MAGNETIC OBSERVATIONS

FOR

THE YEAR 1897.

1. MAGNETIC OBSERVATORY.

It is placed within the circle of the Central Meteorological Observatory at the altitude 21m. above the sea-level. Its geographical co-ordinates are

Longitude 139° 45′ E
Latitude 35° 41′ N

The observatory had been established in 1890. It was rebuilt in July, 1897. It is wooden building, of which every precaution was taken to avoid the use of iron-articles, all nails being made of copper. The observation rooms are taken under the ground. There are two rooms, with the stair case running in the N-S direction between them. In the eastern there is set a Mascart's self-registering magnetograph, and in the western the apparatus for the direct reading.

2. ABSOLUTE MEASUREMENT OF MAGNETIC ELEMENTS.

Absolute measurement is made once every month, the horizontal intensity and the dip being generally observed three or four times and the declination in such a number that it is sufficient to obtain a curve of diurnal variation.

The declination and the horizontal intensity are measured by means of the instrument constructed by Prof. Tanakadate, which is described in a paper published in the Proceeding of the Royal Society of Edinburgh (1884-6) and also in the Journal of the college of Science, Imperial University, Japan (Vol. II., Part III.). It will be sufficient here to give a short description which is chiefly the extraction of the papers.

Declination.—The declinometer is built upon a theodolite which in its ordinary form serves for all the astronomical observations. The magnetometer stage resting on tripods is fitted to the centre of the theodolite base, being able to be fixed either to the base of the theodolite or to the Y's by means of a screw projected downward from the centre of the base of the stage. A telescope with a mirror and a lamp are fixed to the stage.

The magnetometer case is set upon the stage and can be levelled by four screws at the upper surface of the stage and centered by other four screws at its vertical sides. The magnet is a small hollow cylinder piercing a mirror centrally perpendicular to its plane. Mirror and magnet are

fastened to an aluminium stem, whose lower end is broadened, so that it may, when necessary, be securely gripped by means of a vice fitted to the lower part of the case. The suspension is made by means of a spider line.

The peculiar feature of the declinometer is a coil of wire, wound on a flat rectangular frame of brass in two separate parts, a certain portion in the middle being left vacant. Two pivots project from the middle of the sides in a direction perpendicular to the axis of the coil. These pivots are hollow, and are made of the same external diameter as those of the telescope belonging to the theodolite. The upper and lower surfaces are pierced so as to allow the magnetometer to project above the coil

To bring the coil into adjustment, it is necessary to operate as follows. Place the stage and magnetometer on the theodolite, and mount the coil with its pivots resting on the Y's. Adjust the Y's into an approximate east and west direction by sighting the freely hanging mirror edge-on through the pivot cores. Lay the coil horizontal, so that the ends of the coil now face north and south. Adjust the centering of the magnetometer and place the small telescope with attached scale and lamp-counterpoise in due position. Clamp the stage and all its bearings to the base of theodolite, thus rendering them quite free of the Y's and consequently the coil being able to be turned round independent of every thing else. The magnetometer stage is adjusted until some convenient division on the scale, as reflected from the magnet mirror, is brought to coincidence with the cross-wire of the observing telescope. Thus all things are prepared.

The coil is now put in circuit with a small dry battery. This is done by communicating it with the resistance box, whose terminals are joined to the poles of the battery and which enables to change the direction of the current. At the first trial the direction of the current should be such as to make the magnetic field due to the current in the coil have the same (general) direction as that of the earth. This is readily judged of by the quickened movement of the magnet. The reflected image of the scale will in general be seen to move. With the current always on, let the azimuth of the coil be shifted until the originally observed reading of the scale is brought back again to the cross wires. Since the magnetometer and telescope have been absolutely fixed in position during the whole operation, this gives to the first approximation the direction of the declination. The current is now reversed. In general, the result of this will be that the image of the zero scale reading will slowly move to one or other side of the cross wire. The resistance in circuit is then adjusted until the current is such as to cause the time of oscillation of the magnet to be some three or four times as long as that under the earth's force alone. The original division of the scale is again brought back to the cross wire by carefully adjusting the azimuth of the coil. If the current is now broken and the scale image does not shift, it is certain that the magnetic axis of the coil lies in the magnetic meridian. The reading on the theodolite gives it azimuth. An exactly similar observation is made with the coil reversed as regards east and west. Next, two such observations must be made in overturning the coil up and down. The mean of the four readings gives the declination at that instant corresponding to the mean of the two instances of the first and the last adjustments, quite independent of any errors resulting from any (slight) deviation from perpendicurality between the axis of the pivots and the line of magnetic force at the centre of the coil due to the current in it and from any deviation of the centre of the coil from that of the magnet. A complete observation usually takes four or five minutes.

Horizontal Intensity.—For the determination of the horizontal intensity, the declinometer must be removed and in its place a deflection bar substituted. The bar is made of brass and has a V-

groove on its upper surface—or rather two V-grooves extending the one to the east and the other to the west, when the instrument is mounted ready for use. Where the bar rests on the Y's, it is made in the form of a semi-cylinder—the upper surface being flat, the lower having the same curvature as the pivots of the theodolite telescope and the declinometer coil. Between the Y's, the bar swells out into an oblate ring, through which the magnetometer projects. A semi-circular groove is cut in front of the ring, so that the magnet mirror can be sighted by the small telescope. On the V-groove of the bar there are four stops two on each side of the centre. The deflection magnet rests in the groove, and the stops are so placed that the two distances of the magnet from the centre are obtained simply by slipping the magnet along the groove from one stop to the other, without having to lift it out. The stops are placed so as to make the ratio of the two distances the best possible, according to the usual rule.

The instrument is obviously available for use either according to the method of sines or the method of tangents. The former method is the preferable one; and, in using it, it is necessary to clamp the stage to the Y's, and free it from the base of the theodolite. The operations are then conducted exactly as with the Kew instrument. The temperature of the bar is measured by means of two thermometers placed in its opposite sides beyond the further stops. It is advisable to dust with a small brush the surfaces of the magnet and stop just before they are brought together. The chronometer time is taken as the final deflection is adjusted. The beginning of the experiment is given by the first time record in the vibration experiment, which it was found most convenient to make first. The mean of these times is taken as the time corresponding to the value of the horizontal force as finally deduced.

The vibration experiment is made in a vibration box somewhat similar in construction to the one used in the Kew instrument. It is mounted on a second tripod, so that the magnetometer stage need never be removed until the theodolite has to be used for the astronomical observations. The magnet is suspended by two loops of silk from the end of a silk fibre freed from twist in the usual way and its horizontality is well adjusted. A horizontal vibration of about half a degree is given to the magnet, and it is observed by means of a telescope. The observer signals the instant of transit of the middle point of the swing, and these are noted down by the recorder at some distance. The temperature is observed at the biginning and the end of the experiment with a thermometer attached to the inside of the glass window of the box, the mean of two readings being taken as the temperature in the vibration experiment.

For determining the horizontal intensity all the necessary corrections are applied. The torsion and arc correction are applied in the usual way; the time correction is applied so as to reduce the time-unit at once to the mean solar second; besides these we may mention the corrections for induction, expansion of steel magnet and of the brass which constitutes V groove on which the magnet is to be placed in the deflection experiment, and the correction for the temperature difference in the vibration and the deflection experiments.

The vibration experiment is usually taken before the deflection experiment From the first recorded swing to the last deflection adjustment the whole experiment generally takes about 20 minutes.

Dip.—The observations of dip are made by means of a dip circle Cassela 17. The magnetization

of the needle is reversed by means of an electro-magnetic coil. A complete observation usually takes 20 minutes.

The astronomical meridian is sometimes determined by observations of circumpolar stars or of the sun. Thus, the azimuth of the top of a tower of a Cathedral Nicoli at a distance of about 1.5 k.m. is often tested. The reading of the meridian is usually reduced from that of the object.

3. PHOTOGRAPHIC RECORDS OF MAGNETIC ELEMENTS.

Photographic records of magnetic elements are made by means of a Mascart's magnetograph. Let us shortly describe the arrangement of the instrument and the method of reduction.

THE ARRANGEMENT OF THE APPARATUS.

Declinometer.—It is contained in a metal case with a tube on its cover. From the upper end of the tube, a magnet with a mirror perpendicular to its direction is freely suspended by means of a fine silk thread. There is a second mirror fixed to the base of the case. Thus, the rays of light falling upon the two mirrors reflect on a photographic paper moving by a clock-work, one tracing the curve of variation of the direction of the magnetic needle and the other the fixed line.

Bifilar.—Its construction is similar to that of declinometer. But, in this case, the magnet with a mirror parallel to its direction is suspended by means of two fine silk threads and put in equilibrium in the direction perpendicular to the magnetic meridian in virtue of the couples due to the horizontal intensity and the torsion. Its sensibility can be adjusted by regulating the distance between the two points of suspension. The light reflected from the mirror traces the variation of the horizontal intensity.

Balance.—It is a magnetic balance with a hole in its central portion. There is, in the hole, a knife-edge, by means of which the magnet rests on an agate plane, and the magnet is placed horizontally by adjusting the position of its centre of gravity by means of a small index attached to it, the couple due to the vertical intensity equilibrating with that due to gravity. The sensibility can be adjusted by means of two weights movable in the horizontal and vertical ones attached to the magnet. The whole is contained in a metal case. There are two horizontal mirrors, one fixed to the case and the other to the magnet. At the central portion of the cover of the case, there is a hole on which an isosceles rectangular prism is placed, the two faces being, put horizontally and vertically. Thus, the light falling upon the vertical face of the prism is refracted towards the mirrors and again reflected and traces the variation of the vertical intensity and the zero line.

METHOD OF REDUCTION.

Declinometer.—By turning the case through a known small angle and measuring the deviation of reflected light from the fixed mirror, we can obtain the angular value for any ordinate of the curve, the effect of torsion being found to be negligible. The value for 1 m. m. was 1′.47.

Bifilar.—Putting a the half sum of the deviations of declinometer, caused by a horizontal magnet in two positions, once N-pole to the east and the next to the west, and n that of deviations of bifilar when the same maget is placed, once its N-pole to the north and then to the south, we have the formula

$$\triangle H = \frac{H \tan a}{n},$$

where $\triangle H$ denotes the variation of the horizontal magnetic intensity H for unit deviation.

Balance.—Putting I the dip, and m the half sum of the deviations of balance, caused by the magnet formerly used, when its N-pole is placed vertically upward and downward, we have the formula

$$\triangle Z = \frac{Z \tan a \cot I}{m}$$

where $\triangle Z$ denotes the variation of the vertical magnetic intensity Z for unit deviation.

Their mean values for 1 m. m. in each month were as follows :—

	△ H (in C.G S. units)	△ Z (in C.G.S. units)		△ H (in C.G.S. units)	△ Z (in C.G.S. units)

TEMPERATURE COEFFICIENTS OF BIFILAR AND BALANCE.

The temperature of the room where the photographic record is always made can not be constant, the range in a day sometimes amounting to nearly 1° C. Thus, the temperature-coefficients of the bifilar and the balance were determined on June 1, 1898. The method employed was to heat the room by burning the charcoal in suri-bachi (an earthen-ware), the fire being regulated by looking at the self-recording thermo-graph placed in the room, while the observation of the direct-reading system in the other room was made at the same moment when the temperature in the main room was observed. Six suri-bachi were distributed in the room, and the temperature was observed with the thermometers attached to the balance, the bifilar and the thermograph. Three simultaneous readings did not differ more than 0°.4 C. and the range of temperature during the experiment was about 2°. Eliminating the deviation due to the variations of magnetic elements by means of the observation of direct reading system, the following values of coefficients were obtained.

TEMPERATURE COEFFICIENT OF BIFILAR

Time	Temp. diff.	Deviation in m.m.	Deviation in m.m. for 1°.
9h 18m a	0	0	—
11 08 „	9°.0	42.51	4.73

3 13 „	9.1	45.76	5.03
3 39 „	8.9	45.23	5.08

Thus the temperature coefficient in absolute value is

$$4.95 \times .00004183 = .0002073 \text{ C. G. S. units,}$$

.00004183 being the value for 1 m. m. during the experiment.

$$4.16 \times .00007319 = .0003045 \text{ C. G. S. units,}$$

.00007319 being the value for 1 m. m. during the experiment.

4. DIRECT READING SYSTEM.

The system is essentially the same as the self-recording magnetograph. By means of this system, the variations obtained by photographic records are often tested.

5. HARMONIC ANALYSIS OF DIURNAL VARIATION OF MAGNETIC ELEMENTS.

Expressing the mean of hourly values of magnetic elements for every month and the year by means of a formula

$$f(t) = p_0 + p_1 \cos t + q^1 \sin t + p_2 \cos 2t + q_2 \sin 2t + p_3 \cos 3t + q_3 \sin 3t + p_4 \cos 4t + q_4 \sin 4t,$$

the coefficients p_0, p_1, q_1, p_2, q_2, p_3, q_3, p_4, and q_4 were calculated.

Comparing the calculated and the observed values for the year, the following results were obtained:

	Sum of squares of Residuals
Declination	0.0736
Horizontal Intensity	789.50
Vertical Intensity	339.57

the unit being minute for declination and .000001 C. G. S. units for horizontal and vertical intensities.

OBSERVATIONS

OF

ATMOSPHERIC ELECTRICITY

FOR

THE YEAR 1897.

The electric potential of the atmosphere is measured by means of a Thomson and Mascart's self-recording quadrant electrometer. Let us shortly describe the apparatus.

The electrometer is contained in a metal case, on the cover of which is the tube which supports the bifilar suspension, and it allows three electrodes to pass, which are respectively in connection with the quadrants and the needle. Two of electrodes are connected with the pairs of quadrants, their other ends being put in connection with the two poles of a battery formed of 30 or 50 water cells, as the case may be, the middle of which is to the earth. The third is connected to the needle by means of the glass vessel containing sulphuric acid, in which are immersed, on the one hand, a platinum wire attached to the electrode, and, on the other hand, a prolongation in platinum of the axis of the needle, having two leaves between the quadrants.

Sir William Thomson's water dropping apparatus is used to collect the atmospheric electricity. It is a cylindrical cistern of copper, placed in the room next to that where the photographic record is taken. The cistern rests on three glass pillars covered with brass, each one projecting from the interior of a glass vessel containing sulphuric acid and the mouth of the vessel being sheltered with a brass-cover so as not to touch it. A pipe of about 2 metres in length projects towards the west from the cistern into the atmosphere, and from a very small hole at its extremity (1.7 m. above the ground) the water splashes out and breaks almost immediately into drops. The cistern is thus brought to the same potential as that of the atmosphere, near the extremity, and this potential is communicated to the needle with a mirror through the third electrode above mentioned. Thus, in accordance with the variation of electric potential of the atmosphere, the mirror is turned about, so that the light falling upon the mirror reflects to a photographic paper moving by a clock-work, the fixed line being obtained by the light reflected from the glass window at the front of the electrometer.

Owing to the existence of moisture, the zero point is sometimes changed, and therefore it is recorded two times a day by stopping the water spout and connecting the cistern with the earth. Also, to prevent such an error, the sulphuric acid in the instrument is renewed almost every weak.

The sensibility is measured every week by means of a water battery formed of 50 cells. Its mean value for each month is as follows :—

	Value for 1 m. m. (in Volts)
January	3.45
February	3.86
March	2.97
April	3.13
May	3.23
June	1.73
July	1.36
August...	1.15
September	2.36
October	1.61
November	2.13
December	2.69

Lastly, it is to be noticed that, since the curve of electric potential of the atmosphere is in general of zigzag nature, the potential is measured by drawing the mean curve.

HOURLY VALUES OF MAGNETIC ELEMENTS AND ATMOSPHERIC ELECTRICITY FOR THE YEAR 1897.

Time.—

Time is given in the Central Standard Time (the mean time for the meridian 135° E).

Magnetic Elements.—

Declination is measured in degrees and minutes, and the two intensities in C.G.S. units.

The characters of the diurnal variation of the magnetic elements are devided into 5 classes : Calm (C), Agitated (A), Light storm (S°), Storm (S), and Severe Storm (S'), the specimens of which are given at the end of the volume.

Atmospheric Electricity.—

The electric potential is measured in volts.

Weather conditions are represented by international symbols.

The values with the sign × are omitted in taking daily and monthly means, for they do not indicate the normal electric condition in consequence of rain, mist or some other causes.

The sign ± indicates that the oscillation is so rapid that we can not definitely say whether the potential at the corresponding time is positive or negative, the sign + or — the value either too high or too low to be traced on the photographic paper (but the sign − before a number means "negative").

The sign ·· indicates the want of photographic record, owing to the weakness of the light of lamp, the stopping of Clock, etc.

in which t is the Central Standard Mean Time (mean time of the meridian 135°E) converted into arc, and $f(t)$ the mean value of the magnetic element at the time t for each month and for the year.

The values of the Coefficients for Declination are given in degrees and minutes of arc and those for Horizontal and Vertical Intensities in 0.000001 C. G. S. units.
