromoform, etc., are representatives. They depress the activity of the brain, and are useful hypnotics. If used very long the bromine compounds cause skin-eruptions, foul breath, and heart-depression. See ALCOHOL; CHLORAL; INSANITY; INSOMNIA; MELANCHOLIA; NEURASTHENIA; SULPHONAL.

Hypnotism, hĭp'nō-tĭsm (Greek *hypnos*, «sleep»), an artificial sleep. The nervous phenomena exhibited in hypnotism resemble those induced by animal magnetism, though they arise solely from the condition of the patient, and not from any influence proceeding from others. Mr. Braid, of Manchester, England, brought this subject prominently before the public in the 17th volume of 'The Monthly Journal of Medical Science' (1853), but it has been long known in India. The actual foundation of modern hypnotic suggestion was discovered by Liébault, of Nancy, France, the famous "father of the therapeutic application of suggestion." After several years of practical experience, in 1866 he wrote his first book on the subject. It was shelved and he was pronounced erratic. Hypnotism remained a curiosity and Liébault's book was not reproduced till six years after Charcot, in 1878, began his studies in hypnotism. In 1884 Bernheim wrote his charming book on suggestion, and this created a demand for Liébault's book which then gave him lasting reputation. He was Bernheim's teacher. Formerly a profound skeptic, Bernheim became unavoidably converted by seeing the results of Liébault's application of suggestion to invalids. Bernheim was a clever clinical professor in the great hospital of Nancy and in his wards he convinced himself of the great value of hypnotic suggestion.

The word hypnotism is generally and largely misunderstood and misused. For example, if a person seems to be wholly influenced by another, it is commonly said that he has been hypnotized. This is a great error. The word hypnotism means putting a person to sleep and means nothing else. If an individual seems to be subjected to another in the waking state it should be said that he is unduly influenced. He is not hypnotized. That would mean that he was asleep. The means by which hypnotism is used is "suggestion." A person may be influenced by suggestion in the waking state, for suggestion is a great force in daily life. As connected with hypnotism, however, suggestion is the expression of an idea or combination of ideas which becomes impressed upon the mind of the somnolent subject to whom it is addressed. Conscious or unconscious results are sure to follow. This explanation sums up the meaning, use, and results of suggestion as applied to hypnotism and the hypnotic state. If a subject be awake he can, according to the strength of his will and desire, control to a greater or lesser degree the effect of a suggestion which he has received.

In the hypnotic state this self-control is decreased in a degree corresponding to that of the increase of the degree of sleep. Nevertheless, if merely the first degree of hypnosis has been attained, the subject, conscious of all he hears, may be influenced by the suggestion of the operator. In this way a vast amount of relief has been given to individuals who may claim that they have not been affected at all. In the hypnotic state there are nine sharply marked degrees of somnolence. In the first six degrees, notwithstanding he has been perfectly quiet and apparently asleep, the patient remembers all that has been said. In the last three degrees the patient, on waking, remembers nothing. Strange as it may seem, however, a person may be more influenced by suggestion in the lighter degrees of sleep than in the more profound degrees, and *vice versâ*. This is due to the patient's suggestibility. For example, the writer treated by hypnotic suggestion a very severe and prolonged case of intemperance. The patient claimed that not for an instant had he been sleepy, but he so responded to suggestion that from that day to this, a period of eleven years, he has not once touched alcohol. He had been intemperate from boyhood. On the other hand, a person may fall into profound sleep and yet not respond markedly to suggestion. Generally, however, if the subject be made to reach any degree of somnolency he can be relieved by suggestion. In the majority of cases the relief endures. In the popular mind exists the belief that this form of treatment is attended by danger, that the patient once hypnotized is thereafter under control of the operator, even at a distance, that the will is weakened, etc. This is all a mistake. No person can be hypnotized unless he be willing. No person can be hypnotized at a distance, unless by telephone, or if he be a good and willing subject, by letter; and the patient must first have been hypnotized by the operator at some previous time. Otherwise the operator cannot influence him at a distance in the slightest degree. The will is not only not weakened, but there is no other existing treatment which can so strengthen the will as can hypnotic suggestion. If any physician object to the treatment we know that this physician, however intelligent he may be in other professional matters, is ignorant of this method of relief. This treatment is not peculiarly useful in hysteria, as is commonly supposed, but has accomplished greatest benefit in all cases attended by bodily distress, neuralgia, dyspepsia, headache, disturbance of menstruation, pains of rheumatism, mental unrest, sleeplessness in particular, intemperance, opium habit, and all drug habits, vicious propensities, lack of mental vigor, fear, illusions, stammering, and wherever calmness has disappeared. In short, it will give relief in many cases which it cannot cure. It can relieve, but cannot create. It can assuage pain, for instance, in heart ailments, while it cannot dispose of damages which the heart may have received.

It is an absolutely safe and beneficent form of aid. It may not always bring relief, but never in the hands of a competent operator has it done harm. The patient will always choose the operator as he would choose a surgeon. The object of all reliable operators in the use of hypnotic suggestion is the relief of the patient, and to the operator the treatment is a sacred thing.

The method of the operators of the school of Nancy is wholly verbal. The patient is talked to sleep, and on waking he is delighted by the changes in himself which are apparent, and he has become convinced of the agreeable effects of the treatment.

Formerly a bright object was held between and above the patient's eyes, and he was directed to fix his eyes upon it. This created sleep. But it was found that nervous distress was apt to follow this method, and it has been abandoned by followers of the school of Nancy. The rationale of the treatment is that a person whose mind is in a sleepy or sleeping condition offers no resistance to the suggestions of the operator and, just as in thirst, in the waking state, «the mouth waters,» just as a woman blushes, because of a personal remark, or turns pale if a pistol be pointed at her, so the suggestions of the operator made to a sleeping person will follow a nerve path which is in accordance with the quality or nature of the mental impression created by the suggestion. In other words, the suggestion is followed by changes in sensation, act, or idea on the part of the patient, which correspond with the nature of the suggestion. Thus, if a sleeping person be assured by the operator that he will lose his craving for alcohol, or opium, or cocaine, or, that his pain will cease, that he will sleep at night, that his nervous unrest will disappear, that his power of will or a mental concentration will increase, and so forth, in nine out of ten cases the desired result will follow. Lack of space forbids further mention of this phase of the subject.

Brief reference should be made to an influence, wholly unappreciated by the popular mind, which is exerted by what is nothing but suggestion. For example: The sick people who were aided by the «magnetized» tree of Marquis Puysegur thoroughly believed in the therapeutic power of the tree, and therefore were cured or relieved. This was suggestion. The benefit of the electro-magnetic belts and rings formerly so largely in vogue was derived from suggestion. The influence of the waters of Lourdes is due to suggestion. The benefits which occur from many, if not the majority, of the medicines given by regular physicians are due to suggestion and temporary unusual care of the health. Therefore, in the absence of better means they are wisely given.

The people who resort to these things thoroughly believe in their efficacy, and this belief, acting through the mind, so influences the nerve and blood supply of the part or organ for which relief is sought, that the ailment passes away.

There are indeed scores of popular forms of relief which act wholly through the patient's mind and in themselves literally have no value. The effect of the mind cure and Christian Science is due to a weak form of suggestion, behind which an intelligent knowledge of anatomy, physiology, and disease is wholly lacking. The results are owing to influences produced upon the minds of those who seek these forms of relief, which thus have accomplished a degree of benefit but are dangerous aids where serious disease exists. These forms of suggestion, exactly speaking, are auto- or self-suggestion, that is, a belief which creates a mental power over bodily ailments, and which, in a certain percentage of people, is capable of large development.

The wise choice of a source of needed suggestion would be to seek it at the hands of a cultivated physician who is familiar with the application of suggestion to a somnolent patient.

With reference to causation of crime by means of hypnotic suggestion: few or no scientific men believe it possible. Habit is as strong as death. If a man's habit of mind be honest, no suggestion, sleeping or waking, can cause him to commit crime of any sort. If he be dishonest, naturally or by inclination, the suggestion would be unnecessary. In so far as physicians are concerned they are not interested in this phase of the subject because they use the treatment wholly as a means of relief, and, as a class, physicians are reliable men who would not even attempt to misuse hypnotism any more than they would use ether for evil purposes. The so-called «laboratory crimes,» that is, imitation of crime in the presence of the operator who suggests it, would not occur unless he were present. The subject simply feels safe under the direction of the operator and, as has been proved many times, would not attempt suggested wrongs if he were alone.

The hypnotic sleep is a natural sleep. Those who claim that it is not natural are not intelligent in the matter, and their opinions are based upon pure and uninformed theory.

As has been shown by scores of thousands of cases, treated by brilliant and educated physicians, the treatment is absolutely innocuous. It either relieves or produces a neutral effect, and is useful in a multitude of ailments which baffle ordinary means of relief.

But the operator must be educated in the use of this valuable method of treatment. Hypnotism should be used only by physicians, and amateurs should by no means experiment with it as a means of amusement.

HAMILTON OSGOOD, M.D.,
Boston, Mass.

Hypochlorites. See HYPOCHLOROUS ACID.

Hypochlo'rous Acid, an acid having the chemical formula $HClO$, which is formed when chlorine monoxid, Cl_2O, is dissolved in water.

The most convenient method of preparing it, however, is by distilling a mixture of dilute nitric acid and a salt of hypochlorous acid. The sodium salt of hypochlorous acid, known as sodium hypochlorite, $NaClO$, may be prepared by passing a stream of chlorine gas through a cold dilute solution of caustic soda, $NaOH$; the reaction being $2NaOH + 2Cl = NaClO + NaCl + H_2O$. Potassium hypochlorite may be prepared in a similar manner. Crude calcium hypochlorite, $Ca(ClO)_2$, known in the trade as "bleaching powder" (q.v.), is prepared by acting upon slaked lime with chlorine gas. Hypochlorous acid and the hypochlorites possess powerful bleaching properties, owing to the readiness with which they part with a portion of their chlorine or of their oxygen. (See BLEACHING.) Hypochlorous acid is only known in its aqueous solution, which is a colorless liquid, with a peculiar smell. It decomposes readily with the liberation of chlorine, and the formation of chloric acid, $HClO_3$, the decomposition proceeding rapidly in the sunlight. Hydrochloric and sulphuric acids also decompose it with liberation of chlorine, the reaction in the case of hydrochloric acid being $HClO + HCl = H_2O + 2Cl$. Heat decomposes the hypochlorites, with formation of the corresponding chlorates and chlorides.

Hypochondriasis, hī″pō- or hĭp″-ō-kŏn-drī′a-sĭs, a morbid condition of the mind in which an individual fears himself afflicted with various diseases. The name comes from the ancient belief that the symptoms of this disorder came from perversions of the vital force in the liver and pylorus of the stomach. The tendency to this condition is frequently inherited; it is more common in males, and is sometimes brought on by excesses. Patients afflicted with hypochondriasis are apt to watch for any expression of abnormality in their bodies, to connect various symptoms, and to reach the conclusion that they are sufferers from some disease. In conditions of perfect health any individual may have slight, temporary twinges of pain, or may show passing changes in the functions of the organs; but by the hypochondriac these abnormalities are seriously regarded, and efforts to disabuse him are usually futile. Such constant fear and worry divert the nervous energy from its proper course, and may cause actual disturbance of the bodily functions that are serious. The condition known as neurasthenia may follow; also, more rarely, true melancholia. The milder cases continue in actual good health, but become an unhappy burden to themselves and others. In the treatment it is to be remembered that mental occupation outside of the thoughts of self is essential to a cure.

Hypoder′mic Injection (Greek, *hypo*, under; *derma*, skin), a method of introducing medicines through the skin into the subcutaneous cellular tissue, sometimes deep into the fibres of a muscle by an instrument specially made for the purpose. This instrument is the hypodermic syringe, which is made of glass, with a graduated scale engraved on it, and fitted with a long, hollow needle-shaped point of steel. It must be filled before using, to prevent the possibility of introducing air into the veins. Hypodermic injection should never be resorted to excepting under the specific directions of a physician, and no patient should ever employ this method upon himself.

Hypodermic Medication, as opposed to endermic medication, means the administration of medicine by piercing the skin so as to throw the drug directly into the circulation, and bring it immediately in contact with the seat of pain, if pain is to be treated. There are some drugs which act on the system in a manner which differs in accordance with the method of their administration; thus podophyllin is a powerful cholagogue when administered through the mouth; when administered hypodermically it promotes the secretion of the kidneys. There are, however, distinct advantages of a general character in this method of administering drugs. The action of the drug is more rapid, sometimes instantaneous; the effect is concentrated and intensified; it takes a smaller dose to produce the desired effect; it is sometimes easier and pleasanter than administration by the mouth, and often obviates unpleasant or even dangerous complications. The process of hypodermic injection (q.v.) was invented and brought into vogue by Dr. Alexander Wood (q.v.) of Edinburgh.

Hypophosphites, salts of hypophosphorous acid (q.v.).

Hypophosphorous Acid, an oxyacid of phosphorus, having the formula H_3PO_2. The free acid is of no importance in the arts, but its salts, which are called "hypophosphites," are used in medicine. The acid is monobasic, only one of its hydrogen atoms being replaceable by a metallic atom. Sodium hypophosphite, $NaH_2PO_2 + H_2O$, may be prepared by acting upon caustic soda with phosphorus, phosphoretted hydrogen being given off, while sodium hypophosphite remains in solution. It crystallizes in small, rectangular tablets, which are easily soluble in water and in absolute alcohol. The evaporation of solutions of this substance is often attended by explosions. Barium hypophosphite, $Ba(H_2PO_2)_2 + H_2O$, may be prepared by heating baryta, BaO, with phosphorus and water until the elimination of phosphoretted hydrogen has ceased, the excess of BaO being then removed by a current of carbon dioxid, after which the solution is filtered and crystallized. Barium hypophosphite crystallizes in monoclinic needles, which are soluble in water, but insoluble in alcohol. Calcium hypophosphite may be prepared in the same manner as the barium salt. It has the formula $Ca(H_2PO_2)_2$, and crystallizes in thin, monoclinic tablets, which are soluble in six parts of water, but insoluble in strong alcohol. Free hypophosphorous acid may be prepared by decomposing the barium salt with sulphuric acid, and evaporating the solution at a temperature not exceeding 230° F. It crystallizes in large white tablets, which melt at 63° F., and are decomposed by heat, with the formation of phosphoretted hydrogen and ordinary tribasic phosphoric acid.

Hy′poscope (from Greek words meaning "to see under"), is the name given to an instrument adapted to be secured to the stock of a rifle near the breech, and intended to enable a marksman to fire with accurate aim without exposing his head to the fire of the enemy. The successful American contestants for the Palma trophy at Brisley, England, in 1903, brought back with them this device, which seems likely to play an important part in the warfare of the future. It was invented by William Youlton of Brighton, England, who conceived the idea of it after the battle of Colenso in the Boer war, during which it is stated that not a single Boer was to be seen. Later in the war it was employed with good results, its use at Mafeking receiving particular mention.

The hyposcope consists of a series of mirrors mounted in a tube of inverted L shape; the shorter arm lies across the barrel of the rifle, while the longer arm hangs down at one side. The first mirror reflects the light coming in along the barrel of the rifle to a second mirror at the elbow of the instrument, which directs the rays downward to a mirror at the lower end of the tube, and thence it passes out at right angles to the eye. Thus on looking in at the eyepiece one can see the sights of his rifle, and take accurate aim while holding the gun above his head. The vertical arm of the instrument comprises two telescoping sections so that, by means of a thumbscrew at the side, this arm may be extended to elevate the device for long-range shooting. The amount of elevation may be accurately determined by means of a fine scale on the upper section. In order to allow for windage, a thumbscrew at the end of the horizontal arm may be rotated to move the mirror contained therein slightly to one side or the other. A scale on this arm shows just how far the mirror must be moved for different velocities and directions of the wind. The entire instrument is very compact and light, weighing about a pound. It is provided with a holster, in which it may be encased to prevent it from sustaining any injury when not in use.

The advantages of this instrument in actual warfare will be apparent to all. Only the muzzles of the rifles are exposed to the enemy, and the soldiers are entirely concealed in the trenches. But aside from its advantages as a means of protection, the device will be found greatly to increase the effectiveness of the firing. The fear of being shot while taking aim makes the soldier fire hurriedly and at random; with the hyposcope attached to his rifle no fears will be entertained, and the soldier may fire deliberately and with perfect aim. By applying it to the end of a field-glass, an observer can watch the movements of the enemy without danger of discovery. It has also been designed for use on Maxim guns.

Hypostatic Union, the union of the divine and human nature in the one person of Jesus Christ.

Hypoth'esis, in mathematics the term denotes what is assumed in order that the conclusion may follow from it as a consequence. It has sometimes been applied in a disparaging sense to suppositions that have been made for the purpose of drawing foregone conclusions, and not with the view, as has been generally the case in physics, to supply probable antecedents to conclusions which have already been experimentally established. In some cases the hypothesis may only acquire a certain degree of probability; in others it may account for all the known circumstances, and it then acquires the name of a theory; and if subsequent observation reveals no exceptions to its application, it gradually amounts to certainty. The conjecture of Newton that the force of gravity, as exemplified on the earth, might extend to the moon was at first a hypothesis; but when it was found that it accounted for all the facts it became a theory. There has an attempt been made to institute a distinction between a hypothetical cause and a true cause, but it is practically of no value.

Hypsom'etry (Greek, «height-measurement»), the art of determining differences of elevation on the earth's surface. Three distinct modes of procedure may be adopted for measuring a given difference in level. The first and most accurate of these consists in running a «line of levels» between the two stations whose difference in height is to be determined. This operation is conducted as follows: Let A, B, and C be any three points on the earth's surface, such that the difference in level between any two of them is not more than a few feet; and let us suppose that B lies between A and C, and that it is not more than a few hundred feet distant from either of them. A precise spirit level is set up at B, so that its telescope is higher than either A or C. A graduated staff is then held in a vertical position upon the point A, and the observer at the level determines, by looking through the telescope, which division of the staff is of precisely the same height as the cross-hairs of his instrument. If the height of A is known, we have merely to add to it the known length of the graduated staff, from the ground up to the division that has been observed, in order to ascertain the exact height of the cross-hairs of the level. The staff is next carried forward to the point C, and a second observation of the same kind is made upon it at this point. The height above the ground of the division that is here found to be on a level with the instrument is then subtracted from the known height of the cross-hairs in the telescope, and the result is the height of the point C. The instrument is then carried forward to a point, D, situated beyond C, and the altitude of a still more remote point, E, is determined in the same manner, by observing the graduated staff at C and at E, and then calculating the height of E from the known height of C, as determined by the preceding operation. A chain of observations of this sort is called a «line of levels,» and it is obvious that the difference of elevation of any two points whatever may be determined with great precision by running such a line from one of them to the other.

The labor and expense of joining two distant points by a line of precise levels are often prohibitively great; and hence when a high order of accuracy is not essential, trigonometric or barometric methods are used instead. In determining the height of a mountain (for example) by the trigonometric method, a conveniently situated station is selected, from which the summit of the mountain can be well seen, and the horizontal distance from this station to the vertical line passing through the summit of the mountain is first determined by any of the methods used by surveyors for determining the distance of an inaccessible object. The apparent angular elevation of the mountain is next observed; that is, the angle included between the horizontal plane through the station and the line joining the station to the top of the mountain is measured.

If the earth were flat and devoid of any atmosphere, these data would enable us to compute the height of the mountain with considerable precision. For the vertical height of the mountain above the station, and its horizontal distance from the station, and the line joining the station to its summit, would constitute the three sides of a right-angled triangle; and the base of this triangle being known, as well as one of the adjacent angles, its vertical height (that is, the height of the mountain above the observing station,) could be easily calculated by the ordinary rules of trigonometry. In the actual case, however, the problem is complicated by the curvature of the earth's surface, and by the refraction effects due to the presence of the atmosphere. Corrections can be easily applied for the curvature, since that is constant in any given spot, and its value is well known. The refraction effects, however, are variable from time to time, according to atmospheric conditions; and it is impossible to determine them, at any given moment, with a precision sufficient to enable the trigonometric method to compete, in accuracy, with the method of leveling already described.

The third general method of determining elevations on the earth's surface depends upon the fact that the atmosphere possesses weight, so that its pressure diminishes as we pass upward. The difference in depth of two given points below the surface of the sea can be determined with a good deal of precision by noting the hydrostatic pressures at the two points. If these pressures are expressed in pounds per square foot, and their difference is divided by the weight, in pounds, of a cubic foot of the water, the quotient will be the difference in depth of the two points, expressed in feet. The same general principle applies to the determination of the differences of elevation in the atmosphere, only in this case the problem is far less simple in its actual application, because the air, instead of having a practically constant density as water has, is very elastic and compressible, and very sensitive to changes of temperature. The observations, therefore, have to be combined by means of a formula which will take these facts into account, so far as possible. In determining differences of height by this method (which is called "barometric hypsometry"), the difference in atmospheric pressure at the two points that are to be compared is usually determined by means of barometric readings, though the boiling-point method, to which reference will presently be made, is also used. The mercurial barometer gives the most accurate results, but the aneroid form is so much more convenient to manipulate and transport that it is commonly preferred for ordinary work. (See BAROMETER.) When the difference of elevation between two given stations is to be determined, it is preferable to make the barometric observations at both places simultaneously, simultaneous observations of the atmospheric temperature being also taken. This implies the co-operation of two observers, and the possession of two sets of instruments; and hence it is not always feasible. When the work is carried out by a single observer, or with a single set of instruments, the observations should be made first at Station A, then at Station B, and finally at Station A again; the average readings at Station A, both of barometric pressure and of temperature, being adopted as the definite observations at that station. In this way the effects of variations of temperature and pressure are eliminated as far as possible. If h is the average reading of the barometer at the lower station, in inches, and H is the reading of the barometer at the upper station, also in inches, and if t and t^1 are the temperatures observed at the two stations, on the Fahrenheit scale, then the difference in height between the two stations, as expressed in feet, is approximately

$$(\log h - \log H) \times 60384 \times \left(1 + \frac{t + t' - 64^\circ}{900}\right).$$

In place of the barometer, an instrument called a "hypsometer" is sometimes used for determining the difference in barometric pressure between the two stations. The hypsometer is essentially an instrument for determining the boiling point of water with a considerable degree of precision. Water, which at the normal atmospheric pressure boils at 212° F., boils at a lower temperature on the tops of mountains, where the atmospheric pressure is less. The change in the boiling point is approximately 1° F. for every 555 feet of ascent; though this relation is not exact. In the practical application of the method, the boiling point is observed, on the mountain top, by an accurate thermometer which should be graduated as fine as fiftieths of a degree on the Fahrenheit scale. The difference between the temperature so obtained and 212° F. is then multiplied by the constant factor 555, and the product is the desired estimate of the height of the mountain above the sea. This procedure, it will be seen, assumes that at the time the observation is made, the atmospheric pressure at the sea-level has its normal (or average) value, so that water would boil there at 212° F. precisely. This condition will seldom be more than approximately fulfilled, and hence the method by boiling points, as usually carried out, is more uncertain than the barometric method as described above. The thermometric method is very convenient, however, and for this reason it is in strong favor among travelers and explorers, who usually are content with a more or less rough approximation to the height to be measured. The method is capable of being refined further than has here been indicated; but when more accurate results are desired than are obtainable by the process as described above, it is better to make use of simultaneous readings of the barometer and thermometer, at the two stations to be compared.

Hyrax, hī'raks, the type-genus of a group of small rabbit-like animals forming the group *Hyracoidea*. There are two species, not very sharply defined, the daman (*H. Syriacus*), which spreads from the African shores of the Red Sea to Syria, and the Klipdas, or dassy (*H. Capensis*), which ranges from Abyssinia to the Cape of Good Hope. The former is the animal meant by the Scripture reference to "conies," as a "feeble folk." They are gregarious, plant-feeding, and make their homes among loose rocks, where they are little seen during the day. Hence English settlers call them rock-rabbits. The zoological position of these animals is astonishing in view of their size, appearance and rodent-like habits, for they are most nearly related to the elephant and rhinoceros. In west-central Africa live two or three small arboreal species (*Dendrohyrax*). The latest monographer of these singular animals is O. Thomas (Proc. Zool. Soc. of London 1892), who says that the rules of priority require that the family and genus should be called *Procaviidæ* and *Procavia*. They are believed to be little modified descendants of the *Condylarthra*.

Hyrcanus (hėr-kā'nŭs) **I.**, JOHN HYRCANUS, a Jewish high-priest and prince of the Asmonean family, who ruled in 135-105 B.C. He was the son and successor of Simon Maccabæus. At first dependent on the Syrians, he succeeded in throwing off their yoke, and also in subjugating the Samaritans. He next overcame the Idumæans, and obliged them to submit to Judaism. He afterward confirmed his power by an alliance with the Romans and made Judæa more powerful than it had been since Solomon's time. He was originally a Pharisee, but ultimately favored the Sadducees.

Hyrcanus II., high-priest of the Jews and prince of the Asmonean family, who ruled intermittently from 69 B.C. to 38 B.C. He was the grandson of Hyrcanus I. His younger brother, Aristobulus, seized the government, and finally Pompey removed Hyrcanus from the kingship, and made Antipater of Idumæa governor of the colony. In 47 B.C. Cæsar proclaimed Hyrcanus tetrarch and high-priest. Antigonus, son of Aristobulus, deposed Hyrcanus and removed him to Seleucia whence later, at the request of Herod, he returned to Jerusalem, where he was finally put to death (30 B.C.).

Hyslop, hĭs'lŏp, **James Hervey**, American scholar and educator: b. Xenia, Ohio, 18 Aug. 1854. He was graduated from Wooster University (Ohio), studied also at Leipsic and the Johns Hopkins University, taught successively in Lake Forest University, Smith College, and Bucknell University, and was appointed professor of logic and ethics in Columbia University. He became well known for his connection with the investigations of the Society for Psychical Research, and contributed extensively to its proceedings. His further work includes articles in prominent periodicals; an edition of Hume's 'Ethics' (1893) with introduction; a text-book on 'The Elements of Logic' (1892); one on 'The Elements of Ethics' (1895); 'Democracy: A Study of Government' (1899); 'Logic and Argument' (1899); and 'A Syllabus of Psychology' (1899).

Hyssop, hĭs'ŭp (*Hyssopus*), a genus of plants of the natural order *Labiatæ*, with four straight diverging stamens, and a 15-ribbed calyx. The common hyssop (*H. officinalis*) is a perennial shrubby plant about two feet in height. The leaves stand in pairs without footstalks. The flowers are blue, growing chiefly on one side, in short verticillated spikes. It is a native of the south of Europe and the East, and is naturalized in the United States. The leaves have an agreeable aromatic color, and an extract from them is produced by water and spirits. The hyssop of Scripture (that is, the plant whose Hebrew name *ezob* has been translated "hyssop") has not been ascertained. As it "grew out of the wall," it must have been a diminutive plant, and may have been one of the mosses. The most probable and most widely accepted view is that it was the caper-plant (*Capparis spinosa*), but it is not unlikely that the name was applied to several plants of somewhat similar properties. The name of hedge-hyssop is applied to species of plants of the genus *Gratiola*, belonging to the natural order *Scrophulariaceæ*.

Hysteria, a morbid state of the nervous system in which the clinical manifestations present a wonderful variety of symptoms closely simulating some forms of organic disase. There is often increased physical irritability; the condition is frequently manifested by neuralgic pains, hyperæsthesias, hallucinations, and convulsive and paralytic phenomena. It may be regarded as a brain affection — a mild insanity.

Among the causes of hysteria heredity plays a most important part. There may be direct transmission of the hysterical temperament from parent to child, or other nervous manifestations in the family and its branches, such as epilepsy, chorea, neuralgia, insanity, etc. It occurs more frequently in women, but it is much more common in men than is ordinarily believed; it occurs in boys and girls at a tender age or about the time of puberty. Briquet found that one eighth of his cases were in children under ten years of age. Anything which lowers the general tone of the nervous system may give rise to it in predisposed persons. Hæmorrhages, severe illness, poor food, anæmia, overwork in uncongenial occupations, anxiety, fright, jealousy, disappointments make a profound impression; so does an education which fosters and stimulates inherited instability. The enforced social restrictions of women, which they often inflict upon their young children, with lack of proper exercise for physical development and an artificial and premature education and habits heighten this predisposition. Accidents are a frequent cause of the first appearance of hysteria, as has been clearly pointed out by Charcot. The disease may, at times, occur in young girls who have witnessed attacks in others.

To understand the symptoms of hysteria, it must be borne in mind that there are two classes of phenomena. These have been termed the *mental stigmata* and the *mental accidents*. The stigmata are anæsthesias (loss of sensation), amnesias (forgetfulness), abulias (loss of will power), motor disturbances, and modifications of character. These are the cardinal symptom-groups that characterize the mental state of the hysteric. Any or all of the mental accidents may likewise be noted — suggestibility and sub-conscious acting, fixed ideas, ecstasy, automatism, convulsive movements, sleep-walking, deliriums, etc. The occurrence of these constitutes important corroborative evidences of hysteria and while not found in all hysterics, they may be very common symptoms.

Hysterical persons often complain of some of the symptoms found in neurasthenia — neuralgic pains in various parts and hyperæsthetic areas about the abdomen, chest, or back, frequently in the neighborhood of the ovary, mammary gland, etc. There may be anæsthetic patches in various parts of the body, or there may be complete loss of sensation on one side associated with anæsthesia of the mucous membranes. The special senses on that side are involved — sight, taste, and hearing.

There may be irritations of the bladder and urethra; pain in the joints, which may be mistaken for joint disease.

In some cases the senses are exceedingly acute. Persons notice odors imperceptible to others; are often made sick by odors which do not affect normal individuals; may have a liking for odors and substances disagreeable to others. Perverted sense is shown in an abnormal taste, in eating soap, slate-pencils, etc. Hysterical manifestations in some are simply emotional exaggerations; they laugh and cry without cause. In serious attacks there are likely to be various hysterical manifestations. Occasionally tactile sensibility is disturbed, and the muscular sense may be abolished. The anæsthesia may affect the mucous membranes of mouth, pharynx and nose, abolishing the reflexes of the parts. The secretions may be diminished or arrested.

Spasmodic convulsions and paralytic phenomena may occur. The spasmodic attack may be rhythmic; may simulate the trembling of organic disease; may be confined to one member or involve the entire half of the body; may be coarse, as in disseminated sclerosis, or a fine tremor, as in paralysis agitans, or the tremor may simulate the trembling of organic brain disease. It may occur in any muscle or group of muscles; may manifest itself as contracture, which may be intermittent or may last continuously for months or years. Contracture may be confined to the strong muscle of the jaw and other muscles in their neighborhood, causing trismus. Spasms of the glottis may take place, giving rise to severe difficulty in breathing; or of the pharynx, causing difficulty in swallowing. Globus hystericus is a constant symptom, but is not as frequent as it is often thought to be. Persistent and severe vomiting often occurs, but the nutrition rarely suffers materially from these attacks. Retention of urine is frequent, owing to spasm of the sphincter, and the catheter may have to be used for months.

Paralysis occurs in these cases; it is variable in distribution, and may come on suddenly after a convulsive attack or without it; it may be flaccid or associated with contracture; it may come on slowly; it may be confined to one limb or be hemiplegic in type.

Hysterics are easily affected by pleasurable or painful impressions, and there is often a morbid craving for sympathy and attention. They may show moral perversion; may lie, steal, quarrel with and intrigue against their own family; may form and change attachments and dislikes without obvious reason; may manifest aversions, as to frogs, spiders, mice, cats, etc.; may deceive for deception's sake or to excite wonder. Some are painfully depressed; they have forebodings, or are compelled to do certain acts. Here the hysterical insanities are approached on the one hand, and the imperative conceptions and neurasthenias, on the other.

Hystero-epileptic attacks in their greatest severity are often preceded by general discomfort, or by hallucinations of vision and hearing. Usually sudden, they may be preceded by an «aura,» globus hystericus, singing in the ear, etc. Breathing is spasmodic; consciousness is obscured; the convulsion may be similar to those of mild epilepsy. In some cases the body is thrown into all sorts of contortions. An extreme opisthotonos may be present, the body being bent backward, resting on the head and heels. Gestures and noises are made. Sometimes religious ideas have an influence over the attitudes assumed; at other times, ideas of demoniacal possession.

From milder forms, recovery is the rule. In graver cases, and when there is a strong neuropathic tendency, the persons will probably pass from one hysterical manifestation to another.

Treatment.— In cases where there is deterioration of the physical health, tonics and nutritious diet should be given. Hydrotherapy improves nutrition and also the mental state. Many drugs have been recommended, but they are all uncertain in their action, at one time giving a result, and failing at another. Convulsive attacks may at times be stopped by the cold douche to the spine. Isolation from the family circle is of the utmost importance in the treatment of these cases. Every effort should be made to discover the psychic shock which has produced the attack. Only the patient may have knowledge of this, and he will not often reveal it. There is no disease the treatment of which it is more difficult to describe. Suggestion-therapy gives by far the best results, but the great difficulty is that good results are rarely permanent.

Bibliography.—Charcot, 'Leçons sur les Maladies du Système Nerveaux,' tome 3; Jolly, 'Hysteria'; Ziemssen, 'Cyclopedia of Medicine'; Seguin, 'Hysterical Symptoms in Organic Disease'; Janet, 'Mental State of Hystericals' (1902).

Hyvernat, hē'vĕr-nat, **Eugene Xavier Louis Henry**, American scholar: b. St. Julien-en-Jarrêt, Loire, France, 30 June 1858. He was graduated from the University of France at Lyons in 1876, studied divinity at the St. Sulpice Seminary, Issy, in 1877–9, at Paris in 1879–82, was Oriental interpreter to the Propaganda at Rome in 1885–9, and taught in the Roman Seminary in 1885–8. In 1889 he was appointed professor of Oriental languages and archæology in the Catholic University of America at Washington, D. C. His writings include: 'Les Actes des Martyrs de l'Egypte' (Vol. I. 1886); 'Album de Paléographie Copte' (1888); and 'Du Caucase au Golfe Persique' (with Muller-Simonis 1892).

I

I the ninth letter and third vowel of all the alphabets of western Europe, came into the Latin alphabet from the Greek. It is named in Greek iota, which is the yod of the Hebrew and the corresponding letter of the Phœnician alphabet from which the Greeks derived it. Iota and yod (whence jot) being the smallest letter in the Hebrew and Greek, gave occasion for the New Testament phrase «one jot or one tittle.» In ancient Latin the i appears to have stood for a semi-vowel like y as well as for the vowel i: thus the Latins would write Ianus, Iulia, pronouncing them Yanus, Yulia. And till a comparatively recent date words beginning with I and J were in English dictionaries classed together.

The dot over the i appears first in MSS. of the 13th century. The sound value of i in all languages except English is constant and is equal to e in he and to i in him. What is called the long sound of English i as in hide is a diphthong made up of the two vowels a and i: this value of i in English is believed to have been given to the letter not earlier than the 16th century: till then the letter had the same sound in English as in other languages.

In the standard alphabet of philologists the values of the vowels are about as in the languages of continental Europe, in which i is sounded as English e.

It is the general rule in English pronunciation that i followed by two consonants in the same syllable is short: yet when the two consonants are ld or nd the i is nearly always long and diphthongal, for example, mild, rind: in wind (noun) it is short, but in wind (verb) it is long. Combined with o it forms a true diphthong oi as in oil: or mere digraphs representing sounds in which often the i has no part: examples: bail, rein, seize, pier, friend. Usually a final e indicates that the i in a word is to be pronounced as the diphthong: for example, fine, fin: yet genuine is genuin: or the i is pronounced as e long, — marine, quinine, Augustine.

In Pope's time and long after oblige was pronounced obleege and rhymed with besiege: the i in oblique is pronounced either e or i.

Ian Maclaren. See WATSON, JOHN.

Iba, ē'bä, Philippines, pueblo and capital of the province of Zambales, Luzon, situated on a river two miles from its mouth, 85 miles northwest of Manila. It has a good anchorage and is on the south coast road. It is a well built town, and has several fine public buildings. In 1901 a United States meteorological station was established there. Pop. 3,500.

Ibach, Lawrence J., American astronomer: b. Allentown, Pa., 17 Jan. 1816; d. Newmanstown, Pa., 9 Oct. 1888. He learned the blacksmith's trade and followed it throughout his life, chiefly at Sheridan, Lebanon County, Pa. He studied with the astronomer, Charles F. Engleman, who, on his death in 1860, bequeathed all his charts, books, and instruments to Ibach. His benefactor having promised to make several series of astronomical calculations for almanacs Ibach filled the first order (1863), and thereafter till his death made annual calculations for almanacs in the United States, Canada, South America, and Cuba. He was commonly known as the «blacksmith-astronomer.»

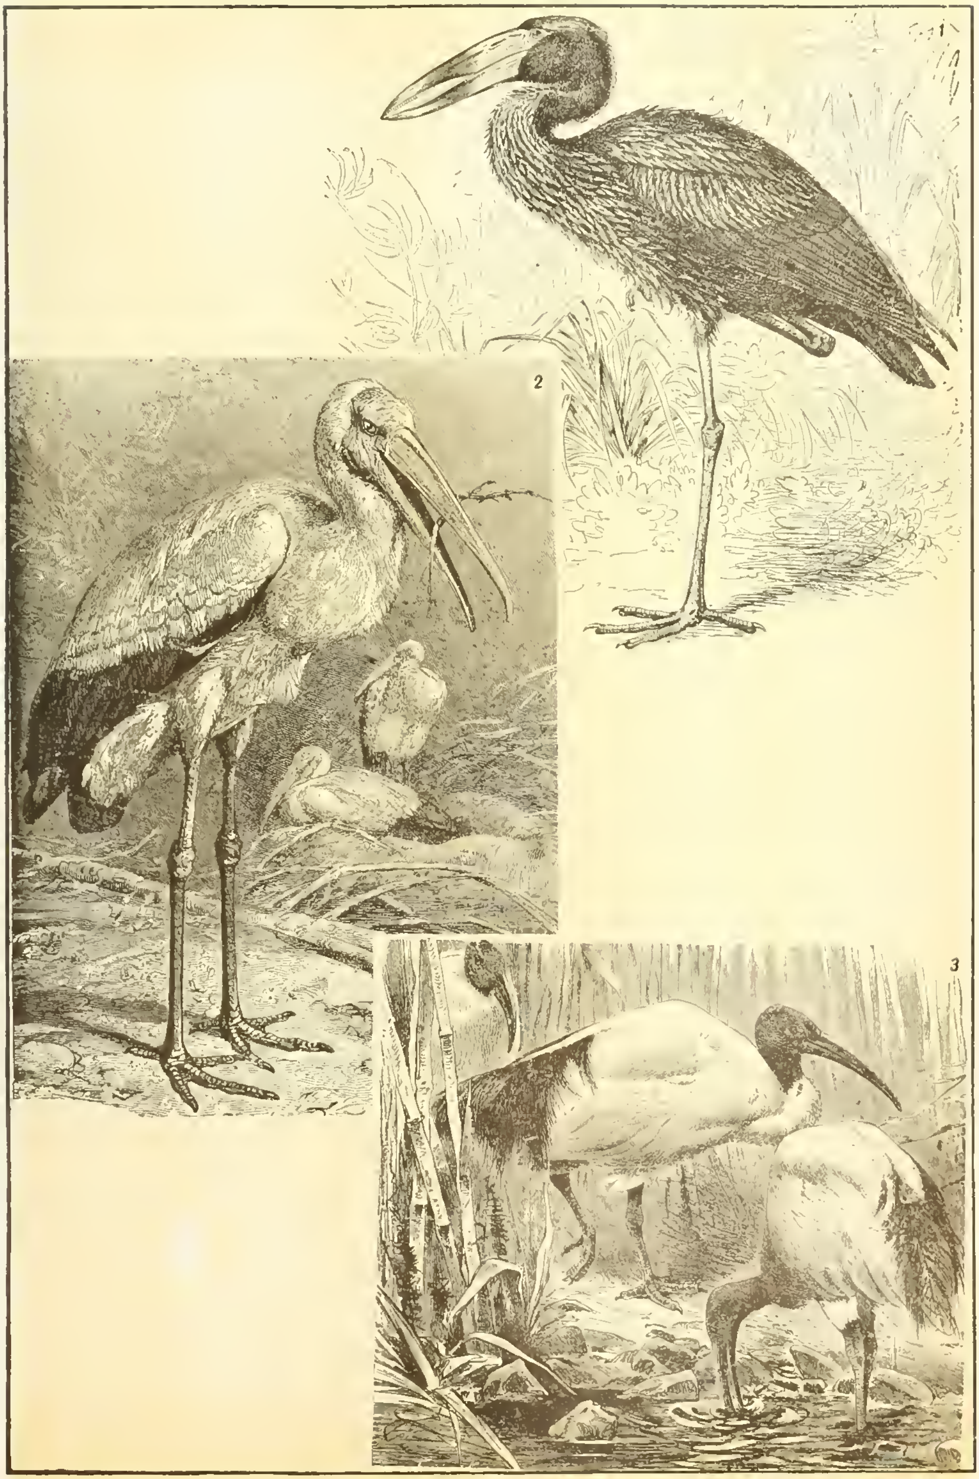
Ibajay, ē-bä-hī', Philippines, pueblo of the province of Capiz, island of Panay, situated on the Ibajay River, 42 miles northwest of Capiz, the capital of the province. Pop. 11,350.

Iberia, ī-bē'rĭa. (1) The ancient name of a district of Asia, between the Euxine and Caspian seas. It now forms part of Russian Georgia, and consists of an extensive fertile plain, surrounded by mountains traversed by four passes. It probably belonged to Persia, until subjected by Pompey and Trajan to the Roman empire, under which it remained till after the time of Julian. (2) The ancient name of Spain, the Ebro, the principal river, being called Iberus. The Iberian language still lives in the Basque. See BASQUES and CELTIBERI.

Iberville, Pierre le Moyne, pē-är lė mwän ē-bër-vēl, SIEUR D', French-Canadian naval and military commander: b. Montreal 16 July 1661; d. Havana, Cuba, 9 July 1706. He entered the French navy, in 1686 took part in the expedition for the capture of the English forts on James' Bay, in 1690 in that for the destruction of Schenectady, N. Y. He took Fort Nelson, on Hudson Bay; captured and demolished Fort Pemaquid, built for the protection of the New England settlements; laid waste all the British posts on the island of Newfoundland; and, having defeated three English vessels with his one, reduced Fort Bourbon, the last station of the Hudson's Bay Company. In 1699 he ascended the Mississippi for some distance, and built Fort Biloxi at the head of Biloxi Bay. This post he removed to Mobile in 1701. In 1706 he captured the island of Nevis. He was considered the ablest officer in the French naval service of his time, and is generally called the founder of Louisiana

I'bex, any of several species of wild goat (q.v.), sometimes placed apart in a sub-genus *Ibex*, distinguished by the form of the horns of the ram, which are large (30 to 50 inches long),

THE IBIS FAMILY.



REPRESENTATIVE IBISES.

1. Open-bill (Anastomus lamelligerus). 2. Wood Ibis (Tantalus ibis). 3. Sacred Ibis (Ibis religiosa).

backward curving, compressed, and marked on the front with bold cross-ridges or knot-like protuberances. The ibexes are larger than other goats, that of the Himalayas standing 40 inches high at the withers. Their coats are harsh, uniformly brown, becoming much grayer in winter, whitish on the under surface and buttocks, and with darker tints on the face and fore-legs. These animals inhabit the most precipitous and inaccessible heights of lofty mountains, where they assemble in flocks, sometimes consisting of 10 or 15 individuals. During the night they feed in the highest woods, but at sunrise they again ascend the mountains, till they have reached the most perilous heights. They are remarkably swift, and display amazing agility and dexterity in leaping. They are objects of the chase, and the hunter must have great skill and hardihood to succeed. Several species are distinguished by locality and minor differences. The typical ibex, bouquetin or steinbock (*capra ibex*), once numerous throughout the European Alps, now exists only as a semi-domesticated animal in certain valleys on the Italian border.

Three other species are recognized: The Arabian ibex (*C. sinaitica*) of Palestine, Arabian and northern Egypt (see BEDEN); the Abyssinian ibex or walie (*C. walie*); and the great Himalayan ibex (*C. sibirica*); which ranges over the high mountains and plateaus of all central Asia, keeping as near the snow-line as possible, and affording the best sport known to that region of game.

Ibicuhy, ē-bē-kwē', or **Ibicui, Brazil**, an affluent of the Uruguay River, which rises in the Serra de Santa Anna, province of Rio Grande do Sul, and after a westward course of about 400 miles joins the Uruguay at Yapeyu opposite St. Martin in Argentina.

Ibilao, ē-bē-lä'ō, a head hunting Philippine tribe inhabiting the border lands of the provinces of Nueva Ecija and Nueva Vizcaya in the central part of the island of Luzon. They are heathens, of the Malay race, with an infusion of Negrito blood. See PHILIPPINE ISLANDS.

I'bis, a family of wading-birds (*Ibididæ*) inhabiting warm regions. They are related to the storks on the one hand and to the spoonbills and flamingoes on the other. Their bills are long, weak, curved, and the nasal grooves are very long. The legs are long, the tibia partly naked, and the toes long with small webs. In size they are like herons, rather less than storks; and in color present a great and beautiful variety of tints, often with a metallic sheen; the sexes are similar. Ibises are shy birds, which inhabit not only watery and wooded country, but dry plains and rocky gorges. They perform a powerful and elevated flight, extending their neck and legs, and uttering a hoarse croak. They ordinarily wade for their food, poking in the mud with the long bill for aquatic insects, worms and small shellfish; they also catch fish, and on land eat insects, especially locusts, frogs, newts and crustaceans. Some species breed in communities, like herons, others apart, but the nest is always a rude cradle of sticks on a tree or ledge of rocks and occasionally on marshy ground, and the eggs are usually green, with or without markings. There are 12 or 15 genera and a large number of species scattered throughout the whole tropical zone. The typical genus, *Ibis*, contains the sacred ibis (*I. æthiopica*), called by the natives of upper Egypt *abu Hannes*, or "Father John," which arrives in Egypt about the time that the inundation of the Nile commences, its numbers increasing or diminishing with the increase or diminution of the waters; and it migrates southward about the end of June. This species is about the size of a fowl; the head and neck are bare; the body white; the wing tipped with shining, ashy black, among which the white forms oblique notches; the secondaries and scapulars, which in summer curve gracefully over the hinder parts, are bright black. This was one of the birds adored by the ancient Egyptians, and of which numerous mummies are found. The Greek and Roman writers give many fabulous stories relating to ibis, which Savigny has gathered in 'Histoire Naturelle et Mythologique de l'Ibis.' He concludes that the reverence for this ibis was not due to its alleged destruction of snakes, which, in fact, does not occur, but arose from the birds' return at the time the Nile began to rise, the commencement of the season of abundance. Modern writers on Egyptian customs and antiquities may be consulted further on this point. Many other interesting species occur in Africa, Asia and the Australian region; and many species reside in the American tropics,— two, the white ibis (*Eudocimus albus*) and the scarlet ibis (*E. ruber*), flocking in summer in the southern United States. Both are birds of extreme beauty of plumage, and both have been so ruthlessly persecuted by plume-hunters, seeking feathers of millinery purposes, that the scarlet ibises are nearly exterminated.

Wood-ibises and shell-ibises are names for birds of other groups, elsewhere described.

Ibn Sina, ĭb'n sē'nä. See AVICENNA.

Ibsen, Henrik, hĕn'rĭk ĭb'sĕn, Norwegian novelist and dramatist: b. Skien, Norway, 20 March 1828: d. Christiania, 22 May 1906. At 16 he became apprentice to an apothecary at Grimstad, a small village on the southeast coast of Norway, and here were composed his first works, 'Hösten,' a poem, and 'Catilina,' a play published in 1850 over the signature Brynjolf Bjanne. After a few months at the University of Christiania in 1850, where he wrote 'The Warrior's Mound,' played at the Christiania Theatre that year, he became manager of the new National Theatre at Bergen and turned his attention directly to dramatic composition. In 1856 his 'Banquet at Solhaug,' a Norwegian historical drama, was produced here, and from 1857 to 1862 he was manager of the Norwegian Theatre at Christiania. To this period belong his historical plays, 'Lady Inger of Östraat' (1857); and 'The Vikings at Helgeland' (1858); 'The Comedy of Love' (1862), and several poems. His greatest historical drama, 'The Pretenders,' appeared in 1864, and indignant at the political position of Norway at the time, Ibsen then left Norway to be absent (save for short visits) for, as it is proved, 27 years, living for a time in Germany and then in Trieste and Rome. His noble dramatic poem, 'Brand,' was first published in 1866, and the Storthing thereupon voted him the "poet's salary." In 1867 appeared the famous dramatic poem, 'Peer Gynt,' followed by a political comedy, 'The League of Youth' (1869); and the play, 'Emperor and Galilean,' his longest work (1873). In 1864 he returned to Norway for a short visit and was everywhere enthusiastically welcomed. His subsequent works include the social dramas which are the basis of his fame: 'The Pillars of Society' (1877); 'A Doll's House' (1879); 'Ghosts' (1881); 'An Enemy of the People' (1882); 'The Wild Duck' (1884); 'Rosmersholm' (1866); 'The Lady from the Sea' (1888); 'Hedda Gabler' (1890); 'Master Builder Solness' (1892); 'Little Eyolf' (1894); 'John Gabriel Borkman' (1896); 'When we Dead Awaken' (1900); 'Digte' (poems) appeared in 1871. By Ibsen's countrymen the poems 'Brand' and 'Peer Gynt' are considered his greatest works, both being intensely national, but nevertheless of universal application. Brand, the hero of the first, represents a protest against compromise, while 'Peer Gynt,' sometimes styled "the Scandinavian Faust," is an analysis of the human soul. The modern life dramas are the works by which Ibsen is best known to the world at large. The setting only is Norwegian, the lesson they convey is of world-wide extension. 'The Pillars of Society' is an attack upon hypocrisy as exemplified in the principal personages in a small town, while 'A Doll's House,' which has had a wide popularity in America, is concerned with the failure of marriage. 'Ghosts' is perhaps the most impressive and awesome of all of Ibsen's works, its theme being the consequences of hereditary vices. 'The Wild Duck' and 'Rosmersholm' are gloomy, despairing dramas; 'Hedda Gabler' presents in the character of Hedda a woman of the undomestic, selfish type, while the fearful price of success forms the motive of 'Master Builder Solness.' The theme of 'A Doll's House' is in effect that of 'Little Eyolf,' but in the latter Ibsen, who has hitherto seemed pessimistically to foretell the dissolution of modern society, now admits a hope of its regeneration. Over Ibsen's works a vast amount of controversy has arisen, and he has been fiercely assailed as cynical and even immoral, and as zealously defended. The truth of the matter appears to be that he was *par excellence* the poet of protest against social sophistry, and that he unerringly indicated the danger spots in modern life. There is nothing conventional in the construction or motive of his plays. More than once the climax of the play is represented as occurring prior to the opening of the drama which is concerned only with the consequences. Ibsen made a deep impression upon the literature of his century and his fame is not likely to decrease. Consult: Brandes, 'Henrik Ibsen,' in 'Eminent Authors of the 19th Century' (1886); Jaeger, 'Henrik Ibsen: a Critical Biography' (1890); Wicksteed, 'Four Lectures on Henrik Ibsen' (1892); Shaw, 'The Quintessence of Ibsenism' (1893); Boyesen, 'A Commentary on the Writings of Henrik Ibsen' (1894).

Ica, ē-sä', Peru. (1) A littoral department bounded north by the department of Huancavelica, east by Ayacucho, south by Arequipa, and west by the Pacific Ocean. Area, 8,718 square miles; pop. (1896) 90,962. (2) A town, capital of the above department on a river of the same name, 46 miles southeast of Pisco on Pisco Bay, with which it is connected by rail. It was founded in 1563. It is in a grapevine and sugar-cane producing region and has manufactures of wine and brandy. Pop. 9,000.

Ice, water in the solid state. When sufficiently cooled, water loses its fluidity, and becomes filled with multitudes of needle-like crystals belonging to the hexagonal system (see CRYSTAL), which increase and interlace until the whole mass becomes solidified. In nature, this change begins at the surface of the water and spreads gradually downward, so that the exact course of the freezing is not so easy to trace as it is in the laboratory, where the water can be uniformly cooled throughout its entire mass. When the freezing process is complete, the crystalline nature of the solid that results from it is not at all obvious. It is clearly visible, however, in snow-flakes, where the hexagonal form is also evident. In a solid block of ice the crystalline structure can also be demonstrated by a method that was used with much success by Tyndall, as a beautiful and instructive lecture experiment. The image of a slab of pure ice is thrown upon a screen by means of a projection lantern provided with a powerful electric light. At first nothing is seen, but very shortly the heat-rays passing through the ice cause it to melt internally, and the melting takes place according to the internal crystalline structure, which is gradually brought out upon the screen in great beauty. Six-sided stars, suggestive of the snow-crystals, appear, and these enlarge and become serrated at the edges as the electric beam gradually destroys the molecular architecture, the process continuing until the ice has been again reduced to the liquid form.

Pure water normally freezes at a temperature which is denoted by 32° on the Fahrenheit scale, and by 0° on the centigrade and Réaumur scales. It is possible, however, to cool pure water to a temperature considerably lower than this, if proper precautions are taken. As long ago as 1836, for example, Gay-Lussac observed that water, when placed in a vessel and covered with a layer of oil, may be cooled to 10° F. without freezing. If the vessel be slightly shaken or jarred, however, solidification ensues at once.

Pressure has a slight effect upon the temperature at which water freezes. This effect was predicted, from theoretical considerations, by James Thomson, in 1849. Dewar has since measured its amount with much care, finding that the freezing temperature is lowered by 0.014° F. for each atmosphere of pressure. Small as this quantity is, it is of importance in some branches of physics. In 1858 Mousson, by the application of an enormous pressure, succeeded in reducing the freezing point to 4° below zero, Fahrenheit. The presence of dissolved substances in the water also depresses the freezing point. Sea-water, for example, freezes at about 27° F. (the ice that is formed being nearly free from salt), and strong brine is used in the circulating pipes and cooling coils of refrigerating plants, since it can be cooled much below this temperature without freezing.

The effect of pressure in lowering the freezing point is illustrated in the familiar process of making a snow-ball from damp snow, — that is, from snow whose temperature is precisely 32° F. Under the pressure of the hand, the freezing point of the snow mass is lowered slightly, with the result that a partial melting of the crystals takes place. When the pressure is removed, the freezing point rises to its normal position, and the water that was formed by the pressure alone freezes again, and cements the mass together. (The superficial moisture, due to the warmth of the hand, is not here contemplated. The melting from this cause is a separate phenomenon.) The slight but real plasticity of large masses of ice, such as are met with in glaciers, is probably related to this phenomenon of the variation of the freezing point by pressure, but there is some difference of opinion among the authorities as to the precise way in which the slow downward flow of these ice masses is accomplished. The melting of ice by pressure, and its subsequent solidification upon the removal of the pressure, is known to physicists as «regelation».

Experiments that have been conducted in connection with precise thermometry, by Pernet and Marek, show that the temperature of melting ice is slightly different, according to the source of the ice, and the way in which it is treated; this variation being independent of the pressure, and existing even when the ice is sensibly pure. A variation in the melting point of as much as 0.164° F. has been observed; and in order to eliminate the effects of error from this cause, it is necessary, for the purposes of precise thermometry, to adopt a uniform mode of procedure in the treatment of the ice that is to be used for the establishment of the freezing point upon accurate thermometers. (Consult: Guillaume, 'Thermométrie de Précision,' ch.ii.).

When water that contains solid matter in solution or in suspension is frozen, the solid matter is mostly eliminated, so that the ice is much purer than the water from which it is produced. Some of the solids are almost invariably entangled among the interlacing crystals of the ice, however, so that numerous little particles of foreign matter often remain in the ice, imprisoned in tiny cavities. Bacteria and other germs that may have been present in the original water appear to be largely excluded from natural ice by the freezing process, though some of them are undoubtedly caught among the crystals and retained. In artificial ice, where a mass of water is frozen simultaneously on all sides, so that the solidification proceeds from the outside toward the centre of the cake in all directions, purification from this cause is hardly possible, and the middle part of the ice-cake is likely to be rich in whatever germs the original water may have contained. Fortunately the recent experiments of Sedgewick and others indicate that freezing and protracted storage of the ice is much more fatal to typhoid bacilli than was formerly supposed. Artificial ice, if prepared from distilled water, or from water that is certainly known to be free from disease germs, is undoubtedly safer than natural ice that is taken from streams or ponds of unknown purity; but in choosing between natural and artificial ice from the same identical water, the preference should be given to the natural product.

Water expands upon freezing, one volume of water at 32° F. becoming transformed, by freezing, into 1.0908 volumes of ice at the same temperature; which is equivalent to saying that water expands by one-eleventh of its own bulk upon freezing. The quantity of heat required to melt one pound of ice, from the state of ice at 32° F. to that of water at 32° F., is 142 times as great as the quantity of heat required to raise the temperature of a pound of water from 32° F. to 33° F. The specific heat of ice, near the temperature 32° F., is approximately 0.50.

Ice Age. See GLACIAL PERIOD.

Ice, Artificial. See ICE INDUSTRY.

Ice Boat. See ICE YACHTS and ICE YACHTING.

Ice-breaker, a vessel, especially a strong, heavy steamer, with powerful engines, for opening up navigable channels in frozen waters. On the Great Lakes of the United States, where such vessels are extensively used, they are generally fitted for carrrying cargoes or transporting railroad cars. Such vessels are usually so built as to run their bows up on the ice and break it by means of their great weight. An ice-breaker called the Yermak, built in England in 1899, for use in Russian waters, is 305 feet long, with 71 feet beam and draft of 25 feet. She did good harbor work in polar ice in 1900, but proved unequal to the heavy pack of the sea. Admiral Marakoff of the Russian navy, who superintended her trials, believes that the best way to reach the north pole is by means of a powerful ice-breaker, using liquid fuel instead of coal.

Ice Industry. Though the use of natural and artificial ice as an article of commercial value practically began only in the first part of the 19th century, yet the artificial production of cold began long before it was generally supposed to have been thought of.

In Greece and Rome during the early ages snow was more commonly used, being placed in cone-shaped pits 45 feet in diameter, 50 feet deep and lined with straw and prunings of trees. The snow was packed down and covered with more straw and prunings, over all of which a thatched roof was placed; after the ice was formed it was cut and carried out through a door left in the side of the pit for the purpose. During the 16th century snow and ice was stored in cellars for the purpose of cooling drinks. This custom spread from Greece and Italy to Western Europe and to France during the reign of Henry III. in the 16th century and by the end of the 17th century the sale of snow and ice had become a profitable trade. From that time until the beginning of the 19th century the ice trade was practically at a standstill, no material advance was made in the direction of improving the methods of harvesting the ice supplied by nature, nor was any attempt of any importance made to produce artificial ice. For purposes of description and comparison, ice may be divided into two classes, the natural and the artificial.

Natural Ice.— Probably the first ice cut and shipped as an article of commercial value was sent, in 1799, from New York to Charleston, S. C. This cargo was cut from a pond near Canal street. While this shipment was the first recorded it was of little importance; the real beginning of the industry came in the year 1805 when Frederic Tudor, of Boston, shipped a cargo of 130 tons to the West Indies. This resulted in a loss of $4,500, and Tudor's second shipment, two years later to Havana, likewise was made at a loss enormous for those days. He stuck to the business, however, and finally, in 1812, was granted by Great Britain a monopoly of the trade with her colonies in the West Indies, and later, in 1815–16, Spain granted him the same concession to export to Havana. In 1817–18 the trade was extended to Charleston and Savannah; to New Orleans in 1820; to Calcutta in 1833; and to Rio Janeiro in 1834. Thus a large and lucrative trade with southern countries and southern cities of the United States was built up; competitors began to come into the field, the first of these to enter the export field being the firm of Gage, Hittinger & Co. of Boston who introduced American ice to the people of London. They were in turn followed by a Salem merchant named Lander, and others. The Treasury Department gives the following figures for the export trade from 1850 to 1900:

Year.	Tons.	Value.
1850	....	$107,018
1855	41,117	190,793
1860	49,153	183,134
1865	59,927	225,825
1870	65,802	267,702
1875	53,724	208,249
1880	45,666	136,686
1885	38,901	89,420
1890	44,849	111,762
1895	17,295	41,915
1900	13,720	29,501

The harvest of natural ice is gathered on an enormous scale in the United States, the demand for the article being due in a large measure to the growth of other industries to which ice was a necessity. Before Croton water was introduced into New York and as far back as 1825, ice was cut on Sunfish pond, on the outskirts of the city, by some butchers who desired to preserve their stock of meat. In 1826 ice was cut on Rockland Lake, and at first all the ice cut was stored in the ground but later storehouses at Hubert street and Christopher street were built, and as the demand for ice gradually developed in all the larger eastern cities, large storehouses were erected nearby the places where the ice was cut. The capacity of these houses ranges from 10,000 to 90,000 tons and in size run from 100 to 150 feet in length by 30 to 50 feet in width. For gathering the ice there is an elaborate system of apparatus, but the usual methods employed are as follows: After the snow is cleared from the ice by means of scrapers or snow-plows, an ice-plow, either propelled by steam or drawn by horses — the latter means more commonly used — cuts deep grooves in the ice in one direction and then repeats the operation at right angles with the first, thus forming a perfect square, measuring a little more than 3 feet. As these grooves extend nearly through the ice it is a simple matter to saw through the remaining thickness, pry the cakes loose with crowbars, and float them to the icehouses through channels provided for the purpose. Upon reaching the icehouse the cakes are lifted on an elevator, run into the house, and packed in sawdust or other suitable material, to be held there in storage till needed.

The cost of harvesting a ton of natural ice varies greatly; it depending to a great extent upon the weather conditions, both during the process of the formation of the ice and during the process of cutting and housing. Under average conditions the cost of harvesting amounts to about 80 cents, though under very favorable conditions it has been known to have cost only from 25 to 30 cents per ton, but this has not been often. This, of course, does not include the cost of transportation, delivery, etc., and as the majority of the icehouses are a considerable distance from the centers of consumption, the cost of transportation is a large factor. The following figures, taken from 'The Ice Journal' give the quantities of ice harvested in Maine and on the Hudson River, the two most important fields of operation in the whole country:

Year.	Maine Tons.	Hudson River Tons.
1878	....	2,225,000
1879	....	2,371,000
1880	1,426,800	800,000
1881	904,800	2,558,000
1882	1,227,200	1,954,700
1883	1,364,500	3,017,600
1884	1,118,000	3,026,000
1885	1,490,400	3,010,500
1886	1,368,400	2,355,500
1887	1,311,100	3,266,000
1888	1,037,000	3,330,500
1889	1,529,600	2,742,000
1890	3,092,400	....
1891	1,285,000	2,624,000
1892	1,435,000	2,500,000
1893	1,444,000	3,407,839
1894	1,600,800	2,638,500
1895	1,413,500	3,409,000
1896	1,466,000	2,735,500
1897	1,526,500	2,675,033
1898	1,242,500	2,172,400
1899	1,326,430	4,300,293
1900	723,780	1,430,670

The moving of this enormous quantity of ice necessitates the maintainance of a large fleet of barges and other boats for the domestic trade, and of sailing vessels for the export trade, and to the cost of maintaining these vessels, when figuring the cost of harvesting, must be added the cost of towing, loading, discharging, dock and stable rent, repairs of boats, icehouses, and wagons, etc., all this before the ice is placed in the hands of the retailer.

The tools used in harvesting this crop are many and varied, and the manufacture of them has become a large and valuable source of income to several concerns in this country who have made this a specialty. Many of the ice tools now in use were invented by Nathaniel Wyeth and John Barker, of Boston. The ice plow was invented in 1830 and the patent clearing-tooth in 1872. Some of the most common tools now in use are: the snow-scraper or plane, the masher and the plow; augers and axes for tapping the ice in order to drain off surface waters; saws; forked bars for prying the cakes loose; trimming bars for squaring the cakes after loose; adzes, edging tongs, and chisels used in packing the ice when in the storehouse; saws and bars for prying loose previous to shipment; and tongs, scales, axes, etc., used on the retail delivery wagon.

Artificial Ice — The manufacture of ice as an industry was begun as early as 1866, but only reached a degree of commercial importance about 20 years ago. The beginning was naturally made in the Southern States, but as it became more generally used, factories sprang up over the entire country. The growth of the "infant industries" throughout the United States gave this industry an added stimulus, because the supply of natural ice was by far too small to meet the requirements of slaughtering and meat packing-houses, refrigerator cars, cold-storage warehouses, etc.

The growth of the industry from its inception may be seen in the following statistics:

	1900.	1870.
Number of establishments	787	4
Capital	$38,204,054	$434,000
Salaried clerks, officials, etc.	1,545	....
Salaries	$1,234,803	....
Wage-earners	6,933	97
Wages	$3,424,305	$40,600
Miscellaneous expenses	1,779,890	....
Cost of materials used	3,339,724	82,165
Value of product	13,874,513	258,250

The first experiments for making artificial ice for mercantile uses started with the Italians in the 16th century. The first machine used for the actual manufacture was invented by Dr. William Cullen, this being based on the vacuum principle, the atmospheric pressure being reduced by means of an air pump. Later, in 1795, several experiments were made by a Mr. Walker of Oxford, England, in the line of freezing mixtures. Prof. Leslie, of England, produced a considerable degree of refrigeration by including in the exhausted receiver of an air-pump, sulphuric acid, a substance rapidly absorbing vapor. In 1834 Jacob Perkins, an American engineer residing in London, obtained a patent for a machine generally credited with being the forerunner of the modern compressor machine. The refrigerant used in this machine was ether and brine was circulated at a temperature of 5° Fahrenheit through pipes which encircled the evaporator containing the ether. After running through the pipes the brine flowed into a receptacle containing boxes filled with water and thus the water was frozen. Later experiments were made by French and German inventors, boxes were supplanted by cans and this developed into the manufacture of can ice. Many of the improvements made in the ice-making apparatus are due to the efforts of Prof. A. C. Twining, of New Haven, Conn. He patented an ice machine in England in 1850 and in the United States in 1853; in 1855 he invented a machine, and put into active operation in Cleveland, Ohio, which produced 1,600 pounds of ice in 24 hours; and later discovered that ice would be transparent, with the exception of a small porous core, if frozen at a temperature slightly below the freezing point. In 1857 Dr. John Gorrie of Appalachicola, Fla., patented his ice-making machine; this was later followed by the compressed-air machine of Dr. Alexander Kirk; in 1858-60 the machine, upon which the modern ammonia absorption system was founded, was brought forth by Ferdinand P. E. Carre; and later the plate-ice system was introduced by Capt. David Smith, of Chatham, Mass., who erected the first machine of this character in the United States at Oakland, Cal. There have been nearly 4,500 patents taken out in the United States alone for refrigeration processes.

Two systems of making ice are now used, the compressor, and the absorption systems, the former the more generally used. The first step is the compression of the anhydrous ammonia (that is, ammonia which contains no water) into the gaseous form by means of a steam pump, a pressure of from 125 to 175 pounds per square inch being exerted. The next step is to reduce the gas to a liquid state by passing the ammonia through pipes which are in contact with the cold water or some other cold substance. The gas as the beginning contained a certain degree of heat, but by the condensation process this heat is eliminated, and, after being reduced to a liquid state, the ammonia reaches the third and last process, that of expansion. As the ammonia in the liquid state reaches the pipes which are in contact with the water to be frozen, it becomes gaseous because of the expansion, its temperature is thus reduced below the freezing point of water and so draws from the water the heat which was taken away by the condensation process. This results in the freezing of the water.

In the absorption process aqua ammonia is first converted into gas by the application of heat which raises the pressure to from 120 to 160 pounds per square inch. The ammonia is then reduced to liquid form by being passed through pipes in contact with cold water. The ammonia is then changed from a liquid to a gaseous form by the expansion process, the methods being the same as in the compressor system. The expansion draws out any heat in the gas, which, as it passes through the pipes in contact with the water to be frozen, absorbs the heat from them till they are of a like temperature.

A large portion of the ice manufactured in the United States is produced by the can system or the plate system. In making ice by the can system the water is first boiled and allowed to settle, in order to free the ice from any foreign substances and to reduce it to the greatest possible degree of purity. The water is then distilled, boiled again, and run through three kinds of filters. A series of tanks, containing a strong solution of brine, is placed under the freezing room, and through this brine run the pipes containing the liquefied ammonia gas. Into the tanks containing the brine are submerged the cans holding the water to be frozen. As in the compressor system, the ammonia in the pipes is expanded into gas as it passes into the brine, and absorbs enough heat from the brine and water to form the water in the can into ice. The whole process requires from 20 to 66 hours, according to the size and weight of the blocks of ice and to the temperature of the brine. The can is then raised from the tanks by means of a hoist and dipped into a well of warm water to loosen the contents.

The production of ice by the plate system is much slower and more cumbersome. In this process the tank contains the water to be frozen and into it is placed a hollow iron plate holding the coils of pipe filled with the freezing medium. Thus the ice is formed on the outside of the iron plate, is taken out and removed, and is then ready for use.

The cost of producing a ton of ice averages throughout the country for all seasons of the year, between $1.10 and $1.50: the average price to the wholesaler ranges from $2 to $2.25; and the retail prices range from 15 to 40 cents per hundred weight according to the season. The changes and improvements in the methods of producing artificial ice have so reduced the cost of manufacture that it can now compete with the natural product.
