PHARMACEUTICAL JOURNAL.

THE
PHARMACEUTICAL JOURNAL

ESTABLISHED 1841.

A Weekly Record of Pharmacy and Allied Sciences.

FOURTH SERIES—VOLUME II.

COMPLETE SERIES—VOLUME LVI.

JANUARY TO JUNE, 1896.

LONDON :
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN,
17, BLOOMSBURY SQUARE, W.C.

THE PHARMACEUTICAL JOURNAL

ESTABLISHED 1842

A Weekly Record of Pharmacy and Allied Sciences

W. I. RICHARDSON, PRINTER,
4 AND 5, GREAT QUEEN STREET, LINCOLN'S INN FIELDS,
LONDON, W.C.

INDEX TO VOLUME II.

(FOURTH SERIES.)

The References in Roman Figures are to Pages in the Weekly Supplement to the Journal.

A

- Aaler, Dr.—Conium Extract in Anal Fissure, 139.
- Abbreviations, Misleading, of Pharmaceutical Titles, 154.
- Aberdeen and North of Scotland Society of Chemists and Druggists, 259; (The Companies Bill, 458; (Annual Picnic), 473.
- Aberdeenshire, East, Chemists' Association (Annual Dinner and Meeting), 18.
- Abney, Capt. W. de W.—Orthochromatic Photography, 430.
- Acacia Gum, Export of, from Suakim, 344.
— Mucilage of (McKellar), 214.
- Acetic Acid, Chloroform from (Squibb), 212.
— Acid, Trichlor, in Chronic Cystitis, 177.
- Acetum Destillatum? What is (Boot), 13, 18; (Corder), 40; (Proctor), 50; (Deck), 80; (Mumbray), 120.
- Acetylene and Pyrophori (Moissan and Moureu), 501.
— as a Tram-Car Illuminant, 505.
— Gas, the Production of (Wigham), 259.
— Its Detection and Ignition in Air (Clowes), 516.
- Acid, Camphoric, Derivatives of (F. S. Kipping), 434.
— Excretion of Roots, The (Czapek), 503.
— Filicic, Assay of (Dacomo and Scocianti), 417.
— Hydrobromic, A Dangerous Impurity in (Cowley), 385.
— Oxalic, As a Colour Preservative (Schroeder), 244.
— Tartaric, The Constitution of a New Acid resulting from the Oxidation of (Fenton), 254.
- Aconitine, The Detection of (Dunstan and Carr), 122, 126; ("A Reader"), 160.
— The Estimation of (Dunstan and Tickle), 121, 126.
- Acrogamous and Basigamous Fertilisation (Tieghe), 242.
- Adulteration, Report of the Parliamentary Special Committee on, 490.
— Select Parliamentary Committee on, Work of the, 210.
- Aërated Water Bottles, Damage to (Sheffield), lxxxv.
- Ætheris, Spiritus Compositus (Clark and Dott), 182.
- Africa, South, The Röntgen Rays in, 438.
- Agar-Agar, Serum, A New Method of Preparing (Kanthack and Stephens), 312.
- "Agreement that Licks Creation, An (Griffin), 419.
- Agriculture, Bacteria in, 174.
- Ainu Medicinal Plants (Batchelor and Miyabe), 147, 442.
- Air, Liquid, Further Researches on (Dewar), 270.
- Albumin and its Allies (Logan), 95.
— Aseptol as a Test for (Barral), 349.
— Determination of, in Urine (Riegler), 81.
— in Urine, Reagent for (Jolles), 161.
- Albumose and Peptone, Conversion of Casein into (Bernstein), 83.
— Separation of, from Peptone (Bömer), 161.
- Alchemy and Pharmacy, their Mystery and Romance (Thompson), 41, 261, 381, 462.
- Alcock, F. H.—Vegetable Histology, 155.
— F. H.—Volumetric Analysis, 337.
- Alcohol in Herb Beer, 57.
- Alcohols (Stoakley), 158.
- Alessandri and Guassini—Detection of Nitrates in Water, 83.
- Alexander, E. G.—The Proprietary Articles Trade Association, 400.
- Algæ, Preservation of (Setchell and Osterhout), 343.
- Alkalies, Action of, on Sugars (Bruyn and Ehenstein), 81.
- Alkaloid Stearates (Zanardi), 422.
- Alkaloids of the Veratrums (Allen), 146.
— Stearates of the (Zanarch), 446.
— The Dispensing of (Bindloss), 235.
- Allen, A. H.—A Complaint against the British Pharmacopœia, 217.
— A. H.—Alkaloids of the Veratrums, 146.
— A. H.—An Improved Method of Determining Urea by the Hypobromite Method, 134.
- Allspice, or Pimento (Sawer), 305.
— Powdered (Spaeth), 85.
- Aluminium, Deposition of (Warren), 244.
— Solder for Dental Work, 250.
— Succinate, Natural (Maiden and Smith), 344.
— The Production of (A. E. Hunt), 174.
- Amaun, J.—Some New Preservative Solutions, 503.
- Ambulance Stations, New, for Paris, 399.
- America, College Courses in Pharmacy in, 251.
— South, The India-Rubber Industry in, 429.
- American Committee on Scientific Research, Appointment of an, 93.
— Pharmaceutical Association, 493; (Blue List), 494.
- Ammonia, Household, Formula for, 270.
— Water, Determination of the Strength of, 500.
- Ammonium Chloride, The Volumetric Composition of (Carnegie and Wales), 372.
— Sulphocyanide, Cause of the Reddening of (Liesegang), 500.
- Amygdophenine (Stuvel), 162.
— in Acute Rheumatic Arthritis (Stave), 139.
- Anaglypta Paper, Harging, 317.
- Analysis, A "Farcical" (Dubun), cxxvii.
— Spectrographic, of Coins, etc. (Hortley), 425.
— Volumetric (Alcock), 337.
- Analyst, Enlargement of the, 93.
- Analysts and their Opinions, 513.
— Public, and Somerset House Decisions (Saunders), 114.
— Public, The Vagaries of (Warrell), 340.
- Analyst's Report for Glamorganshire, 19.
- Aræsthetics for Operations on the Throat, Nose, and Ear (Holloway), 473.
- Analytical Chemist, Qualification as an, 500.
- Analytical Notes, 50.
- Andrew—Sulphonat for Cramp, 418.
— F—Photo-micrographs of Iron and Steel, 494.
- Andrews, Dr. W.—The Relations of Expert Pharmacy to Modern Medicine, 327.
- Anise, Oil of Russian (Bouchardat and Tardy), 164, 243.
- Anniversary Meeting of the Pharmaceutical Society (Editorial Remarks on the), 411.
- Annual Meeting, The, 1895, 3.
- Anthelmintic, Pine Seeds as an (Gonzalez), 237.
- Anti-Cutting Agitation, The ("Live and Let Live"), 140, 236.
— -Cutting—An Appeal (Johnston, William), xx.
— -Cutting Campaign (Thompson, Chas.), xxviii.
— -Cutting Meeting at Plymouth, lvii.
— -Cutting Movement, Discussion on the (Western Chemists' Association of London), 434.
— -Cutting Record, The Policy of the ("Anti-Humbag"), 50.
— -Venom Serum, The Action of, 118.
- Antinosine (Kruse), 317.
- Antipyrine, Poisoning by, 113.

- Antipyrine, The Dispensing of, with Chloral Hydrate, 349.
- Antipyrine and Tannin, Combination of, as a Styptic (Park), 150.
- in Infantile Diarrhoea, 178.
- Antiseptic, Mentho-Phenol as an (Schaefer), 289.
- Value of Sodium Fluoride (Duclos), 33.
- Antiseptics, Silver Salts as (Credé), 243.
- Antithermics, Combination of (Berger and Vogt), 418.
- Antitoxin and Diphtheria (Lennox Browne), 394.
- Treatment of Diphtheria, The, 292.
- The Value of, for Diphtheria (Boulger), 331.
- Aphis and Pear Sucker, Spray for, 417.
- Spray for, 417.
- Apocodeine Hydrochloride as an Expecto- rant, 454.
- Apothecaries Act, Proceedings under the (Preston), 373.
- Apparatus, New, for Extraction (Hoseason), 477.

PHARMACEUTICAL SOCIETY, TRANSACTIONS OF THE:—

Acknowledgment, Letters of, from Corresponding Members, 447.

— Letters of, from Honorary Members, 447.

Annual Dinner, The, 415.

— General Meeting, The, 402.

— Meeting, The Adjourned, 409.

— Report of the Council, 361.

— Report of the Council, Discussion on the, 404.

Ashby, Mr. C. E., Appointment of, as Laboratory Demonstrator, 449.

Associates, Election of, 26, 27, 104, 185, 264, 265, 366, 367, 448.

Attfield, Prof., Resignation of, 449.

— Prof., Vote of Thanks to, 450.

Auditors, Appointment of, 409.

— Nominations for, 204.

Auditors' Report, The, 363.

Benevolent Fund Committee, Reports of the, 28, 105, 185, 265, 363, 369, 449.

— Fund, Grants from the, 28, 105, 185, 265, 369, 449.

— Fund, Legacies to the, 449.

Bristol Pharmaceutical Association, Resolution from the, 188.

Burroughs Memorial Scholarship, The, 109, 449.

— Memorial, The (Appointment of a Subcommittee), 28; 126, 185.

Buda-Pesth, Pharmaceutical Congress at, 369.

Carteighe, Mr. Michael, Vote of Thanks to, 447.

Committees, Appointment of, 448.

Companies Act Amendment Bill, The, 370.

— Bill, Discussion on the, 186, 187.

— Bill in Parliament, The, 266.

Correspondence, 29, 110, 188.

Corresponding Members, Election of, 367.

Council, Election of Members of the, Result of the, 410.

— Meetings of the, 26, 104, 185, 264, 366, 402, 447.

— Members who Retire, 104.

— New Members of the, 447.

— Nominations for the, 204.

— Retirement of a Member of, 188.

— The New, 410.

Diplomas, Granting of, 104, 366.

Divisional Secretaries, Appointment of, 109.

Donations to the Libraries, Museums and Herbaria, 47, 125, 207, 290, 410, 470.

Dunstan, Prof., Resignation of, 268.

Early Closing, 267.

Edinburgh and District Chemists' Trade Association, Resolution from the, 29.

Education, Pharmaceutical, Provincial, Discussion on, 108.

Evening Meeting in Edinburgh, 189.

— Meetings in London, 126, 207.

Examiners, Appointment of, 26, 448.

Examination, First, Attendance at the, 350.

— First, Certificates Received in Lieu of the, 48, 109, 334, 370.

— First, Discussion on the, in Edinburgh, 334.

— Major, Questions Set at the, 14, 269.

— Major, Results of the, 34, 48, 310.

— Minor, Results of the, 34, 48, 334.

— Preliminary, Discussion on the, 266.

— First, Questions Set at the, 49, 310.

PHARMACEUTICAL SOCIETY, TRANSACTIONS OF THE—continued.

Examination, First, Results of the, 110, 350.

— First, Resolution from the North British Branch in Regard to the, 368.

Examinations in Edinburgh, 34, 310, 334.

— in London, 48, 310, 334.

— Report of the, 370.

Finance Committee, Reports of the, 27, 105, 185, 264, 369, 448.

Financial Statement, The, 362.

General Purposes Committee, Reports of the, 29, 110, 189, 268, 370, 449.

Glasgow and West of Scotland Pharmaceutical Association, Resolutions from the, 188.

— and West of Scotland Pharmaceutical Association, Letters from the (in Regard to Early Closing), 267; (in Regard to the Representation of the Pharmacy Acts), 267.

Government Visitor, Report of the, 265.

Honorary Members, Election of, 367.

Illegitimate Trading, Discussion upon, 29.

Inaugural Address, Resolution in Regard to the, 449.

Inverness Chemists' Association, Letter from the, in Regard to the Companies Bill, 266.

Law and Parliamentary Committee, Reports of the, 186.

Lee, Mr. H. L., Appointment of, as Lecture-room Assistant, 449.

Legal Business, 450.

Library, Museum, School, and House Committee, 28, 105, 186, 265, 369, 449.

Liverpool Pharmaceutical Students' Association, Grant to the, 105.

Members, Election of, 26, 104, 185, 264, 366.

North British Branch, Discussion on the Report of the Executive, 368.

— British Branch, Election of the Executive, 473, 514.

— British Branch, Meetings of the Executive of the, 334.

— British Branch, Report of the Executive, 367.

Officers, Re-Appointment of, 448.

Parliamentary Committee, Special, Appointment of a, 186.

Pharmacy Acts, Representation of the, in the Scottish Law Courts, 267.

Pharmaceutical Congress at Buda-Pesth, 369.

— Society, The Constitution of the, Discussion on, 267.

President, Election of the, 447.

— Retiring, Vote of Thanks to the, 447.

Proprietary Medicines, The Prescribing of, 267.

Register, Restorations to the, 27, 104, 185, 265, 367.

Report, Registrar's, 105, 106, 107.

Research Committee, Reports of the, 109.

Schacht, Mr. G. F., Letter from, 264.

— Mr. G. F., Retirement of, from the Council, 188.

School of Pharmacy, Prize Examination Questions, 252, 269.

Secretaries, Divisional, Appointment of, 188.

— Local, Appointment of, 188.

Scrutineers, Appointment of, 409.

Scrutineers' Report, The, 409.

Shops (Early Closing) Bill, Discussion on the, 186, 187.

PHARMACEUTICAL SOCIETY, TRANSACTIONS OF THE—continued.

Standing Orders, Re-enactment of, 448.

Students, Election of, 27, 104, 185, 265, 367, 448.

Trading, Illegitimate, Discussion upon, 29.

Treasurer, Election of the, 447.

Unqualified Managers of Branch Shops, Letter from the Glasgow Pharmaceutical Association in Regard to, 110.

Vice-President, Election of the, 447.

Western Chemists' Association (of London), Letter from the, in Regard to the Prescribing of Proprietary Medicines, 267.

Pharmaceutical Society, A Suggestion in Regard to the Library of the (Hartness), 500.

CONTRACTIONS OF TITLES.

The following is a list of the contractions and the corresponding full titles of Journals most frequently used in "The Month," and elsewhere in the "Pharmaceutical Journal." The titles prefixed by an asterisk (*) are those of official Journals.

- Amer. Journ. Pharm.* = American Journal of Pharmacy Philadelphia. Monthly.
- Annalen* = Justus Liebig's Annalen der Chemie. Leipzig. Monthly.
- * *Apot.-Zeit.* = Apotheker-Zeitung. Organ of the Deutsche Apotheker-Verein. Berlin. Twice a week.
- * *Apot. Zeit. Rep.* = Repertorium der Pharmacie. Supplement to the Apotheker-Zeitung.
- * *Archiv* = Archiv der Pharmacie. Berlin: J. Greiss. Monthly.
- * *Berichte* = Berichte der deutschen chemischen Gesellschaft. Berlin. Once or twice a month.
- * *Brit. Med. Journ.* = British Medical Journal, London. Weekly.
- Bull. com.* = Bulletin commercial. Supplement to L'union pharmaceutique. Paris: Pharmacie centrale de France. Monthly.
- * *Can. Pharm. Journ.* = Canadian Pharmaceutical Journal. Toronto. Monthly.
- Chem. News* = Chemical News. London. Weekly.
- Chem. Zeit.* = Chemiker Zeitung. Cöthen. Twice a week.
- Chem. Zeit., Rep.* = Chemisches Repertorium. Supplement to the Chemiker Zeitung.
- * *Comp. rend.* = Comptes rendus des séances de l'Académie des Sciences. Paris: Gauthier-Villars. Weekly.
- * *Journ. Chem. Ind.* = Journal of the Society of Chemical Industry. Monthly.
- * *Journ. de pharm.* = Journal de pharmacie et de chimie. Paris: G. Masson. Twice a month.
- Med. Press* = Medical Press and Circular. London: A. A. Tindall. Weekly.
- Mon. scient.* = Moniteur scientifique. Paris. Monthly.
- Münch. med. Woch.* = Münchener medicinische Wochenschrift. Munich. Weekly.
- Nouv. rem.* = Les nouveaux remèdes. Paris. Twice a month.
- Pharm. Centralh.* = Pharmaceutische Centralhalle Dresden. Weekly.
- Pharm. Post* = Pharmaceutische Post. Vienna. Weekly.
- Pharm. Zeit.* = Pharmaceutische Zeitung. Berlin: J. Springer. Twice a week.
- * *Proc. Chem. Soc.* = Proceedings of the Chemical Society. London. About twice a month.
- Répertoire* = Répertoire de pharmacie, archives de pharmacie et journal de chimie médicale réunis. Paris. Monthly.
- Scient. Amer.* = Scientific American. New York. Weekly.
- Union pharm.* = L'union pharmaceutique. Paris: Pharmacie centrale de France. Monthly.

THE

PHARMACEUTICAL JOURNAL

VOLUME LVI. (FOURTH SERIES, VOLUME II.)

LONDON: SATURDAY, JANUARY 4, 1896.

1895.

ALTHOUGH the events of the past year have not been particularly remarkable, indications have been afforded of an important development of opinion in regard to the representative function of the Pharmaceutical Society. The special attention that has been directed to the subject of organisation has led to a very general recognition of the principle that membership of the Society requires to be synonymous with registration under the Pharmacy Act of 1868, in order that the influence which has been acquired by the Society as an administrative and qualifying body may be proportionately exercised in conserving and promoting the interests of the craft. The weakness at present existing in this respect does not affect the Society as a public body, but it materially lessens its capability of protective or defensive action, for which power must be supplied from within. Compulsory membership has been suggested as a means of effecting adequate pharmaceutical organisation, and thus supplementing for internal purposes the partial organisation that has been effected solely from the outside point of view of general public interest, by the establishment of a Register of persons authorised to use the title of chemist and druggist, and to carry on business in that capacity. In any case further legislation will be requisite for effecting the object in view, and provision for it will probably form an important part of next year's work.

The Work of the Council.

The constitution of the Society's Council has not undergone much alteration. At the January meeting the vacancy which had been created by the resignation of Mr. A. C. ABRAHAM was filled up by the election of Mr. WARREN. The subsequent retirement of Mr. GREENISH and Mr. RICHARDSON at the annual election made two other vacancies, which were filled by the election of Mr. CORDER and Mr. A. L. SAVORY. Various matters have been dealt with besides routine business.

At the Council meeting in January, the PRESIDENT announced the receipt of a communication on the subject of the Pharmacopœia from the President of the General Medical Council, inviting assistance from the Society in obtaining statistics as to non-official remedies in demand and official remedies that have fallen into disuse. In accordance with a recommendation of the Pharmacopœia Committee of the General Medical Council, the Council was also invited to nominate members of a Pharmaceutical Committee to report to the General Medical Council through its Pharmacopœia Committee on the general subject of revision of the British Pharmacopœia. This was referred to the General Purposes

Committee and, at the next meeting of the Council, the members of the Committee which had been engaged in the preparation of the addendum to the Pharmacopœia in 1890 were nominated, with the addition of Mr. WALTER HILLS in the place of the late Mr. GALE. Mr. P. W. SQUIRE had been asked to serve on this Committee, but was unable to accept the invitation. Among the other proceedings of the Council in January a resolution was passed to support a Bill for amendment of the Weights and Measures Act, in order to allow metric weights and measures to be used in export trade. This was done in accordance with a request received from Mr. UMNEY on behalf of a special committee of the London Chamber of Commerce. At the same meeting a resolution was passed, on the motion of the PRESIDENT, seconded by Mr. HARRISON, that the Parliamentary Committee should consider the expediency of applying to Parliament for further powers in reference to company trading and other matters.

At the meeting in February, directions were given to forward to the Privy Council copies of regulations affecting the sale of drugs in the United Kingdom, information on the subject having been asked for, through the Foreign Office, by the Austro-Hungarian Government. A letter from the Deputy Coroner for North Derbyshire informed the Council that he had sent to the Privy Council a recommendation that carbolic acid should be added to the list of scheduled poisons.

At the meeting in March, the President and Mr. MARTINDALE were appointed to give evidence before a Select Committee of the House of Commons, to which the Bill relating to amendment of the Weights and Measures Act had been referred. The report of the Parliamentary Committee on amendment of the Pharmacy Act recommended that no Bill should be introduced during the current session. Regret was expressed that this decision was inevitable, and Messrs. HARRISON, MARTIN, and SOUTHALL advocated the drafting of a Bill embodying provisions in regard to consolidation, a curriculum, and company trading, so that members of the trade might consider these subjects and come to an agreement upon them.

At the April meeting, a resolution, passed at a meeting of members and associates of the Society held in Birmingham, was received from the local secretary, thanking the Council for enforcing the Pharmacy Act, and calling upon it to take immediate steps to remedy the evil of company trading. On the presentation of the report on the examinations at this meeting, Mr. ATKINS remarked that the proportion of failures in the Preliminary appeared to be increasing. Referring to the recommendation made years ago as to this examination being passed before apprenticeship, he, as well as Mr. ALLEN, Mr. GROSE, and the Vice-President, expressed the opinion that while many entered the business thoroughly unprepared,

the higher scientific teaching now provided is not accompanied by equally good practical training.

At the first meeting of the Council in May, the resignation of Mr. RICHARDSON was announced, and a resolution was passed expressing regret that continued ill-health rendered that step necessary. The report of the Executive of the North British Branch presented at this meeting, showed that the several departments connected with the Branch continued in a satisfactory state and that the extension of the Society's premises in Edinburgh had been productive of great convenience in all respects. After the adoption of the report Mr. STORRAR referred to the services rendered during the last two years by the Chairman of the Executive and the Assistant-Secretary as having been especially useful, and on behalf of the North British Branch he thanked the Council for the complete and handsome equipment of the new premises. The annual report to the Privy Council by the Government visitor of examinations in England and Wales was brought before the Council at this meeting. The results of the Preliminary examination continued to give evidence of very defective education. In the Minor examination there had been a slight increase in the proportion of passes, but the failures were still upwards of 63 per cent. The appointment of examiners engaged in teaching was spoken of with approval as being likely to work well and to the advantage of the candidates. In the Major examination some improvement indicated better scientific training, but the percentage of failures was still above 50 per cent. The report of the Research Committee stated that the applications for admission to the laboratory had increased, and that the benches were fully occupied. The continuation of the aconite investigation by synthetical experiments had not furnished very conclusive results, but a number of new compounds had been obtained having considerable chemical and physiological interest. Other inquiries had also been conducted, part of the expense having been defrayed by the Chemical Society. The great assistance rendered for three years by the Royal Society through a grant from the Government Fund, was referred to as having rendered the continuance of this costly investigation possible. Prior to the passing of the resolution that the report should be received and entered on the minutes, Mr. MARSH and Mr. GOSTLING expressed regret that the work of the Research department had so little bearing on medicine and that, after seven years, it would probably contribute little to the new Pharmacopœia. Mr. BOTTLE and Mr. STORRAR spoke of the financial statement as being insufficiently clear. After consideration of the subject of the Research Laboratory in Committee it was resolved, on the motion of Mr. HARRISON, seconded by Mr. STORRAR, that further consideration should be left to the incoming Council. In a communication from the Privy Council, attention was directed to a fatal case of poisoning reported to the Home Office by the Coroner for Worcester, in which Winslow's soothing syrup had been given to a boy thirteen months old, and at the inquest a verdict was given that death was caused by morphine poisoning. A letter from the chemists' association of the Plymouth district, enclosing a resolution in reference to the early closing Bill was referred to the Parliamentary Committee, but a protest against legislation interfering with the conduct of business was entered by Mr. HAMPSON. An application from the Registrar of the Pharmaceutical Society of Ireland, asking the Council to accept the Preliminary examination of that

Society was referred to the Board of Examiners. The annual report was agreed to and ordered to be published.

At the second meeting of the Council in May, Prof. H. G. GREENISH, as Secretary to the Pharmacopœia Committee, submitted lists of the articles proposed to be omitted and added in the new edition of the British Pharmacopœia and it was resolved that these recommendations should be communicated to the Pharmacopœia Committee of the General Medical Council, in accordance with the terms of Sir RICHARD QUAIN's letters of December 12, 1894.

At the June meeting Mr. CARTEIGHE introduced Mr. CORDER and Mr. SAVORY, the two newly-elected members of Council, with some references to their previous connection with the Society. Mr. CARTEIGHE was again elected President and Mr. HARRISON was elected Vice-President. The office of Treasurer was filled by the re-election of Mr. HAMPSON and Mr. RICHARD BREMRIDGE was re-appointed Secretary and Registrar. On the motion of Mr. HAMPSON, a resolution was passed expressing regret at the retirement of Mr. T. GREENISH, after serving for twenty-four years as a member of Council, as well as Treasurer and President of the Society. A special committee was appointed to consider questions relating to the Research Laboratory, and report as to its conduct for the future.

At the July meeting, Mr. HILLS called attention to the report of the Committee on Weights and Measures, showing that the information given by the President had contributed to the suggested legalisation of the metric system. In a communication from the Pharmacopœia Committee of the General Medical Council, Sir RICHARD QUAIN forwarded a statement of the points on which the assistance of the Society was invited and he requested that some report should be sent in before the 25th of that month. The members of the Society's Committee were, therefore, re-appointed, together with Mr. CROSS and Mr. JOSEPH INCE. Attention was directed by the PRESIDENT to a memorandum of the Local Government Board, relating to the qualification of persons acting as dispensers in workhouses, which appeared to indicate disregard of the principle that the sick poor should be treated with every consideration and have the benefit of the highest skill and knowledge. After some discussion of the matter it was decided that the President should be requested to communicate either with the Secretary of the Board or with Sir WALTER FOSTER, and point out the desirability of having properly qualified persons to perform the duties of dispensers in public institutions. The Special Committee appointed to inquire into the subject of the Research Laboratory presented its report, stating the opinion that the completed work which had emanated from the laboratories was, on the whole, satisfactory, and reflected credit on the Society. In regard to the future, several suggestions were made as to the kind of work desirable and as to the conduct of the Laboratory. A resolution passed by the Western Chemists' Association—to the effect that while supporting the Council's administration of the Pharmacy Act, the opinion was held that future legislation should be directed to improved registration of the owners and managers of pharmacies, to restricting the dispensing of medicine to registered pharmacists and to raising the standard of the Preliminary examination—was referred to the Law and Parliamentary Committee.

At the meeting in August, Mr. HAROLD BROWN was elected Redwood Scholar, and the award of the Hanbury medal to

Professor VOGL was announced; the President and other delegates to the Conference reported on the proceedings at Bournemouth, and the recommendations of the General Purposes Committee as to the award of prizes, medals, and scholarships, etc., were agreed to. On the reading of the report of examinations in July showing failures in the Minor examination amounting to over 76 per cent., Mr. CORDER asked whether any reason could be assigned for that large proportion of failures.

At the meeting in October, the Law and Parliamentary Committee reported that the consideration of the question as to drafting a Pharmacy Bill had been deferred, but the Committee recommended that steps should be taken, in co-operation with other public bodies, to urge the necessity of such amendment of the law relating to companies, as had been suggested by the Departmental Committee of the Board of Trade.

At the meeting in November, a resolution was passed conferring upon Dr. C. M. LUXMOORE the Research Fellowship. The PRESIDENT and Mr. ALLEN reported on the proceedings of the conference at Plymouth. In reference to the judgments in the Scotch appeals, mention was made of the circumstance that neither judges nor sheriffs in Scotland appeared to understand the position of the Pharmaceutical Society in carrying out the Pharmacy Act, but were, on the contrary, disposed to regard the Society as acting unfairly and in a trade union spirit rather than as discharging a public duty imposed upon it by the Legislature.

At the meeting in December, attention was directed to a peculiar technicality of Scottish law, by which prosecutions of offenders under Section 17 of the Pharmacy Act must apparently be undertaken by the Procurator Fiscal. In a case of that kind the Sheriff held that the REGISTRAR has no authority to prosecute in Scotland under Section 17 of the Act. At the same meeting a grant of twenty pounds was made for the purchase of a collection of materia medica specimens to be placed in the museum of the Technical College at Exeter, in order to facilitate the instruction of pharmaceutical students, for which arrangements have been made by the College authorities with the aid of the Town Council.

The Annual Meeting.

The report presented by the Council at the Society's anniversary meeting dealt with several matters relating to the work of the past official year, among which the most important were the changes in the Boards of Examiners, the additions to the Society's premises in Edinburgh, the successful issue of the appeals in cases of prosecutions under the Pharmacy Act in England and Scotland, and the revision of the Pharmacopœia. In regard to a Pharmacy Acts Amendment Bill, Mr. CAMPKIN suggested the desirability of taking steps to increase the representative character of the Society, and make it inclusive of the entire trade, with the object of providing protection of the interests of registered chemists in a manner analogous to that afforded to members of the legal profession by the Incorporated Law Society. Mr. MACKENZIE (Edinburgh) and Mr. TAPLIN (Hampstead) spoke to the same effect, and the PRESIDENT, in replying, pointed out that there is not much protection afforded now to any form of occupation by legislative measures, but that indirect means of obtaining it are much more effectual. That is the case with different branches of the legal profession, and the protection they enjoy is the result of internal organisation. Chemists and druggists have in the Pharmacy Act and the Pharmaceutical Society, more than ordinary

facilities for such organisation, but they have not yet turned those facilities to practical account for their own benefit.

North British Branch of the Society.

At the regular meetings of the Executive, in addition to the ordinary routine proceedings, various matters of general and local interest were considered, viz., the metric system, the sale of methylated spirit, the Preliminary examination, etc. At the meeting held in June for the selection of members of the Executive, votes were given in favour of MESSRS. BOWMAN, COULL, and MOIR, as the new members replacing MESSRS. KINNINMONT, NOBLE, and SUTHERLAND, who retired from office.

Administration of the Pharmacy Acts.

The judicial decision of several disputed points of pharmacy law within the last few years has furnished opportunity for more effective administration of the Statute by which the practice of pharmacy is to some extent regulated, and that opportunity has been utilised by the Council of the Pharmaceutical Society in a large number of instances during the past year. The endeavour to prevent evasion of the Act of 1868 by the patenting of medicines containing scheduled poisons has been partially successful, but it has not yet been consummated by an authoritative judicial decision on this point, since the proceedings taken for the revocation of patents relating to such preparations have in all instances led to judgments given by consent of the persons proceeded against. But although, for that reason, no legal precedent has yet been established, the principle contended for has been sufficiently well supported to leave little doubt as to the ultimate decision that, by reason of the special proviso contained in all Letters Patent, a patent granted for a preparation containing a scheduled poison must be invalid because it would otherwise sanction a proceeding contrary to the statute law relating to the sale of poisons, and, therefore, inconsistent with the above-mentioned proviso. The cases brought before the Court of Chancery during the past year were those of WALLACE, SIMMONS, and INGRAM. In the first two the patents were revoked. In the last case notice of opposition was given by the defendants, and it stands over for future hearing. Still more decisive results have been obtained in establishing the principle that in connection with retail trade, the use of the title chemist or any equivalent qualification of that title is unlawful for any but persons legally qualified under the Pharmacy Act, 1868.

Action has been taken against a large number of unregistered persons unlawfully selling poisons, keeping open shop for their sale, and using the title of chemist and druggist. In the majority of instances the penalty incurred has been paid upon application in accordance with the provisions of the Statute. In the cases tried at Oldham, Carnarvon, Newcastle, Greenwich, Stonehouse, London, Edinburgh, Greenock, Ayr, Glasgow, Paisley, Salford, Bootle, Dundee, Forfar, Nottingham, and Dumbarton, decisions were given in favour of the Society, and penalties were inflicted on the offenders. Unqualified assistants have also been prosecuted in several instances. Several prosecutions were instituted for the sale of arsenical preparations employed for killing weeds, ants, etc. In one of them the defendants were MESSRS. SPIERS AND POND, Limited, who appeared, from the statement of their counsel, not to have been previously aware that the article sold came within the Statute, and to have given up its sale on ascertaining that

it did. They were, however, fined in the full penalty, the Lord Mayor remarking that the respectable position of the company made the offence more serious. A seedsman at Helensburgh was fined for selling a similar preparation, and in another prosecution of a firm of seedsmen in Glasgow, under the 17th Section of the Act, an objection was raised that the Procurator Fiscal was the only person competent to take action under that section. An assistant of the firm, who sold a similar arsenical preparation, was, however, convicted of an offence under the 15th Section, but the Sheriff, in giving judgment, expressed himself as having no sympathy with the prosecution of employé's. The mode of procedure peculiar to Scotland would appear, therefore, to offer some considerable obstacle to the administration of the Statute.

Pharmaceutical Examinations. During the past twelve months the examinations have been conducted under the altered conditions decided upon in the previous year. It is interesting therefore to compare the results with those for 1894, when the new system was partially introduced, and also with those for 1893, when the older system prevailed. In the qualifying examination, which is the most important and the one chiefly affected by the alterations, the total number of candidates during 1895 was 1304, as against 1410 in 1894, and 1189 in 1893. The percentage of rejections in 1895 was 65·72, in 1894 it was 62·83, and in 1893 it was 60·55. It may therefore be inferred that the gradual elevation of the examination standard has not been accompanied by corresponding improvement in the training and acquirements of candidates generally. The rise in the percentage of rejections is still most marked in the figures for England and Wales, as the following table shows:—

Minor Examination.

	1893.		1894.		1895.	
	Lond.	Edin.	Lond.	Edin.	Lond.	Edin.
Number of candidates	817	372	970	440	819	485
" " rejections	532	188	626	260	574	283
Percentage of failures	65·11	50·54	64·53	59·09	70·08	58·35

The figures for October last were especially remarkable. The candidates presenting themselves for examination in London usually constitute two-thirds of the total number, but on that occasion the numbers were almost identical in London (116) and in Edinburgh (113), whilst the percentage of rejections was 59·48 in London as compared with 65·48 in Edinburgh. This unusual result may have been due to the existence of a fancy on the part of weak candidates that the tests imposed at the northern centre were likely to be more favourable to them than the London ones. Assuming that to have been the case, there would have been a preponderance of the weak element in Edinburgh, but the result proved that the Scottish examiners are quite capable of dealing with such emergencies, and that the examination standard is not likely to degenerate in their hands.

The statistics of the Major examination during the same period are as follow:—

	1893.		1894.		1895.	
	Lond.	Edin.	Lond.	Edin.	Lond.	Edin.
Number of candidates	140	12	136	11	130	16
" " rejections	78	5	68	5	70	8
Percentage of failures	55·71	41·66	50·00	45·45	53·84	50·00

It will be noticed that both the number of candidates presenting themselves and the number of passes are less in 1895 than during the two preceding years, whilst the pharmaceutical chemists registered during 1895 amount to little more than 15 per cent. of the chemists and druggists registered during the same period. Additional evidence is thus afforded that the legal qualification is regarded as sufficient by an overwhelming majority of those becoming entitled to practise pharmacy on their own account.

With regard to the First examination, which, being purely scholastic, has no title to be considered a pharmaceutical examination, its inadequacy as a test of general education is sufficiently established. The statistics for the past three years are as follow:—

	1893.	1894.	1895.
Number of candidates...	1489	1541	1430
" " rejections ...	750	788	753
Percentage of failures...	50·37	51·13	52·65

Schoolboys unable to satisfy the requirements of this examination—the lowest of all professional preliminaries—would not be fitted for admission as pupils in pharmacy. But the worst feature of this examination is that it is not made a test of fitness to be admitted as an apprentice. Many of the rejected candidates have already been engaged in the business as apprentices, though it would have been to the advantage of all concerned if they had been compelled to seek employment in some other direction at an earlier period. The pharmacy of to-day requires its recruits to be of the best material available, not modest mediocrities or scholastic failures.

The report on the examinations presented to the Privy Council by Dr. THOMAS STEVENSON, the Government visitor, dealt with the twelve months ending March 31, 1895. It included only one of the examinations held during the past year, and therefore the figures given by him, which have been already referred to on page 2, are not quite the same as those given above. In regard to recent changes in connection with the qualifying examination, Dr. STEVENSON expressed his belief that "since there is no one so well fitted to examine and to gauge the knowledge of students as he who is engaged in teaching a science," the introduction of examiners engaged in teaching chemistry, physics, and botany is likely to work well and to the advantage of candidates. Dr. STEVENSON showed that the failures in the Minor examination were chiefly in chemistry (28·2 per cent.), pharmacy coming second (22·1 per cent.), practical pharmacy and dispensing third (16·9 per cent.), whilst in materia medica there were only 4·9 per cent. of rejections. In speaking of the Major examination, Dr. STEVENSON inferred that the scientific training of the candidates had undergone improvement, but he expressed regret that so few chemists and druggists present themselves for this examination. Dr. STEVENSON pointed out that the failures in the Preliminary examination were due more especially to weakness in arithmetic. The report confirms the opinion that this examination, as now carried out, is totally inadequate as a test. Candidates too frequently present themselves after becoming engaged in business, and he suggests that the examination should be confined to the admission of apprentices.

Pharmaceutical Meetings.

The evening meetings of the Society, both in London and Edinburgh, have furnished opportunity for the discussion of several important subjects, such as the histology and chemistry of ipecacuanha; and the standardisation of galenical preparations—infusions, decoctions, etc. Papers were read on buchu, false chiretta, Chinese opium, and calumba. A demonstration was given of SIR GEORGE JOHNSON'S method of determining sugar in urine, and several interesting contributions to the Museum were shown and described by the Curator. In Edinburgh papers were read on magnesium ricinoleate, chloroform, aloin, linseed and linseed meal, ferrous phosphate, continuous percolation, etc., while several evenings were devoted to the discussion of subjects connected with the revision of the British Pharmacopœia, metric weights and measures, etc. A very interesting historical notice of the Society of Druggist Apothecaries in Edinburgh was contributed by Mr. JAMES MACKENZIE.

In London the meetings of the Western Chemists' Association, held under the presidency of Mr. R. H. PARKER, have been made useful by the discussion of subjects connected with the British Pharmacopœia and pharmaceutical politics, and at the first meeting of the present session, Mr. HYSLOP, his successor in the chair, delivered an opening address, in which he showed that notwithstanding much improvement effected within the last fifty years there is still great want of provision for the adequate education and practical training of persons taking up pharmacy as an occupation. To that deficiency Mr. HYSLOP traced many of the evils of which pharmacists have reason to complain, and he suggested that the remedy for them should be sought for by more thorough co-operation for mutual advantage.

The meetings of provincial associations during the year have been rendered exceptionally interesting by the reading of papers on subjects connected with pharmaceutical practice and politics.

At Manchester, in addition to various papers read, Mr. CARTEIGHE delivered an address on the possibilities of future legislation in the interests of pharmacy. At the annual meeting the subject of company trading was discussed, and the action taken in regard to that mode of evading the Pharmacy Act was heartily approved of. At the opening of the present session Mr. W. KIRKBY read a paper on "Pharmaceutical Education," in which he insisted upon the necessity of extending the scope of the Preliminary examination. In the discussion Mr. RYMER YOUNG drew attention to the need for making the passing of that examination an indispensable condition of apprenticeship, suggesting that as the direction in which improvement is most essential.

At Liverpool, Mr. JOHN SMITH, the President of the Chemists' Association, opened the session with an inaugural address, in which he dealt with some practical details of the chemist's business, and insisted on the importance of education as a basis for improvement. In speaking of the utility of local associations and the beneficial influence of occasional meetings, he urged that by promoting unity and consolidation they are broadly conducive to the protection of trade interests. Papers on the revision of the British Pharmacopœia have been read by Dr. SYMES and Mr. A. C. ABRAHAM, besides others relating to dispensing, on jaborandi leaves, pepsin, etc. A very interesting address was delivered by

Dr. WILLIAM CARTER on "Nature's Poly-pharmacy," Mr. WARDLEWORTH gave an account of botanical observations made during his rambles in northern Spain, and Professor GIBSON read a paper on "Old Herb Gardens." A resolution was passed to admit junior members of the trade to the meetings, library, and museum.

At Glasgow several meetings have been devoted to discussions of Pharmacopœia revision, two of which were opened by Mr. THOMAS DUNLOP and Mr. GEORGE LUNAN. At the annual meeting in April a report was presented recommending various desirable alterations of the Pharmacopœia, which had been suggested by a committee appointed in reponse to the invitation of the General Medical Council. Another report on pharmaceutical legislation was presented, stating, among other suggestions as to the amendment of the Pharmacy Acts, that all persons on the Register of Chemists and Druggists should be members of the Pharmaceutical Society, and the cost of registration be defrayed by an annual fee. At the same meeting Mr. W. L. CURRIE was re-elected President, and in the address delivered at the opening of the session he strongly advocated the views put forward in the above-mentioned report. The Edinburgh Trade Association has also held several meetings under the presidency of Mr. BOA and discussed matters of practical interest.

At Birmingham papers of considerable interest were read by Mr. JOHN BARCLAY and Mr. LIVERSEEGE, on scientific subjects connected with practical pharmacy; but the meetings of the Midland Association at the early part of the year were but poorly attended. This indication of indifference in the majority was lamented by the PRESIDENT, and, with the object of inducing a better attendance, an evening was given to the consideration of "Cutting in the Retail Trade."

At Sheffield the papers read at the early part of the year were more of general than pharmaceutical interest, with the exception of one by Mr. RHODEN on "Examinations," in which he discussed the appointment of teachers as members of examining boards. At the opening of the present session Mr. CARTEIGHE distributed the prizes gained by students in the Sheffield School of Pharmacy, and at the annual dinner he spoke on several of the subjects which require to be dealt with in a Bill to amend the Pharmacy Acts.

At Plymouth the newly formed local association has been very active, and the meetings have been chiefly engaged in considering matters of pharmaceutical politics. Mr. P. A. KELLY brought forward the subject of pharmaceutical organisation, pointing out its necessity and the neglect chemists now show to their own interests, by complaining of the Pharmaceutical Society instead of taking part in its work. Subsequently a paper was read by Mr. E. A. HODGE, in which he treated of the means by which improvement in the position of the pharmacist is to be attained, and urged the great importance of thorough organisation for that purpose. In the discussion of these papers the views expressed by the authors were very generally concurred in. In October a conference of west of England chemists was held at Plymouth, at which Mr. CARTEIGHE, Mr. C. B. ALLEN, Mr. R. BREMIDGE, and Mr. HOLMES were present, and a long discussion took place on the points to be dealt with in a Pharmacy Acts Amendment Bill.

At Bristol only two meetings of the local association have been held during the year. In the annual report of the Council the experimental arrangement made with the aid of the University College and Messrs. KEEN, WHITE, and TOWERZEY,

for providing instruction in chemistry, botany, materia medica, and pharmacy, was stated to have been distinctly successful. At a subsequent meeting, Mr. KEEN, the Honorary Secretary, reported that a class of thirteen had met weekly, and taken satisfactory interest in the subjects taught.

At Cambridge useful lectures on water analysis, the phenomena of diffusion, qualitative chemical analysis, and the use of spectacles have been delivered by Mr. E. S. PECK, Mr. F. STOKLEY, the teacher of chemistry at the Technical Institute, Mr. PATTISON MUIR, of Caius College, and Mr. A. IVATT, of Christ's College. At the annual meeting in October, Mr. Ald. DECK was elected President, and delivered an address upon "Pharmacy in the Forties."

The associations at Bolton, Dover, Halifax, Leeds, and Nottingham have held several meetings during the year, the proceedings at which have been reported in the Journal.

The work of the Society and of the senior associations has been well supplemented by the various assistants' associations. At the London Chemists' Assistants' Association papers have been read upon drug adulteration, volumetric analysis, dispensing problems, filtration, nostrums, pharmaceutical preparations, pharmacopœia revision, the metric system, and essential oils. Lectures have been delivered by Mr. F. RANSOM on "Diatoms," by Mr. MEYJES on the "Pharmacist in Fiction," by Mr. J. HARRISON and Dr. SYMES on "Pharmaceutical Politics," and at one of the meetings the reading of a paper on the "Commercial Application of Electrical Energy" was followed by a visit to the St. Pancras Electric Light and Power Station, where the various operations and appliances were explained by Mr. SNELL.

In Edinburgh, also, the Chemists', Assistants', and Apprentices' Association has well maintained its position in respect to the senior associations by the production of papers on pharmaceutical subjects. At the January meeting a discussion on the Preliminary examination was opened by Mr. COULL, and at another Mr. W. M. LOCK gave an interesting account of an apprentice's experiences.

At the annual meeting Mr. A. SUTHERLAND was re-elected President, but was subsequently obliged to resign in consequence of ill-health, and at the opening meeting of the present session the vacancy was filled by the election of Mr. J. MACKINTOSH CAMERON, who delivered an instructive address on the "Evolution of Pharmacy." The Aberdeen Assistants' Association and the Brighton Junior Association have also continued their meetings.

The School of Pharmacy Students' Association has continued its activity, and a number of interesting papers and reports were read during the year. At the last meeting Professor REYNOLDS GREEN was elected President on the retirement of Professor ATTFIELD, who has held that position for the last twenty-one years.

At the meetings of the Liverpool Students' Association various useful papers have been read on pharmaceutical preparations and other subjects of interest.

Pharmacography. Several important drugs have received attention which has resulted in material additions to our knowledge of their structure and constituents. GREENISH has studied the comparative anatomy of Brazilian and Carthagenia ipecacuanha, and has shown the means by which the root and stem of each may be distinguished even in the form of powder, as well as the extent to which the diagnostic characters can be relied upon. Applying the

knowledge thus gained to the examination of commercial ipecacuanha powder, GREENISH showed that the quality of the powder supplied to the public is frequently inferior. Almost simultaneously RANWEZ and CAMPION published a similar investigation of French ipecacuanha powder with similar results. Jaborandi has again been exhaustively dealt with by HOLMES, who has shown that another variety of the drug, characterised by its simple leaves, has recently appeared in commerce; the presence of pilocarpine and the proportion in which it exists in this variety remains to be determined. WARD has identified a drug recently offered as chiretta with *Andrographis paniculata*, and GREENISH has given an account of its histology, pointing out the important features, and showing to what extent they are useful in identifying the drug. By similar means HARTWICH has identified an adulteration of senega root, previously attributed to *Richardsonia scabra*, as the root of *Triosteum perfoliatum*, a North American plant. Histological investigations of various drugs have been communicated by BASTIN, but in this department the most valuable contributions are those which have appeared in the atlas of TSCHIRCH and OESTERLE, where many new observations are recorded. BARCLAY has called attention to a substitute for cusparia bark, and UMNEY has compared the constituents of the leaves of *Empleurum serrulatum* with those of *Barosma betulina*, showing that the former contain less volatile oil than the latter, and no diosphenol. HERLANT has contributed to the study of useful plants from the Congo by examining the fruits known as "Poivre de Clusius"; which, according to HERLANT, contain 5 per cent. of piperine and 11 per cent. of volatile oil, and should, therefore, be classed with the true peppers, although in structure they resemble cubebs. PFISTER finds the powdered cinnamon of commerce to be frequently of inferior quality, and has advanced the somewhat remarkable opinion that the addition to it of powdered cassia buds is admissible, since the proportion of volatile oil would thereby be increased. HOOPER has examined tea seed, and determined the proportion of fixed oil present to be 22 per cent., and that of saponin 9 per cent. The same chemist has investigated the vesicant principle contained in the fruits of *Holigarna*, and shown it to be closely allied to, if not identical with, the cardol of the cashew nut. HOOPER has also examined the bitter principle contained in the bark of *Ailanthus excelsa*, and considers it to be a neutral rather than an acid body, and related to quassiin. FRASER and TILLIE have isolated from the wood of *Acokanthera schimperi* a crystalline glucoside, probably identical with ARNAUD's ouabain, but for which they propose the name of acokantherin.

The investigation of gum-resins has again this year been vigorously prosecuted by TSCHIRCH and his pupils. LUZ has proved that the resins of ammoniacum are free from sulphur and that one of them yields by saponification salicylic acid. On the sound basis of identity of structure of the vegetable *débris* found in commercial opoponax, BAUR refers this drug to the natural order Burseraceæ, and probably to *Balsamodendron kafal*. He found the resin unsaponifiable and the drug free from sulphur and umbelliferone, the latter, with the exception of ammoniacum, being a constant constituent of umbelliferous gum resins. In sagapenum, HOHENADEL found 15 per cent. of combined umbelliferone and 40 per cent. of a peculiar resino-

tannol. MJÖEN has investigated the nature of the vegetable *débris* in opium and found in the Turkey drug abundant fragments of the epidermis of the poppy capsule, whilst Chinese, Indian, and Persian are free, or almost free, from such remains, but Persian frequently contains starch. BRAITHWAITE has given an interesting account of a spurious balsam of tolu, showing that, by digestion with carbon bisulphide, a larger proportion is extracted than from the genuine balsam and that after evaporating the solvent the residue differs in appearance and saponification number.

In the Buitenzorg laboratory, in Java, BOORSMA has occupied himself with the examination of a number of plants and discovered several new alkaloids. In the same laboratory interesting results have been obtained in the examination of the leaves of *Palaequium borneense* and *P. gutta*; they have been shown to contain quantities varying from 4 to 8 per cent. of pure white gutta-percha. *Erythroxylon coca* var. *spruceanum* has been successfully cultivated in Java.

In connection with the valuable work carried on in the state-supported laboratory in Java, it is satisfactory to note that the Government of India has appointed a committee to consider, amongst other things, the practicability and utility of encouraging the systematic cultivation of medicinal plants indigenous to India. In Germany, also, more attention is being directed to vegetable drugs, and Russia is exerting herself to introduce into suitable districts of her empire the cultivation of plants yielding useful products. The results of these movements will be awaited with much interest.

Botany. In the domain of practical or economic botany, viewed from whatever side, whether as yielding drugs, food, or articles of manufacture, the year has not been behind its predecessors either in the introduction of new products or in developing the application of old ones. Early in the year HOOPER drew attention to tea seed for the expression of oil and the use of the residual cake. It is well known that the Chinese use the oils of *Camellia drupifera* and *C. Sasanqua* for a variety of useful purposes: the cake is applied to the ground for the double purpose of manuring and killing earthworms, but the application of the seeds of the common tea as an oil seed was comparatively new, and HOOPER showed that in Northern India hundreds of maunds of tea seeds were being wasted on the bushes of abandoned tea estates, so that if there were any demand for tea seeds for this purpose, there would in all probability be a supply. It was not, however, for the sake of the oil that the seeds were recommended for pressing, because the yield is smaller than that of many better known oil seeds; besides, much saponaceous matter is found in combination with it. But as a manure and an insecticide it was strongly recommended for trial either in the form of a powder for sprinkling over plants or in decoction for washing them. In consequence of the rise in the price of kino and its comparative scarcity early in the year, attention has been directed to other sources than that from which it is usually obtained and Bengal kino from *Butea frondosa*, as well as the African kino, from *Pterocarpus erinaceus*, have since appeared in the market. Considering the activity now shown in the opening up of Africa, the supply from that source will be probably increased, and other kino-yielding plants discovered.

In consequence of the comparative scarcity of camphor, its high price—owing to the disturbed state of the far

East, and the new uses to which the substance is now put, a good deal of attention has been given to the possibility of introducing the tree into other than its native countries, and amongst these it has been suggested that California might be made the camphor producing country for the supply of the American trade. In this connection it may be noted that in a recent number of the *Kew Bulletin* the plant is stated to grow freely in Southern Europe, and to be suitable for planting in any warm temperate climate. With reference to the popular opinion that camphor is largely used in the manufacture of smokeless powder, a note by Sir FREDERICK ABEL in the same number of the *Kew Bulletin* dispels that notion by stating that it was only used as an experimental ingredient, and never in its actual manufacture. But camphor has been used for many years past for the conversion of collodion cotton into celluloid, which is applied to the manufacture of imitation ivory, tortoise-shell, horn, etc. While on the subject of camphor, it may be well to draw attention to an article on the peculiar Ngai or Ai camphor of the Chinese (*Blumea balsamifera*) in the November number of the *Kew Bulletin*. Knowledge of the produce and extraction of Siam gamboge (*Garcinia hanburyi*, Hook. f.) has been considerably increased by the excellent account given in a report to the Foreign Office by Mr. DE BUNSEN, Her Majesty's Chargé d'Affaires at Bangkok (see *Ph. J.* [3], xxv., 1030). Under the name of "Iboga" a root from the Gaboon was exhibited so long ago as the Paris Exhibition of 1867. It was described as possessing tonic properties and in large doses was said to stimulate the nervous system. The same root is known on the Congo as "Bocca." BAILLON was the first to identify it, and named it *Tabernanthe iboga*, belonging to the Apocynaceæ. Very little is known about the uses of the plant at present, besides those just referred to, but attention is being paid to it, and when further material arrives the medicinal properties of this interesting root will probably be more fully investigated.

Turning to plants not so immediately connected with pharmacy the *Kew Bulletin* has extracted from the *Louisiana Planter* some interesting facts relating to maple sugar, from which it seems that the total production of maple sugars in the United States exceeds 10,000,000 pounds. And as the article is sold as candy rather than sugar, and as an immense amount of maple, molasses, or syrup is sold without being manufactured into sugar, it is evident that the total production of sugar and syrup from maple sap reaches in value about 1,000,000 dollars annually. Over 3,600,000 trees were tapped to produce 7,500,000 pounds of sugar, indicating an average production of about two pounds per tree per season. In this connection it is interesting to note that Brigade-Surgeon AITCHISON, who was much interested in the introduction of the sugar maple into Kashmir, applied to Kew for assistance in obtaining a supply of seed, and after some difficulty it was supplied to him. Numerous interesting notes on economic plants have appeared in the *Kew Bulletin*, besides those already referred to, notably on the distribution and collection of Siam benzoin. In these notes, however interesting though they be in regard to the details of the benzoin trade, no light has yet been thrown on the botanical origin of the plant furnishing this particular kind of resin. Under the name of "Shulang," a Chinese species of *Dioscorea* has been known as furnishing a root used in Formosa for dyeing and tanning

fishing nets. The plant occurs plentifully in the mountains, whence the roots are brought down to the coast. This plant has been described by OLIVER as *Dioscorea rhipogonoides*. Dr. HENRY says that the French in Tonkin know it as "faux gambier." In Pakhoi it is extensively used for dyeing coarse native cotton cloth and fishing nets a dark tan colour; a large trade appears to be carried on in different parts of China in this peculiar root. One of the most important contributions to the history and botany of useful plants is that on the "Vanillas of Commerce," by Mr. R. A. ROLFE, of Kew. His work has established the importance of *Vanilla planifolia*, Andr., as furnishing the true Mexican vanilla of commerce: it has also proved that *V. pompona*, Schiede, is the source of the West Indian vanillons of commerce. While hoping that competent botanists may be induced to study other equally important plants concerning which doubts may yet exist, the work done in that direction during the year just passed cannot be looked upon as uninteresting or unimportant.

Chief amongst matters of interest to botanists during the past twelve months has been the completion of the 'Index Kewensis,' but the year has also been prolific in English class-books and text-books. It is gratifying to note that Professor GREEN'S 'Manual' has been well received. DARWIN'S 'Elements of Botany' and DARWIN and ACTON'S 'Practical Physiology of Plants,' POTTER'S translation of WARMING'S 'Systematic Botany,' and VINES' more advanced 'Text-book' are all commendable books, more or less in advance of previous English works. The study of the cellular cryptogams has been assisted by the publication of the fourth volume of G. MASSEE'S 'British Fungus Flora,' containing the Gymnoascaceæ, Hysteriaceæ, and Discomycetes; M. C. COOKE'S 'Introduction to the Study of Fungi,' and G. MURRAY'S 'Introduction to the Study of Seaweeds.' WILLIAMSON and SCOTT'S 'Further Observations on the Organisation of the Plants of the Coal Measures' is an important contribution to fossil botany. Count SOLMS-LAUBACH has paid a splendid tribute to the value of WILLIAMSON'S discoveries, especially in relation to the secondary formation of wood from a cambium in the Archegoniata. The publication of F. F. BLACKMAN'S interesting researches on vegetable assimilation and respiration is one of the most important events connected with physiological botany. EDMOND GAIN'S articles entitled "Rôle physiologique de l'eau dans la végétation," and GASTON BONNIER'S "Adaptation des plantes au climat alpin," are also of more than ordinary interest. The chemistry of plant-life has been enriched by CROSS and BEVAN'S book on cellulose, and its practical applications. CORDEMOY'S "Flore de l'île de la Réunion," and BAUR'S articles on the Galapagos group are highly interesting contributions to geographical botany. The foregoing is by no means an exhaustive account of the botanical activity of 1895. Indeed, it is a mere glance at some of the more prominent pieces of work, which means that things, especially among foreign publications, equally important have not been mentioned.

Pharmacopœia Revision. The approaching revision of the British Pharmacopœia caused additional interest to be centred on the annual report presented by Professor ATTFIELD to the Pharmacopœia Committee of the General Medical Council. In this report—the ninth of the series—a large amount of critical and suggestive work was embodied. In regard to general principle, the opinion was expressed that

many of the suggestions put forward on the maintenance of the value of the Pharmacopœia as a student's manual have a too extreme tendency. Considerable attention was devoted to detailed suggestions of standardisation of the official preparations of belladonna, conium, hyoscyamus, ipecacuanha, jalap, nux vomica, opium, stramonium, cinchona, and the tinctures generally, specific suggestions being made in order to secure definite proportions of the active principles, although it was at the same time pointed out that the application of these methods would be only a partial advance to the required ends. In regard to nomenclature, reference was made to INCE'S suggestion that words at present regarded as indeclinable should follow the ordinary rules.

At the beginning of the year several articles were published in the *British Medical Journal*, written by Professors LEECH, WHITLA, and CASH, Drs. STOCKMAN and LAUDER BRUNTON, Professors DUNSTAN and GREEN, Messrs. DAVID HOWARD and KIRKBY. Some of these attracted a considerable amount of criticism at the hands of pharmaceutical writers, and it was made apparent that a considerable conflict of opinion exists amongst medical men as to what is desirable in the way of pharmacopœial revision. In this work of suggestion and criticism several of the local associations have been particularly prominent, and a bare enumeration of the papers would occupy considerable space. MARTINDALE opened a discussion at a meeting of the Western Chemists' Association of London, in which, after expressing himself strongly in favour of the official adoption of the metric system only of weights and measures, detailed reference was made to the preparations and suggestions for deletion and addition. The evening meetings in Edinburgh have been particularly productive of sound work, several evenings being devoted to the reading and discussion of papers, in which prominent medical men took a share. DOTT expressed himself in favour of the general omission of detailed processes for the preparation of chemical compounds. He considered that the inclusion and accurate description of such substances as milk, cotton-wool, copper, iron, etc., was quite unnecessary, and that they should at any rate be relegated to a schedule by themselves. On the same occasion he detailed his suggestions, and subsequently published a further communication on the subject in the pages of the *Pharmaceutical Journal*.

MABEN has contributed a reply to the criticisms which had been previously published in the *British Medical Journal* by WHITLA, CASH, STOCKMAN, LEECH, and LAUDER BRUNTON, expressing the opinion that they had been productive of few valuable suggestions. He also deprecated the tendency shown to belittle the work done by the Editor of the Pharmacopœia. STEPHENSON dealt with pharmacopœial processes, COULL urged that pharmacists had a right to co-operate with medical men in the revision of the Pharmacopœia, and after a criticism of Dr. LAUDER BRUNTON'S remarks, noticed in detail several of the official preparations. BOA, in discussing the ointments, spoke with disfavour of the proposal to establish one common basis, lest there should be a suspicion of sacrificing efficiency to uniformity. He also reiterated his previous statement that the pharmacopœial directions of stirring till cold are in many cases unnecessary, and sometimes objectionable. LYON dealt with infusions in detail, FRASER with pills, and SWAN with extracts. GLASS suggested, as a ready method for the preparation of aromatic waters, maceration in hot water with occasional

agitation and filtration when cold through a double fold of filtering paper. This process, which was recommended in 1874 in the *American Journal of Pharmacy*, has given excellent results with all the pharmacopœial waters, except cherry laurel and elder flower. DEY insisted upon the necessity for the adoption of characters and tests of linseed meal. LYON read a communication on smaller-sized pharmacopœial pills, in which the views previously expressed by STOCKMAN were embodied. In this it was shown there were many instances in which the active principle of the drug could be advantageously substituted for the drug itself, such as aloin for aloes. Ordinary excipients were found to be unsuitable as a rule, the best results being obtained by using a modification of glycerin of tragacanth, in which the proportion of glycerin was increased 25 per cent. SYMES, in a paper read before the Liverpool Chemists' Association, expressed the opinion that more harm is likely to be done by curtailing the materia medica than by retaining or adding preparations which to some may seem superfluous. DUTTON contributed a series of notes upon official preparations, suggested by work at the dispensing counter.

MITCHELL, in discussing the ointments, alluded to the indiscriminate use of paraffin bases in the present edition. In addition to the foregoing, communications were read at the Glasgow and West of Scotland Pharmaceutical Association, the scope of which was too comprehensive to allow of more than bare mention, viz., "Laboratory Notes and Suggestions for the Revised Pharmacopœia," by DUNLOP, an extensive series of notes on the same subject, by LUNAN, and the laboratory notes of BRODIE, which contain a considerable amount of information worthy of consideration, especially with reference to tinctures and infusions. The suggestion made by ABRAHAM in the course of a paper read before the Liverpool Chemists' Association, that all the preparations of each drug should be arranged alphabetically under the name of that drug, seem to be especially worthy of consideration. NAYLOR, in discussing pharmacopœial revision from the point of view of a pharmacist, combatted the arguments advanced by BUNTON in favour of embodying information which would change it into a prescriber's manual pure and simple, and briefly detailed the lines to be followed in order to effect improvement. LANGFORD SYMES has discussed the extended official recognition of animal oils, and advocated the use of goose-grease as a basis for liniments and soft ointments.

Pharmaceutical Work.

At an evening meeting in London ELBORNE described an automatic process for the preparation of medicated waters, with especial reference to those of chloroform, lime, and peppermint, based upon the Pharmacopœia process for camphor water. CRIPPS has summarised the results of previous workers on the alkaloidal strength of belladonna root and leaves, and suggested formulæ for standardised preparations of the former, taking a strong liquid extract prepared by repercolation as a basis. The deletion of the succus on the ground of its variability was recommended, but it was thought advisable to retain the green extract for the present. B. S. PROCTOR contributed a ready test for ascertaining the purity of beeswax, as well as useful notes on the preparation of mercurial ointment and approximate determination of tannin. The Pharmacopœia test for pepsin was discussed by MOFFAT, who recommended

that the official standard should be raised to five times the present strength, and also that a more detailed account should be given of the method of carrying out the assay. The opinions advanced by HARDING on the subject of pepsin testing were remarkable, as being contrary to all preconceived notions. He stated that the real proteolytic action of pepsin was but very small, the proportion of albumin dissolved in the process of assay being almost entirely due to its solubility in diluted hydrochloric acid alone. These statements were controverted by MOFFAT, who found that only 3 per cent. of albumin is dissolved by acidulated water under the most favourable conditions, and none whatever when the proportion is small. CRIPPS, after summarising the results published at various times by investigators of ipecacuanha, with special reference to those of PAUL and COWNLEY, recommended the official recognition of Brazilian root only, which, when assayed by LYON'S process, yielded between 2.0 and 2.5 per cent. of the total alkaloids. In addition, it was suggested that the methods at present official for the preparations should be retained, except that a weaker acid be used for extraction in the case of the wine, the dry extract of which should be assayed, so that the finished product may have an alkaloidal strength of 0.1 per cent. The same author has drawn attention to the use of repercolation in official pharmacy, with special reference to liquid extracts, and his results confirm those of SQUIBB, INGLIS CLARK, and BIRD as to the general advantages of the process over those entailing evaporation.

LOMULLER, after experimenting with various excipients from the preparation of glycerin ovules and suppositories, has decided in favour of agar-agar, but his method has recently been subjected to much criticism. MARTINDALE, in a paper read at an evening meeting in London, advocated the adoption for infusions and decoctions of a uniform strength of 1 in 20 with certain exceptions, and suggested that the time occupied in their preparation might in most cases be considerably reduced. His experiments showed that the latter condition only slightly reduced the proportion of extractive. In the discussion which followed, ATFIELD alluded to the probability of the introduction into the new Pharmacopœia of a class of preparations to represent the so-called "concreted infusions," and expressed a preference for their classification under the name of "essence," but this term was subsequently objected to by HALLAWAY as likely to lead to confusion with other preparations which will readily suggest themselves. KILIANI has continued his investigation of the glucosidal constituents of foxglove leaves and seed with satisfactory results. Starting with the substance prepared by MERCK from the seeds under the name of *digitalium pur.*, a process has been devised for the preparation of the glucoside digitalin in a state of purity. It has also been shown that the leaves contain a mixture of glucosides altogether different from those of the seeds, and amongst them a substance to which the name β -digitoxin has been applied by KILIANI on account of its close resemblance to the digitoxin prepared by SCHMIEDEBERG. In spite of the work of KILIANI and SCHMIEDEBERG, much remains to be done in the investigation of the active principle of this drug. GUNN has drawn attention to the presence of a fluorescent constituent in calumba root which he does not consider due to any body which has yet been isolated. An interesting summary of the views which have been entertained as the etymology of the substance at present designated

officially under the name of creosotum has been published by J. INCE, who shows clearly that creosotum (creosote) is the only correct form in accordance with its Greek construction. Articles supplementary to that published last year on "The Early History of Phosphorus," giving an historical account of the introduction of phosphorus and its compounds into pharmacy, have demonstrated the important position now occupied by preparations of this class. The requirements of elegant pharmacy have also received due attention. STANWOOD has advocated the use of tablets in preference to pills, capsules, and powders, and in an exhaustive account of the preparation of compressed tablets, published in this Journal, full details were given of the apparatus required, as well as hints on the manipulation necessary in special cases.

COWIE has recommended a 20 per cent. proof spirit tincture of elderberry pericarps as an indicator for the determination of acids, the end reaction being sharp and unmistakable. A method of preparing small quantities of aromatic waters was described by SAGE, suitable for the requirements of the retail pharmacist. GUNN has devised a laboratory filter on the principle of a syphon, which was originally intended to minimise oxidation, and has also been found useful in dealing with liquids which went indifferently through flannel and twill, and absolutely refused to go through paper. Essential oils were dealt with by J. C. UMNEY, who in a lengthy paper described in detail their chemical and physical properties as met with in commerce, and threw out suggestions in the way of descriptions, characters, and tests which he considered should be embodied in the pharmacopœial descriptions.

BARCLAY, after determining the amount of extractive in tinctures which have been kept for some time, finds that if stored under normal conditions for a reasonable length of time, there is no serious loss. He has also re-directed attention to well-known variability in the ash of kamala, and the difficulty in obtaining a sample answering the requirements of the Pharmacopœia. LIVERSEEGE, after investigating methods of analysis of sal volatile, recommends a modification of GRAVILL'S process for the determination of the ammonium carbonate, in preference to that described in the Pharmacopœia, which has proved very unsatisfactory. The keeping properties of spiritus ætheris nitrosi have received further attention, and W. SMITH—after an examination of thirteen samples obtained from retail pharmacists, when only six were above the minimum pharmacopœial requirements—reiterates the statement that this preparation should either be deleted from the Pharmacopœia or be preserved by some better menstruum than rectified spirit. BOA has objected to the official formula for belladonna plaster on the ground of excessive softness and want of adhesiveness, and suggests a reduction of strength to 1 in 10, and the use of more resin. HENRY has proposed various combinations of cod-liver oil, both alone and in combination with malt extract, or eucalyptus oil, as suitable for official recognition, and he has also devised a formula for castor oil emulsion to take the place of the official mistura.

H. WYATT, JUN., has directed attention to the presence of a blue aniline dye in a sample of crystallised sugar, and contributed a useful note on the preparation of suppositories. The same author recommends the use of an alkaline cyanide in place of the hydrocyanic acid in the tincture of chloroform and morphine of the Pharmacopœia, in order to prevent the formation of the heavy deposit which forms on standing.

HORNBLLOWER read a note on the solvent action of pepsin on albumin without heat. WALKER, in recording his experience of the use of Irish moss as an emulsifying agent, has reported in favourable terms of its use.

British Pharmaceutical Conference. The Conference at Bournemouth was an exceptionally pleasant meeting, though not so well-attended as it deserved. The President, Mr. N. H. MARTIN, distinguished his second year of office by an address as vigorous in character as that delivered at Oxford. It is doubtful, however, whether some of the principles he endeavoured to inculcate will ever find a ready response from British pharmacists as a class. To entirely eliminate trade from the practice of pharmacy would be to put an end to pharmacy as a separate profession. At the same time, even the extreme views propounded by Mr. MARTIN may prove of ultimate value in determining the true position of the craft. The papers read at the meeting came up to the usual standard, and were disposed of in good time; the excursions, etc., were exceptionally enjoyable; and the hospitality of the local pharmacists was boundless. The affairs of the Conference appear to be in a somewhat critical condition at the present time, but whatever developments may take place, the members will doubtless be unwilling, and wisely so, to forego their annual picnic. The social side of pharmacy requires frequent attention no less than its political and scientific aspects, and it would be a matter for serious regret were these annual holiday meetings to be discontinued. As a means of recording the results of scientific and technical investigations, it may perhaps be thought that they are somewhat superfluous, but no such argument can be maintained with regard to the social character of the meetings.

Death Roll of the Year. The most distinguished names in the list of those deceased during the past year are undoubtedly those of T. H. HUXLEY, LOTHAR MEYER, Dr. HUGH CLEGHORN, and LOUIS PASTEUR, the last two being Honorary Members of the Pharmaceutical Society. To these must be added Sir GEORGE BUCHANAN, Sir W. S. SAVORY, Sir JOHN TOMES, Dr. HACK TUKE, M. DUJARDIN BEAUMETZ, KARL VOGT, MILES H. SMITH, H. HELLRIEGEL, and Professor BAILLON. ANDREW FERREIN, of Moscow, Dr. RICHARD GODEFFROY, of Vienna, and Professor JEAN EDOUARD BOMMER of Brussels, were Corresponding Members of the Pharmaceutical Society; R. O. FITCH, of Hackney, was a divisional secretary; J. B. MERRIKIN and R. PARKINSON, were formerly local secretaries for Bath and Liverpool respectively. W. GUNN, of Duns; W. B. CORDLEY, of Colchester; A. SEATH, of Dunfermline; and R. GRIFFITH, of Slough, were acting local secretaries. W. DARLING, of Manchester, was a founder; G. DUDGEON, of Nottingham, was a life member, and left a legacy of five hundred pounds to the Benevolent Fund; and J. S. LINFORD, of Hull, another life member, was formerly an examiner. Other old members of the Society who have departed were JOHN BLAND, of London; EDWARD TAYLOR, of Rochdale; A. J. CALEY, of Norwich, and J. W. FORBES, of Bolton, a well-known figure at the Conference Meetings. S. M. BURROUGHS was a generous donor to the Benevolent Fund, and amongst other deceased wholesale traders are W. H. PEAT, of London; W. H. SCHIEFFELIN, of New York; C. SARG, of Vienna; W. MATHER, of Manchester; and MORITZ ZIMMERMANN, of London.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

FIFTY-FIFTH YEAR OF PUBLICATION.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, JANUARY 4, 1896.

EDUCATION AND RESEARCH.

IN the January number of *Science Progress*, Dr. ARMSTRONG repeats the story of the manner in which the manufacture of aniline colours has now largely been transferred to Germany, though the first of the colours was discovered in England by PERKINS. British policy, he points out, is the precise reverse of that followed in Germany, as manufacturers in this country generally do not know what the word "research" means. They place their business under the control of practical but untrained men, who are too often and necessarily unprogressive; and such men, as a rule, actually resent the introduction into the works of scientifically-trained assistants. As a result there is no demand in Great Britain for men who have been carefully trained as investigators, and such people are only born and grow spontaneously, the schools not seriously attempting to train investigators. "If the English nation is to do even its fair share of the work of the world in the future its attitude must be entirely changed—it must realise that steam and electricity have brought about a complete revolution, that the application of scientific principles and methods is becoming so universal elsewhere that all here who wish to succeed must adopt them, and therefore understand them. It rests with our schools to make the change possible. English boys and girls at the present day are the victims of excessive lesson learning, and are also falling a prey in increasing numbers year by year to the examination demon, which threatens to become by far the most ruthless monster the world has ever known either in fact or in fable." In the great majority of cases, students fresh from school are said to have little if any power of helping themselves, little desire to learn about things, little if any observing power, and little desire to reason on what they see or are called on to witness. Moreover, the sweeping charge is made that such students are also destitute of the sense of accuracy, and are satisfied with any performance however slovenly, being neither inquisitive nor acquisitive, and too often idle as well, so that the opportunities offered to them are blindly sacrificed. As a remedy, it is urged that boys and girls at school must be taught from the very earliest moment "to do and appreciate." No facts must be taught without their use being taught simultaneously, and, as far as possible, students must be led to discover the facts for them-

selves. With regard to the existing competitive examination system, Dr. ARMSTRONG points out that it is not a likely one for "catching the potential Faraday," and that both Germany and Japan afford evidence that it is possible to prosper without it. China is the only country beside England that believes in the system, and "recent events do not encourage us to derive any consolation from that circumstance."

THE PROGRESS OF BACTERIOLOGY.

IN this subject there is nothing startling to chronicle during the past year. In morphology, JÖRGENSEN has published an investigation on the origin of wine yeasts, from which it would seem that the *Saccharomyces ellipsoideus*, associated with wine fermentation, is a peculiar development, brought about by natural conditions, of the *Dematium* or *Chalara*-like moulds which are always present on grapes. SOREL also (*Comp. rend.*, 1895, December 16) has by certain culture methods produced a yeast-like development from *Aspergillus orizae*. MARSHALL WARD (*Nature*, vol. 52, 1895, p. 658) has described a form which gave all the ordinary reactions of a bacterium on the usual culture media, but on cultivation under high powers it was found to be a minute oidial stage of a true fungus. ELSNER (*Zeitschr. f. Hyg.*, xxi., 1895) has devised a new culture medium, a potassium-iodide-potato-gelatin, for the isolation of the typhoid bacillus, by means of which he has been able to isolate the bacillus in fifteen out of seventeen cases. PETERS (*Brit. Med. Journ.*, 1895, vol. ii., p. 1557, Path. Soc.) has described the following varieties of the diphtheria bacillus: (1) Long Klebs-Löffler bacillus; (2) short diphtheria bacillus; (3) short pseudo-diphtheria bacillus. The latter is wide-spread and non-virulent, and he regards it as possibly being unconnected with the diphtheria bacillus, though closely resembling it.

The antitoxin treatment has not only not lost ground, but has been extended in several directions. A number of statistics are now available by which its efficacy in diphtheria may be gauged, and these have been ably analysed by WELCH (*John Hopkin's Hosp. Bull.*, vi., 1895, p. 97). The final result would seem to be that the mortality in diphtheria for all cases under antitoxin treatment is about 17 per cent., as against 29 per cent. the lowest, and 40 to 50 per cent. the highest previously recorded death rates.

Antitoxin is still the best mode of treatment in tetanus, and in some cases has produced remarkable amelioration in the symptoms. Its use as a vaccin or prophylactic has been advocated in veterinary practice by no less an authority than NOCARD. The latest development of the antitoxin treatment is in the direction of an anti-streptococcus serum for use in septic conditions and puerperal fever, and the reports up to date are most promising (*An. de l'Inst. Pasteur*, 1895, p. 615, Marmorek). The work of CALMETTE (*ib.* May, 1894, and April, 1895) on the preparation of an antidotal serum against snake venom has been confirmed and extended by FRASER (*Brit. Med. Journ.*, 1895, vol. i., p. 1309), who has given many additional details. In cancer, serum therapy by means of an anti-erysipelas serum has been advocated by EMMERICH and SCHOLL (*Deut. med. Woch.*, 1895, April 25) and by COLEY (*Med. Rec. N.Y.*, 1895, May 18), but so far it seems to have been useless. COLEY's method of treatment for sarcoma by means of a fluid containing the erysipelas and prodigious toxins seems to have gained ground, and COLEY states that he has cured eleven out of forty-

three cases by means of it (*Journ. Amer. Med. Assoc.*, 1895, ii., p. 131). At the end of last year SMIRNOW and also KRUGER independently made the important discovery that bacterial toxins could be converted into antitoxins by electrolysis, and SMIRNOW has employed this artificial antitoxin for treatment (*Berl. klin. Woch.*, 1895, Nos. 30, 31). The report of the Royal Commission on tuberculosis, published last April, contains some important conclusions, chief among which are the extremely virulent nature of the milk derived from a tuberculous udder, and the fact that ordinary cooking does not sterilise the centre of a joint unless it is under six pounds in weight.

THE SOCIETY'S LIBRARY AND MUSEUM.

THE steady growth of the Library in London has necessitated a further supply of shelf accommodation during the past year; by means of this supply the Librarian has been enabled to re-arrange certain portions of the Library, which, through overcrowding, had become inconvenient to work. Among the chief additions to the Library in the course of the year may be instanced the concluding volumes of the great Index-Catalogue of the Library of the United States Army Surgeon-General's Office, which extends to sixteen volumes of about 1000 pages each volume; Ladenburg's 'Handwörterbuch der Chemie,' in thirteen volumes; 'Index Kewensis,' in four parts, compiled at the expense of the late Charles Darwin, and prepared by Mr. Daydon Jackson under the direction of Sir Joseph Hooker; Kerner and Oliver's 'Natural History of Plants'; and Vines's 'Text-book of Botany.'

Of new books there may be noted Green's 'Manual of Botany'; a translation of Warming's 'Systematic Botany'; the third volume of Trimen's 'Handbook of the Flora of Ceylon,' with accompanying plates; the first published portion of Durand and Schinz's 'Conspectus Floræ Africae,' being the fifth volume; Griffith's 'Flora of Anglesey and Carnarvonshire'; the first and second parts of the second supplement to Wurtz's 'Dictionnaire de Chimie'; Sadtler and Trimble's 'Medical and Pharmaceutical Chemistry'; the second edition of Sadtler's 'Industrial Organic Chemistry'; parts 1 and 2 of Dammer's 'Chemische Technologie'; the third edition of Remington's 'Pharmacy'; the second edition of Coblentz's work on the same subject; Planchon and Collin's 'Drogues Simples'; Buchheister's 'Drogisten-Praxis'; and new editions of the 'Extra' and Norwegian Pharmacopœias. The circulation of books has been more than 2000, nearly equally divided between London and country borrowers; for the latter class the cost of carriage one way is defrayed by the Society, and the term of three weeks allowed for the retention of books, thereby approximating an equality of privilege with town borrowers, who have to collect and return books at their own charges, and are entitled to retain the volume fourteen days only. A slight decrease is found in the number of signatures of readers attending the Library, the numbers for the year being about 4200 during the day, and nearly 1500 in the evening hours.

The circulation of books from the Edinburgh Library is increasing, upwards of 1400 volumes having been sent out last year, as compared with 1300 issued in 1894. Various new books have been added, amongst them being Green's and Vines's works on botany, and Kerner and Oliver's 'Natural History of Plants.' Several atlases of the micro-

scopic structure of plants, and some valuable works in organic chemistry, have also been placed on the shelves. The Library has been increasingly taken advantage of for reference. A detailed plan for the fitting up of the old boardroom as a library has been prepared for the approval of the Council, and it is expected that the work will be proceeded with in the course of the year just begun.

The donations to the Museum of the Society during 1895 consisted of 183 specimens of drugs, and 1771 specimens of dried medicinal plants, chiefly North American and Australian, the latter including a large number of species of eucalyptus. A descriptive report of the donations received during the year 1893-94 has recently been issued in the form of a pamphlet of 105 pages.

SCHOOL OF PHARMACY.

THE School of Pharmacy is at the present time in a very flourishing condition. The number of students attending the lectures and demonstrations is much larger than has been the case for many years past, in the Laboratory of Practical Chemistry the demand for places having been especially great. As has been pointed out on numerous occasions, the establishment of a school where those who have entered upon the calling of pharmacy should be properly instructed in the arts and sciences necessary for practising that calling in an efficient manner, was one of the principal objects that the founders of the Pharmaceutical Society had in view. It was, of course, never expected that the School would be large enough to accommodate all those who at any one time were engaged in study and preparing for examination, but it was intended that the School should be a model School where all that was necessary should be taught in the best way by teachers skilled in their respective subjects, and that the instruction given and the method of imparting it should keep pace with the progress of the times. It is matter of common knowledge that the Council of the Pharmaceutical Society have spared neither pains nor money in carrying out these objects. How well on the whole they have succeeded may be gathered from the increasing number of students attending the School, and from the very large proportion of those that present themselves for examination that are successful in satisfying the examiners. This success is the more noteworthy when it is considered how very limited is the time in which the course of instruction has to be gone through. On referring to the examination schedule officially issued, it is evident that both teachers and students must work very hard to go over a complete course for the Minor examination in about five and a half months, and then proceed immediately to a complete course for the Major examination lasting about another ten weeks. With the best intentions in the world it is clear that an average man cannot properly assimilate so much knowledge in so short a space of time. A much more satisfactory plan would be to have a two years' curriculum, one year being devoted to a course of study suitable for the Minor examination, and the second year to more advanced work. The two courses of instruction could very well exist side by side. At present all that can be done is to advise intending students to acquire as much knowledge as they possibly can before entering the School; and in order to assist them in such preliminary studies, the Society has issued a little pamphlet entitled "Advice to Students," which is sent gratis to all who apply for it to the Secretary and Registrar, Mr. RICHARD BREMRIDGE.

ANNOTATIONS.

WHAT IS WHITE WINE VINEGAR?—A fuller report of the case referred to in last week's *Supplement* appears in this week's issue (see page 18), the arguments for the defence being added. In a communication received from Mr. Jesse Boot, the statement is made that "Without question the sale of diluted acetic acid as white wine vinegar has been common in the trade, and a well-understood thing between buyer and seller." So far as the legitimate drug trade is concerned, this statement is not true, whatever custom may prevail outside. The further statements in the letter that the firm had given "very definite and positive instructions" that diluted acetic acid was not to be sold for white wine vinegar, and do not countenance the substitution in their shops, are sufficiently answered by the report of Mr. Whitwell's evidence. It is very satisfactory to note the attitude of the Stipendiary in the matter, both with regard to the responsibility of employers for the acts of their servants, and to the extra necessity for carefulness on the part of salesmen who are qualified chemists.

CHEMISTS' ASSISTANTS' ASSOCIATION.—A smoking concert will be held by the members of this Association at the Frascati Restaurant, Oxford Street, London, on Thursday, January 9. The chair will be taken at 8 p.m. by Professor Reynolds Green, Sc.D., F.R.S., Dean of the School of Pharmacy, and the vice-chair by Mr. C. B. Allen, Member of Council of the Pharmaceutical Society. Tickets (1s. each) may be obtained from Mr. T. Morley Taylor, 13, Queen's Terrace, St. John's Wood, N.W. Referring to the Cinderella dance recently held (see last week's *Supplement*, p. ii.), Mr. H. H. Robins points out that the number of tickets issued and dancers present was 150, and that Mr. C. W. Martin acted as M.C. The programme for the second half of the session includes papers on the action of certain drugs on the human eye, by Dr. Juler; the chemical training of pharmacists, by J. C. Evans, F.I.C.; nutrient preparations of beef, by A. W. Gerrard; British and foreign syrups, by Jos. Ince; and other interesting topics. There will also be the usual short papers by members, the annual dinner, a social evening, and another Cinderella dance, in addition to a visit to Idris and Co.'s factories.

GERMAN PHARMACY IN NEW YORK.—The official organ of the New York Deutscher Apotheker-Verein—the *Monatsblatt*, a monthly publication—has now ceased to represent the Society officially, but it will hereafter be issued independently, in the same manner and under the title: *Monatsblatt zur Förderung der Gesamtinteressen des pharmaceutischen Standes in den Vereinigten Staaten von Nord-Amerika*. The former publishers have assigned to the new proprietors, Messrs. A. Wortmann and R. A. Matter, all rights to existing contracts, subscriptions, etc., and ask their readers and collaborators to kindly transfer to the new firm all the favours and goodwill shown to the old concern.

THE SALE OF POISONS IN SCOTLAND.—Plain speaking seems to have been in favour at the meeting of the Glasgow chemists and druggists on Thursday last, and it is gratifying to learn that the proceedings were fully reported in the local press. There is no doubt that this is one of the best methods of educating the public to a sense of the care taken to protect it from the effects of the careless handling of poisons, and pharmacists in other places, but especially in other Scottish towns, should promptly follow the example set by their Glasgow brethren. A report of the proceedings at the meeting will be found on page 16.

MISUSE OF THE TITLE "CHEMIST."—Another instance of the too frequent misapplication of the title "chemist" was afforded by the *Bedfordshire Advertiser* for December 20, in the report of a case heard at the Luton County Court on the previous day. The defendant, T. Jackson, Hightown Road, Luton, who is not registered as a chemist and druggist, was sued for damages by a domestic servant, who alleged that she had been supplied from his shop with oxalic acid in mistake for Epsom salts. A boy of fourteen was sent for a quarter of a pound of Epsom salts and was served by Jackson, who maintained that he was asked for oxalic acid, which he supplied accordingly. The packet appears to have been properly labelled, but the plaintiff either could not or did not read the label, and swallowed a fourth of the contents of the packet dissolved in water. She realised at once that something was amiss, and emetics were administered in time to prevent a fatal result, though the girl was for some time in a dangerous condition. There was a conflict of evidence as to what the boy actually asked for, and judgment was given for the defendant, the judge observing that there was no doubt the boy was sent for Epsom salts, but it was not clear what he asked for. It is to be hoped that chemists and druggists in the neighbourhood of Luton will take steps to disclaim the connection of Jackson with themselves.

PRIZE FOR THE DISCOVERERS OF THE SERUM TREATMENT.—It can no longer be maintained that the study of experimental science does not conduce to pecuniary profit. Ramsay and Rayleigh have received large sums of money in the form of prizes for their work on "argon," and now the Albert Lévy prize has been awarded by the Academy of Medicine to Dr. Behring, of Berlin, and Dr. Roux, of Paris, for their investigations which have resulted in the serum treatment of diphtheria. The prize is worth two thousand pounds sterling—a fair reward for the introduction of a remedy which may yet prove generally inefficacious. For though it has already been fully assumed in certain quarters that the serum treatment effects the cure of diphtheria, the evidence is very contradictory, and definite proof is not yet forthcoming.

THE BOTANICAL SOURCES OF ESSENTIAL OILS.—Some little time ago a descriptive catalogue of essential oils and organic chemical preparations employed in perfumery, compiled by Dr. F. B. Power, was published in New York. This summarises the information contained in the half-yearly reports of Schimmel and Co., of Leipzig, up to the year 1894, the oils being classified alphabetically, according as they are official in the United States Pharmacopoeia or non-official. The botanical sources of the oils are stated, also their physical properties, uses, and, in many cases, the tests for purity. The organic chemical bodies form a separate chapter. It is to be regretted that the compiler has neglected to notice the occasional criticisms that have been published concerning the botanical sources of some of the oils. Thus, oil of costus is not obtained from *Costus speciosus*, but from *Aplotaxis auriculata* a Composite plant, whilst oil of cassia is erroneously stated to be distilled from an "undetermined" species of *Cinnamomum*, and oil of opoponax from *Opoponax chironium*. It would also have been an advantage if an attempt had been made to introduce a more definite terminology, by reserving the termination "one" for ketones, "al" for aldehydes, and "ol" for alcohols. Thus, carvol might have been written—carvone (carvol). This has been done in the case of salviol, which is now given as thujone. Making due allowance for these slight inaccuracies and deficiencies, the compilation should be found very useful for reference purposes by those interested in essential oils.

A NEW HEAVY LIQUID.—In the December number of the *American Journal of Science*, S. L. Penfield describes the preparation of a new heavy liquid obtained on mixing equal proportions of silver and thallium nitrates. On heating the mixture it fuses at 75° C., forming a clear mobile liquid of density 4.5. This mixes with water in all proportions, and can therefore be used to separate mineral particles of densities below 4.5. When still heavier particles have to be separated, the proportion of thallium may be increased. When the ratio is 3 : 4, the mixture fuses below 100° C. and has a density of about 4.7; at 2 : 4 the fusing point becomes 150° C., and the density 4.8; at 1 : 4 it is about 4.9, and fusion only takes place at 200°. Finally, when pure thallium nitrate is used, the point of fusion is 250° C., and the density closely approaches 5.

NEW JOURNALS OF PHARMACY AND CHEMISTRY.—America is to the fore with new pharmaceutical publications, of which that continent already produces more than any other. *Le Pharmacien Canadien*, edited by Edmond Giroux, jr., and published at 216, Rue Saint Laurent, Montreal, Canada, is a monthly review of practical pharmacy, containing also current news and professional notes. The *Southern Journal of Pharmacy and Materia Medica*, edited by Dr. R. C. Bicknell, and published at 309, North Market Street, Nashville, Tennessee, U.S.A., also appears monthly, as does, moreover, the *San Francisco and Pacific Druggist*, edited by W. A. Taylor, and published at 23, Second Street, San Francisco, U.S.A. The first number of a new French paper, the *Annales de Chimie Analytique*, edited by C. Crinon and published under the patronage of the *Syndicat Central des Chimistes et Essayeurs de France*, at 45, Rue Turenne, Paris, is dated January 1, 1896. The foreign subscription is twelve francs, and the paper will appear on the 1st and 15th of each month.

THE WORK OF THE PASTEUR INSTITUTE.—The report of the work done at the Institut Pasteur, Paris, during the third quarter of the past year shows that 382 persons were under treatment in July, August, and September, of whom 360 were French, and 22 foreigners. Fifteen individuals had been bitten by animals experimentally proved to be mad, and 137 by animals only suspected of being so. It is alleged that a boy under treatment at the Jassy branch actually recovered from an attack of hydrophobia, but this statement will probably be accepted with reserve.

NEW YEAR'S HONOURS.—The list of honours published on Wednesday, January 1, includes the names of Surgeon-General Sir Joseph Fayrer, K.C.S.I., M.D., LL.D., F.R.S., and Mr. Thomas Boord, F.S.A., of the firm of Boord and Son, upon whom baronetcies are conferred. Professor Joseph Prestwich, D.C.L., F.R.S., the distinguished geologist; Dr. Willoughby Wade, who was President of the British Medical Association at the Birmingham meeting; and Mr. Robert Martin Craven, F.R.C.S., of Hull, receive the honour of knighthood, and Mr. Harry Charles Fischer, Controller of the Central Telegraph Department of the General Post Office, is appointed C.M.G. The Poet-Laureateship has been conferred upon Mr. Alfred Austin, the appointment evoking considerable surprise in the daily press.

GLUCINUM FROM EMERALDS.—It is stated that H. N. Warren, of Liverpool, has recently extracted the glucinum from six pounds of emeralds. Stones of dull water, and of comparatively little value from the jeweller's point of view, were specially imported from various parts of the world; and, the reducing operation having been successfully performed, the metal was worked into various articles and sent to the Ameer of Afghanistan.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

MAJOR EXAMINATION QUESTIONS.

Monday, December 30, 1895.

A Paper.*

BOTANY AND MATERIA MEDICA.

Time allowed—10 a.m. to 1 p.m.

1. Describe the structure of the inflorescence and flower of any gramineous plant. Give a diagrammatic sketch of a section passing through the seed, showing the relation of the embryo to the endosperm.
2. A growing plant is placed in sunlight and a warm atmosphere until its leaves show signs of withering; it is then transferred to a very moist atmosphere. Explain any change which would take place in the appearance of the plant.
3. Compare the structures in which spores are produced in a fern, a moss, and a horsetail.
4. Give the botanical name and natural order of the plants from which the following preparations are obtained: Kola Nut, Cubebs, Catechu, Gamboge, Croton Oil. Mention the distinguishing features which will enable you to identify the above substances. What is the active constituent of each?
5. What official preparations are obtained from plants of the natural order Rhamnaceæ? Give a full account of one of them, mentioning the part of the plant from which it is obtained, and briefly describe the mode of its preparation.

A Paper.*

PRACTICAL BOTANY AND MATERIA MEDICA.

Time allowed—2 to 5 p.m.

1. Describe in botanical language the plant provided, taking its parts when present in the following order:—
Root, stem, leaves, inflorescence, flower, fruit, seed.
2. Make not more than two microscopical preparations illustrating the structure of A. Leave with your slides explanatory sketches for examination. What is A?
3. Prepare a section of the drug B. Identify it, sketch, and briefly describe your preparation. Call attention to any characteristic features which it presents. Examine it micro-chemically for the active principle it yields. Show in your drawing where this occurs.

B Paper.*

BOTANY AND MATERIA MEDICA.

Time allowed—2 to 5 p.m.

1. Describe the structure of the inflorescence and flower of any ligulate composite plant. Give a concise account of the arrangements in the flower which tend to secure cross-fertilisation.
2. A leaf is detached from a green plant which has been growing in sunlight. Both leaf and plant are placed in the dark for twelve hours. At the end of that time the detached leaf is found to contain an abundance of starch, but the leaves on the plant have little or no starch in them. Explain these facts and mention what test you would apply in searching for starch.
3. Compare the gametophyte (sexual generation) of a vascular Cryptogam with that of a flowering plant.
4. Give the botanical name and natural order of the plants from which the following preparations are obtained:—
Liquorice, Calabar Bean, Gum Arabic, Bear-berry, Wintergreen Oil.
What is the active principle in Calabar bean? In what proportion does it exist? How would you isolate and identify it?
5. What official preparations are obtained from plants of the natural order Malvaceæ? Give a full account of one of them, mentioning the part of the plant from which it is obtained, and briefly describe the mode of its preparation.

* Part of the candidates received the papers A, A, and the remainder had the papers B, B.

B Paper.*

PRACTICAL BOTANY AND MATERIA MEDICA.

Time allowed—10 a.m. to 1 p.m.

1. Describe in botanical language the plant provided, taking its parts when present in the following order:—

Root, stem, leaves, inflorescence, flower, fruit, seed.

2. Make not more than two microscopical preparations illustrating the structure of C. Leave with your slides explanatory sketches for examination. What is C?

3. Prepare a section of the drug D. Identify it, sketch, and briefly describe your preparation. Call attention to any characteristic features which it presents. Examine it micro-chemically for the active principle it yields. Show in your drawing where this occurs.

Tuesday, December 31, 1895.

CHEMISTRY.

Time allowed—10 a.m. to 1 p.m.

[Six Questions only are to be attempted.]

1. What is osmotic pressure, and how can its measurement be applied to the determination of molecular weight?

2. State and explain the laws which have been found to govern the solubility of gases in water, and account for the fact that the air which is dissolved in water contains two volumes of nitrogen to one volume of oxygen.

3. Describe fully how you would propose to quantitatively determine the calcium and phosphoric acid respectively in a specimen of bone-ash. Indicate also the principles on which the analytical process is based.

4. What is the source and mode of manufacture of arsenious anhydride? Compare the modes of preparation and properties of the several oxides and oxy-acids of arsenic and phosphorus.

5. What are Fehling's and Pavy's solutions? For what purpose, and how, are they employed, and what precautions must be observed in using them if accurate results are to be obtained?

6. How can acetylene be now obtained in large quantities? Indicate how ethyl alcohol and benzene can be respectively obtained from acetylene?

7. What is mannite? Explain fully how it is related to dextrose and lævulose respectively.

8. How would you propose to obtain phenol and mono-chlor-benzene respectively from aniline?

9. How are lactic and butyric acids commonly obtained from sugar?

PHYSICS.

Time allowed—2 to 5 p.m.

[Six Questions only are to be attempted.]

1. Describe the construction and use of the hydrometer, and show how the principle of the instrument is connected with that involved in the usual method for determining the densities of solids.

2. Describe methods for determining the relative illuminating powers of two flames, and explain the principle on which such methods depend.

3. Give some examples of the influence of light in promoting chemical change.

4. Give an account of some experiments illustrating electric induction. How can the gold leaf electroscope be used for the purpose?

5. What is the mode of action of the electrophorus?

6. What is the meaning of the terms "absolute expansion" and "apparent expansion of a liquid?" How has the absolute expansion of mercury been determined?

7. What is meant by the term "unit of heat?" Describe an experiment in which units of heat are measured.

8. A steel tool that has been used in a lathe for turning metals will frequently attract iron filings: what is the cause of this? Can a steel bar be magnetised without the use of artificial magnets or of an electric current?

9. What is meant by magnetic lines of force? Describe experiments indicating their existence in the case of a bar magnet and also in the case of one with consequent poles.

* Part of the candidates received the papers A, A, and the remainder had the papers B, B.

PROCEEDINGS OF SOCIETIES.

LIVERPOOL CHEMISTS' ASSOCIATION.—At the meeting of this Society on Thursday, December 19, Messrs. E. Dowzard and Donald Cameron and Professor Harvey-Gibson, of University College, were elected members.

Mr. T. H. Wardleworth exhibited some of the false white horehound shown by Mr. E. M. Holmes, F.L.S., Curator of the Pharmaceutical Society's Museum, at the evening meeting held in London on December 11, and identified by him as the *Marrubium candidissimum*. The following paper was then read:—

"Note on Blaud's Pills," by R. C. Cowley, Ph.Ch.

Such an amount of literature already exists on the subject of Blaud's pills, that I must almost apologise to this meeting for bringing to its notice such a well-worn theme. However, it is not my purpose to deal with the many and various methods, good, bad, and indifferent, of making these pills, nor yet to discuss the somewhat nice point as to whether the chemical reaction of their ingredients should take place before or after the pills reach the patient's stomach, but rather to place before you a few facts relative to the quantity of ferrous carbonate present in ordinary commercial specimens, such as are now being retailed at extremely low rates. With this purpose I obtained recently in all about thirteen specimens, several of which are being pushed amongst medical men as having peculiar advantages not possessed by the pills of other manufacturers. Tabulated below is the result of my analysis, the ferrous iron being all calculated as carbonate. The apparent low quantity of carbonate in No. 4 is due to the small amount of ferrous sulphate used in making it, for the dried sulphate had been used from the formula published on the package, and bicarbonate of sodium instead of carbonate of potash. Doubtless the dried sulphate was deficient in ferrous salt from over-heating in its preparation.

No. 7 represents a four-grain pill; a five-grain pill of the same strength would be equal to .956 grain of FeCO₃.

In each pill.	FeCO ₃ present.	When made.
No.	Grains.	
1.....	1.946	Fresh.
2.....	1.253	6 months old.
3.....	1.079	3 " "
4.....	.698	New stock.
5.....	1.692	9-12 months old.
6.....	1.409	18 " "
7.....	.765	12 " "
8.....	1.017	6 weeks "
9.....	1.047	12 months "
10.....	1.163	10 " "
11.....	.905	Fresh.
12.....	.785	2 years "
13.....	.898	A few months "

It will be observed from this table that many of the Blaud's pills on the market are stronger than the Pharmacopœia demands, a serious objection. The quantity of ferrous carbonate there stated is about 1 grain in each pill.

Mr. Conroy said he should like to ask Mr. Cowley how it happened that in sample No. 4 more ferrous carbonate was found than would be yielded by the amount of sulphate of iron used. The point was not very clear to him. Mr. Cowley's paper was useful from its showing that Blaud's pills of commerce if they erred at all, erred on the side of being above the B.P. requirements, still the amount of FeCO₃ in the first sample was quite abnormal, being double that of the official pill—a very serious error, and one quite inadmissible in his opinion.

Mr. Mitchell asked if Mr. Cowley had tested the solubility of the coatings on the pills he examined, for in his experience this varied considerably. His method was to place the pill in an acidulated weak solution of pepsin contained in a test tube and kept at about 93° F., shaking from time to time, and noting the length of time taken to entirely dissolve the coating.

Mr. P. H. Marsden expressed an opinion that the coating might have an influence on the result of the iron determination, and wished to ascertain if there was a method by which the coating could be effectually removed before the determination was proceeded with. He had examined Blaud's pills, and, as far as his memory served him, he got an average result of about 20 per cent. of ferrous salt.

Mr. Conroy assured Mr. Marsden that the coating had little or no effect on the determination. His method was to take ten pills, so as to get a fair average sample and to have plenty of material to work upon, dissolve them with a little acid, and then determine the ferrous iron in the usual way. The action of the stomach, he would remind Mr. Mitchell, was by no means to be represented by a test tube containing an acid liquid at the temperature of the body. There was mechanical action of a very effective nature always going on, for which the test tube offered no equivalent.

Mr. T. F. Abraham thought it a pity Mr. Cowley had not determined the total iron, both ferrous and ferric, present in the pills, as then one would have known whether the proper amount had been used in their manufacture. It was just as wrong to exceed the B.P. requirements as to be below them, and from the particulars given by Mr. Cowley there were several of the samples examined far in excess of the proper content of ferrous salt. An encouraging point, as pharmacists would admit, was that the pills made by the dispenser from the B.P. form had turned out so satisfactory.

Mr. Cowley then replied to Mr. Conroy's criticism, saying his meaning was perhaps not very clear as regarded sample No. 4. What he intended was that .698 grs. of FeCO_3 was more than the amount of FeSO_4 in the formula published on the package would yield, so that the dried sulphate had most certainly been used, though the makers did not say so. He had not determined the total iron nor had he timed the solubility of the various coatings.

Mr. Harold Wyatt, Jun., wished to draw the attention of the members, whilst Bland's pills were under their notice, to a formula published in the *Pharmaceutical Journal* of November 30 from *Il Bollettino Farmaceutico*, of Milan, by Signor Ravà, a Doctor of Pharmacy of Parma. A sample of the pill mass produced by the formula was passed round, and excited considerable interest from its light colour and evidence of containing the maximum amount of ferrous carbonate in its true, nearly white, and unoxidised condition. This was the result, Mr. Wyatt thought, of using bicarbonate of sodium, the CO_2 given off during the reaction acting as a protection to the ferrous carbonate.

The next communication was a—

"Note on Vinegar," by R. C. Cowley, Ph.Ch.

In the Pharmacopœia, vinegar is described as a brown coloured liquid with a peculiar odour, specific gravity 1.017 to 1.019. After the addition of ten minims of solution of barium chloride and filtration, a further addition of BaCl_2 solution should cause no precipitate. No change of colour is caused by H_2S . At a previous meeting I remarked that I should be sorry to see a standard given for vinegar in the Pharmacopœia attainable by but few commercial specimens, and observing that of late in the discussions relative to the new Pharmacopœia and its contents many persons advise the deletion of vinegar from its pages. I thought it might be interesting to get to know something about the commercial article. I accordingly obtained from various retailers twelve samples of vinegar, subjected them to the B.P. tests, and also determined the extractive matter dried on a water bath. The extractive yielded is important, as it

Sample.	Acid per cent.	Extractive at 212° F. per cent.	Specific gravity.	Sulphates.
A	4.78	2.13	1.015	Faint trace.
B	5.09	2.47	1.016	Did not exceed B.P. quantity.
C	4.08	2.69	1.017	Traces.
D	5.19	3.17	1.019	Not in excess of B.P. quantity.
E	2.47	1.77	1.011	Traces.
F	2.29	.46	1.005	Nil.
G	4.009	2.26	1.014	Traces.
H	4.87	2.10	1.016	Traces.
I	4.13	2.86	1.017	Traces.
K	4.26	1.71	1.013	Not exceeding B.P. limit.
L	4.206	2.55	1.015	Traces.
M	4.25	1.36	1.011	Trace.

enables one to judge whether the vinegar under examination is what it professes to be, or whether it is only dilute acetic acid.

Not one of the specimens reached the B.P. standard, but only one could be regarded as a "doctored acetic acid." This specimen was

not obtained from a pharmacist; still, the best of the series was not either, if that be consoling to pharmacists generally.

The question naturally arises, is vinegar a food or a drug? From its being contained in the Pharmacopœia it undoubtedly is a drug, and as such is used in certain pharmaceutical operations, therefore it behoves every pharmacist to strive to attain, as regards vinegar, the standard demanded by the Pharmacopœia.

In the discussion which ensued, the President said that from the sources of Mr. Cowley's samples one could not be altogether surprised at the general result. That vinegar was both a drug and a food within the meaning of the Act he for one was certain.

Mr. Conroy did not think that the specific gravity of a sample was a very safe guide as to its being a good vinegar or not, for the gravity was so easily altered and manipulated by the addition of glucose, etc. The general characters and reactions, coupled with an intelligent reading of their purport, were the only safe and reliable data from which to judge a sample.

Mr. E. Davies, F.C.S., F.I.C., speaking as an analyst, would welcome a definite and authoritative standard by which to judge vinegars. Mr. Cowley's results were fairly satisfactory except the last sample, which was undoubtedly not vinegar.

The succeeding lecture on "Some Relations of Pharmacy to Mythology," by Mr. Edward Cox, was an interesting and learned description, illustrated in many instances by drawings of antiquarian relics mostly existing in the Chester Museum of the general analogy between mythology and pharmacy. The origins of mythology, human and pantheistic, the connection of Nature's powers and products with mythological ideas, such as those dealing with life and immortality, in which alcohol in the form of wine played a great and important part, were gone into. Various ancient theories were discussed relative to the proper use of resins, gums, etc., and their action when burnt in producing sleep or unconsciousness, or a species of inebriation in which the person affected was held to become endowed with prophetic power, the Sibyls being given as examples of this form of excitement. The part played by gems and precious stones, as well as certain parts of animals, in mythology was the reason of their introduction into medicine. These the lecturer rapidly surveyed, mentioning the decadence of medical knowledge during the Renaissance, and concluding by describing minutely the various flint implements, stone altars, and sketches of other curiosities, which contributed not a little to make his remarks a highly pleasing and uncommon intellectual treat, at the close of which a cordial vote of thanks was passed to the lecturer.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.—At the fortnightly meeting of this Association, held on Thursday, December 26, Mr. W. L. Currie, Dowanhill, presiding, a discussion took place regarding the administration of the poison laws in Scotland, and the animadversions made upon the Pharmaceutical Society by High Court and Sheriff Court Judges were strongly denounced.

The subject was introduced by Mr. D. Watson, who, in the course of a paper on the "Poison Laws," said it behoved every registered chemist, not only as a public duty, but in the general interest of the craft, to see that all the statutory obligations imposed upon the chemist were carried out faithfully. If that had been done during the last twenty-five years the trade would have been in a better position to-day, and they would not hear those remarks so often made by sheriffs, who had no sympathy with the provisions of the Pharmacy Acts. The judges would not have been in such darkness about the laws regulating pharmacy, and would have shown by this time that it was their duty to carry out the Pharmacy Acts. Recent decisions obtained in their favour in the highest Courts by the Pharmaceutical Society, although legal, were evidently not popular, judging from the remarks made by the judges in several important decisions. Trade protection pure and simple and the prohibition of company pharmacies were scarcely possible at present with such unfriendly expressions of opinion from the Bench. The public mind must be educated, and every opportunity seized to explain the true nature of things.

Mr. Laing said that, in view of several decisions recently given in the law courts, he thought it would be well for chemists to make a united protest against the way the Pharmacy Acts were administered in Scotland. Not only was odium cast on the Pharmaceutical Society, and every encouragement given to make the public look upon the Society as a persecutor of respectable tradesmen, but slurs and innuendoes against chemists

whose rights—not privileges—were usurped and abused by those tradesmen, were too common. In Glasgow, not a fortnight ago, there was a case notorious for the unintelligent reading of the Act displayed by the Sheriff and counsel on both sides, and the conviction in that case was followed by a mere admonition, without costs. It was the duty of the trade to take the matter up, for clearly the Society could not, without being seriously misrepresented; and if chemists had not sufficient stamina to assert their rights they deserved to suffer for ever after. Chemists enjoyed neither privilege nor monopoly. A complaint should be forwarded, through the Society, to the Privy Council, and he hoped the Glasgow Association would take some action, because the way in which the law was at present administered in Scotland was a scandal.

The Chairman said the absurd opinions expressed from the Scottish Bench should not be allowed to pass without comment. A strong protest ought to have been made against the remarks that fell from the judges, and a representation made to the Privy Council on the matter. A judge was there not to give his private opinion, but to administer justice, and he had no right to say that he had no sympathy with the action of the Society. In a recent Glasgow case the Sheriff said he had no sympathy with those prosecutions against employes. That was all very well, but it was not justice. The observations of the Glasgow Sheriff in particular should not be allowed to pass without comment, and he would be very willing to undertake to frame a communication and send it to the public press, protesting in the name of the Glasgow Association against the misrepresentations to which those remarks exposed chemists. There was an opinion in the public mind that the prosecutions were for the benefit of chemists themselves, but that was an error which ought to be corrected.

Mr. Russell said this was a matter which could not be proceeded with too carefully. At present the doorsteps of many of the chemists in the city were not too clean, and if they lived in glass-houses they knew what to expect.

Mr. Watson remarked that the feeling of the public undoubtedly was that the Pharmaceutical Society existed purely in the interests of chemists. That feeling was helped to a great extent by the attitude taken up on this question by the public press.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.—At a meeting held on Wednesday, December 18, at the Exchange Rooms, Birmingham, the newly-elected President, Mr. T. C. Clarke, delivered the opening address. Owing to the recent organisation of the Association, and the ground traversed being so very limited, his remarks would be confined in great measure, he said, to the outlook generally and the objects the Association has in view and desires to achieve. He was sure that anyone giving even a cursory glance at the programme for the session could not fail to be impressed with the utility of the meetings, treating, as they did, with topics of such a nature as could be turned to practical advantage by anyone desiring to become conversant with the intricacies of the profession, and at the same time not sufficiently far advanced to be beyond comprehension and appreciation.

There was a deplorable want of appreciation and respect shown to pharmacists, and of respect due to them as men above the average tradesmen's standing, both educationally and socially, and in consequence the trade was losing caste. In years gone by chemists could claim far more respect than can those of the present day, despite the fact that a period of apprenticeship was then the only qualification needed, just as in these days a grocer and a draper blossoms forth. This he accounted for by assuming that in those days there was a public tendency to regard pharmacy as a calling of an essentially and indisputably scientific nature, and so long as that opinion prevailed things went well with pharmacists, and Mr. Clarke reasoned that, in view of the fact of there now being a considerable amount of science necessary to make competent pharmacists, they were not unreasonable in looking for and desiring that respect. Moreover, he was of opinion that the best way to bring this very desirable state of affairs about was by joining and heartily supporting such an Association as the one there assembled, and in that way take a definite step in the right direction. That he thought would help to bring about a far more satisfactory state of affairs, both socially and financially, than was now extant.

He proceeded to say that another reason in favour of the formation of the Association, and, moreover, one which should in itself induce members to accord it their heartiest support, was that the social meetings which they proposed holding would alone be a means of affording facilities for making friendships and acquaintances which

otherwise would never be formed, and thereby promote that good fellowship so essential to the general welfare. Having set forth several other advantages, he concluded by reminding the assembly that they had now definitely formed an association, the destiny of which was entirely in their own hands, and therefore it remained for each member who joined their ranks to do his utmost to ensure its success. He wished to impress upon all the importance of treating that Association as a serious undertaking, and to make a point of attending each meeting, whether of a business or social nature. He promised them that the Committee would provide a programme sufficiently attractive to engage their attention at every meeting held. There were difficulties to be overcome, however, in the infancy of any association, and they could not expect to commence where others of considerable standing had finished. They would very soon, unless he was much mistaken in the character of the members, have a spirit of emulation among them, tending to improve their claim to hold a better position in the estimation of their friends, among whom, he was sure, they all reckoned their respective and respected employers.

A hearty vote of thanks was given to the President, and this having been suitably replied to, the proceedings terminated.

LONDON INSTITUTION.—Professor Vivian Lewes gave the first of a course of three lectures, intended for young persons, on "Three Great Chemists and their Work," at the London Institution on December 27. The subject of the lecture was Joseph Priestley. Beginning with a short sketch of Priestley's early life, the lecturer proceeded to mention some of his more important discoveries and investigations. His researches upon carbonic acid gas were described, and it was shown that, in addition to various observations on its properties, which were not altogether novel, he found out that it was soluble in water, and, in view of the way in which he turned this fact to practical account in the imitation of highly-purified German natural waters, he might be called the father of the aerated water trade. Noticing that a candle burning in a closed vessel of common air soon went out, while a mouse shut up in the same vessel did not live long, carbonic acid gas being formed in both cases, Priestley was led on to the discovery that a sprig of growing vegetation placed in the vessel in a few hours so revived the air that the candle could burn and the mouse live. Owing, however, to his ignorance of the true nature of the atmosphere, he was unable wholly to explain the wonderful cycle of nature by which the vegetable undoes the work of the animal, and, by continually assimilating the carbon of the carbonic acid produced by the latter, provides the constant supply of oxygen necessary to its life. Priestley's experiments with nitrous gases and with hydrochloric acid were next referred to, together with the most important discovery of his life—that of oxygen gas—in 1774.

The second lecture was delivered on December 31, and was devoted to the French chemist Lavoisier. The lecturer began by contrasting Priestley and Lavoisier. The former showed what could be done with very rough apparatus, of what might be called the pickle-bottle type, and worked in a hap-hazard way, trying numerous experiments and noting if anything happened. Lavoisier, on the contrary, never started without a preconceived idea of what he wanted to arrive at. Some of Lavoisier's earliest experiments were devoted to the subject of plaster of Paris, and to showing the falseness of the old idea that water by long-continued heating would become solid. Research into the nature of combustion might be considered his life-work. Reasoning from the observed fact that the products of combustion were heavier than the original substance burnt, he rejected the phlogistic theory, and inferred that the increase of weight must be due to something abstracted from the air in which combustion took place. He next inquired what this something was, and enunciated that the atmosphere contains two gases. It was one blot, however, on Lavoisier's fair fame that he allowed his followers to talk of him as the discoverer of oxygen though he had been informed by Priestley himself of the latter's discovery of it. The name oxygen was given by Lavoisier to the gas because he found when phosphorus was burnt in it over water that the water gave an acid reaction, and he concluded that oxygen was the producer of acids. Lavoisier was credited with the invention of the oxyhydrogen blow-pipe, and found out the identity of diamond and graphite. He was also supposed to be the discoverer of the composite nature of water, but in truth, though the explanation was Lavoisier's, the experiment which demonstrated the fact was performed by the English chemist Cavendish.

ENGLISH NEWS.

MR. WM. ROBERTS, of Lowestoft, has been selected from numerous applicants for the appointment of Dispenser to the Stockport Infirmary.

BUSINESS CHANGE.—Mr. Thomas Coleman, Chemist and Druggist, late of Bicester, has taken the business lately carried on by Mr. G. E. Clarke at 216, London Road, South Lowestoft.

NORTHERN SCHOOL OF PHARMACY.—The students of the Northern School of Pharmacy, held their Annual Smoking Concert, on Friday, December 20, at the Alexandre Hotel, Manchester. A most enjoyable evening was spent, listening to songs, etc., given by the students. The two principals also delighting the students with songs and speeches bearing upon the work of the past session. Mr. A. C. Bateson occupied the chair.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.—At a meeting held at 18, St. Edward's Passage, Mr. E. Saville Peck, M.P.S., in the chair, Mr. L. A. J. Hutchin proposed, and Mr. C. S. Addison seconded, "That this Association desires to express its loyalty to the Pharmaceutical Society, and looks to it for aid to enable the pharmacist to maintain the position to which his State-enforced education entitles him." Mr. A. S. Campkin, J.P., proposed, and Mr. H. F. Cook seconded, that the discussion should be postponed until a larger and more representative body of chemists be got together. This was carried. Mr. S. F. Barker then proposed, and Mr. H. T. Parker seconded, that invitations be issued to the pharmacist in the neighbouring counties. This was also carried. It has been arranged to hold the annual dinner on Friday, January 10, at the Prince of Wales' Hotel.

PLYMOUTH, DEVONPORT, STONEHOUSE, AND DISTRICT CHEMISTS' ASSOCIATION.—At the next quarterly meeting of the members of this Association, convened for Wednesday, January 8, at 7 p.m., at the Foresters' Hall, Plymouth, after the general business has been transacted, Mr. T. Kinton Bond, B.A., B.Sc., will lecture on the metric system.

TAKING CARBOLIC ACID IN MISTAKE FOR WHISKY.—An inquest was held on Monday, December 30, by the Coroner for Bradford, on the body of William Squires, aged seventy-two years, a quarryman, lately residing at 1, Ellacombe Terrace, Torquay, who met his death by drinking carbolic acid in mistake. It was stated that the deceased, owing to failing eyesight, seven weeks ago went to reside with his son-in-law, named Hankin, at Bradford. The family were removing on Friday to another house, and while left in the latter with a granddaughter the deceased took up a bottle of carbolic acid and drank the greater part of the contents. When his granddaughter told him what he had drank, deceased answered, "I thought I was drinking whisky." He soon became insensible, and though the stomach pump was applied he died in an hour. The jury returned a verdict of "Death from misadventure."

ACETIC ACID FOR WHITE WINE VINEGAR.—At the Hanley County Police Court, on Monday, December 23, before the Stipendiary (Mr. Harold Wright), Messrs. Boots, Limited, of Nottingham, and Frederick William Whitwell, the manager of one of Messrs. Boots' shops at Burslem, were summoned under the Food and Drugs Act for selling diluted acetic acid for white wine vinegar on November 15.—Mr. E. W. H. Knight, inspector under the Act, prosecuted; Mr. Hinde, solicitor, Nottingham, defended the firm of Boots; and Mr. F. W. Harris appeared for Mr. Whitwell.—It was stated that Messrs. Boots and Co. were in business at Nottingham, and had branch shops to the number of about fifty throughout the country. On the date mentioned Charles Frederick Grocott, an assistant to the Inspector, went to the Burslem shop and asked for a quart of white wine vinegar, and was supplied, 4*d.* being paid. The county analyst certified that the article was not white wine vinegar at all, but diluted acetic acid.—For the defence Mr. Hinde submitted that Messrs. Boots were not liable in this case, inasmuch as they had employed as their agent a duly qualified man at their shop at Burslem, and had given general instructions to all their managers that they were simply to sell the articles demanded, and not to substitute others or diluted articles

for them. On July 12 a special circular was sent out to all their shops that acetic acid must not be sold as white wine vinegar. He called Mr. Boot, who gave evidence to that effect.

Mr. Harris, for the defence of Mr. Whitwell, submitted that he had been trained to believe that diluted acetic acid was the article known in the trade as white wine vinegar, and he had been in the habit of selling it as such. He called Mr. Whitwell, who went into the box and gave evidence to that effect. He admitted that when he was selling the article he knew it was diluted acetic acid. It transpired that Mr. Whitwell was not the manager of the shop when the circular regarding acetic acid was sent out in July, as he had been at the Burslem shop since September 2 only. He said the goods sold at the shop were supplied direct from the company's headquarters at Nottingham. White wine vinegar, however, was not supplied but acetic acid was, and he had always taken that to be the same thing and sold it as such.

The Stipendiary, in giving his decision, said there was not the slightest doubt in this case that both the master and the servant were liable. To his mind, had the evidence been such as was proposed to be given, it would not have freed the master. But there was no evidence given at all on the master's part of any instructions sent to the defendant Whitwell, and all the principal defendants could put forth was that the firm had sent general instructions to their servants that they were to sell only what they were asked for.—He (the Stipendiary) never knew any shop where those instructions were not given, and if that were going to free the masters they would be free from every burden. Both parties were, to his mind, very culpable in this case, but he would have taken a more lenient view of Whitwell's case had he not been a qualified chemist. He should impose a fine on Messrs. Boots of £10 and costs for this fraud on the public, and their manager Whitwell would have to pay £5 and costs.

Mr. Hinde asked the Stipendiary to grant a case for the Queen's Bench.

The Stipendiary said he would do so if Mr. Hinde would show him a point. All the evidence he had from Mr. Boot as far as the present case went amounted to nothing. The only evidence he could give a case upon was that the firm appointed a duly qualified chemist.

Mr. Hinde said that was no use to him, and the Stipendiary remarked that there was no other point on which he could give a case.

Mr. Hinde said he should appeal to the Court of Quarter Sessions. The Stipendiary said he might take what course he thought fit.

SCOTTISH NEWS.

EAST ABERDEENSHIRE CHEMISTS' ASSOCIATION.—The annual meeting and dinner of this Association was held at Maud on Thursday, December 19, Mr. Johnston, Aberdeen, in the chair, in the absence of Mr. John Grant, President. Mr. Paterson, Aberdeen, was croupier, and there were present as members of the Association, Mr. McGregor, Ellon, Mr. Lee, Strichen, Mr. Robertson, Fraserburgh, and Mr. Tocher, Peterhead (Secretary). A telegram was read from the President stating that the inclemency of the weather prevented him from being present, and wishing a successful meeting. After loyal and patriotic toasts, current pharmaceutical topics were discussed. At the annual meeting a cordial vote of thanks was passed to Mr. Grant, the retiring President, and on the motion of Mr. Robertson, Fraserburgh, seconded by Mr. McGregor, Ellon, Mr. A. M. Lee, Strichen, was elected President of the Association for the ensuing year. Thereafter a hearty vote of thanks was passed to Mr. Johnston and Mr. Paterson for their kindness in coming so far to be present at the meeting, and for the interest they had always taken in the proceedings of the Association.

IRISH NEWS.

A NEW PHARMACY is about to be opened in Clones, Co. Monaghan, by Mr. John Beatty, L.P.S.I., at present manager of Bowers' Medical Hall, Dublin. There is only one medical hall at present in Clones, that of Mr. E. P. Murray, J.P., M.C.P.S.I.

MR. A. J. PATERSON, L.P.S.I., for many years the principal pharmaceutical assistant in the establishment of Messrs. William Hayes and Co., Grafton Street, Dublin, has been appointed to succeed Mr. Beatty as manager of Bowers' Medical Hall.

MISCELLANEOUS NEWS.

(Reprinted from last week's Supplement.)

THE DANGERS OF CHLORODYNE.—At the police court on Dec. 23, before Dr. Pike, John Chapman, 31, Southfield Street, Worcester, an Army pensioner, was charged with attempting to commit suicide by taking a large quantity of chlorodyne on Saturday. Evidence having been given, Dr. Pike said that, as a medical man as well as a magistrate, he should strongly advise the defendant to leave off the habit of taking drugs. It was a gross fault of the law that chemists should have the power to sell dangerous drugs to any one who asked for them. He did not blame chemists as the law now stood, but he considered that they should use great discretion in supplying "patent" drugs. With regard to the present case he did not think there was sufficient evidence that defendant took the chlorodyne with a felonious intent. He would, therefore, have the benefit of the doubt and be discharged.

HYDROCHLORIC ACID IN A MEDICINE BOTTLE.—On December 20 Mr. A. Braxton Hicks, the Mid-Surrey coroner, held an inquiry at Battersea with reference to the death of George Arthur Head, aged 23 years, of 33, St. Andrew's Street, Battersea, who died on December 17 from the effects of hydrochloric acid, purchased at an oilshop in the neighbourhood.—The coroner said the bottle, an ordinary eight-ounce medicine bottle, bore the following label:—"One tablespoonful to be taken three times a day, after meals." The oilman had not even taken the ordinary precaution of putting the word "Poison" on the bottle, and the landlady was much to blame for leaving the bottle in a cupboard where anybody might pick it up by mistake.—Dr. Sutcliffe said that the deceased died from the effects of hydrochloric acid poisoning.—The jury returned an open verdict: "That the deceased died from poisoning, but that there was not sufficient evidence to show for what purpose the acid was taken." They also requested the coroner to caution the oilman to be more careful in future.

CASE OF COVERING BY A CHEMIST.—In the Queen's Bench Division, on Saturday, December 21, before Mr. Justice Kennedy, the two actions—Butler and Crispe v. G. H. Doveton and Idris Water Co. v. Same—were tried together. In each case the plaintiffs sought to recover a sum of money, amounting together to some £40 odd, in respect of goods alleged to be supplied to the defendant while trading as chemist under the style of Christmas and Co. at 818, Holloway Road. It appeared that Mr. Doveton* had paid off a mortgage which the late Mr. Christmas had on his business. At the date of Mr. Christmas' death last year, a considerable sum was due for interest on the mortgage, and Mr. Doveton, in order to secure himself, had paid a sum of £50 to the widow for the chattels not secured by the mortgage. Mr. Doveton then entered into an agreement with a qualified chemist, a Mr. Norfolk, whereby Norfolk was to have a salary of two guineas a week, for which he was to use his best endeavours to carry on the business, to keep down the expenses out of the receipts, and to share with Mr. Doveton at the end of the year the surplus, if any, after paying out to Mr. Doveton interest on the capital he had in the business. There was a clause in the agreement that Mr. Norfolk was not in any way to pledge Mr. Doveton's credit. When notice was given to Mr. Norfolk to determine his engagement, it was discovered by the defendant that there were unpaid creditors of the business to the extent of some £160.—The defence was that Mr. Norfolk was not carrying on the business in partnership with the defendant, nor had Mr. Norfolk any authority to pledge the defendant's credit.

His Lordship postponed his decision until the first day of next sittings.

THE LIMITED COMPANY QUESTION IN IRELAND.—At Dublin, on December 20, in the Queen's Bench Division, before Mr. Justice O'Brien, Mr. Justice Johnson, Mr. Justice Holmes, and Mr. Justice Gibson, the case of Cleeland v. the Pharmaceutical Society of Ireland came on for argument on a motion by counsel for Mr. Cleeland to make absolute a conditional order for a mandamus to compel the Society to admit him to their examination for the licence as a pharmaceutical chemist. The conditional order had been granted on affidavits showing that Mr. Cleeland had served six years' apprenticeship with Grattan and Co., of

Belfast, and afterwards was five years with them as an assistant, and that he had attended all the requisite lectures, besides passing the Preliminary examination, but that the Council of the Society had refused to accept a certificate from Grattan and Co., because they were a limited company, all the members of which were not pharmaceutical chemists. The arguments, which were of a purely legal character, occupied the entire day; and at their conclusion Mr. Justice O'Brien said that judgment would be given on the second day of next sittings.

WELSH NEWS.

THE UNRESTRICTED SALE OF CARBOLIC ACID.—A lady named Mrs. Bancroft, residing at Bryntirion Hall, near Wrexham, last week committed suicide by taking carbolic acid. She had complained of headache and nervousness, and was of a hysterical disposition. She had spoken of suicide, and had previously attempted to take her own life, but on the night in question she appeared in fairly good spirits, and had been selecting Christmas presents for her children. The jury at the inquest, held on Friday, returned a verdict of suicide whilst temporarily insane, and added a rider to the effect that carbolic acid and similar poisons should not be sold without proper restrictions.

SUCCESS OF A STUDENT.—Mr. Wilfred S. Davies, of Tenby, who has been apprenticed to Mr. George James, High Street, Tenby, has gained the only medal offered by the Westminster College of Chemistry and Pharmacy in the last competition in dispensing. He is the second Welshman who has won the medal in twenty-five years. There were sixty-nine competitors.

THE PURITY OF DRUGS IN GLAMORGANSHIRE.—At the quarterly meeting of the Glamorgan County Council, the public analyst, Mr. C. A. Seyler, B.Sc., F.I.C., reported that during the previous three months he had analysed 239 samples of food and drugs. Amongst them were fourteen samples of pepper, eight of ginger, one of mustard, one of linseed meal, one of castor oil and castor oil pills, one of salad oil, one of spice, one of carbonate of soda, one of flour of brimstone, one of cream of tartar, one of honey, and one of baking powder. The salad oil was not olive, but cottonseed oil—an inferior article. The castor oil was pure, and the honey was genuine. Of the samples of ginger, five were genuine, two were of poor quality, and one contained 40 per cent. of spent or exhausted ginger. The samples of pepper, spice, mustard, and linseed meal were genuine, and all the drugs were pure and called for no special remark.

DEFICIENT SWEET SPIRIT OF NITRE.—At the Mold Petty Sessions, on December 30, before Mr. P. B. Davies-Cooke and other magistrates, Richard George Williams, The Stores, Tryddyn, was summoned for an offence under the Sale of Food and Drugs Act. Superintendent Davies stated that on Thursday, November 28, he called at the defendant's shop and asked the defendant for sweet spirit of nitre. He was supplied with four ounces, for which he paid 1s., and told the defendant that the article was for analysis. Defendant said, "All right; I know all about it. With every quantity I sell I give one of these labels (handing one to witness). These will protect me if it is not right. I sell it as I get it from the firm, and they supply me with the labels." The label read, "Sweet spirits of nitre. This is a special preparation, not the spirits of nitrous ether of the British Pharmacopœia, and not full alcoholic strength."—The Chairman (to the defendant): Who supplies these labels?—Defendant: I get them from Messrs. Bell, Sons, and Co., Liverpool, and they ought to be liable.—The Chairman: These labels are worthless.—Mr. W. F. Lowe, county analyst, said he received one of the samples from Superintendent Davies. It only contained 1-25th of the minimum of active principle ordered by the British Pharmacopœia, and 23 per cent. of water. It was a worthless drug.—Defendant, in reply, said he had nothing to say. He had always sold the article ever since he had been in business.—The Chairman: Is it usual for chemists to be supplied with these labels?—Mr. Lowe: No, it is not. At this point the defendant handed in a letter from Messrs. Bell, Sons, and Co., which the Chairman read.—The Chairman: It is evident that the firm are conversant with this.—Defendant: I have sent them all the stuff back.—The Chairman: You are liable to a fine of £20, but we believe you have not done this thing wilfully, and we therefore have decided to inflict a fine of 10s., and 19s. 6d. costs.

* The name of G. H. Doveton does not appear in the Register of Chemists and Druggists.

NOTICES, LETTERS, AND ANSWERS TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULE should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

LETTERS.

THE ANTI-CUTTING AGITATION.

"ALOES" wishes to say a word of encouragement to those firms who have, single handed, striven to maintain a minimum retail price for their manufactures. He says "Messrs. Elliman, Blondeau, Allen and Hanburys, and others, deserve the best thanks of the retail trade for their action. When I had read the first number of the *Anti-Cutting Record*, I thought the scheme would not become universal, but that any extension of the principles introduced by the above firms would be welcome to the retailers. . . . The sale of proprietary goods, although all pills and smaller articles are placed in drawers out of sight, does not diminish with me. Just let us look at the expenses and outlay on these goods: probably my stock is never under £50, therefore there is that cash laid by, then carriage on the goods will average 1s. 6d. per week, and on returned empties, 8d. per month; the time of unpacking, labelling, putting away, and wrapping up at the time of sale will therefore show a decided loss on many of the quicker selling goods. . . . If the above manufacturers have read the correspondence on this subject recently appearing in the Journal, I fear they will think that their endeavours are not appreciated by the trade, but, personally, I hope the system will be, ere long, extended so as to include most of the more widely advertised proprietaries, and that manufacturers will join hands to further the interests of the trade in this direction."

"ASSISTANT" thinks "one form of combination which probably would show good and immediate results would be the formation of a company having for its object the bringing out of proprietaries—'A Chemists' Proprietary Association'—the company to include chemists and druggists and their assistants, and begin operations with a few of the most popular forms of proprietary medicines in request. The members could, at small expense, flood their immediate localities with advertisement matter and oust all outside preparations." This project is scarcely likely to meet with commendation from many pharmacists.

MR. JOHN HALLAWAY, of Carlisle, says, "Like other of my brother pharmacists, I am interested in this anti-cutting controversy, and beg to send you some of my thoughts on the matter. I think the anti-cutting schemes brought forward by Elliman, Allen and Hanburys, Vinolia Cie, and others (I have no doubt with the best intentions) are useless, and will not remove the evil. Those schemes being based upon cutting prices, they have a minimum and

maximum price, the minimum price being the cutting price, and the cutting man will always sell at the minimum price. I suggest that there be one price only, whatever that price may be fixed at; it should be a price that would allow a fair and reasonable profit to the retailer. I dare say it is a very difficult problem to solve, and when solved perhaps difficult to carry out. Still, I beg to suggest one way, viz., for the manufacturers to charge wholesale houses one price, whatever was the quantity taken, and to fix the price they (the wholesale) are to charge retailers, both wholesale and retail being bound by agreement to sell at stated prices. I take this opportunity to thank you for your opinions on this matter as expressed in the *Pharmaceutical Journal* of December 21."

ANSWERS.

C. MACKANESS.—Thanks for your suggestion, which, however, is an impracticable one. In most cases admission is readily secured by the introduction of a member.

W. RALPH.—We do not know any process that can be depended upon for the purpose you mention. You would probably find also that the use of such a process is illegal.

F. H. SLYNN.—Exchange notices are not inserted unless the conditions specified are complied with.

WILLIAM MAIR.—Your letter was received some days ago, but nothing more had arrived at the time of going to press.

"C. M."—You have omitted to indicate your name and address.

OBITUARY.

SMITH.—On May 31 last, Miles Henry Smith, aged 63 years. Mr. Smith commenced his professional career in the laboratory of Mr. J. Lloyd Bullock some forty years back. After passing a few sessions at the College of Chemistry in Oxford Street, where, in consideration of his intelligence and industry, part of his fees were remitted by the then director of the College, Dr. A. W. Hofmann, he obtained an engagement in Perkin's Aniline Dye Works, where he was at one time a co-worker with the late Mr. Greville Williams. Subsequently he entered the well-known firm of Messrs. Hopkins and Williams, and was for many years chemist in their factory at Wandsworth, where he was always on the most pleasant terms with his employers, the latter of whom, with characteristic generosity, frequently acknowledged his indebtedness to his "friend Miles Smith" in many of his scientific papers. At an early period of his career, and whilst working in the laboratory of the London Institution, in conjunction with his friends, Messrs. Wanklyn and Chapman, they devised the permanganate process for the detection of nitrogenous organic matter by its conversion into albuminoid ammonia, in water analysis. For the last four or five years of his life Mr. Smith gave up professional work, and being an ardent lover of the country and of rural scenery, passed his latter days in the picturesque neighbourhood of Dorking.

MILES.—On December 17, George Miles, Chemist and Druggist, Pokesdown, Bournemouth. (Aged 59.) Mr. Miles had been a member of the Pharmaceutical Society since 1875.

PUBLICATIONS RECEIVED.

THE VALLEY OF KASHMÍR. By WALTER R. LAWRENCE, I.C.S., C.I.E., Settlement Commissioner, Kashmir and Jumna State. Pp. 478, with illustrations and map. Price 12s. net. (London: Henry Frowde, Amen Corner, E.C. 1895.) From the Publisher.

ANATOMISCHER ATLAS DER PHARMAKOLOGIE UND NAHRUNGSMITTELKUNDE. By Drs. A. TSCHIRCH and O. OESTERLE. Part 9. Price 1s. 6d. (London: Williams and Norgate, 14, Henrietta Street, Covent Garden, 1895.) From the Publishers.

PROCEEDINGS OF THE KENTUCKY PHARMACEUTICAL ASSOCIATION for 1895. From the Secretary of the Association.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Adamson, Allen, Barber, Barker, Bateson, Bentley, Bindloss, Boot, Burge, Clower, Crouch, Davies, Davis, Dixon, Durrant, Eastes, Greenish, Guyer, Hale, Hallaway, Harries, Hender, Heron, Hewlett, Hodges, Jackson, James, Jeffs, Liverseege, Lorch, Mackaness, Mair, Morris, Plattin, Price, Ralph, Reynolds, Robins, Sharpe, Sinclair, Sincox, Smith, Smith-Elder, Spencer, Slynn, Taylor, Thornburn, Tocher, Tyler, Ward, Wardleworth, Welsh.

CAMPHOR LEAF OIL.

BY DAVID HOOPER, F.C.S.

The recent high price of camphor, on account of the war between China and Japan and trade monopolies, has caused some anxiety in countries where it is largely consumed, and China and Japan being at present the only two countries where camphor is produced on a large scale, it has been thought desirable that its cultivation should be taken up in other lands. In Japan the camphor trees grow at high elevations away from the sea, and only large trees of about one hundred years old are selected for use in making the camphor. From the export returns of this country, it seems that the supply is gradually becoming exhausted. In the island of Formosa the camphor trees are said to be by no means plentiful, and they grow only in certain favourable situations, as far as the climate is concerned, with savage tribes in the immediate vicinity. Here the trees are not considered worth taking until they are fifty years old, and the wood only of the roots and stems is subjected to distillation.

The camphor tree grows very well in India. The Calcutta Botanic Gardens possess a fine avenue of trees, which were introduced in 1802. It grows well in the Ootacamund Botanical Gardens and in other parts of the Nilgiris. It has been planted, as an experimental measure, at Jhansi in the North Western Provinces, and in other districts in the plains. Camphor has been known and used in India for many centuries. In A.D. 642, Indian princes sent camphor as a tribute or offering to the Chinese emperors. At one time the tree flourished in Nepal and Tipperah, a large tract of land lying between Bengal and the Upper Irrawaddy. Within the present century camphor was imported from Chittagong, but it has been said that the discovery of the hill-men of distilling it from the root led to the extinction of the trees.

In Ceylon the camphor tree grows well at elevations of 5000 feet and less; it has the habit of a willow in the island, and it has been suggested that, like a willow, the trees should be coppiced, and the leaves and branches used for preparing the oil. The tree grows for ornamental purposes in Naples and other parts of Italy. Professor Maisch in 1891 reported on the cultivation of camphor in Florida, where it flourished in almost any soil. The solid oil was made from the leaves and branches; the yield was 4 per cent., and the product was more like that of Japan, as it had an odour of safrol. California has lately become the scene of an industry which has for its objects the planting of the laurel camphor and the preparation of the oil for the American market. The tree has also become naturalised in Java, Brazil, Jamaica, and other isles of the West Indies, Mauritius, and Madeira.

It is very evident that the camphor tree is able to grow very luxuriantly and extensively in the warmer temperate and tropical parts of the world, far removed from China and Japan, but the slow growth of the tree would prevent all but large capitalists from opening up plantations and waiting for the plants to sufficiently mature. If it is true that in the island of Formosa the wood only of the larger trees is used, and the leaves and branches rejected, then there can hardly be a scarcity of the trees, or the manufacture must be conducted in a very reckless and extravagant manner. The

camphor from the Dryobalanops tree is said to be quite liquid if a young tree is tapped, and solid if the tree is old. Under such circumstances it would seem that the liquid oil constituted the first stage in the development of the solid substance. It is stated in some text-books on materia medica that the stearopten exists in every part of the plant, including the leaves. On the other hand, it is remarkable that the leaves are not used in China and Japan; perhaps the natives have found that the leaves only give a liquid product which cannot be profitably turned into camphor. As there is no definite information on this point to be found in any description of the industry, I thought it would be interesting to try the effect of distilling the leaves. Another reason that encouraged me to make some experiments in this direction was the hearty manner in which some energetic planters of Ceylon have taken up the camphor question.

A large number of experiments have been made, and a great deal has been written, with regard to camphor oil, the bye-product obtained in refining crude camphor before it is formed into blocks. This has been proved to be a very variable liquid with a specific gravity ranging from 0.88 to 1.00, an erratic optical rotation, although usually to the right, and containing camphor in suspension, or in solution, or none at all.

The first sample of leaves came from an umbrageous tree growing in the Government Gardens at Ootacamund. Fifty pounds of the leaves in a fresh state were distilled in a large copper still with sufficient water for six hours. Eight fluid ounces of oil were separated from the distillate, giving the yield of essential oil one per cent. The oil had a slightly yellow colour, a specific gravity at 15° C. of 0.9322, and a rotation of +9°·4 in a 2 decimetre tube. It gave off a small quantity of liquid at 160°, and began to boil regularly at 175°.

Collected below 180°	=	20.6
185°	=	31.0
190°	=	15.5
195°	=	10.6
200°	=	5.6
205°	=	3.3
Residue	=	8.6
		95.2

The loss here was occasioned by some of the camphor congealing in the condenser; the amount, however, in this sample could only be about 10 or 15 per cent. The residue in the retort was quite solid in the cold, and had a yellowish colour and strong camphoraceous odour.

The second sample was obtained from some younger trees grown at Naduvatam on the Nilgiris, a district more than a thousand feet lower than Ootacamund. The leaves were distilled in the same manner as in the previous experiment, but a large quantity of camphor condensed during the process and almost choked up the worm of the still. About four ounces of liquid were collected, having a mass of crystalline matter suspended in it. The oil was strained through cloth, and the solid matter, pressed hard to remove all the liquid portion, was left as a cake of camphor, weighing two ounces. The clear oil had a specific gravity of 0.9314 at 15° C., and twisted a ray of polarised light +54° in a 2 decimetre tube. It began to boil regularly at 165°.

Collected below 185°	=	13.3
190°	=	20.0
195°	=	15.5
200°	=	20.0
Residue	=	25.0
		93.8

The loss was again accounted for by some of the camphor condensing in the cool tube. About one-half of this oil consisted of solid camphor, or, calculating the camphor already separated, the oil from the Naduvatam leaves contained 75 per cent., which is a very satisfactory result. The camphor dissolved in rectified spirit, twisted a ray of light + 30°. The altitude of the Government Gardens in Ootacamund is 7300 feet, and it is possible that this elevation influences the formation of the solid stearopten in the leaves. At any rate, it is interesting to know that a large proportion of camphor can be obtained from the oil of the leaves and from the leaves themselves, and probably, if taken from trees grown at a much lower elevation, a much larger proportion of this useful substance could be collected.

COLOURED FILMS FOR SHOW CARBOYS.

BY T. MALTBY CLAGUE,
Pharmaceutical Chemist.

Perchance my experience has been unfortunate, but though not yet out of my teens in the service of pharmacy I have three times been a witness of that officinal catastrophe, the breakage of a show carboy. The danger to which these emblems of our craft are exposed and the care required in their handling make them a constant source of anxiety. But when Jack Frost's ruthless grip has seized on one of them and three or four gallons or more of a strongly-coloured liquid possessed of the mischief-making properties of, say, ammonio-sulphate of copper, come showering down on a well laid out window full of costly stock-in-trade, there is a stress of circumstances with which the capabilities of the English language are utterly inadequate to cope. It would be a Vandal's act to suggest that we do without them, the sentiment that values a grand historic past and the business view which uses them as a mark of trade identity in the present, alike demand their retention.

Lately, however, I had to face the question of supporting carboys in a position where it was well nigh impossible to provide what would stand a mechanical stress of three-quarters of a hundred-weight. Attempts were made to coat the inside of a carboy with a coloured film, which would suit the requirements of window display. My experiences are now given in the hope that some—

“Forlorn and shipwrecked brother
Seeing may take heart again.”

Perhaps others have solved the problem for themselves, but I decided to rush into print when I saw that a chemist in a neighbouring town was obliged to find refuge from his difficulty by keeping an empty uncoloured carboy in his window.

First, solutions of shellac and aniline dyes in methylated spirit were tried, but the tendency to chip off was found to be an objection. Next, the dyes were tried, dissolved in spirit, and the solution combined with ether and gun-cotton to make a collodion film. This was partially successful, but the difficulty was to get the film free from rolls and thicknesses.

Lastly, gelatin was adopted as a basis, and after some experiments the following formula was found to work well. For a five-gallon carboy:—

Aniline dye.....	grs. xv. to xxv.
Gelatin (not opaque)	1 oz.
Water	6 ozs.
Carbolic acid	ʒi.

Soak the gelatin in water, dissolve the dye in warm water, and next add the softened gelatin and warm till melted, then add the carbolic acid. When the solution has cooled to about 150° F., pour it into the carboy. Place the carboy in a warm position until it has acquired a temperature of from 90° to 100° F., and then remove, now keep turning it upside down and round about until the gelatin shows signs of setting, then put it on its stand and allow the jelly not adhering to the sides to settle at the bottom. Leave the stopper out for a few hours. If the first attempt is not a success, it is only necessary to put the carboy into a warm place and try again. The process is an easy one, and has been applied to half a dozen carboys with ease and success.

As to the colours the following have been tried:—Malachite green, a good colour to work with, and strikingly like sulphate of copper solution; about 25 grains to 6 ounces is required. The colour fades somewhat, so that it is well to make it a trifle dark. Methylene blue, 15 grains; a rich colour very like ammonio sulphate of copper. Methyl violet, 15 grains, a rich bluish red; can be made to vary according to the dye used. Technically, R. means red, R.R. redder, R.R.R. still redder. The blue shades are similarly indicated by the affix B. Flamingo gives the nicest red of those I have tried, 15 grains. Browns may be got with Bismarck Brown; brownish yellow with the same dye in smaller proportion, but the colours are not so striking as those named earlier. Methyl orange is wanting in brightness and transparency.

Of course, if the window is exposed to sun, the film must be allowed to harden well before being placed in its position. The carbolic acid or some other preservative is required to prevent moulds from liquefying the gelatin. The weight of a six-gallon carboy is thus reduced from 70 pounds to 10½ pounds, and the ease in handling and safety when in position are great gains. Nothing is sacrificed in appearance, and if you don't tell anybody nobody will know.

ARTIFICIAL WINTERGREEN OIL.

Thayer gives the following practical method of applying the hydrochloric acid process for the manufacture of synthetic wintergreen oil: Take 505.47 grammes of salicylic acid and 690.85 grammes of methyl alcohol (sp. gr. 0.820); place the alcohol in a wide-mouthed flask and add portions of the acid until a saturated solution is obtained.

Make the additions slowly, as all of it will not dissolve. Connect the flask with an upright condenser and heat it on a water bath until the contents are brought to the boiling point, then pass dry hydrochloric acid gas into the hot solution until the latter is saturated. Then add about 10 grammes more of the salicylic acid, again saturate the solution with hydrochloric acid and repeat the operation until all the salicylic acid has been added, the passage of the hydrochloric acid gas being continued for two hours after the last addition of the acid. It is necessary that the gas be thoroughly dried by being passed first over anhydrous calcium chloride, then through three bottles of sulphuric acid, before being conducted into the salicylic acid solution.

The lower oily layer which separates is washed with water until no longer acid to litmus, then distilled from a flask by the aid of live steam, the distillate is freed from excess of water by the use of a separating funnel, and finally dried thoroughly over anhydrous calcium chloride. The product thus obtained is of a slightly yellowish colour, has an agreeable odour, and costs 90 cents to \$1.00 per pound, the above quantities yielding 500 grammes of methyl salicylate. Ethyl salicylate, which has a more delicate odour, and a lighter specific gravity, can be prepared in the same way.—*Amer. Journ. Pharm.*

CHAPTERS IN PRACTICAL PHARMACY.

CACHETS AND CACHET MACHINES.

The administration of medicines in the form of powder presents certain advantages, and will probably increase with the growing simplicity in prescribing. For, as knowledge of the action of drugs becomes more complete, it may be anticipated that it will become more customary for physicians to prescribe single remedies, and in a large number of instances the best effect of the medication will be obtained by administering it without the addition of vehicle or excipient. Even simple solution in water or alcohol often possesses minor disadvantages, and in the case of calomel, bismuth compounds, ipecacuanha, opium, the synthetic remedies, etc., solution is of course out of the question. At the same time, to the majority of people, the dry powder form of administration, especially in the case of bitter or nauseous substances, is particularly objectionable. To avoid this difficulty the use of compressed tablets, the preparation of which has recently been described in the *Pharmaceutical Journal* (see last volume, pp. 348 and 367), is largely resorted to. But the characteristic taste of bitter and nauseous substances is perceptible whilst the tablets remain in the mouth, and disintegration is much too slow in many cases. Better methods of masking the taste of powders and yet permitting them, by the rapid solution of the envelope, to act in the briefest possible space of time, is to enclose them in wafers, cachets, or gelatin capsules.

Wafers are small, square or circular sheets of thin paper made from rice-flour. The powder is placed in the middle of a sheet, the edges are gathered and twisted together, and the package is then dipped in water, and swallowed. Or, the wafer may be dipped in water first, the powder enclosed by folding the edges over, and the wet mass swallowed with a draught of water. The whole of the manipulation must be performed by, or for, the patient at the moment of administration. Cachets, however, which may be described as modified wafers, are intended to be filled and closed by the pharmacist, who dispenses them much as he would dispense ordinary "powders," the wrapping papers being replaced by concave discs made of rice or wheat flour. The powders are weighed out in the usual manner, and then enclosed in the cachets, as described later in this article. After dipping one of the finished cachets in water, it is easily swallowed by the patient, the envelope being exceedingly flexible, and disintegration being speedily effected in the stomach, the medicament is free to act in a minimum of time. Powders thus enclosed are rendered perfectly tasteless for the time being, and they are not acted upon until they reach the stomach, whilst the particles are not compressed so as to impede solution. Moreover, the personal responsibility of the dispenser is allowed full scope, and the product of his labours is typical in the highest degree of present-day elegant pharmacy.

There are various makes of cachets now on the market, and in selecting stock it is well to bear in mind that a perfect cachet should be convenient in shape, elastic, tasteless, readily soluble, and easily digested. In price they are extremely moderate, three shillings per thousand being the usual charge for ordinary plain white cachets. So far as the cost is concerned, therefore, they compare favourably with good wrapping paper, or the use of solvents or excipients, to say nothing of the immense saving in labour. The main points to be observed in filling them are (a) the selection of cachets of the most suitable size to contain the required dose of medicament, (b) the protection of the edges whilst filling, and (c) the observance of due care in moistening the edges before closing.

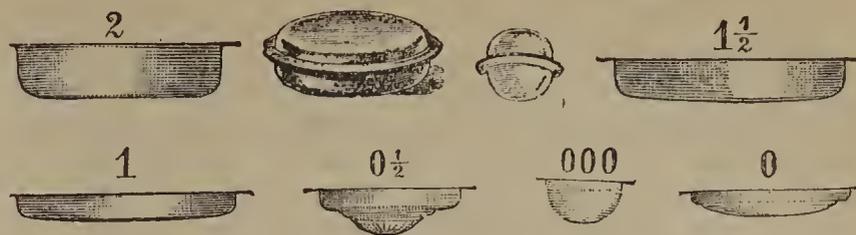

FIG. 1.—"MOHRSTADT" CACHETS.

The "Mohrstadt" cachets* may be had either white or in a large assortment of colours, and, if desired, names and addresses can be embossed upon them, or printed in grey or black lettering. The colours employed are perfectly harmless. The cachets are manufactured in six sizes (Fig. 1), as follows:—

No.		Capacity.
000		1½ grs. Quinine or Acid. Salicyl.
0	flat	3 - 4½ " " " " "
0½	deep	6 - 7½ " " " " "
1	flat	9 - 10½ " " " " "
1½	deep	10½ - 15 " " " " "
2	very deep	15 - 18½ " " " " " (or 28 " Sulphonal)

The simplest form of apparatus enables only one cachet to be closed at a time (Fig. 2), of two, three, or all sizes of cachets. It is made in four sizes, costing half-a-crown each, and must be selected in accordance with the size of the cachets to be closed. A half cachet is placed on the small cup (a), the powder in-

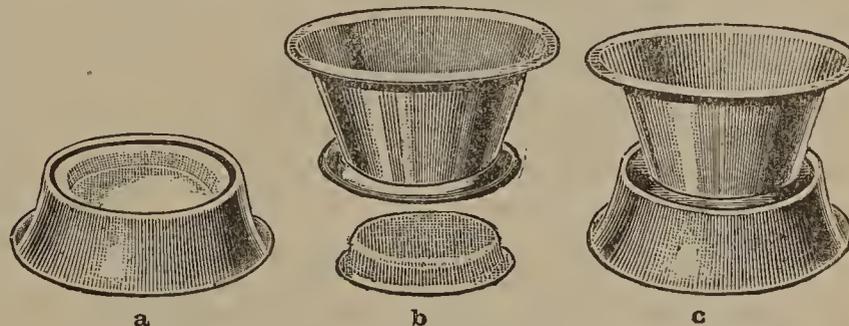

FIG. 2.—"MOHRSTADT" MACHINE FOR ONE CACHET.

serted by means of the funnel, and then gently pressed down with a thimble kept on the first finger; the funnel is next removed and placed on another half cachet lying with the opening downwards (b). This may then be lifted up and pressed on a small damping pad, after which it is superposed on the filled half cachet in the

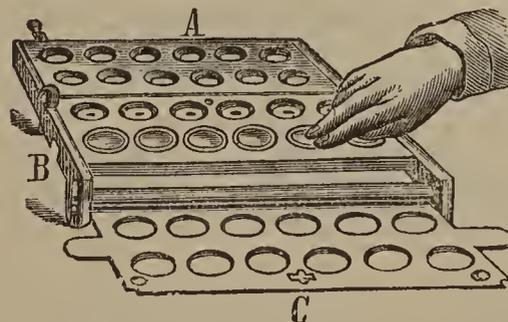

FIG. 3.—"MOHRSTADT" IMPROVED APPARATUS.

cup (a), which is thus closed and sealed (c). The finished cachet is finally pushed out by means of the thimble.

* Supplied by Thos. Christy and Co., 25, Lime Street, London, E.C.

An improved filling and closing apparatus can be obtained in zinc or nickel, at prices ranging from twelve to thirty shillings. This form enables the dispenser to fill and close a number of cachets at once, the largest size serving for twelve of each of the six sizes of cachets, without any adjustment of the apparatus to suit the different sizes of cachets. It absolutely prevents the powder from penetrating between the edges of the cachets, thus ensuring a firm closure, which is most important. The apparatus opened ready for use is represented in Fig. 3. The half cachets are

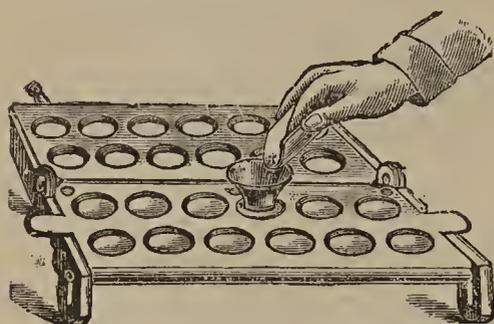

FIG. 4.—FILLING CACHETS.

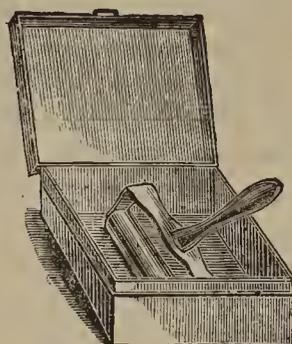

FIG. 5.—ROLLER.

pressed with the fingers into the inner spaces of plates A and B. Plate C is then turned over on B, and the powder placed in the cachets by the aid of the funnel (Fig. 4). After gently pressing the

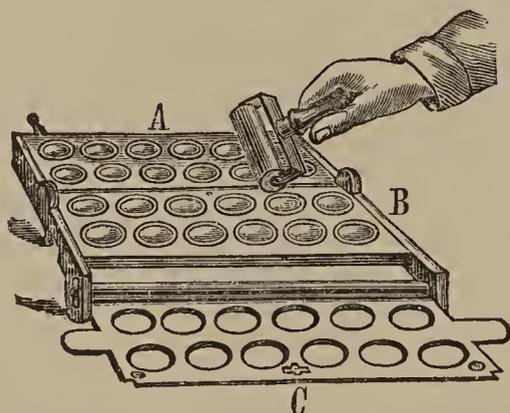

FIG. 6.—MOISTENING CACHETS.

powder down with the thimble, the plate C is lifted and the damping roller (Fig. 5), which should not be too wet, is passed over the half cachets in plate A (Fig. 6). The latter, in turn, is then turned over

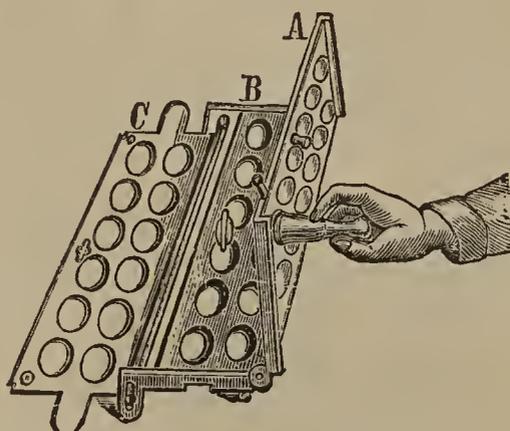

FIG. 7.—DETACHING CACHETS.

B, when a slight pressure suffices to close all the cachets, which, on opening the apparatus, may be pushed out of the plate A, to which they adhere by means of the pusher supplied (Fig. 7).

By means of the "Mohrstadt" filling and closing apparatus it is said to be possible to fill and close a dozen cachets in four minutes, including the weighing of the powders.

FIG. 8.—"FINOT" CACHETS.

The "Finot" Cachets* are made of pure wheaten flour, and can be obtained in the following seven sizes:—

No.	Capacity.	
	Antipyrine.	Quinine.
0	5 grains	3 grains
1	10 "	7½ "
1 bis	13 "	10 "
2	20 "	16 "
2½	23 "	18 "
2 bis	26 "	20 "
2 ter	28 "	24 "

The exact dimensions of the last six sizes are represented in Fig. 8. They are very flexible, tasteless, and readily soluble, and are supplied either white or coloured. They may also be obtained white, with name and address or name of medicament printed in various colours (Fig. 9). This forms a very attractive-looking cachet; or, again, the names may be embossed, the embossing being done on the surface of the cachets, thus rendering them quite smooth inside. The older method of embossing frequently caused perforation of the cachets.

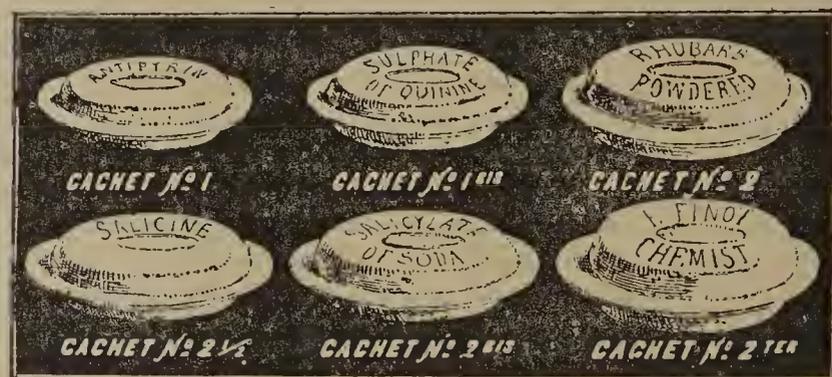

FIG. 9.—PRINTED "FINOT" CACHETS.

The "Finot" cachets can be made to fit any machine, but the filling and closing apparatus specially supplied for use with these cachets is very simple, and the complete outfit for filling twelve cachets of six sizes at a time is supplied for fifteen shillings. The cachets are placed in the holes of the wooden tray (Fig. 10), and the cups in those of the metal tray, which is then superposed upon the former. The powder is poured through

* Supplied by Cooper and Co., 80, Gloucester Road, South Kensington, London, S.W.

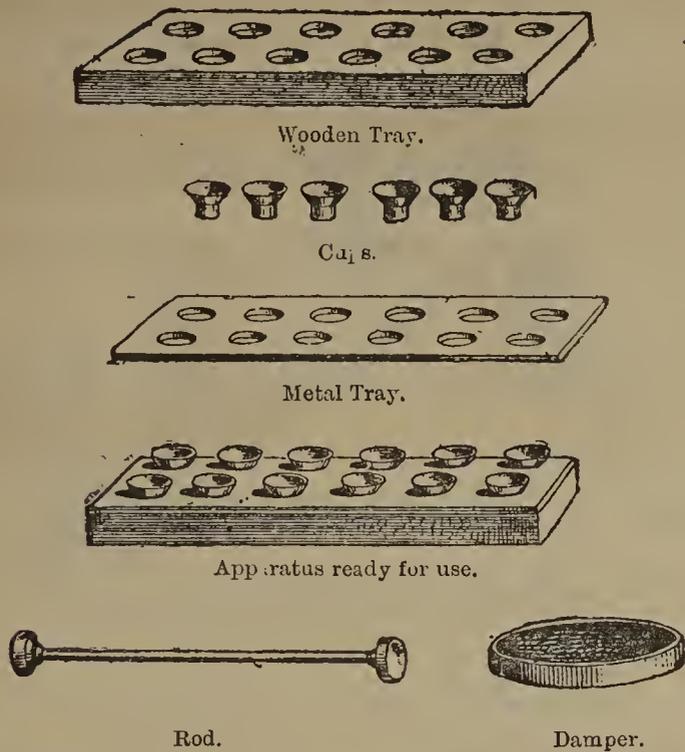

FIG. 10.—THE "FINOT" CLOSING APPARATUS.

the cups into the cachets, any particles adhering to the sides being detached by the rod, after which the metal tray and cups are lifted bodily. Next, lift one of the upper half cachets by means of the nickelled holder (Fig. 11). This is represented both closed and open, as well as in section. Pressure upon the lever at the side causes the movable

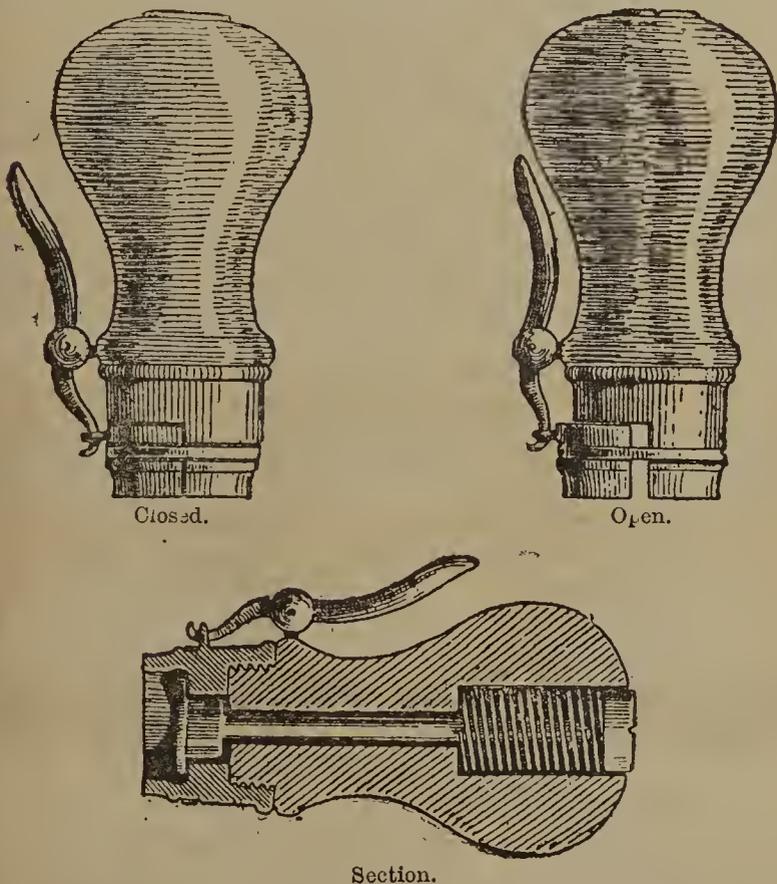

FIG. 11.—THE "FINOT" CACHET HOLDER.

jaw to open so that the half cachet can be grasped; the latter is then gently moistened upon the damper (Fig. 10), placed upon the lower half containing the powder, and closed by a slight pressure. The finished cachet adheres to the holder, and is removed by pressing the ejector shown in the section of the holder.

The "Primus" cachet machine (Fig. 12) serves for closing cachets singly, and is supplied complete with a wooden tray and

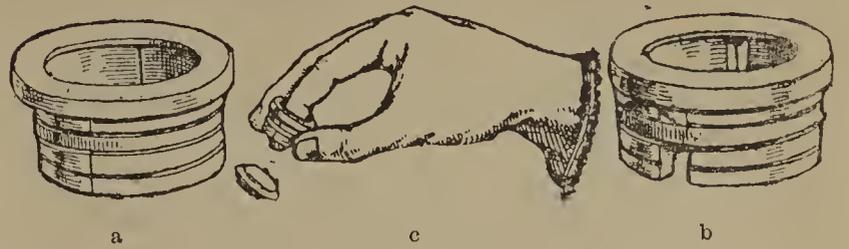

FIG. 12.—THE "PRIMUS" CACHET MACHINE.

an improved damper for five shillings. The holder consists of two metallic rings, and is shown closed at (a). By turning these rings the holder opens, as at (b), and a cachet lid can then be picked up, damped, and placed upon the filled cachet in a wooden tray, the same as with the large apparatus. The method of detaching the finished cachet is represented at (c).

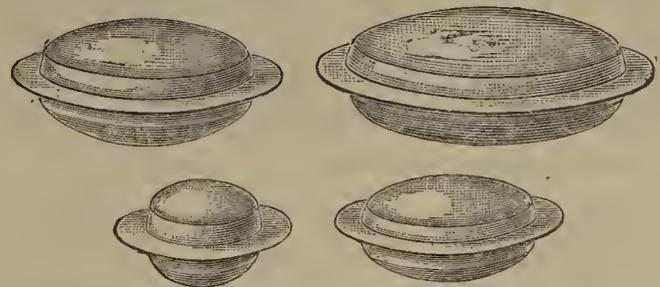

FIG. 13.—"MAW" CACHETS.

The "Maw" cachets (Fig. 13) are not characterised by any special peculiarity, but seem as well adapted to the purpose in view as any other kind examined. The machines supplied for filling and closing them probably possess the greatest simplicity attainable.

A handy little apparatus for closing six cachets* (Fig. 14) consists of two metal plates hinged together, and is supplied complete with a rubber roller for damping at the extremely low price of four shillings. It is opened as shown in the figure, cachets are placed in the holes in plate 1, and plate 2 being turned over, the powder is poured in through the apertures. Plate 2 is then raised, and the holes in it are filled with cachet lids. The moistened

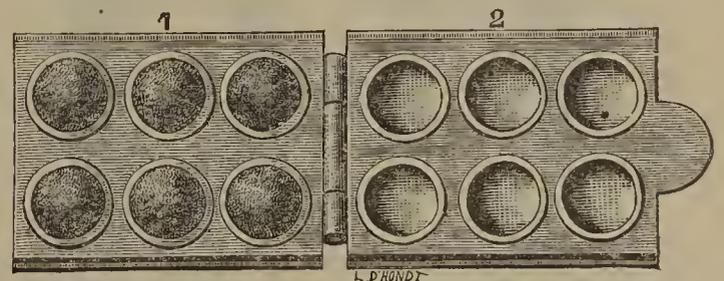

FIG. 14.—THE "MAW" CACHET MACHINE.

roller is next passed very lightly over the edge of the lids, and plate 2 again turned over and pressed gently. The cachets are thus closed and may be readily removed. A similar apparatus is also made for eight cachets, and the cachets themselves are supplied in four sizes, and of various colours.

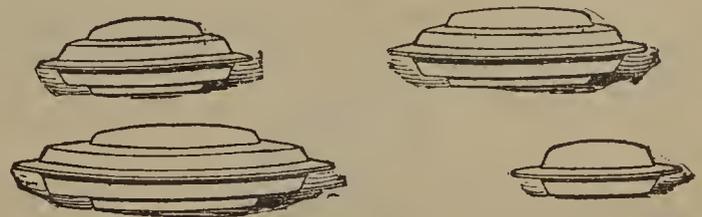

FIG. 15.—"CHAPIREAU" CACHETS.

The "Cachet S. Chapireau"† (Fig. 15) is another beautifully

* Supplied by S. Maw, Son, and Thompson, 7 to 12, Aldersgate Street, London, E.C.

† Supplied by Warrick Brothers, 18, Old Swan Lane, London, E.C.

finished article, made of the thinnest possible wafer. On account of its peculiar shape, the makers contend that it possesses a greater capacity than any other form on the market. There are four sizes—Nos. 0, 1, 2 (2 bis is of the same capacity but deeper) and 3. Any desired name can be impressed on the cachets.

The apparatus for filling and closing them is very simple and elegant in appearance, but is also practical and durable. The No. 2 outfit, recommended for a general dispensing business, costs thirteen shillings and sixpence only, and is contained in a strongly-made box, the lid of which serves as a solid base for ten of the nickel-plated moulds (Fig. 16). The moulds are fixed at

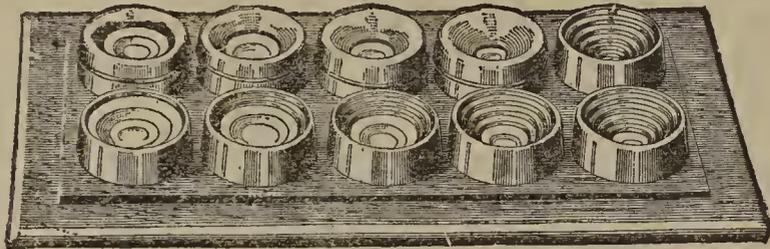

FIG. 16.—THE "CHAPIREAU" CACHET MOULDS.

equal distances on the under side of the lid, and this, on being reversed, is ready for use. Each mould is graduated so that any

FIG. 17.—THE "CHAPIREAU" CACHET FILLERS.

of the four sizes of cachets immediately falls into place on being dropped in. Four nickel-plated fillers (Fig. 17) are also supplied, one for each sized cachet.

The moulds being filled, the proper sized filler is placed over each in turn, so as to ensure the cleanly and complete filling of the

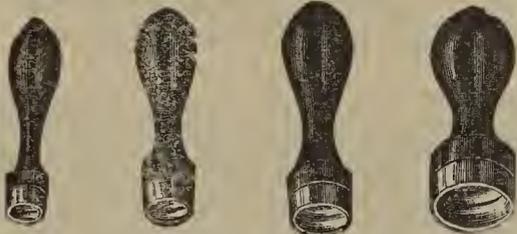

FIG. 18.—THE "CHAPIREAU" COMPRESSORS.

cachets. The filling process at an end, one of the compressors (Fig. 18) is used to accurately compress and shape the powder to

FIG. 19.—THE "CHAPIREAU" CACHET HOLDERS.

the cachet. A nickel-plated holder (Fig. 19) of the right size is then screwed on to the automatic handle (Fig. 21). By means of

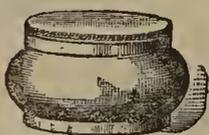

FIG. 20.—THE "CHAPIREAU" MOISTENER.

this the cachet lids are picked up one by one, and after moistening on the specially supplied cup (Fig. 20), superposed on the filled half cachets. The finished cachets are ejected from the holder by

pressing an ivory push at the top of the handle as represented in Fig. 21. It will be seen that the outfit is comprehensive, every-

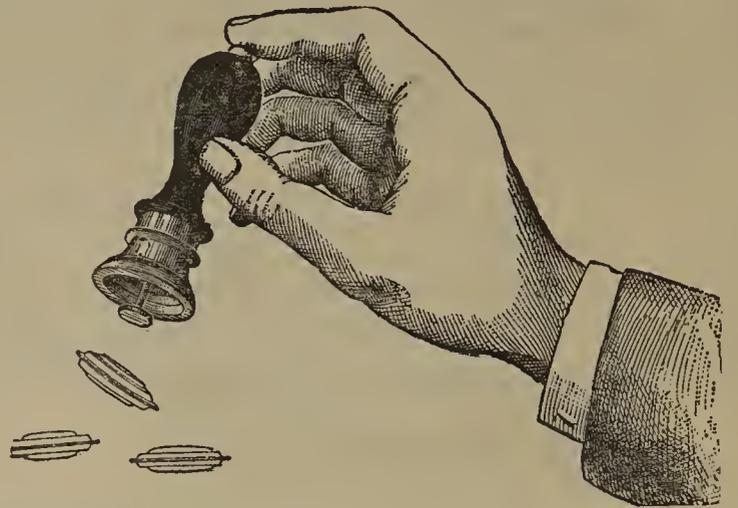

FIG. 21.—METHOD OF DETACHING CACHET FROM HOLDER.

thing necessary being included, and all parts can be readily duplicated at a slight cost.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

MEETING OF THE COUNCIL.

WEDNESDAY, JANUARY 8, 1896.

Present:

MR. MICHAEL CARTEIGHE, PRESIDENT.
MR. JOHN HARRISON, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bottle, Corder, Cross, Grose, Hampson, Hills, Martin, Martindale, Newsholme, Savory, Schacht, Southall, Warren, and Young.

The minutes of the previous meeting were read and confirmed.

BOARD OF EXAMINERS.

A letter was read from the Privy Council Office, approving the appointment of the Boards of Examiners for the year.

ELECTION OF MEMBERS.

Pharmaceutical Chemists.

The following having passed the Major Examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Cooper, Walter Temple London.
Dean, Arthur Shiers London.
Innes, James Hong Kong.
Massey, Cecil Nottingham.
Wright, Charles George..... London.

The following who was in business before August 1, 1868, having tendered his subscription for the current year, was elected a "Member" of the Society:—

Chemist and Druggist.

Coleman, William Juby.....Brundall.

ELECTION OF ASSOCIATES IN BUSINESS.

The following having passed their respective Examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Agar, RalphSouth Bank.
Chatterton, Benjamin Tunbridge Wells.
Coleman, Thomas Lowestoft.
Dickins, Frederick B idlington Quay.
Gambling, John Pattison Sheffield.

Nicholls, Alfred Nice.
 Pipe, William Philip Liverpool.
 Simpson, Stewart Richard Hoxton.
 Smith, Herbert Workington.
 Stephen, Alexander Liverpool.
 Thomas, Hugh William Llanfairfechan.
 Thompson, Henry Edward Birmingham.
 Wood, Charles Granville Oldham.

Modified.

Darling, William Howorth Manchester.
 Watkinson, William Joseph Preston.

ELECTION OF ASSOCIATES.

The following having passed the Minor Examination and tendered their subscriptions for the current year, were elected "Associates" of the Society.

Blamey, Charles Austin London.
 Bremner, William Aberdeen.
 Bridges, Herbert Norwich.
 Cole, Vincent Theobald London.
 Evans, John Lampeter.
 Farrow, Albert Edward London.
 Fishbourne, James William Markinch.
 Fletcher, Samuel Thomas Horncastle.
 Green, George Turton Stourbridge.
 Harry, Elias Hamilton Carmarthen.
 Horn, John William Penrith.
 Keeley, James Philip Blackburn.
 Lockwood, Harold Stephenson Stalybridge.
 Marshall, Arthur Austen Waltham Abbey.
 Parkinson, Thomas Gott Burnley.
 Pattinson, Joseph Wigton.
 Peirson, Herbert Sidney London.
 Pigott, William Edmund Wadsley.
 Taylor, Archibald Leonard Camberwell.
 Taylor, John Pontefract.
 Thomas, John Aubrey Redditch.
 Usher, Alfred Musgrave Newcastle-on-Tyne.
 Wilkes, Harry Smith Upton-on-Severn.
 Wilkinson, John Horsley Colne.
 Wood, Ernest James Tockwith.

ELECTION OF STUDENTS.

The following having passed the First Examination and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Alexander, Ernest Glover Sheffield.
 Barnes, Arthur Swaby Barnsley.
 Beer, Bernard East Dereham.
 Bintliffe, John William Holywell Green.
 Blackburn, Oswald Vincent Selby.
 Blakeley, William Bramley.
 Blanchflower, George Percy Gt. Yarmouth.
 Blythe, George William Bow.
 Brice, Henry Doyle Guernsey.
 Brown, Charles Northallerton.
 Burgham, Harry Hinsley London.
 Burman, William Sheffield.
 Burnett, Albert Edward Bristol.
 Butler, Richard Drighlington.
 Cannell, John Wilfred Patrick Douglas.
 Chambers, Frank Dawson Eastwood.
 Clarke, Henry Jackson Stockton-on-Tees.
 Collin, John Francis Diss.
 Curtis, Arthur Lowestoft.
 Dance, James George Brighton.
 Davies, Wilfred Sydney Paddington.
 Dell, Walter John Webber London.
 Dixon, Charles John Sunderland.
 Eaton, Henry Lutterworth.
 Evans, James Herbert Everett Liverpool.
 Firth, Fred Wakefield.
 Foggitt, Benjamin Thirsk.
 Forster, William Seaham Harbour.
 Francis, John Merthyr Tydvil.
 Gardner, Hermann Charles T. Forest Hill.
 Godkin, Archibald Aston Burton-on-Trent.

Goode, Arthur Frederick Nuneaton.
 Grisdale, William Keswick.
 Halkyard, George William Manchester.
 Hanbury, Alfred Cornelius London.
 Hass, Hermann Leo Limehouse.
 Hirst, Frederick Beaumont Batley Carr.
 Hopkins, William Edward Llandoverly.
 Horniblow, Frederick Herbert Worcester.
 Irving, George Annan.
 Jackson, Percival George William Preston.
 Johnson, Cornelius Trim Falmouth.
 Jones, Ernest William Manchester.
 Jull, Alfred Proctor Ealing.
 Lambley, Frederic Charles Blackheath.
 Leak, Frederick Thomas Edinburgh.
 Leins, Heinrich London.
 Lester, William Henry Nuneaton.
 Lewis, Richard Rice Barmouth.
 Lincoln, John Edward London.
 Lloyd, Thomas Henry Southport.
 Lowe, John Hadfield Blackpool.
 McGavin, William Preston.
 Melville, John Fraserburgh.
 Moody, Thomas Adam London.
 Oldbury, Thomas Richard Knighton.
 Owen, Samuel Arthur Bristol.
 Padgett, Edwin Austin Guiseley.
 Palk, Harold William Totnes.
 Pattinson, Thomas Guisborough.
 Peck, Harold Robinson Cambridge.
 Penistan, Arthur H. New Cross.
 Pinnington, Arthur Liverpool.
 Rackham, Charles George Halesworth.
 Rhodes, John William Leeds.
 Roberts, John Bangor.
 Robinson, James Stacey Blyth.
 Robinson, Joseph Ellis Stockport.
 Robinson, Walter Frederick London.
 Shakerley, William Arthur Clapham.
 Sheldrake, Albert Mason Colchester.
 Simpson, Henry Higson London.
 Skinner, Ernest Pape Boston.
 Smith, Ernest Edward Bristol.
 Smith, Ernest Hartmann Gosport.
 Taylor, Robert Stanley Royston.
 Temple, Frederick William Driffild.
 Todd, George Hollinwood.
 Turner, Horace Derby.
 Wellington, Charles John Rean Fowey.
 Wendon, William Totnes.
 Westlake, Lionel Leopold Windsor.
 Whitechurch, Ernest W. Nottingham.
 White, Robert S. Halifax.
 Williams, Frederick Newport (I.W.).
 Winship, Annie York.
 Woodhouse, George Ernest Bedale.
 Woolley, Percy Manchester.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who have severally made the required declarations, and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

Francis Henry Appleyard, 14, Napier Street, Fitzroy, Victoria.
 Archer Farr, 1, The Grove, Hammersmith, W.
 Samuel Sargeant, 171, Kilburn Park Road, N.W.
 Thomas Taylor, 70, Connaught Road, Liverpool.

Several persons were restored to their former status in the Society upon payment of the current year's subscription, and a nominal restoration fee of one shilling.

FINANCE COMMITTEE.

The report of this Committee was read, recommending sundry accounts for payment.

The PRESIDENT (as Chairman of the Committee) moved the adoption of the report and recommendations. On the General Fund Account the principal receipts had been for examination fees, and the payments were of the usual character, not requiring any special notice.

With regard to the Benevolent Fund, he was glad to report that several old subscribers had come back, and there had been a donation of five guineas from Mr. Gosling. The Orphan Fund remained practically about the same, and he thought the Committee would soon be able to consider the propriety of providing for another orphan. He had also to report that the Secretary of the "Camwal" Association had forwarded 100 one pound shares fully paid up, for the benefit of the Benevolent Fund, fifty from Mr. Davenport, the chairman, personally, and fifty from the chairman and directors, in accordance with the letter read last month, asking if the Society could accept the shares. A reply had been sent, saying that they would be gladly accepted, and he presumed his colleagues would all concur in the suggestion that two letters of cordial thanks for this gift should be sent, one to Mr. Davenport and one to the board of directors. The shares now stood in the name of the Pharmaceutical Society, which they could legally do, though it would not be proper for the Society to invest money in the shares of any trading company.

Mr. SOUTHALL asked if the shares could stand in the name of the Society.

The PRESIDENT said they could, the Society being a corporate body. He was sure they would be all grateful for this addition to the income of the Fund.

Mr. BOTTLE said he noticed amongst the payments a sum for the expenses of the Director of the Research Laboratory. He presumed that did not mean his personal expenses.

The PRESIDENT explained that the expenses in question formed a portion of the £150 which was granted annually for the expenses of carrying on the work of the Research Laboratory, in addition to the salary paid to the Director.

The report and recommendations were then unanimously adopted.

BENEVOLENT FUND COMMITTEE.

The report of this Committee included a recommendation of the following grants:—

£20 to the widow (64) of a registered chemist and druggist and subscriber to the Fund. Applicant's late husband had three grants previous to his death, and was elected an annuitant in December but died the next day. Applicant is in bad health and unable to earn anything. (Cheltenham.)

£12 to the widow (62) of a chemist and druggist who died in 1887, and who for some years previous had acted as dispenser. Applicant is in bad health, and her children are unable to help her. (London.)

£10 to the widow (46) of a registered chemist and druggist and subscriber, who carried on a small business but died in October last in debt. Applicant is endeavouring to carry on a general business with Post Office attached. Five children are dependent, or partially dependent upon her. (Leeds.)

£12 to the widow (66) of a former member and subscriber, who has had five previous grants. (Doncaster.)

£15 to a member and former local secretary (69), who had a grant of £20 in November, 1894, and was an unsuccessful candidate at the late election. He is suffering from hernia. (Barry.)

£15 to a registered chemist and druggist (70) who has had one previous grant. He is unable to work, and has no friends able to assist him.

One other application was again deferred for further information, and one the Committee declined to entertain.

Mr. HAMPSON, in moving the adoption of this report, went through the individual cases it embraced, in order to point out that the Committee had done its best, with the funds at its disposal, to meet the more pressing needs of applicants. He added that he thought the help the Committee was able to render encouraged self-help, which he supposed they all recognised was a feature to be encouraged.

Mr. ATKINS said he should like at the start of the new year to make an earnest appeal to friends for assistance to this Fund. Whilst he did not complain of lack of assistance, he would remind all interested in this part of the work of the Society that the Committee is giving away all that was available, and that the new year seemed a favourable time for all to remember the existence of this Benevolent Fund, and to consider whether they could not extend their aid to it. Though the Committee recommended grants amounting to a large sum he did not see that less could be done. One thing that struck him in the Committee's proceedings was the large amount of local interest excited in almost every case that came before it. The members were greatly aided in their deliberations and decisions in regard to

the applications with which they dealt by the large amount of information received, and the practical help given by local secretaries and other friends resident in the different neighbourhoods. He hoped this feeling would continue, and that friends throughout the country would graciously remember the needs of the Fund, and help it as far as possible.

Mr. HAMPSON said he quite concurred in the views to which Mr. Atkins had given expression, and that further help would be most acceptable, and could be made eminently serviceable.

The VICE-PRESIDENT, calling attention to the case where an annuitant died the day after being placed on the Fund, said the incident, to his mind, enforced a view which he had long held, that they would have to consider whether something better than the present system of election could not be adopted, with the aim, if possible, of relieving the more pressing cases before death put an end to their distressed friends' troubles and anxieties.

The PRESIDENT said that having nothing to do with the practical administration of this Fund it was the more gratifying to him to see a tendency in the Committee to vote what he would call respectable sums when recommending relief. He liked to see sums of £20 in the lists of proposed grants because he felt that in many cases such an amount would be infinitely more serviceable than two grants of £10 each. Although he knew what this involved, he had the fullest confidence that their brethren would support a generous policy, and he was glad to recognise in many quarters indications of a kindly disposition towards the Fund and its administration, especially on the part of those who came forward at the elections and acted as scrutineers, and those who assisted the Society as divisional and local secretaries. Such things, he thought, gave good promise for the new year. In this connection they must remember that the times are not brilliant, and probably those who could give large sums are much fewer now than they were twenty-five years ago; but it should equally be remembered that those who could afford to give smaller sums had greatly increased. There could be no doubt there were many of their friends who were getting a fair livelihood and could well afford to give small contributions to this Fund; and for his part he hopefully looked forward to the future, if providing them less large subscriptions, materially increasing the smaller ones.

The motion was then agreed to.

LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

Library.

The SECRETARY read the report of this Committee. It stated that the report of the Librarian had been received, (including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
November ...	Day	545	31	10	21
	Evening.....	172	15	4	8
Circulation of Books.		Total.	Town.	Country.	Carriage paid.
November	223	123	100	£1 7s. 4d.	

Donations to the Library had been announced (*Pharm. Journ.*, Dec. 14, p. 500), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the under-mentioned works be purchased:—

For the Library in London:—

Sadtler, Industrial Organic Chemistry, 2nd ed.
Stevenson, Spirit Gravities and Tables.

Museum.

The report of the Curator had been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
November ...	Morning.....	644	37	12	21
	Evening.....	60	7	1	2

Donations to the Museum had been received (*Pharm. Journ.*, Dec. 14, p. 500), and the Committee had recommended that the usual letter of thanks be sent to the respective donors.

The report also stated that a Sub-Committee had been appointed, consisting of the President, and Messrs. Martindale and Bottle, to confer with the Burroughs' Memorial Committee, with a view to formulate details and to report. The Committee had recommended that the evening meetings be held in future on the Tuesdays following the Council meetings in February, March, April, November, and December, instead of on Wednesdays. An application for a grant from the Liverpool Pharmaceutical Students Association was considered and adjourned.

The PRESIDENT, in moving the adoption of the report and recommendations, said it was hoped that the Sub Committee appointed would soon have a meeting with the Burroughs' Memorial Committee, and be able to report to the next meeting. With regard to the evening meetings, it was found that the officers of the Society, including the President, had so much to do on the Wednesday following the Council meeting, when the Library Committee met, and sometimes other special Committees, that it interfered with the necessary preparations required for the success of the evening meeting. The meeting was sometime ago moved from the day on which the Council met for the same reason, and it was then thought that the business of the Library Committee would not take so long as to interfere with preparing for the evening meeting, but it was found that it often occupied several hours, and it was suggested that for country members of the Committee who liked to take the opportunity of being in town to attend the evening meetings, it would be as convenient to come up on the Tuesday evening as to stay in town on the Wednesday; and on the whole the Committee thought the proposed change would be beneficial. An additional reason for it was that the Chemists' Assistants' Association held its meetings on Thursdays, and it was not always convenient for young men to get away on two successive evenings. With regard to the application from Liverpool, he might say that the Committee was prepared to recommend a grant, and the matter had simply been adjourned for the purpose of arranging details.

The report and recommendations were adopted.

CORRESPONDENCE.

The PRESIDENT said a letter had been received from the Honorary Secretary of the Edinburgh and District Chemists' Trade Association, enclosing a copy of a resolution recently passed by that body, thanking the Pharmaceutical Society for its endeavours to bring about an amendment of the Companies Acts, and promising to assist in any effort to put an end to the recognised evils associated with one-man companies. The usual letters had also been received from the Examiners, thanking the Council for their appointment.

ILLEGITIMATE TRADING.

The PRESIDENT said he would like to draw the attention of the Council and of local secretaries to some difficulties in which the Council was placed by the fact that, through the mistaken kindness of some of their brethren, others were allowed to carry on business by means of branch shops under conditions which were now held to be contrary to law. Cases of apparent hardship occurred from time to time, in which information was placed before the Committee, which was obliged to recommend the Council to act if it was found that a branch shop was left in charge of an unregistered assistant as manager. It was intimated privately that there must be many of these branch businesses still extant where registered persons were not in charge; and it was only right he should say, that when the Council found cases of that sort occurring—whether of one month's standing or more—it was obliged to exercise the powers vested in it, and to enforce the law without any personal consideration whatever. He referred to the matter publicly because it was becoming the habit of some of their brethren to ask for consideration and clemency in certain cases, and he conceived there was nothing more detrimental to the interests of the body politic than that any of their brethren in any city or town should calmly allow one of their number to carry on two or half a dozen branch pharmacies, knowing all the while that they were in charge of unregistered persons. The ethics of their craft, he thought, required that a neighbour should call on such persons and ask them to put themselves right. That would be true kindness; but to allow them for years to carry on business under such conditions, and then when information came to the Council—sometimes from public sources—and it was obliged to take action, to come forward and ask for clemency was a thing he could not consider to be right. It was the duty of every member of the Society and everyone on the Register not only to carry on his own business strictly in conformity with the law, but it was also his duty both to his neighbour and to the Council that he should do whatever in him lay to get his neighbour to do the same thing. If the Council could get the law carried out in its entirety, without any prosecutions, that would be preferable. The Council did not desire to recover penalties either from registered persons, or from grocers, or indeed any other class of persons, but its duty was to enforce the law. Sympathising as he did with all his brethren in their desire to

ameliorate their condition and to fight the battle of life as cheerfully as possible, he could not sympathise with, but was bound to condemn, both personally and officially, that form of friendship which allowed a wrong thing to go on for many years, and when it was found out, endeavour to shield the wrongdoer on the ground that it had been a thing of long standing. He made this statement in order to save himself from any possible misconception. Neither, he as President, nor the Registrar, could have any feeling in this matter. Their duty was plain and must be carried out, whether it were against a friend or a neighbour, or an outsider.

Mr. BOTTLE said he endorsed to a very large extent what the President had said. The only qualification he would make would be to throw the duty of remonstrance on the Local Secretary rather than on the neighbour of the offending party. He had felt it his duty as Local Secretary when he came across anything illegal, either committed by a member of the craft or an outsider, to intimate to that man that he was doing wrong, and if the wrong were corrected he heard no more about it. On the other hand, when such a hint had not the desired effect, more active measures had to be taken. He thought it was the duty of local secretaries in all cases to do their utmost to see that the trade in their own district was carried on upon strictly legitimate lines.

Mr. HILLS thought the truth probably lay between the President and Mr. Bottle. In some cases the local secretary would have more influence, but where a friend could intervene he might sometimes produce more effect.

The PRESIDENT said he quite endorsed what Mr. Bottle had said; but, at the same time, the greatest kindness one friend could do to another was to put him right if he were wrong.

Mr. BOTTLE said it sometimes happened that near neighbours were not friendly, and the local secretary could speak with the authority of the Society.

GENERAL PURPOSES COMMITTEE.

The report of this Committee was, as usual, read and considered in committee. It included the usual letter from the Solicitor as to cases in which proceedings had been instituted.

On resuming, the report and recommendations were unanimously adopted, and special resolutions were passed authorising the Registrar to take proceedings against certain persons named.

AN OLD DRUG SHOP.

A hundred and fifty years ago the practice of pharmacy was probably altogether in the hands of members of the Society of Apothecaries, but the interval between that period and the year 1815 is interesting as having been the time when the evolution of the chemist and druggist took place, and the business carried on under that designation became more definite. There are perhaps few shops now in existence where a business of that nature was carried on so long ago as in one which has recently been pulled down in the Briggate at Leeds. As will be seen from the accompanying illustration, it bore the inscription "Established in 1750," and the locality where it was situated was then known as "near the Cross." According to some old manuscript records one of the proprietors of this shop was Samuel Glover. Some extracts from the manuscripts above referred to were published last year in the *Leeds Mercury*, and they serve to give an idea of the conditions under which business was carried on prior to the commencement of the present century. Samuel Glover was a native of the West Riding of Yorkshire, and after receiving a moderate education in the district, and serving his apprenticeship in Yorkshire, he spent several years as an assistant with a large firm of druggists in London. At the age of twenty-four he began business on his own account in Knaresborough, and subsequently removed to Leeds in 1804, taking the Briggate shop with the aid of money borrowed from relatives and friends. He lived at his shop as was then the custom, and in moving from Knaresborough his effects were carried by waggon or canal. The premises were newly fitted up and furnished, probably the bow windows shown in the engraving date from that period. The interior was fitted with oak shelves, counters, drawers, etc., by a local joiner at a cost of about seventy pounds, the painting and decoration cost thirteen pounds. A desk purchased in London was brought to Leeds by sea, and a three-light oil lamp costing three pounds seven was hung in the shop. The invoice of this lamp describes it as being of the most improved description. Outside a large sign was put up over the shop windows representing the figure of a snake in the grasp of an eagle. Among

other provisions for business, a tea licence was obtained, for which five shillings were paid for the year. Advertising seems to have been but moderately adopted in those days, as the sum expended in that way is entered as thirteen shillings.

After these preliminary operations had been completed, a circular was issued in the following terms:—

Leeds, January 1st, 1805.

Sir, or Madam,—Permit me to acquaint you, I have taken and entered to the shop occupied many years by Mr. David Joy, at the Rose and Crown Yard end, near the Cross, where I intend carrying on the business of druggist, grocer, tea dealer, and seedsman. Having laid in a stock of every article of the best quality, from the first markets, and having lived upwards of three years in a very respectable house in London, I flatter myself I have an opportunity of serving you upon equal terms to any house in town; if therefore the utmost attention, punctuality, dispatch, and unceasing regard to your interests afford any claim to, I trust, I shall not be found altogether unworthy of, which circumstance, aided by my constant endeavours to merit your favours, augments the zeal with which I hope for your patronage.

Remaining very respectfully,

Your most obedient humble servant,
SAMUEL GLOVER.

Mr. Glover appears to have been sensible of the necessity of making a good personal appearance judging from the record that he provided himself with a suit of superfine black cloth at 25s. per yard, and with a clean-shaven chin, neatly powdered hair, a white neck-handkerchief tied in a handsome bow, a frilled shirt, knee breeches, black silk stockings and buckled shoes, was prepared to wait upon ladies or gentlemen who might favour him with their patronage as solicited in the circular above quoted.

Druggists in those days sold many things besides drugs, oils and colours, varnishes, gums, etc., and these more bulky articles were stored in an old warehouse at the top of a back-yard. The flow of custom was such as to lead to the desire for a partner soon after commencing, but no suitable replies having been received to the advertisements for one, Mr. Glover altered his mind and remained sole master. Some of the prices charged are of interest, as marking the altered conditions now prevailing:—Black tea, 4s.; Congou, 8s.; Pekoe, 12s.; gunpowder tea, 13s.; best Turkey coffee, 6s.; White's cocoa, 4s. 8d.; Fry's chocolate, 6s.; Sir Hans Sloane's chocolate, 7s.

Between 1805 and 1809 trade prospered. Various additions were made to the shop fittings and the stock increased. It is recorded that Mr. Glover kept a good table and generally indulged in a glass or two of wine after dinner. In summer he took a week or two at the Spa and braced himself for work by a dip in the sea at Scarborough.

From some letters sent to him it appears that he did not always satisfy customers for whom he procured things that were not in his stock. A Witherby shopkeeper complains that four dozen lemons he supplied at 2s. 6d. a dozen were "rubbish, and not worth a penny."

The influence of taxation is shown by the changes in price of various articles, white pepper changing from 4s. to 6s. and 8s., vinegar being advanced 3d. per gallon. In anticipation of a reduced tax on coffee, the stock was allowed to run low, and then the dealer in York could not roast it fast enough to supply his customers.

After some time Mr. Glover took an apprentice, and the guardians of the parish hearing of this asked him to take a parish apprentice as well, and, failing to do so, he had to pay a fine of £10 to the Leeds Workhouse.

The hour of opening shop was eight, and when the postman delivered letters there was a long adding up of postages, so many at 10d., 8d., 5d., or 4d., and 9s. 7d. to pay in all. The letters were written on post letter paper, folded and doubled one end into the others, with the addresses on the back, as envelopes were then unknown. The fire insurance premium in the Phoenix was 12s. on £400, and the duty ten shillings. A notice for the payment of a rent amounting to 1s. 7d. ran as follows:—

"Manor of Whitkirk, in the county of York. Parcels of the possessions of the late dissolved Monastery or Priory of St. John of Jerusalem in England." You are hereby summoned to appear at the Court Leet of our Sovereign Lord the King and Court Baron of the Right Honourable Frances, Lady Viscountess Irwin, Lady of the said Manor, on the 21st day of April instant, by ten of the clock in the forenoon, at the house of Mrs. Atkinson, in Whitkirk aforesaid, then and there to pay your rents and do your suit and service. Dated the 12th day of April, 1809.

MICHAEL SCHOLEFIELD, Steward.

After business hours time was passed in reading last Saturday's newspaper, or the *National Register*, or *John Bull*. Friends dropped in to talk over the news of the day, bad debts, etc., all lamenting that money was never so hard to get, and they don't know what the country is coming to. Then about eleven o'clock the shutters were put up, and all retired to bed.

But notwithstanding bad times, Mr. Glover made the acquaintance of a lady further down the street, and putting on a pair of Austrian boots, which cost him two guineas, a green cloth coat with brass buttons, fawn-coloured cashmere breeches, and a hat which cost 28s., with an allowance of 7s. for the old one, he pays his addresses, and is soon afterwards married. In the preparation for that event the house is redecorated, the parlour papered with paper costing 7s. 3d. a piece, and the drawing-room with one at 9s. 6d., besides an elaborate French green border costing £1 18s. 6d. Some furniture is brought from London, the rest made in Leeds. Pots, dishes, and jugs costing £11 came from Liverpool by canal. After the wedding at the Parish Church the whole party drive off to Harewood in three chaises for the day, and Mr. Glover pays for them £2 8s., with 7s. to each of the jockeys.

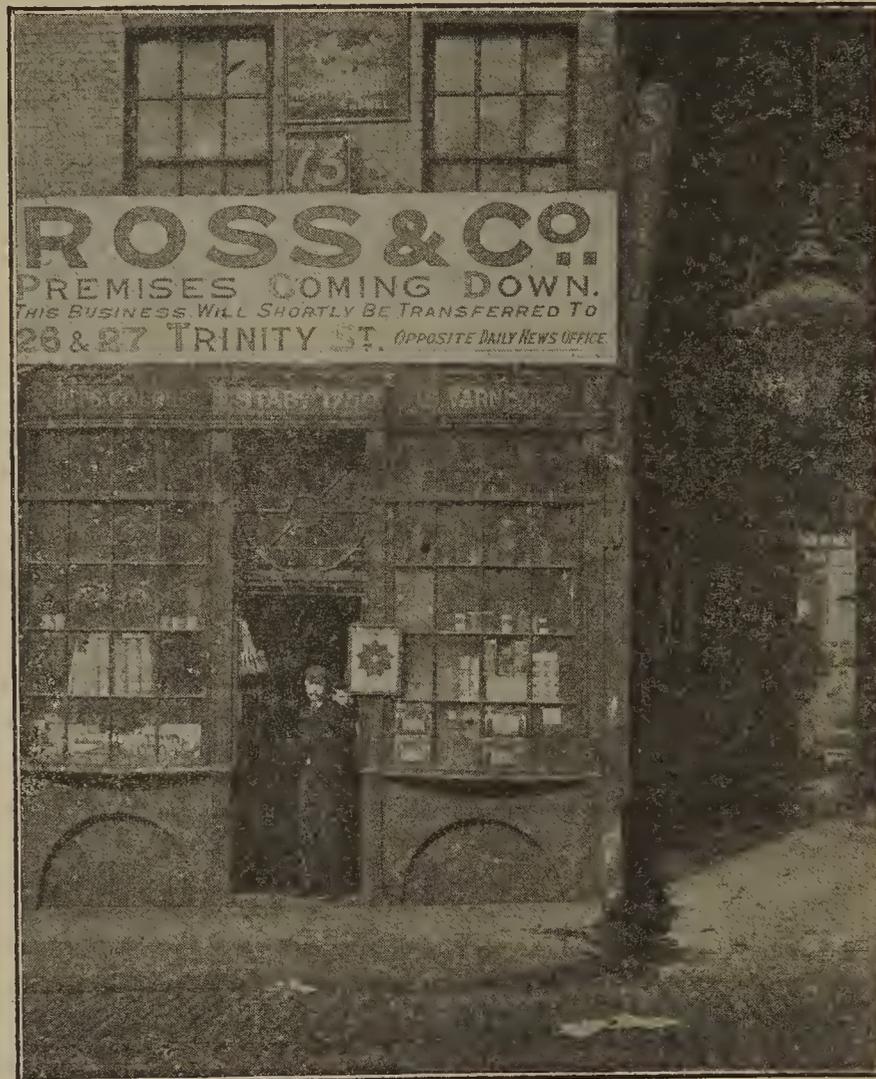

He had scarcely settled down to business after his marriage when he finds himself liable to serve in the Militia for five years, and has to find an acceptable man to take his place,

as appears from the following certificate:—

Borough of Leeds, in the West Riding of the County of York.—I do hereby certify that Samuel Glover, of the Upper Division in Leeds, in the said borough, druggist, was balloted to serve in the Militia of the said West Riding, and that he provided James Kays, of Blackburn, in Lancashire, cotton weaver, a substitute in his place and stead, who was sworn and enrolled the 1st day of September, in the year of our Lord 1810, as a substitute of the said Samuel Glover, for the space of five years, and for such further time as the Militia should remain embodied. As witness my hand this third day of September, in the year of our Lord 1810.

THOMAS BOLLAND,
Clerk of the Sub-Division Meetings of the said Borough.

These records of the period antecedent to the passing of the Apothecaries Act when the pharmacists of that day became recognised medical practitioners, do not say much of drugs or pharmacy, although the business carried on by Mr. Glover was called that of a druggist. It was evidently of a very miscellaneous character, and probably the business carried on by persons registered in 1868 as having been druggists before that date was, in many instances, of the same character.

LONDON: SATURDAY, JANUARY 11, 1896.

THE COUNCIL MEETING.

AT the opening of the proceedings last Wednesday a letter from the Privy Council Office was read by the PRESIDENT, communicating approval of the appointments of Examiners made at the previous meeting of Council.

The additions to the Society comprised six Members, thirty-eight Associates, and eighty-six Students.

The report of the Finance Committee, in addition to ordinary details, mentioned that several former subscribers to the Benevolent Fund have resumed their position as contributors to the Fund, and that a donation of five guineas has been received from Mr. GOSTLING. The shares of the Camwal Association given by Mr. HORACE DAVENPORT and the directors for the benefit of the Benevolent Fund, have been received, and directions were given that letters of thanks should be sent to the donors. These shares, which are fully paid up, will be held by the Pharmaceutical Society in its capacity of a corporate body, and will produce a welcome addition to the income of the Benevolent Fund. In reply to a question put by Mr. BOTTLE, the PRESIDENT explained that part of the sum mentioned in the report as having been paid for the Research Laboratory was for the expenses of carrying on work.

On the recommendation of the Benevolent Fund Committee, six grants amounting in all to eighty-four pounds were ordered to be paid, one of twenty pounds, two of fifteen pounds each, two of twelve pounds each, and one of ten pounds. Mr. HAMPSON, in moving the adoption of the report, remarked that in endeavouring so far as possible to meet the more pressing need of applicants, the Committee hoped to encourage self-help. Mr. ATKINS, taking the start of a new year as an opportune time to appeal for assistance, called attention to the fact that the Committee is giving away all its available money, and could not well have done less than it has done. He also expressed satisfaction at the evidence of local interest taken in the applications, affording in several instances much assistance to the Committee. The Vice-President called attention to the recent death of a candidate immediately after his election as suggesting the desirability of some better system of election. Before the adoption of the report the PRESIDENT remarked that the tendency of the Committee to grant more respectable sums was especially gratifying, although it involved full confidence, in the

generosity of supporters, and he referred to various indications of kindly disposition to the Fund which justify a liberal policy. If those able to give large subscriptions are less numerous than formerly, the number of those who can contribute small amounts is now much greater, and therefore the future may be looked forward to with confidence.

The report of the Library, etc., Committee stated that arrangements have been made to confer with the Burroughs' Memorial Committee, and that the consideration of a grant to the Liverpool Students' Association was adjourned for arrangement of details. It was decided, on the recommendation of the Committee, to hold the evening meetings of the Society in future on Tuesday, instead of Wednesday.

Among other correspondence a letter has been received from Mr. CLAUDE F. HENRY, enclosing a resolution passed by the Edinburgh District Trade Association, thanking the Council for its endeavours to bring about amendment of the Companies Acts with a view to prevent the recognised evils of one-man companies, and promising assistance in that direction.

The report of the General Purposes Committee gave information as to the progress of cases in the hands of the Society's solicitors, and, on the recommendation of the Committee, instructions were given for proceedings to be taken in several instances of infringement of the Pharmacy Act, which had been considered by the Committee.

Before the close of the meeting the PRESIDENT drew attention to the circumstance that in the administration of the Pharmacy Act the Council is sometimes placed in difficulty through the mistaken kindness of members of the craft in asking for consideration and clemency in cases where the Council has had to enforce the law. When information is given that branch shops are being carried on without registered persons in charge, the Council cannot do otherwise than fulfil the duty imposed upon it by the Act. Cases of apparent hardship may occur, but the Council cannot be influenced by feeling or personal considerations, and while it is the duty of every person on the Register to carry on his business in strict conformity with the law, it is equally a duty to induce others to do the same. By the exercise of friendly influence that might often be done to general advantage. But nothing can be more detrimental to the common interest of the craft than to ignore a breach of the law by a neighbour, and then to plead for clemency when the offender is found out. True kindness and regard for the obligations of each registered person to the whole body should be manifested in a different manner.

Mr. BOTTLE concurred in these remarks, and added that as Local Secretary he had felt that his duty was to remonstrate with anyone acting illegally. He thought local secretaries should do their utmost to see that the trade is legitimately carried on.

THE USE OF FOOD PRESERVATIVES.

WE have on several occasions referred to applications of the Food and Drugs Act, which were indicative of excess of zeal on the part of public analysts, and the case reported in the Journal of November 9 last appears to be of that nature. A decision has been given in the case only this week (see page 38), and as it is in favour of the defendant the inference may be drawn that the prosecution was a vexatious interference with the sale of the article to which it related.

The question at issue was purely medical, and the opinion that a small proportion of salicylic acid used to preserve sweet wines can be injurious is distinctly opposite to medical opinion, so that the only ground for the charge of adulteration was an exaggerated doctrinaire on a subject outside the province of an analyst.

ON PEPSIN AND ITS ACTION.

THE value of reliable preparations of pepsin in certain cases of functional disorder of the stomach is established, whilst, as has been previously pointed out in these columns, preparations which profess to contain all the digestive ferments are valuable or otherwise solely in proportion to the amount of pepsin they contain, trypsin and the other ferments, except pepsin, being destroyed by the acid of the stomach. It is of importance to know the relative value of samples of pepsin obtained from the stomachs of different kinds of animals, and also what effects different acids and substances, such as caffeine, may have in modifying the rate of gastric digestion. In this connection a series of experiments recently published by WRÓBLEWSKI (*Zeitschr. für Physiol. Chemie*, July, 1895) deserve attention. Two parallel series of observations were made; in one pepsin obtained from the stomachs of children soon after death, and in the other pepsin obtained from the stomachs of pigs, was used. Fibrin stained with carmine was the material by which the digestive power of the preparations was tested in the usual way, the rate of the process being judged by the relative depth of the colour the various liquids assumed after a given time. The acids were made equal to viginti-normal alkali solution by means of litmus, except in the case of phosphoric acid, which differs from the other acids in its action on litmus, and so the solution was made by means of estimating the sp. g. of the solution. A second solution of phosphoric acid was also made having a litmus equivalence of $\frac{1}{20}$ Na_2CO_3 , and it was found by taking the specific gravity that this solution had the equivalence of a deci-normal alkali solution.

Two kinds of pepsin were used: pig's pepsin prepared by WITTE'S method, *i.e.*, glycerin extraction and subsequent filtration; and human pepsin obtained in the same way from the stomachs of infants that had perished during birth. The pig's pepsin extract was more powerful than that of infants, so that the former required dilution to make it of exactly the same digestive power as the extracts from the stomachs of children. Ten C.c. of the different acid solutions were placed in two sets of twelve similar test tubes. One tube was set apart with distilled water to serve as a control. One C.c. of carmine fibrin was placed in each tube, and then 1 C.c. of child's pepsin extract in the first series of tubes, and the same amount of diluted pig's pepsin extract in the second series. The tubes were shaken from time to time, and were kept at a temperature of 15° C.

The tabulated results of these experiments show that digestion is most rapid with oxalic acid solution ($=\frac{1}{20}$ normal alkali solution), and after that successively with HCl, HNO_3 , and H_3PO_4 , tartaric, lactic, citric, malic, paralactic, sulphuric, and acetic acids. With pig's pepsin and oxalic digestion was complete in thirty minutes, and with child's pepsin in forty minutes; in the rest of the series a gradual decrease of digesting power was observed—with the exception mentioned below—so that the acetic acid tube showed only a trace of red colour in the liquid after twenty hours' digestion with child's pepsin, and none, after

the same period, with pig's pepsin. With stronger H_3PO_4 ($=\frac{1}{10}$ normal alkali) the process was complete in both cases after forty minutes. The control tube showed no colour in the water after twenty hours. Some differences were observed in the behaviour of the two kinds of pepsin; thus, with pig's pepsin, phosphoric acid ($=\frac{1}{20}$ normal alkali) came fifth on the list, whilst with child's pepsin it came sixth, and lactic acid fifth. A further series of observations were made to test the effect of various substances in modifying the rate of digestion. The results showed that whether as hydrochlorates or as the free base, caffeine hastened digestion, as did also, but less markedly, theobromine and codeine. On the other hand, veratria delayed the process to a marked degree, and to a less extent the same effect was noticed with morphia, conine, or atropine. The hydrochlorides of narceine, strychnine, quinine, and coniine also delayed digestion.

THE INTERPRETATION OF THE PHARMACY ACT.

So much difficulty has been experienced in time past in convincing County Court judges of the exact scope and meaning of Section 15 of the Pharmacy Act, 1868, that the remarks of His Honour Sir HORATIO LLOYD, on the 3rd inst. (see pp. 37-38), seem worthy of special reference. The offence having been fully proved, acknowledged indeed by the defendant, the judge observed that, according to the strict letter of the law, the moment it is proved to his satisfaction that a man who is not a registered chemist has sold any of the poisons mentioned in the Schedule or any preparation of them, the defendant is proved to have committed an offence against the law, and therefore liable to the specified penalty, which the judge has no power to remit. The question of quantity, it was pointed out, has no bearing upon the matter, so long as it is proved that poison is sold. This is a very satisfactory reading of the Act, and, if upheld, should go far to obviate some of the difficulties experienced in proving such cases in court. The judge also pointed out that "it is most important that the sale of poisons should be restricted to the hands of fully qualified and registered chemists." Incalculable mischief, he observed, may arise through the sale of poisons which it may not be possible to trace to the seller, when obtained through other than legitimate sources. This, of course, is the chief reason for restricting sales from the legal point of view, but it is equally important that public interests should be safeguarded by all poisons passing through the hands of persons specially trained to deal with them.

OLD-TIME PHARMACIES.

It has been suggested that some information relating to the business of the chemist and druggist during the early part of the century would be interesting to readers of the Journal, and that many members of the trade throughout the country could furnish details as to the past history of the business with which they are connected or others of which they have a knowledge. We shall be glad to receive communications of that nature or to be informed of sources from which particulars may be obtained. In the present number (see p. 30) an illustration is given of a shop in Leeds, where a druggist's business was carried on from 1804, and probably even from an earlier date.

ANNOTATIONS.

INTERNATIONAL PHARMACEUTICAL EXHIBITION IN PRAGUE.—The Prague Pharmaceutical Society has decided to celebrate the termination of the twenty-fifth year of its existence, by holding an international pharmaceutical exhibition in the exhibition palace in the Král O'ora, between August 15 and September 15 next. A general invitation has been issued to chemists and druggists, pharmaceutical associations, producers of pharmaceutical and chemical preparations, makers of machines and instruments for pharmaceutical purposes, and all other firms having business relation with chemists and druggists, to participate in this, the Second International Pharmaceutical Exhibition at Prague. Applications for particulars, programmes, etc., should be addressed to the President of the Executive Committee, Dr. K. Fragner, pharmaceutical chemist, Prague III. nro 203, by whom the invitation is signed.

DATE OF NEXT EVENING MEETING IN LONDON.—To prevent inconvenience to members and associates of the Pharmaceutical Society who attend the evening meetings in London, special attention is directed to the fact that the Council has decided to hold the next meeting on Tuesday, February 11, instead of Wednesday. This alteration of the day of meeting will be a permanent one (see pp. 28-29).

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.—This Society has taken the Montgomery Hall, Sheffield, for Mr. W. Lamond Howie's lecture on the Swiss Alps. The date is January 29, and Sir H. Stephenson, J.P., has accepted an invitation to preside.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.—The annual dinner of this Association was announced to be held at the Prince of Wales' Hotel, Cambridge, on Friday, January 10, at 8.45 p.m. precisely. Members and friends who open their Journals promptly on receipt, on Friday morning, are reminded that they are cordially invited, and may obtain tickets (3s. 6d. each) by applying at once to either of the honorary secretaries, Messrs. E. Saville Peck, 30, Trumpington Street, and S. F. Barker.

INDEX TO THE 'PHARMACEUTICAL JOURNAL.'—The index to the first volume of the new series of the Journal is published with this week's issue. To suit general convenience it has been so arranged that it may be placed either at the beginning or end of the volume. Probably in most cases the former alternative will be adopted, and instructions should be given to the bookbinders accordingly. This index is fuller than any previous one, extra cross references being given wherever likely to prove useful.

THE CHEMISTS' BALL.—A committee meeting to make the final arrangements for the Chemists' Ball, will be held at 16, Bloomsbury Square, W.C., on Monday next, January 13, at 2 p.m. The Ball will take place on the following Wednesday, January 15, at the Portman Rooms, Baker Street, W. The quadrille band will be conducted by Mr. Dan Godfrey, Mr. T. C. W. Martin will officiate as M.C., and the proceedings are to commence at 9 p.m. Inclusive tickets (Ladies 12s. 6d. each, Gentlemen's, 17s. 6d.) may be obtained from the Honorary Secretary, Mr. John C. Umney, 48 and 50, Southwark Street, S.E., or from Mr. Richard Bremridge, 17, Bloomsbury Square, W.C. Applications for tickets should be sent without further delay, and must be accompanied by remittances.

ANTISEPTIC VALUE OF SODIUM FLUORIDE.—According to the *Nouveaux Remèdes*, fluoride of sodium (fluorol) is reported by Daclos to be a valuable antiseptic. It is prepared in the form of a bluish white, odourless powder of saline taste. It is preferable to sublimate, which is sixteen times more poisonous, also to silver nitrate, formalin, and permanganate, for when employed in hypodermic injections it is painless. In one per cent. or even half per cent. solution it acts as a powerful germicide. Lagrange states that probably its efficacy as a disinfectant and bactericide is due to the fact that it does not coagulate albumin like sublimate, consequently the microbes are not protected by an envelope of coagulated albumin. It is specially useful in ophthalmic practice; the lachrymal mucous membrane tolerates injections of fluorol without the least reaction, since it is neither caustic nor painful and provokes no irritation.

TU-CHUNG BARK.—The botanical source of this curious bark, which is much valued as a medicine by the Chinese, and forms a considerable article of commerce in China, has at last been definitely settled, and a full description of the plant published. A partial account was published in the 'Icones Plantarum,' pl. 1950, but as the plant was unisexual (*Ph. J.* [3], xxi., p. 738; xxii., p. 613) and the male flowers were unknown, it was doubtfully referred to the Euphorbiaceæ. Now that complete material, collected by Mons. R. P. Farges, in Szechuen, has been examined, Professor Oliver refers the plant to the Trochadendraceæ, of Prantl, a group of plants which includes also the genera *Cercidiphyllum*, *Euptelœa*, *Trochadendron*, and *Tetracena*. This group, he thinks, should be separated from the Magnoliaceæ; the late Professor Baillon considered it to be allied to the Hamamelidaceæ and Saxifragaceæ. The tree is cultivated in the district of Tchen-keou in Szechuen. The following is the description now given in the 'Icones Plantarum,' No. 2361:—"*Eucommia ulmoides*, Oliv., 'Ic. Pl.,' 1950, floribus præcocissimis, masculis pedicellatis in axillis squamarum cataphyllacearum solitariis, staminibus circa 8 (6—10) receptaculo nudo insertis; filamentis brevissimis, antheris elongato-linearibus, obtuse tetragonis, apice in connectivo oblongo-lanceolato acutiusculo productis, longitudinaliter dehiscentibus: rudimentis; gynœcii O; floribus fœmineis breviter pedicellatis solitariis ovario nudo uniloculari, longe stipitato elongato compresso-apice æqualiter vel subæqualiter bifido, lobis intus papilloso-stigmatosis, stigmatibus apices productis patentibus reflexisve, ovulis anatropis geminatis pendulis, arcte applicitis."

A THOUGHT MACHINE.—From that "perennial source of stupendous sensations," as the United States has been described, come details of a marvellous invention by J. Emmner, jun., of Washington, who is alleged to have produced a machine capable of permanently recording thought. "Man can think directly into a machine, and produce an accurate permanent record of his thought, transcribable at any time." The National Press Association describes the machine as seen by some newspaper correspondents, with the utmost gravity, and proceeds, "Mr. Emmner then requested silence for a moment, seated himself before the thought machine, adjusted it for recording, and opened the electric circuit. The mechanism began its smooth, noiseless motion, the cylinder, revolving on its axis, pressed softly by the electric pencil passing along its face. Then, as the inventor brought his head within a foot of the recorder, directing his mind upon the machine, a thin cloud-like thread wound spirally about the glistening film from left to right. This was the thought-record, which, after several minutes of silent work, had overspread the entire film with its smoky, tinted coils." The description seems exact, whether true or not.

CALENDAR OF THE PHARMACEUTICAL SOCIETY.—The Calendar of the Pharmaceutical Society for 1896 will be ready for publication on the 15th inst. The advanced proof sheets show that the contents have been thoroughly revised and brought up to date. Reference to page vi. of our advertisement columns will show that the text of the Calendar covers a very wide field of information—pharmaceutical, legal, and official—and should appeal to every one connected with the Society, if not to every member of the trade. Registered persons will find a perusal of that portion of the book dealing with the various enactments affecting the practice of pharmacy of great value in the conduct of their business, as it is possible for the most conscientious man to offend against the law if he is ignorant of or only partially acquainted with the provisions regulating his calling. A copy of the Calendar will be sent, post free, on receipt of application, enclosing remittance (2s. 4½d.), by Mr. Richard Bremridge, 17, Bloomsbury Square, London, W.C.

PERCHLORIDE OF MERCURY IN WHOOPING COUGH.—The *Giornale Medico del Esercito* advises painting the throat of children affected with whooping cough with a 1 per 1000 solution of perchloride of mercury, going well to the back of the tongue and over the uvula and tonsils every morning. No toxic effect has been observed, and most cases can be cured in from eight to fourteen days.

FRENCH HONOURS FOR SCIENTIFIC WORKERS.—On the occasion of the Centenary of the French Institute, Professor Max Müller, who is an Associate of the Academy of Letters, was appointed Commander of the Legion of Honour. Professor Ramsay and Lord Rayleigh, as well as Messrs. Simon Newcombe, Alexander Agassiz, and Rowland, of the United States, who are all corresponding members of the Academy of Science, were made Officers of the Legion of Honour; while Mr. Adolphus Hall, of America, a corresponding member of the Academy of Science, was appointed Chevalier of the Legion of Honour.

A REMARKABLE PHOTOGRAPHIC DISCOVERY.—According to the Vienna correspondent of the *Standard*, Professor Röntgen, of Würzburg University, has performed a truly remarkable feat, being nothing less than the photographing of bones *in situ* in the human body, or metals enclosed in wooden or woollen coverings. The light emitted by electrically excited vacuum tubes was employed, and photographs of the human hand are said to be obtainable in Vienna, which show the bones and rings, but not the accompanying flesh. The proffered explanation of this phenomenon is that wood and other organic substances are transparent to the invisible light rays, whilst metals and bones are opaque and absorb the rays, a representation of those substances alone therefore appearing on the photographic plate. Further confirmation of the discovery will be required before the facts are accepted in this country, in spite of the assurance of the *Presse* that "there is no joke or humbug in the matter."

'HISTORY OF THE CHOLERA CONTROVERSY.'—In a work bearing this title (Churchill, 3s.), Sir George Johnson, F.R.S., describes his experiences in the study and treatment of cholera, and gives directions for treating the disease, based on those experiences. Sir George is of opinion that the practice of arresting most forms of diarrhoea by means of opium is unscientific and dangerous, and he expresses satisfaction (*vide* p. 55), at finding that, "after forty years of controversy, the evacuant or eliminative treatment is now being generally looked upon not only as rational and scientific, but in practice most successful."

Lamb, Henry Alexander.	

ENGLISH NEWS.

SOCIETY OF CHEMICAL INDUSTRY (MANCHESTER SECTION).—At the third meeting of the session, held on January 3, at the rooms of the Chemical Club, Victoria Hotel, under the chairmanship of Mr. G. E. Davis, the first paper read was by Dr. B. W. Gerland, on "Some New Methods of Testing Indigo." Dr. Gerland, in his paper, stated that there were innumerable methods of testing indigo, but none that was absolutely reliable—a circumstance which was all the more surprising in view of the value of indigo as an article of commerce. He favoured the nitrobenzol process, which differs very much from the ordinary methods. In the course of the discussion which followed a good deal of diversity of opinion was manifested. Mr. Rawson, of Bradford, said he had come to the conclusion that the best method was that of oxidising with permanganate of potash. He had heard, he said,

of experiments with the nitro-benzol process, in which it was found that the high temperature destroyed some of the indigotin. The Chairman also favoured the use of permanganate of potash, the action of which, he said, was constant and reliable. Dr. Gerland admitted that it was so when the indigo was pure. Mr. Wilfrid Irwin followed with a paper relating to gas manufacture. At the closing meeting of last session he read an interesting paper on the enrichment of gas, a subject which is at present receiving much attention from gas companies and corporations owning gas works, as it is found that by the use of oil, benzol, and other enrichers, it is possible to dispense to some extent with the use of high-priced cannel coal. He now discussed the effect of heat on the illuminating power of coal gas, and its relation to the theory of flame. He described some of the phenomena of flame, referring in particular to the stratification, observable in an ordinary gas flame, a point as to which, he remarked, we did not yet know all that was to be known. In certain experiments he had made he had found that on subjecting coal gas to a high temperature there was a great reduction in the illuminating power. Luminosity he found to be due to two different sets of reactions, and he pointed out that while one burner was more favourable to one set, another might be more favourable to another set. The results he had obtained seemed to show that the argand burner, which was used for the purpose in most gas works, was scarcely a fair method of determining the commercial value of gas, and he suggested that a fairer method would be to take the average of the union jet and the slit burners, which were those in everyday use.—The discussion of Mr. Irwin's paper was postponed.

LONDON INSTITUTION.—Sir Humphry Davy was the subject of the third and last of Professor Vivian Lewes's Christmas lectures, delivered at the London Institution (see *ante*, p. 17). As at the other two lectures, there was a large and interested audience. The lecturer, beginning with Davy's early life, gave an account of his more important researches. It was while living in Penzance that, with primitive apparatus, he learnt that marvellous skill in manipulation which stood him in such stead afterwards. At a "Pneumatic Institute" in Clifton he investigated the physiological action of various gases, and discovered the anæsthetic properties of nitrous oxide. Being appointed Professor of Chemistry at the Royal Institution in 1801, he carried on his researches in galvanism, and, by means of the large battery which he had at his disposal there, was able to effect the decomposition of soda and potash and isolate the elements sodium and potassium. Later on he demonstrated the elementary nature of chlorine and, showing muriatic acid to be a compound of that gas with hydrogen, broke down the old supposition that oxygen was a necessary constituent of acids. In 1815 he invented the miner's safety lamp. In connection with this occurred a lamentable incident of his career, for he was somewhat embittered because George Stephenson invented the same thing almost simultaneously with himself. The investigations he carried on when engaged on the safety lamp led to the enunciation of his theory of the luminosity of flame. In conclusion, Professor Lewes exhibited the splendid light obtained by burning pure acetylene—a gas which Davy had noticed, but had not fully investigated.

THE USE OF POISONOUS WEED KILLERS.—On Monday, December 30, Mr. T. Buss, County Coroner, held an inquiry at the Bicycle Hotel, Sevenoaks, into the circumstances attending the death of Ebenezer Upton, aged 44, which occurred on the previous Saturday, from the effects of drinking weed-killer containing arsenic. The jury returned a verdict of "Suicide during temporary insanity," and added a rider to the effect that the jurors "thought there should be some restrictions as to the sale and exposure of so deadly a poison. This was not the first case of the kind which had occurred in the neighbourhood, one on the Montreal Estate being the result of an accident. The label on the three-gallon jar of weed-killer found in the potting-shed was printed very indistinctly in small letters, and they thought the vessel should be kept under closer observation."

A SHEFFIELD CHEMIST ROBBED.—Several cases of shop-breaking have occurred recently in Sheffield, and an exceptionally impudent instance of theft has taken place on the premises of Mr. S. P. Lowe, chemist and druggist, of 42, London Road, and 1, Lansdowne Road. During the temporary absence of Mr. Lowe the thief had effected an entrance by the use of a skeleton key. A lady's gold watch was broken, and a number of valuable articles were stolen.

SUPPOSED SUICIDE OF A TORQUAY CHEMIST'S ASSISTANT.—A distressing case of supposed suicide occurred at Torquay on Monday afternoon, January 6, the victim being Charles Albert Snow, 19 years of age, assistant to Mr. Bathe, chemist, of Fleet Street. It appeared that Mr. Bathe returned to his shop from dinner about 2.30 and found his assistant quite dead with three prussic acid bottles lying beside him, and the circumstances point to a case of suicide. The body was removed to the mortuary at the Torquay Hospital to await an inquest. Deceased had been with Mr. Bathe for about three and a half years.

DEATH OF A PROMINENT SHEFFIELD SURGEON.—By the death of Mr. Arthur Jackson, surgeon, at the comparatively early age of fifty-one, the pharmacists of Sheffield have lost a good friend. He was present and spoke at their annual meeting and then seemed hale and hearty. About a month since he caught a chill on returning from visiting a patient, from the results of which he has died. In his profession, in connection with the medical charities of the city, is all church and educational matters, Mr. Jackson filled a large and important place. He took the keenest interest in the history and topography of Sheffield, and not many men knew more about it and its people than he did. He had a large collection of the biographies of Sheffields, as well as of local books, pamphlets, and papers, and the hope is entertained that they will be secured for the city.

SCOTTISH NEWS.

CARBOLIC ACID FOR WHISKY.—The steamer *Cholmley*, belonging to Whitby, arrived in Leith early on Saturday morning from Grangemouth, and a fireman, about thirty years of age, named Ivan Nieminen, belonging to Finland, died from carbolic acid poisoning while being removed from the ship to Leith Hospital. It appears that on the previous evening, about four miles above the Forth Bridge, a seaman gave deceased a drink from a gill bottle, which contained carbolic acid. The seaman believed that the bottle contained whisky, as he had bought a gill bottle of whisky before leaving Grangemouth, and placed it in his locker. Nieminen became ill, and died shortly after the arrival of the steamer in Leith docks. The seaman, named James Russell, was detained by the police for a short time pending inquiries, and then liberated.

THE PRESCRIBING OF PROPRIETARY REMEDIES.—At a meeting of the Glasgow Parish Council on December 3, Mr. J. Anderson Russell called the attention of the Medical Committee to the circumstance that medicines of a proprietary nature were being prescribed by the medical officer. A Sub-committee was appointed to make inquiry and report, and on January 7 Mr. Russell was enabled to state that the Sub-committee had reported as follows:—"Your Sub-committee met at the collector's office yesterday (December 18), the medical officer who prescribed the proprietary medicine particularly commented upon. The mind of the Medical Committee was shown to him as being opposed to the practice of this, or proprietary medicines generally, being prescribed by the medical officers of the Council. After some discussion, he expressed himself as being quite agreeable to fall in with the wishes of the Committee." The Committee had approved of the Sub-committee's report, and, on the suggestion of Mr. Russell, it had been agreed that an excerpt of this part of the minutes should be sent to each member of the outdoor medical staff. The latter proposal was not approved of by the Council without some lively discussion, but was finally confirmed by an overwhelming majority.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND.—The monthly meeting of the Council was held on Wednesday, the 1st inst., the President, Mr. W. F. Wells, jun., in the chair. The report of Dr. George W. Duffey, the Lord Lieutenant's Visitor, on the Society's examinations held during the past twelve months, was received. The answering at the Preliminary examinations during the year was, the report stated, indicative of an improvement in the elementary education of a majority of the candidates. The number of candidates for the licence had exceeded that of any former year, but of the sixty-eight candidates only one-half passed. The subject in which the largest number of failures occurred was chemistry, but a noticeable improvement had shown itself in compounding. Dr. Duffey took exception to a practice on the part of

the examiner in chemistry of devoting a two-and-half-hours' examination entirely to a paper of twelve questions, of which only eight were to be attempted, and recommended a paper of six questions and an oral examination of ten minutes for each candidate, the examination to last not less than three hours.

The President remarked that it would be only necessary to convey to the examiner the wish of the Council that oral examination in chemistry should be continued at the licence examination, in order to have that course followed. The report was referred to the House Committee. A letter from Dr. Montgomery, secretary of the Apothecaries' Hall, stated that William Stevens, of 6, Rock View, Old Swan, Liverpool, whose case was referred to at the previous meeting of the Council (see *Ph. J.*, December 21), did not hold the licence of the Hall, but was a qualified assistant. Donations were acknowledged from the Pharmacy Board of New Zealand of copies of their October examination papers, and from the Editor of the *Pharmaceutical Journal* of a copy of the work entitled 'The Discovery of Oxygen.' The House Committee submitted a plan for the improvement of the druggists' examination. A copy of the plan was ordered to be sent to Mr. Turkington, a member of the Council, who had initiated the matter.

Mr. Hayes read a letter from Mr. R. S. Moone, L.P.S.I., of Belfast, stating that a fund was being raised there to give medals and prizes at the Society's final examination for the licence, and inviting the Council to join in the project. Mr. Hayes moved a resolution affirming the desirability of such a step being taken. In the course of discussion, it was remarked by Mr. Grindley that if the Council took the step suggested, they should keep the control of the medals and prizes in their own hands.

The resolution was passed, and other business having been disposed of, the Council adjourned.

THE USE OF PATENT MEDICINES IN PUBLIC DISPENSARIES.—The Local Government Board has addressed a long letter to the Edenderry Poor Law Guardians on the subject of the use of patented or proprietary medicines in dispensaries, the report having special reference to medicinal preparations used at the Rathangan Dispensary. The inspector, Dr. Stafford, recently reported on the supplies of medicine in that district, and the explanation received being considered unsatisfactory, the Board ordered the facts to be noted in the records of the department against the medical dispensary officer. The Local Government Board proceeds to say that the list of authorised drugs and medical preparations given in the dispensary rules was prepared from the British Pharmacopœia, the resources of which are found sufficient for the requirements of medical practitioners generally. As, however, the Guardians had entered into a contract for medicines, including "a number of patent and proprietary preparations not authorised by the British Pharmacopœia, the Local Government Board has directed the attention of the auditor to the matter, with the view to his disallowing any expense incurred in respect thereof. . . . The Local Government Board cannot sanction the use of the list, as they are not prepared to recommend the Treasury to recoup any portion of the cost of patent and proprietary medicines." Dr. Stafford's report on the same matter stated that he had found that the dispensary medical officer of this district had ordered some of these expensive patent medicines which had not yet received the approval of the British Pharmacopœia, and added that if a dispensary medical officer "desired to experiment with new drugs or non-official remedies he must do so at his own expense, as the ratepayers and the Treasury cannot be expected to pay for this class of experiment." In his explanation, the dispensary medical officer, Dr. Bray, denies that the outlay was extravagant, as only a very small sum was so expended, and shows that the cost of medicines last year was only about half what it was in the former year, whereas there were in 1895 some hundreds more of patients prescribed for. The Guardians have decided to adhere to the Pharmacopœia list in future.

IMPORTANT PROSECUTION UNDER THE PHARMACY ACT—At the Rathfriland Petty Sessions, David Wilson, Church Street, Rathfriland, was prosecuted "for that he, on October 17 last, did sell and retail and dispense a poison—to wit, cantharides—contained in a bottle of Leeming's essence, to Sergeant Nelson, R.I.C., Rathfriland, contrary to the Pharmacy Act (Ireland), 1874, 38 and 39 Vic., cap. 57, section 30, he not being a person properly qualified in that behalf according to law." In a second summons the defendant was charged with having kept open his shop for retailing and dispensing poison, contrary to the

same Act. Mr. Galway, solicitor, Belfast, prosecuted on the part of the Pharmaceutical Society of Ireland, and Mr. Crothers, solicitor, Rathfriland, defended. After hearing evidence, the chairman said that the magistrates had nothing to do but to impose the full penalty of £5 in each case, and order that one-third of the sum be paid to the person who had been the means of bringing the defendant to justice—Sergeant Nelson, he supposed. They would allow £1 costs in each case to meet the expenses of the Pharmaceutical Society in connection with the prosecution and the costs of the Court.

PRESENTATIONS during the festive season seem more than usually appropriate when feelings of cordial friendship animate both donors and recipient. Under such a heading comes undoubtedly the presentation to Mr. A. J. Paterson, L.P.S.I., last week, of a silver tea and coffee service by his late fellow-assistants in the establishment of Messrs. William Hayes and Co., on his leaving to manage another pharmacy. The presentation, on the 6th instant, of the distinguished chemist, Sir Charles Cameron, M.D., by the Governor (Professor Tichborne, LL.D., F.I.C., etc.) and Company of the Apothecaries' Hall of Ireland, of the Honorary Diploma of that body, probably reflects as much honour upon the donors as upon the amiable and highly respected new apothecary.

FOREIGN NEWS.

FRENCH SPECIALTIES.—In France *spécialités*, which are similar to English so-called "patent" medicines, but unstamped, are much prescribed by medical men. Their composition is stated on the label or in the circular with each one. Legally their composition should be approved of by the "Académie de Médecine," as not being injurious to the health of the general public. A case bearing on this point was heard at Paris, on December 18, and the decision is of vital interest as to the responsibility of *pharmaciens* delivering these medicines. The mother of a girl, eleven years old, who suffered from "incontinence d'urine," read a prospectus giving details of the benefit to be obtained from the use of the "Dragées B" for this complaint. This statement was supported by testimonials from medical men and private individuals. In June, 1894, she commenced the treatment, and continued for some time according to instructions given, but not obtaining satisfactory results the treatment was ceased. Some months afterwards, March, 1895, not feeling well, she asked her mother's permission to recommence, which was accorded, and as there were still some left in the bottle she took "several."

Shortly afterwards she died after much suffering. Analysis and medical evidence proved death to be caused by strychnine. Consequently the maker and the chemist who sold them were charged with manslaughter, imprudence, and negligence by not observing the law (*Loi Germinal l'an, xi., 1846*) of causing the death of the girl.

The prosecution was based principally on the fact that these dragées were stated to owe their virtue to *Scopolia japonica*, but each dragée contained in addition two milligrammes (1/33 grain) of strychnine, which fact was admitted by the maker, and also that they were stated to be "inoffensive." The defence was that they were inoffensive if taken as directed, two daily, gradually increased to six; that instead of three at least ten were missing from the bottle, and also they had been sold for thirty years with satisfactory results and no complaints. The law necessitating the approval of the Académie de Médecine had fallen out of use, although existing since 1857, as since that date no *spécialité* had been authorised, although formally applied for, as in this case. Great importance was also attached to the negligence of the mother in allowing the girl to take them without control. The decision of the court was that the maker was considered culpable of manslaughter by imprudence, and fined 600 fr. The *pharmacien* was considered culpable simply for delivery of a *spécialité* not authorised and without a physician's prescription, and fined 500 fr., with the rights of the *Loi Beranger*, which pardons the first offence, but adds the penalty to the second.

Consequently the *pharmacien* is legally responsible for the negligent use of any *spécialité* he sells. The "*Loi Germinal l'an, xi.*" (Oct., 1846) is now only used to approve of the insertion in the Codex (Pharmacopœia) of products recognised to be of public utility, and known as "antipyrine," "phenacetine," "sulphonal," etc., and formulæ such as our tinct. chlorof. et morphinæ (chlorodyne substitute), pilula ferri (Blaud's pill), etc.

LOSS OF GOODS IN THE POST.—It may interest English firms to know that a Paris magistrate has recently given a decision to the

effect that the value of articles sent by post, and lost in transmission can be recovered from the vendor if he despatches the goods. The plea that a registration fee should have been paid by the purchaser, as well as the postage, did not hold good.

THYROID EXTRACT.—At the Therapeutic Society, M. Vigier has explained a process for the preparation of an extract of thyroid gland, which consists in reducing to pulp the fresh gland and mixing with it powdered sugar, and then borax and charcoal to prevent decomposition. Excellent results were obtained by the use of this medicine, and numerous doctors testified to its activity. The glands should be quite fresh and healthy, and the manipulation must be carried out quickly. The dose is the same as that of the fresh gland.

REDUCED PRICES IN PARIS.—Pharmacies where goods are sold at reduced prices have now become so common in Paris that the public regard it as a matter of course to be allowed 20 or 25 per cent. off the prices marked on specialties, but the preparation of prescriptions has always commanded a fair remuneration. Now, however, this department has received its first attack. A *pharmacien*, M. Chabaud, late analyst to the Municipal Laboratory, has just opened an establishment in the Rue Monge, the appearance of which testifies to its revolutionary intentions. The shop front is devoid of the usual chemist-shop appearance, the windows being painted over and bearing the startling inscription "Commerce de Pharmacie." Prescriptions dispensed for fifty centimes, one franc, and one franc and a half. Circulars are distributed in the neighbourhood containing the following:—"Without discussing the reasons, good or bad, that are urged in support of the antiquated privileges of the *pharmacien*, which constitute one of the devices now existing for the exploiting of one man by another, we ask whether it is not restricting in a singular manner the liberty of the subject to compel anyone needing a medicine of little value to pay, for example, one franc, for what costs ten centimes or less, without taking into consideration that a doctor's prescription, costing a considerable sum, is required in order to obtain this medicine. Therefore, thinking it expedient to acquaint the public with the real value of those drugs that are in common demand, we have appended a list, marking the prices at which we retail them and what they cost wholesale." Then follows a catalogue of medicines, with particulars of wholesale cost, and the rates adopted by M. Chabaud.

The circulation of this prospectus naturally excited a great deal of indignation among the pharmacists of the quarter and also at the School of Pharmacy, resulting a few nights ago in the assembling of between two and three hundred students, who marched in a body to the pharmacy in question, and to the cries of "Down with Chabaud! Down with the Grocer Pharmacist," proceeded to bombard the shop front, the convenient proximity of a barrow loaded with apples supplying the missiles. In a few minutes mirrors, glasses, and bottles were all demolished, and the place wrecked before the arrival of the police, by which time the manifestants had dispersed. The proprietor, who thought it inadvisable to show himself to his unwelcome visitors, has lodged a complaint with the police, and measures have been taken to prevent a recurrence of any disorder.

PROCEEDINGS UNDER THE PHARMACY ACTS.

THE SALE OF WINSLOW'S SOOTHING SYRUP.

At the Rhyl (North Wales) County Court, held on Friday, January 3, before His Honour Sir Horatio Lloyd, the Council of the Pharmaceutical Society of Great Britain sued Joseph Littler, a grocer, carrying on business at Prestatyn, in the county of Flint, for the recovery of £10, being two penalties of £5 each, to which it was alleged he had rendered himself liable by selling poison, he not being a registered chemist in accordance with the Pharmacy Act, 1868.

Mr. R. E. Vaughan Williams, barrister-at-law (instructed by Messrs. Flux, Thompson and Flux, of 3, East India Avenue, London, E.C.), appeared on behalf of the plaintiffs, and the defendant, who was not legally represented, appeared in person.

In opening the case, Mr. Williams said the action was brought under the Pharmacy Act, 1868. The defendant carried on business as a grocer at Prestatyn, and the penalties were sued for in respect of two sales of a preparation called "Winslow's soothing syrup,"

which on being analysed was found to contain poison. Defendant was not a registered chemist and druggist. The first sale took place on October 26, 1895, when two bottles were sold, and the subsequent sale of one bottle took place on November 20. Mr. Foulds was instructed by the Society to go to the defendant's premises at Prestatyn. He did so, and on the first occasion he asked for two bottles of the soothing syrup. There was none at that moment in the shop, although the defendant kept it in stock. Defendant's wife offered to send for it, and on Mr. Foulds returning a few minutes later he was served with two bottles by Mr. Littler. On November 20, Mr. Foulds went to Mr. Littler's establishment and asked for the syrup, which was immediately produced, and he purchased one bottle. All the syrup was handed over to Mr. Moon, Clerk to the Registrar of the Society. He handed it over to the analyst of the Society, who found, as may have been expected, morphine, which was the most active principle of opium. The company which manufactured the preparation advertised it as containing morphine, but not so little as had been obtained in this case. Upon production of the Register and proof of the sale, counsel submitted that the plaintiffs were entitled to recover the penalties.

Mr. Arthur Foulds said he was instructed by the Registrar of the Pharmaceutical Society to make these purchases. On October 26 he went to the defendant's shop and bought two bottles of Winslow's soothing syrup. They were wrapped in the wrappers produced, on which was printed the words, "This preparation contains, among other valuable ingredients, a small amount of morphine, and in accordance with the Pharmacy Act is hereby labelled Poison." On November 20 he bought one bottle, which was wrapped up in the same way. He handed them over to Mr. Moon. The bottles were sold in the wrappers produced, and were closed.

Mr. Harry Moon, clerk in the office of the Registrar of the plaintiff Society, said the last witness handed him three bottles, the wrappers of which were produced, the first two on October 29, and the third on December 11. They all remained in his possession until December 16, when he handed them over to Mr. Eastes, the analyst.

Mr. Ernest John Eastes said he was an analyst and a Fellow of the Institute of Chemistry, also Demonstrator of Practical Chemistry to the Pharmaceutical Society of Great Britain. He was handed three bottles on December 16 by Mr. Moon. They were enclosed in wrappers, and were opened in his presence. He analysed the contents of the bottles, and found that each bottle contained morphine. He mixed the contents of two bottles together, and found that the mixture contained the equivalent of .08 of a grain of morphine per bottle. The third bottle contained .09 of a grain of morphine. The quantity of morphine present would be sufficient to injure the taker, if an infant.

Defendant: That is if the person took the whole bottle.

Witness: Yes, or for a young child, only a portion.

Defendant: It is only intended to take a portion.

Witness: It depends mainly on the age of the child. Children are very susceptible to opium.

The Judge: I suppose this syrup is intended for children?

Witness: Yes.

The Judge: What quantity would be harmful to a child of one year?

Witness: Probably a whole bottleful would be dangerous to a child of less than one year, a smaller quantity might prove harmful.

Defendant here interposed and said he was not a chemist, but held a licence to sell "patent" medicines, and he thought he was perfectly right in selling this. He had not the faintest idea that he did anything against the law, or that he was doing anything wrong or harmful in any way.

Counsel handed up the Register of the Society, and, after citing cases, said: A small quantity of poison is sufficient to secure a penalty, whether sold alone or mixed with other substances.

The Judge: The Schedule includes opium.

Counsel: Yes, and morphine preparations have been included in it. If this preparation were taken by a child or an infant it might prove hurtful to the taker.

The Judge: It does not appear to me that quantity enters into the question. (To defendant): What have you to say?

Defendant: I admit having sold it. I consider that I have committed a technical offence, but I had not the slightest idea that I was doing wrong. I think common sense will tell you that I should never incur the risk of these penalties for the sake of the paltry penny or twopence profit that I get.

The Judge: I have had to look at these cases before, and it seems to me that I am in a very helpless position. The moment it is proved to me, so the law says, that a man who is not a registered chemist sells any of the poisons mentioned in the Schedule of the Act, or any preparation of them, he is proved to have committed an offence against the law, and renders himself liable to certain penalties which I have absolutely no power to remit. I have had cases which have been very hard indeed—or may be thought so by the defendants—where a man has done his very best to prevent a sale of poisons; but some may have been left in stock and sold by an assistant. I have no power to remit the penalties.

Defendant: I thought you had the right to use your judgment, and had power to reduce them.

The Judge: No, I have no power to reduce them or to remit the penalties if the case is proved that you sold poisons.

Counsel: I am afraid, as you say, that your Honour has no power to reduce or remit if we prove the offence.

The Judge (to defendant): Read the section of the Act, it is clear enough.

Defendant: I saw that there was a case where the Pharmaceutical Society applied for a much larger amount—I do not know whether it was on all fours with mine—and where His Honour reduced the penalty to ten shillings.

The Judge: That was not in the County Court but in the Police Court.

Defendant handed a letter to the Judge and said that was the first intimation he had of the case, but he took no notice of it as he thought it was an attempt to extort money.

The Judge: The letter is from the Society's solicitors. I need hardly tell you that it is most important that the sale of poisons should be restricted to the hands of fully qualified and registered chemists; there are so many unfortunate people who might do a great deal of harm if they could easily get hold of poisons. Incalculable mischief may arise through the sale of poisons, which it may not be possible to trace to the seller.

Defendant repeated that he had not the slightest idea he was committing any offence, and he thought it was rather hard that he should have to pay such high penalties.

The Judge: That is a matter you will have to leave in the hands of the Society. The moment it is definitely proved that you sold poison it is incumbent on me to impose the full penalty and nothing else. I give judgment; I cannot help myself.

Counsel then asked for judgment for the two penalties of £5 each, and a certificate for counsel and witnesses' costs. He did not ask for costs on the higher scale, though he was entitled to it, as this was a matter of great public interest.

The Judge: Very well. I shall have to impose two penalties of £5 each, ordinary costs of witnesses, and certificate for counsel.

Counsel: These proceedings are taken in order to put a stop to this thing, whether done innocently or otherwise.

The Judge: I quite understand that.

Defendant suggested that the Society might have asked him if he kept the preparation, and informed him of the penalty he was liable to. They could have told him not to sell it, or they might have proceeded for one offence only, which would have been quite sufficient to deter him from selling it.

The Judge: I am afraid they know their business better than I do.

Counsel: The preparation is labelled poison, and people must get to know to what they are liable if they sell poisons illegally. They cannot sell poisons unless they are registered chemists and druggists.

POLICE PROSECUTION UNDER SECTION 17.

At the Haslingden Police Court on Monday last, before the Mayor (Councillor Law), Mr. G. A. Smith, and Dr. Harrison, William Henry Halstead, grocer, Blackburn Road, Haslingden, was charged with an offence under Section 17 of the Pharmacy Act, 1868. It was alleged that he had unlawfully sold to P. C. Bailey a quantity of morphine, contained in a bottle of Winslow's soothing syrup, the bottle not being labelled with his name and address as the seller of the article.

The sale of the bottle was duly proved, but P. C. Bailey said he knew nothing about the contents, except what was stated on the label. It appeared that the contents had not been analysed, the prosecution depending upon the fact that the label indicated the presence of morphine, and bore the word poison.

Mr. Whitaker, who was instructed for the defence by the Patent Medicine Vendors' Association, submitted that the prosecution must make out the nature and quantity of the poison present.

As they had failed to do so, he asked the Bench to dismiss the case.

The Mayor said, inasmuch as there was no evidence what the bottle contained, the magistrates had decided to dismiss the case.

LEGAL REPORTS.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT.

THE PRESENCE OF SALICYLIC ACID IN ORANGE WINE.

After a long adjournment through the vacation of the magistrate, the decision was given on Monday, the 6th inst., at Westminster Police Court, in the prosecution under Section 6 of the Sale of Food and Drugs Act, of the well-known firm of Walton, Hassell, and Port, for selling orange wine containing per bottle .038 per cent. of salicylic acid. The proportion of the acid which, it was said, was necessary for antiseptic purposes was equivalent to 26.6 grains per gallon.

Mr. A. Gill prosecuted for the vestry of St. George, Hanover Square, and Mr. Rose-Innes, instructed by Messrs. Loxley, Elam, and Gardner appeared for the defence. A *résumé* of the evidence given has already appeared in the *Pharmaceutical Journal* of November 9.

Mr. de Rutzen said he had given very earnest consideration to the case. The analysis of the wine showed that there was an amount of salicylic acid added equal to 26 grs. per gallon, a proportion in the opinion of Mr. Cassall, the Vestry Analyst, which was injurious to health. Whether this was so or not was really the question of fact which he had to determine, and was the subject of evidence of the very learned experts who had been examined. Salicylic acid appeared to have been first discovered about 1838, and had since then come into general use as a medicine for acute rheumatism and other complaints. It was apparently admitted on both sides that the acid possessed powerful antiseptic properties, and acted upon wines of different sorts which contained but a small proportion of alcohol in themselves, as a preventive from fermentation, and the decomposition which would render them unfit for human food. It also seemed to be admitted that orange wine was one of those productions which could not be preserved (owing to the small amount of alcohol which it contained in its pure state) without the addition of some antiseptic, either pure alcohol or some other ingredient which has the same properties. Mr. Cassall, the analyst, said that when salicylic acid was added to any article of food, the outside quantity required to produce the antiseptic effect was 1 part in 10,000, or 7 grains per gallon, and that therefore, there were 19 grains too many in a gallon of this wine; but the analyst went further, and said that the acid of salicylic acid in sufficient quantity to produce that antiseptic effect was injurious to health. His Worship proceeded: The only witness called to corroborate the view taken by the analyst is a very eminent gentleman, Dr. Corfield, who, while generally agreeing with what Mr. Cassall has said, materially qualifies it by saying that a bottle containing 4½ grains, equal to 18 grains per gallon if not more, would not perhaps be prejudicial. That is, without reading it, practically the effect of the evidence given on behalf of the Vestry. For the defendants the following gentlemen have been called—Mr. Bond, Dr. Paul, Dr. Luff, Dr. Wm. Murrell, Dr. Thudichum, and Mr. A. Gordon Salamon, consulting analyst; and Dr. Bond says as to the quantity in this wine "there is no possibility of injury to the human body. I don't think, taken in these quantities, it would affect anyone. It is a preservative and retards decomposition." Dr. Paul says:—"I think the quantity present in this wine is necessary as a preservative; it would preserve the article from acetous fermentation. It would become unfit for consumption without it. The quantity found in my opinion is absolutely uninjurious." After quoting the opinions of other experts for the defence, Mr. De Rutzen continued: That is the result of the evidence for the defendants, and I am sorry that it should be left to me to decide where doctors differ, but after giving the evidence the most careful consideration, and after looking at the subject in the different learned works to which I have been referred, I have no hesitation in coming to the conclusion that the summons should be dismissed, on the ground that the case comes within the first proviso to Section 6, viz, that salicylic acid is not injurious to health, and has been added to the wine because it is required for the production of the wine in a fit state for consumption, and not fraudulently to increase the bulk or conceal the inferior quality thereof.

My attention has been called to cases which have been decided in this and other courts, and no doubt there have been decisions both ways, but I have not been able to gather much from them, as it is a question of fact and more or less turns upon the evidence given in each particular case.

Mr. A. Gill remarked that the vestry could not appeal, as the case was decided on the question of fact. There was a second summons against another firm, charging a similar offence, but it would be withdrawn in view of the decision given. No application was made for costs.

COMMERCIAL NOTES.

THE PRODUCTION OF HONEY.

BY P. L. SIMMONDS, F.L.S.

We have not to consider honey in its food aspect, but in its medicinal uses it deserves some consideration. From 1870 to 1885 the imports were left out of our trade returns, but for the last ten years it has reappeared, our imports from abroad ranging now from 19,000 to 21,000 cwt. yearly.

In 1850, Braithwaite Poole, in his 'Statistics of British Commerce,' estimated the production of honey in the United Kingdom at 2000 tons, value £80,000. Indeed, in the preamble to the Act, 23 Elizabeth, Chap. 8, it is stated that "the land doth yield great plenty of honey and wax, as not only doth suffice the use of the Queen's Majesty and her subjects, but also a great quantity to be transported to other realms." In this and some other minor rural industries we are somewhat retrograding, considering we have now to import honey, instead of exporting it.

There is both commercial honey and clarified or depurated honey used in pharmacy in most countries, besides oxymel and other preparations.

Recent statistics show that the production of honey in Europe was about 80,000 tons annually, and in the United States 30,000 tons. But it is produced in all countries, the West Indies, South and Central America, India, Africa, and Australasia.

Indeed, we drew our supplies in 1894 mainly from the United States, Chili, the British and foreign West Indies, Australia, and France. Although the honey we import is chiefly used for food purposes, yet, as in early times, it constitutes the principal ingredient of several medicinal preparations, and serves as a means of taking powders and the sweetening of medicines.

Honey may be used when suffering with a cough, stoppage of the lungs, shortness of breath, and in all affections of the chest. An admirable preparation for coughs, especially during feverish or inflammatory attacks, is composed of honey, olive oil, lemon juice, and sweet spirit of nitre—each 1 fluid ounce—to be taken several times a day in $\frac{1}{2}$ fluid drachm doses.

Besides grape-sugar, honey contains manna, mucilage, pollen, acid, and other vegetable odoriferous substances and juices. The manna of itself is both food and medicine, and the pungent vegetable extracts have rare virtues. The honey collected by bees retains some of the physical qualities of the flowers from which it has been obtained. Thus Commerson found that the bees in Bourbon or Réunion produced a honey which retained the perfume of the flowers of the *Acacia heterophylla*. Biob and De Candolle also noticed, the first in the Balearic islands, and the second in the neighbourhood of Narbonne, that the rosemary gave to the honey of those two countries their superior qualities. Paul Louis Couvier also states "That the orange blossoms are the reason why at Reggio, in Naples, they have better honey. The bees of Mount Hybla have only the thyme, and have no orange trees to feed on." The honey of Mount Hymetta owes its exquisite flavour to the Labiatae, which cover that mountain; that of Provence to the lavender, and those of Valence and Cuba to the orange flowers; that of Southern India to the *Strobilanthus*.

But while there are some plants that permit bees collecting an exquisite and more perfumed honey, there are others which communicate less perfect properties, and in some cases produce deleterious effects on the system. Olivier de Serre states that the flowers of the elm, broom, euphorbium, arbutus, and box yield a bad honey. Seringe also relates the fact that two Swiss priests having been poisoned from eating honey which had been collected by bees from the flowers of *Aconitum dyaconum* and *A. napellus*. The hemlock of the Levant (*Cocculus suberosus*, Dec.) communicates its properties to the honey of Asia Minor, which, although very sweet, is often

dangerous in its effects. Accidents are attributed to the circumstance that the bees collect the nectar of the flowers of the *Azalea pontica*, and probably those of *Rhododendron ponticum*.

Analogous phenomena were observed by B. S. Barton ('Trans. Amer. Soc. of Philadelphia,' v., p. 51) from honey collected by bees on plants of the same family, such as *Kalmia angustifolia*, *K. latifolia*, and *K. hirsuta*, and *Andromeda mariana*.

There are also many rank and poisonous plants in the tropics. Honey from certain districts of Turkey produces headache and vomiting, that from Brazil is used chiefly in medicine.

There are other insects besides the bee that produce honey. There is an ant in Mexico, which has been named *Myronecocystus mexicanus*, which produces honey in its distended abdomen. The natives make a pleasant drink of it mixed with water, which they also use in cases of fever where medical attendance cannot be obtained. The honey is also used by them as a cure for eye diseases, especially for cataract.

In subterranean cavities in Ethiopia a honey is found which is made without wax by an insect resembling a great mosquito. The natives call it "tazma"; the following is an analysis of it:—

Water	25.5
Levulose and glucose	32.0
Mannite	3.0
Dextrine.....	27.9
Ash	2.5
Impurities and loss	9.1

100.0

The composition of this honey is similar to that of the mannas of Sinai and Kurdistan, which were formerly analysed by Berthelot; and that of the sugary matter of the leaves of the linden, analysed by Boussingault; as well as that of ordinary honey. It differs from all these substances in the absence of cane-sugar.

POISONING CASES AND INQUESTS.

Laudanum.—Mr. William Brown, a gentleman of Croughall, near Whitchurch, died on December 10 from the effects of an overdose of laudanum taken to induce sleep. Verdict: "Death from an overdose of laudanum, taken by mistake."

Poisonous Liniment.—Mr. John Jakes Jones, aged 75, of Malvern Link, died on December 12 from the effects of inadvertently drinking from a bottle containing a poisonous liniment. Verdict: "Death from misadventure."

Laudanum.—Thomas Charles Need, a florist, of Malvern, died on December 17, from the effects of an overdose of laudanum, taken to induce sleep. Verdict: "Deceased died from failure of the heart's action, consequent upon his taking laudanum, but whether taken accidentally or not there was not sufficient evidence to show."

Hartshorn.—Philadelphia Hazelden, aged 79, of Maresfield, died on December 18 from the effects of inadvertently drinking hartshorn. Verdict: "Death from taking a dose of hartshorn."

Ammonia.—Henry Rooke, a labourer, of Kidderminster, died on December 24 from the effects of drinking ammonia in mistake for beer. Verdict: "Death from misadventure."

Chloral.—William Kemmish, aged 65, of 38, Lena Gardens, Hammersmith, died on December 21 from the effects of an overdose of chloral, taken to induce sleep. Verdict: "Death from misadventure."

Carbolic Acid.—Mrs. Barcroft, wife of Mr. W. G. Barcroft, of Bryntirion Hall, committed suicide on December 26 by drinking carbolic acid. Verdict: "Suicide whilst temporarily insane," and the jury added a rider that carbolic acid and similar poisons should not be sold without proper restrictions.

Cyanide of Potassium.—Charles Marcus Guttenberg, aged 31, of 41, Belsize Road, South Hampstead, died on December 12 from the effects of taking cyanide of potassium. Verdict: "That the deceased died from poisoning, but that for what purpose the poison was taken there was not sufficient evidence to show."

NOTICES, LETTERS, AND ANSWERS TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally, must be Addressed "Editor, 17, Bloomsbury Square London," and not in any case to individual supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the Journal, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

LETTERS.

LIN. BELLADONNÆ.

MR. R. A. CRIPPS, of Haywards Heath, writes as follows:—"In your issue of December 21 (p. 514), the author of an article on the official liniments states that belladonna liniment when prepared from the alcoholic extract possesses a colour different from that of the official preparation, and if prepared from standardised liquid extract, as proposed by me, 'the same difference will be apparent.' Permit me to point out that this latter remark is incorrect. If prepared as described by me, the colour differs very little from that of the official liniment; whereas that from the solid extract is much darker. This is as might be expected, no heat being needed in preparing the liquid extract of belladonna."

SPIRIT OF NITROUS ETHER.

MR. E. WARRELL, of 202, Caledonian Road, London, N., refers to the recent charge against him, under the Sale of Food and Drugs Act, for selling spirit of nitrous ether adulterated with 50 per cent. of rectified spirit, an article of equal value. He observes that the magistrate, in convicting him, "somewhat inconsistently" stated that had he taken the line "that the article sold was as labelled, viz., 'Sweet Nitre,' he would have held it a good defence." In conclusion, Mr. Warrell expresses the opinion that the sooner the official formula and test for spirit of nitrous ether are "abolished, the better for the reputation of the B.P."

THE B.P. STANDARD FOR VINEGAR.

MESSRS. C. G. MOOR AND T. H. PEARMAIN write with reference to the note on vinegar by Mr. R. C. Cowley, reported in the *Pharmaceutical Journal* for January 4, p. 16. They say: "Mr. Cowley criticises the standard laid down in the British Pharmacopœia as being too exacting, and in support of this contention gives some figures obtained on twelve 'commercial samples,' obtained from various retailers. We would point out that we think Mr. Cowley cannot fairly argue from these figures that the standard as laid down in the British Pharmacopœia either is not or cannot be maintained. We would refer Mr. Cowley to papers in the *Analyst* for 1893, pages 180 and 240, by Alfred H. Allen and one of us, in which analyses of several vinegars are given. It will there be seen that vinegar is made by the chief makers in six different strengths, from 'No. 24,' the strongest, containing about 6.2 per cent. of acetic acid, down to

'Diamond,' the weakest, containing about 3.3 per cent. of acetic acid. We have analysed the malt vinegars as made by all the principal makers, and we find their Nos. '24' and '22' fulfil in every case the British Pharmacopœia requirements, so there is absolutely no need for any lowering of the official standard. It does not seem altogether reasonable to expect a strictly B.P. article from retailers taken at random, but that the B.P. article can and ought to be supplied by pharmacists is indisputable, and we strongly urge everyone to resist any attempt to lower the quality or strength of vinegar at present required."

ACETUM DESTILLATUM.

MR. OCTAVIUS CORDER, of Norwich, writes as follows:—"After more than fifty years' experience I may inform your readers that I have always considered acetum dest. to mean white wine vinegar or distilled vinegar, and not dilute acetic acid. I may add that a most respectable firm in this place has distilled this article for many years, and still continues to do so from malt vinegar. I need hardly state that this is not retailed at fourpence a quart in your own jugs."

A CORRECTION.

MR. W. S. DAVIES says our Welsh Correspondent's note (*ante* p. 19), is somewhat incorrect. He is not aware that he is the second Welshman to win the medal referred to, and he says the number of competitors is exaggerated.

ANSWERS.

E. J. EVANS.—Your package arrived, but was found to contain fragments of broken glass only.

W. MAIR.—Received with thanks.

"PROVINCIAL PHARMACIST."—If, as you suggest, diluted acetic acid is sometimes supplied for white wine vinegar, the practice is much to be regretted. Individuals who do so cannot be representative pharmacists.

OBITUARY.

THOMPSON.—On December 31, William Thompson, chemist and druggist, Sunderland. (Aged 79.) Mr. Thompson was one of the oldest chemists in Sunderland, and had been president of the local association for many years. On retiring, two years ago, he was presented with an illuminated address by the members of the Association. He was the father of the Sunderland Town Council, to which body he was returned in 1847. He was made an alderman in 1865, and was twice Mayor of the town. He was also a River Wear Commissioner and a Justice of the Peace, and in every position he held did his duty well and conscientiously. The funeral on Friday, January 3, was a very large one, being attended by the Mayor, Corporation, Justices, and many of the public men of the town, as well as by the members of the Sunderland Chemists' Association.

RITSON.—On December 27, John Ritson, Chemist and Druggist, Manchester. (Aged 63.)

JEWELL.—On December 28, John Jewell, Chemist and Druggist, Liverpool. (Aged 59.)

ARCHER.—On January 2, Albert Archer, Chemist and Druggist, Sheffield, late of Torquay. (Aged 48.)

MICHIE.—On January 2, Harry Michie, Chemist and Druggist, Marywell, N.B. (Aged 74.)

OGDEN.—On January 4, Henry Ogden, Chemist and Druggist, Leeds. (Aged 55.)

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Allen, Atkinson, Bayley, Bindloss, Bird, Blackburn, Blinkhorn, Bowman, Brown, Burge, Callaway, Cammack, Carter, Clarke, Cooper, Cripps, Cupit, Davies, Davis, Dewar, Dixon, Evans, Essam, Ferguson, Gadd, Hall, Harvey, Holmes, Hudson, Hughes, Jarvis, Johnson, Knight, Line, Mair, Male, Marshall, Moor, Morris, Pearmain, Pike, Polkingham, Ranken, Reeve, Reynolds, Richards, Robbs, Robson, Russell, Saunders, Spalding, Stapel, Thompson, Tndor, Tunnicliffe, Walker, Warrell, Warrick, Welsh, Wright.

ALCHEMY AND PHARMACY. THEIR MYSTERY AND ROMANCE.

BY C. J. S. THOMPSON.

[All rights reserved.]

(Continued from Vol. I., page 394.)

CHAPTER V.

The Philosopher's Stone.

The dominating ambition of those pioneers of science—the early alchemists—was to search after the unknown. In the same spirit the modern worker in science gropes onward, and dreams of discovering some contribution towards solving the elixir of life, in the form, it may be, of conquering at least one fell disease. The ancient workers in alchemy confined their researches almost exclusively to metals; they believed that all natural things were composed of four elements, which they termed Fire, Air, Earth, and Water. "When these four elements are conjoined," says Roger Bacon, in his 'Radix Mundi,' "they become another thing, whereas it is evident that all things in Nature are composed of the said elements being altered and changed."

But the patient researches of the alchemists were not so much due to a love for scientific research as to the overwhelming desire to gain wealth.

The majority had two fixed objects in view as the goals of their ambition, one being the discovery of some body that would be capable of transmuting the baser metals into gold and silver; and the other, the discovery of an elixir which would prolong the span of human life to an indefinite period. Both these objects seem to have been sought for by man from pre-historic times, and their origin is lost in antiquity.

The philosopher's stone was sought for by the Chinese philosophers at a very remote period, afterwards by the Greeks and Arabs, and by others down to the seventeenth century.

Men of undoubted ability and genius wasted both their lives and fortunes over the search for this illusive chimera, and others descended into fraud and trickery of the meanest description in its pursuit. Apparently no alchemist of any repute thought it right to die until he had at least claimed to have solved one of these great problems. Thus the claimants of the discovery were numerous. The descriptions given of the various processes in ancient manuscripts and works for producing the philosopher's stone are usually of a very elaborate description, and couched in the most fantastic language.

Failure to produce the desired result was invariably accounted for by the omission to carry out some minute

detail. Some who professed to have discovered the secret demanded large sums of money to reveal it, and several visited the various Courts of Europe to demonstrate it by means of trickery and conjuring.

The notorious Dr. Dee, who flourished in the time of Queen Elizabeth, was one of the last claimants to the discovery, and is said to have received immense sums of money from dupes for imparting the coveted secret, which he demonstrated by means of an ingenious trick.

Realgar, mercury, sulphur, and many other substances were credited with the magical property of transmutation.

In the illustration, which is taken from an authentic engraving of the sixteenth century, we have a figure of the apparatus used for distilling the "Water of Life," the process for which is described by Gesnerus in the 'Newe Jewell of Health,' printed in 1576. The alchemist, arrayed in his imposing robes, is depicted as giving instructions to his assistant as to certain precautions to be taken in conducting the process.

Bacon states that sulphur and mercury are the mineral roots and natural principles upon which nature herself acts and works in the mines and caverns of the earth; the latter metal he believed to be the true elixir of the philosopher's stone; others, such as Euclid—Rhazes and Merlin believed it to be an amalgam of gold and mercury, fantastically called the Red man and his White wife.

Concerning the vessels for producing this "Citrine body" as Bacon calls it, the most exact precautions were taken. Special apparatus was used, and a special heat, which was not to exceed the heat of the body. For this purpose horse-dung was used. Senier, the philosopher, says, "dig a sepulchre and bury the woman (mercury) with her man (gold) in horse-dung, the fire of the philosopher, until such time as they be conjoined."

Bacon's definition of alchemy was, "Alchymie is the art or science teaching how to make or

generate a certain kind of medicine which is called the elixir. It teaches how to transmute all kinds of metals, one with another; and this by a proper medicine." George Ripley, a monk, in 1476, thought that he had discovered the much coveted stone in pure sulphur. He says, "let the two sulphurs, viz., the white and the red, be mingled with the oil of the white elixir that they may work the more strongly, and you shall have the highest medicine in the world to heal and cure human bodies, and to transmute the bodies of metals into the most pure fine gold and silver." One cannot but think with pity of the immense labour expended and lost in the attempts made by many of these pioneers of science in their pursuit after this chemical chimera.

A STILL FOR DYSTILLING THE WATER OF LYFE.
From 'Newe Jewell of Health,' Gesnerus. 1576.

CHAPTER VI.

The Black Art and Occult Sciences.

To make a thorough analysis of this interesting subject and trace the origin of magic, would take much more space than we have at our command, and we can only mention a few of the many forms which may be grouped under the head of the occult sciences, and those especially which had any connection with the alchemists and apothecaries of mediæval times. There is little doubt that most of the alchemists were students, if not practitioners, of magic or some of its branches.

The antiquity of magic is very great, and we have record of magicians and wise men in early Jewish times, as well as the magic formulæ of the Vedas in India, as handed down to us in the religion of the Hindoos. Moreover, magic was practised by the Chaldeans, of whom a certain tribe devoted their energies to studying the occult sciences. Pliny tells us of the dealings in the supernatural in the time of Homer, and other writers record that magic was also known to the Etruscans and Assyrians from a very early period. As time rolled on, the different forms of magic practised, became specialised according to their several natures. For instance, we had Astrology and Oneiromancy, which comprised the various forms of divination; Theurgy and Goetry, the art of evoking good or evil spirits; Necromancy, by means of which communication was held with the dead; and Sorcery, which exercised its power by the influence of dreams.

The longing after the supernatural and unknown felt by the great ignorant masses brought forth individuals in plenty to take advantage of their credulity. During the thirteenth and fourteenth centuries the occult sciences were openly taught in the universities and schools, and two hundred years later reached the zenith of their influence, and practitioners of astrology and the black arts, abounded and flourished throughout Europe.

The professors of oneiromancy were those who divined or interpreted dreams, and founded their traditions in the art from its being in accordance with the Scriptures. The explanation of dreams also did not go counter to the doctrines of the Church, and so the cult found many believers among all classes of society. It was denounced by Pope Gregory II. as a detestable practice, but this did not prevent it being largely employed in forecasting the future.

Arnauld de Villeneuve, who wrote a work on the subject in the thirteenth century, gives a certain code by which those who practised it worked.

Whoever dreamt that his hair was thick and carefully curled, would soon become wealthy. If anything was wrong with the hair, evil was betokened. It also foreshadowed harm if a wreath of flowers was worn that were not in season. Other codes signified, that to dream of the eyes, it related to children; the head, to a father; the arms, to brothers; the feet, to servants; the right hand to the mother, to sons, and to friends; and the left hand to the wife and daughter. Another method was founded on a theory of whatever was dreamt the antithesis or opposite would follow in life. From this we have probably the saying common to-day, dream of a wedding and it is a sign of a funeral. According to many old writers there was scarcely any important event in the middle ages which was not announced by a dream.

The day before Henry II. was struck by the blow of a lance during a tournament, Catherine de Medicis, his wife, dreamt that she saw him lose one of his eyes. Three days before he fell beneath the knife of Jacques Clément, Henry III. dreamt he saw the royal insignia stained with blood, and trodden under foot by monks and people of the lower orders.

Henry IV., also, before he was murdered by Raveillac, it is said heard during the night his wife, Marie de Medicis, say to herself as she woke, "Dreams are but falsehoods!" and when he asked her what she had dreamt, she replied, "That you were stabbed upon the steps of the little Louvre!" "Thank God it is but a dream," rejoined the King.

The necromancers, who were supposed to be able to conjure up spirits and raise the dead, were accounted on a somewhat higher plane than the interpreters of dreams. They also based their authority on the Old Testament. The nature of the art was gruesome and awe-inspiring, and there is little doubt many dark deeds were perpetrated by those who practised it. One method of evocation was to kill a child, and place its head upon a dish surrounded by lighted candles; the desired spirit was supposed to enter this ghastly object and speak through its mouth. Sometimes the spirit simply consisted of some muttered words from behind a curtain in a dark cellar; or another method was to cause the appearance of a sepulchral figure out of smoke or vapour, which would indicate by gesture and reply to questions asked. To evoke a dead man's spirit, it was necessary to go to the grave at midnight with a companion who bore a candle in the left hand and a crystal stone in the right, the conjuror holding a hazel wand with the name of God written on it, and repeating the words.

Teragrammaton + Adonai + Agla + Craton +.

Then striking three times on the ground, with a prayer he commanded the spirit into the stone, when it appeared in the shape of a child.

The conjuror often wore a girdle of lion's skin with the name of God written on it, and the Solomon's circle he described with a bright knife, on the blade of which was written certain mystic words. Necromancy gradually merged into sorcery, which has occasionally come to the surface in comparatively recent years.

Chiromancy, the art of divining or foretelling future events from marks on the palm of the hand, was also practised in antiquity, but in mediæval times was strongly opposed by the Church. The practice is supposed to have been brought into Europe from the East by the Bohemians in the early part of the fifteenth century. This art eventually merged into astrology, which exerted the greatest influence of all the occult sciences.

The antiquity of astrology is very great, it having originated in Chaldea, and was thought by some of the Jews to have been a method by which the Creator could communicate with his people. The art itself was based on astronomy, and like alchemy was the beginning of the study of real natural science. The teller of the stars was not only supposed to foretell forthcoming misfortunes to individuals, but also to forecast the destinies of kings and empires.

The belief in its power was so great, that it became the fashion among royal personages of the sixteenth century to keep their own special astrologers, who were lodged easy of access and loaded with honours and wealth. These men were mostly astute Jews well versed in the science of

their time, and by means of their supposed powers often played a very important part in the political affairs of the nation. In the fifteenth century Rovigo, an astrologer of eminence, who is said to have perfected the astrolabe, was attached to the court of King John II. of Portugal, also Simon Pharès, who figured at the Court of France in the time of Charles VIII. We must not forget to mention Cosmo Ruggieri the Florentine astrologer, and the confidant of Catherine de Medicis, and the celebrated Nostradamus, astrologer and trusted adviser of Charles IX. This extraordinary man played a prominent part in the history of his time, and was supposed to practise magic and alchemy, as well as the healing art. He was consulted by the king in all positions of difficulty, and it is said became immensely wealthy. He died in 1566 at Salon, after having written several notable works.

(To be continued.)

SHORT NOTES ON THE PREPARATIONS AND FORMULÆ OF THE BRITISH PHARMACOPŒIA.

SOLUTIONS.

The solutions of the Pharmacopœia are aqueous in character, the exceptions being those of sodium ethylate, gutta-percha, and blistering liquid. The last two should have a class to themselves, and along with liquor iodi be termed pigments.

Liquor Ammoniac Fortior.—The directions for preparing this solution may be safely omitted, as it can only be made on a commercial scale from such sources as "gas liquor," obtained as a by-product in the manufacture of illuminating gas.

Liquor Ammoniac Acetatis Fortior.—The present formula is a great improvement over the 1867, as a definite amount of ammonium carbonate is neutralised with acetic acid to form a solution of ammonium acetate of definite strength. In the German Pharmacopœia a solution of ammonia may be used instead of the carbonate, but the final product requires to be boiled to expel any traces of tarry matter that may be present. In the U.S.P. definite amounts of both acid and carbonate are taken, which yields a product containing free acetic and carbonic acids. This latter form is preferable to that of the B.P., as it is extremely difficult to ascertain when the exact point of neutrality is reached, while the excess of acetic acid prevents the solution becoming alkaline from absorption of ammonia from the atmosphere after the bottle has been opened a few times.

Liquor Ammonii Citratis is in little demand, and except that it is perhaps more palatable than the acetate, there seems no sufficient reason for its inclusion, particularly as it can be made directly from the stronger solution. If, however, it is to be retained, 5 or 10 per cent. of alcohol should be added to prevent cryptogamic growths.

Liquor Antimonii Chloridi.—Butyr of antimony is still very largely used in some affections and is one of the most powerful caustics employed in modern surgery. The solution should be filtered through glass wool or asbestos, as it destroys cotton fabrics so rapidly.

Liquor Arsenicalis.—The official synonym, liquor potassii arsenitis, is hardly correct, as, to ensure combination, the mixture of potassium carbonate and arsenious acid should first be boiled with a very small quantity of water, the liquor then containing potassium arsenite, which is probably HK_2AsO_3 . When this is diluted with water, carbonic acid is absorbed and decomposition takes place, the solution finally containing arsenious acid and alkaline carbonate. The proof of this is that if Fowler's solution is kept any length of time crystals of arsenious acid are slowly deposited. The solution is liable to fungoid growths, which are retarded but not altogether prevented by the addition of compound tincture of lavender.

Liquor Arsenici Hydrochloricus is simply a solution of the two acids. When arsenious and hydrochloric acids are heated together and submitted to distillation, volatile arsenious chloride, As_2Cl_6 , is formed, which decomposes into the compounds from which it was prepared as soon as it is dissolved in water.

Liquor Arsenii et Hydrargyri Iodidi.—This again is a solution which merely contains the iodides dissolved in about molecular proportions. Care should be taken to see that the arsenic iodide is in good condition, as if any free iodine is present dark coloured solutions result. When freshly made the solution has a pale yellow colour, which on exposure to direct light gradually disappears, hydriodic and arsenious acids being formed. This preparation was first introduced into medicine by Dr. Donovan, of Dublin, who recommends it to be made by rubbing arsenious acid, mercury and iodine with a small quantity of alcohol, which was supposed to aid combination, the resulting dry mass being afterwards extracted with water and boiled.

Liquor Atropinæ Acetatis.—Now that this preparation is made with camphor water, it certainly keeps much better, but still has a tendency to decomposition. Tichborne showed in 1877 that solution of the alkaloid in salicylic acid would keep without change for an indefinite period.

Liquor Bismuthi et Ammonii Citratis.—The present method of preparing this solution is distinctly better than that followed in the former edition of the B.P., contamination with ammonium nitrate being avoided. As generally met with, however, it scarcely fulfils the official requirement of being colourless. The reason for this has been frequently explained. The use of stained mortars and earthenware pitchers should be carefully avoided, only glass vessels being employed. Absolute cleanliness is a *sine quâ non*. Secondly, the solution of ammonia should be added to the citrate very gradually as directed, care being taken that no rise of temperature takes place. If, notwithstanding all precautions, darkening still occurs, the solution may be rendered colourless by shaking with equal parts of talc and purified animal charcoal, and subsequently filtering through white paper.

Liquor Calcis Saccharatus, if prepared as directed, develops a brown colour, rapidly becoming darker, even when preserved in sealed bottles and away from the light. This has been shown to be due to the formation of an organic compound of iron derived from the impurities in the lime, and may be avoided by the use of lime prepared from Carrara marble, which is practically free from iron and manganese. Some slight colour is no doubt caused by the action of the soluble alkalies in the lime. These may, however, be removed by a previous washing with water, as directed for lime water. It is a well-known fact that strong syrup may be even boiled with pure lime for a long time without darkening taking place, but if the slightest trace of soda or potash be present, a faint coloration appears almost at once.

Liquor Ferri Acetatis Fortior was modelled after the German formula, but the product of normal acetate with excess of acetic acid is different. If less acid were used, the salt would have the formula $(\text{FeOH})_2(\text{C}_2\text{H}_3\text{O}_2)_4$, which is the one commonly used on the Continent, but is much more readily affected by heat and light, precipitation taking place even in the dark.

Liquor Ferri Perchloridi was introduced to take the place of the tincture, inasmuch as it retains the salt in an unchanged condition. Perhaps this substitution may actually take place in the next edition.

Liquor Ferri Pernitratitis is officially prepared by dissolving iron wire in dilute nitric acid, with directions that if the action becomes so violent as to volatilise the nitric acid, it is to be moderated by the addition of cold water. The U.S.P. seeks to overcome this difficulty

by preparing ferric hydrate which is dissolved in the nitric acid. This would appear to be the more scientific method, as Berzelius observed that besides ferrous nitrate, ammonium nitrate is also formed, and no gas evolved, if a mixture of iron and dilute nitric acid is kept below 120° F.— $2\text{Fe}_2 + 10\text{HNO}_3$ yielding $4\text{Fe}(\text{NO}_3)_2 + \text{NH}_4\text{NO}_3 + 3\text{H}_2\text{O}$. The formation of ammonia is a secondary reaction, and depends upon the action of the nascent hydrogen on the nitric acid; it is lessened, but not entirely prevented by a stronger acid and a higher temperature, and augmented as the temperature and the strength of the acid are decreased.

Liquor Hydrargyri Nitratii.—In the preparation of this solution mercury is dissolved directly in dilute nitric acid, heat being applied after solution to convert any mercurous salt that may have formed into the mercuric variety. The U.S.P. accomplishes the same result more rapidly by dissolving red oxide of mercury in dilute nitric acid, which may be done without disengagement of objectionable fumes.

Liquor Hydrargyri Perchloridi would be rendered more stable if hydrochloric acid were employed instead of ammonium chloride.

Liquor Iodii as suggested in the early part of this paper would be more correctly termed pigmentum iodii. The directions require a little amplification—dissolve the iodine and iodide in a very little water, and then add sufficient to produce 1 pint. By this method solution may be effected in a few minutes.

Liquor Magnesii Carbonatis.—This solution, when freshly made, forms an agreeable antacid drink, but after the bottle has been opened a few times, carbonic acid is lost and normal magnesium carbonate is deposited. It would be better to direct the solution to be preserved in ordinary aerated water syphons, so that any required quantity can be withdrawn without prejudice to the remainder. There need be no sentiment about this procedure, as the official directions for the effervescing solutions of lithia, potash, and soda can only be carried out by an aerated water manufacturer, and the solutions themselves kept in bottles specially constructed to stand the pressure.

Liquor Magnesii Citratis is probably never used.

Liquor Morphine Acetatis is only occasionally used, and might be omitted altogether. The acetate is one of the most unstable of the morphine salts, the acetic acid being slowly decomposed in aqueous solutions with separation of a brown compound, while at the same time crystals of the alkaloid are deposited.

Liquor Morphine Bimeconatis.—It is difficult to advance any good reason why this solution should not be made of the same strength as the other solutions of morphine. If it is necessary to make this one $1\frac{1}{4}$ per cent., so as to correspond with the morphine strength of tincture of opium, then the same ought to apply to the other two. The present cry is for uniformity, therefore let these be made uniform.

Liquor Plumbi Subacetatis.—Several basic compounds of lead are known, which may be obtained by treating solution of the neutral acetate with the requisite quantity of lead oxide. The B.P. directs nearly six molecules of the oxide to five of the acetate, so that the solution contains chiefly $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot \text{Pb}(\text{OH})_2$, and in addition a small quantity of the triplumbic acetate. When diluted with water, the mixture becomes turbid almost at once, either from the carbonic acid held in solution, or in the atmosphere producing some carbonate. This may be avoided to some extent by directing the distilled water to be recently boiled, but decomposition will take place again directly the solution is exposed to the atmosphere.

Liquor Potassæ.—The process for the manufacture of this solution is an extremely troublesome one, and might be very well simplified by directing the requisite quantity of potash to be dissolved in water and the strength determined in the usual manner.

The strength, by the way, would be more convenient if made exactly 5 per cent. The same remarks apply to liquor sodæ.

Liquor Sodæ Chlorinatæ.—The carbonate of sodium should be directed to be dissolved in boiling water and added to the solution of chlorinated lime in a closed vessel. By this means a very dense instead of a very bulky precipitate is obtained, which minimises the loss.

Liquor Sodæ Arseniatis.—The solutions of arsenic, like those of morphine, are redundant.

Liquor Strychninæ Hydrochloratis.—This solution is liable to deposit crystals of the acid (? neutral) salt if exposed to a low temperature. This never occurred before 1885, and Paul and others have shown that the excess of hydrochloric acid is the main cause. As this is, perhaps, one of the most frequently prescribed, as well as one of the most potent, remedies in the Pharmacopœia, the compilers will no doubt take care that the relative proportions of acid and alkaloid, as well as the relations between the alternative formulæ, are more accurately adjusted in the next edition.

PHOTOGRAPHY EXTRAORDINARY.

Within the last fortnight a statement has been published which has certainly startled not only the laity but even the initiated in photography. The following is the extract from the *Standard* :—

“Professor Röntgen, of Würzburg, uses the light emitted from one of Crookes' vacuum tubes, through which an electric current is passed, to act upon an ordinary photographic plate. The invisible light rays, of whose existence there is already ample evidence, then show this peculiarity, that to them wood and various other organic substances are transparent; whilst metals and bones, human and animal alike, are opaque to those rays. That is to say, they will, for instance, absorb the rays which have passed through a wooden case in which bones or metals are enclosed. Thus it is possible to photograph in the manner described any bones or metals which may be contained in wooden or woollen coverings.

“Moreover, as human flesh, being organic matter, acts in the same way as such coverings towards the invisible rays from a Crookes' vacuum tube, it has become possible to photograph the bones, say, of a human hand, without the flesh surrounding the bones appearing on the plate. There are said to be photographs of this description already in Vienna. They show the bones of the hand, together with the rings that were worn on the fingers—metals, as remarked above, being opaque to these rays—but they show nothing else. They are ghastly enough in appearance, but from a scientific point of view, they open up a wide field for speculation.

“Among the practical uses of the new discovery, it is stated that it will henceforth be possible for surgeons to determine by help of this new branch of photography the exact position of any bullet that may be embedded in the human body, or again, to render visible any fractures there may be in the bones prior to performing any operation on that respective part of the body. And there are various other uses to which the method may be put, as for example, in connection with caries and other bone diseases.”

It is almost superfluous to say that some of the photographic journalists have made much fun out of this, but as a matter of fact it is no more chimerical than ordinary photography.

When the negative pole of an induction or influence machine is connected with a wire sealed into a tube, which can be partially or completely evacuated, certain rays proceed from the negative pole or cathode, which are for the most part invisible, but become visible, roughly speaking, the more perfect the vacuum. These cathodic rays have the curious property, like the Hertzian waves, of penetrating organic matter, but not metallic substances, except when the latter are in very thin plates; quartz and glass are quite opaque to them, whilst paper, wood, flesh, etc., are transparent. These facts account for the extraordinary statements reprinted above.

It is not necessary to use a lens, in fact, as will be seen, that would vitiate the experiment. All that is required is a Crookes' tube for the production of the cathodic rays, and a wooden box—light-tight, of

course, or else the plate would be fogged by light—in which the sensitive plate or paper is placed with the object to be photographed.

It must be understood that though the results obtained may be called photographs pure and simple, yet they are not quite what this word would convey to the mind of the uninitiated; they are, or might be more strictly called, shadowgraphs, in that the sources of light being behind the object, the shadow of the object rather than an image of the detail of its surfaces would be obtained.

On the other hand, it is quite possible that these rays, like the now famous Hertzian waves, are capable of refraction, polarisation, and reflection like the ordinary waves of light, and therefore, it might be possible to obtain by photography images of the surfaces of objects by the reflection of these waves.

Though the term "source of light" has been used, it is not strictly correct, because essentially the cathodic rays are not light, and for want of a better term they are simply called "cathodic." A practical application of these rays for the production of light has been worked out by Ebert, and described in Wiedemann's 'Annalen.' He uses a compressed mass of some luminous substance, such as phosphorescent calcium sulphide, in the interior of an exhausted globe. On the outside of this are cemented two strips of tinfoil, which are connected with the negative and positive poles of an induction coil. The phosphorescent substance glows with great brilliancy with a total expenditure of energy of about two thousand times less than that required to maintain the normal Hefner-Alteneck amyl-acetate lamp. This approaches very nearly, therefore, the economical light of the glow-worm and other light-giving forms of lower life in which no heat is evolved, as enunciated by Professor Langley.

Röntgen does not seem to have been the first to obtain photographs by means of the cathodic rays, as M. Lenard describes in *La Nature*, July, 1894, some such experiments.

The importance of this discovery cannot as yet be appreciated, but the statement that it could be applied to the examination of the body by surgeons is not without foundation, and certainly there are many other uses and abuses to which it could be put. Psychic photography, or photographs of ghosts, would, of course, be rendered extremely easy, as it would only be necessary to make a metal shape resembling that of the human form and place the same against a wooden partition, and behind this to place a Crookes' tube, to obtain, without the aid of a lens or camera, the image of a veritable psychic form.

COD-LIVER OIL EMULSIONS.*

BY PROFESSOR GAY (MONTPELLIER UNIVERSITY).

Cod-liver oil emulsions, the use of which has become general, have their origin in the old form of emulsive syrups with a cod-liver oil basis, but the objection which caused the latter to fall into disuse is avoided. These syrups, although satisfactorily disguising the taste and smell, only contained about 8.5 per cent. of oil. Emulsions as now prepared are intended to disguise the appearance, taste, and smell of the oil, and to contain as a rule 50 per cent. of the active ingredient; they also serve for administering such remedies as phosphates, hypophosphites, arseniates, creosote, eucalyptol, etc., when their association with cod-liver oil is desired. Numerous processes have been proposed for the preparation of cod-liver oil emulsion. The main object of this paper is to discover a formula which can be used extemporaneously, and, in addition, fulfil other necessary conditions. We will first discuss the conditions which should be fulfilled by a formula for an emulsion as we now understand it.

1. *Simplicity; no Special Form of Apparatus being Needed.*—All commercial formulæ have their good points. It has been shown that a prolonged and energetic pounding—which is ensured by using mechanical beaters, or Merier's beater with its three-jointed pestles—ensures the stability of the emulsion by favouring the perfect division of the fatty body, but a pharmacist's working formula should only require the use of a mortar.

2. *Use of the Usual and Unobjectionable Emulsifying Agents.*—The most popular agents can be grouped as follows:—

A. Usual Emulsifying Agents.

Gum Acacia.

Gum Tragacanth.—Acacia emulsions are more stable if tragacanth is used as well.

Gum and Starch.—This combination is useless.

Glycerin.

Glycerin and Gum.

Gelatin (white gelatin or Irish moss).

Yolk of Egg.

Condensed Milk.

Saponin.

B. Digestive Ferments or Their Products.

Malt Extract.—The preparation of the U.S. Pharmacopœia should not be used, as it is only the dextrin and maltose contained in this extract which are of service, the diastase being no use at all.

Pancreatin.

Peptone.

C. Alkaline Substances.

Sodium Carbonate.

Lime Water.

Glycerin and Lime (prescribed by many practitioners).

Saccharated Lime.

With regard to the above emulsifying agents the use of saponin or quillaia does not seem free from danger; malt extract, condensed milk, and other agents are not generally used, whilst alkaline substances answer in special cases. I prefer to use gums.

3. *Stability of the Emulsion.*—Absolute stability is impossible; even the best makes require to be shaken before taking, still separation should be slow, and brisk agitation should cause perfect re-emulsification. This result is easily arrived at by means of gums.

4. *Greater Strength.*—Fifty per cent. is the usual standard. This leaves a sufficient margin for alteration in the emulsifying agent, and, if necessary, in the other remedies.

5. *Suitable Correctives.*—Although it is difficult to disguise the odour, the taste is more easily masked, but the acrid sensation in the throat is seldom entirely suppressed. Two classes of correctives are used:—

A. Sweetening Correctives.

Sugar, glycerin, and various syrups have often been combined with the oil with good results. Stout has recommended ammoniated liquorice, using 50 to 60 grammes to each litre of oil. Saccharin may perhaps be looked upon as the most powerful corrective. Its intense sweetness overcomes the taste of the oil. The proportion used varies from 0.05 to 0.2 gramme per litre. M. Eisenchitz has proposed to dissolve it in its own weight of acetic ether previous to introducing it into the oil. But as the question arises whether it is advisable to give saccharin in long-repeated doses, especially to children or to invalids whose digestive organs are weak, it is, perhaps, better to confine ourselves to sugar and liquorice.

* Translated from the *Repertoire de Pharmacie*.

B. Aromatic Correctives.

The combination of various essences with the oil is a well-known plan: bitter almond, citron, neroli, eucalyptus, mint, canella wintergreen, aniseed, sassafras, vanilla, and roasted coffee are looked upon as the most efficacious, whether used alone or variously combined. The use of a perfumed spirit is in my opinion still more efficacious, cognac, rum, and kirsch can be recommended. Robinson has proposed using a 10 per cent. solution of chloroform in alcohol in the proportion of 4 grammes to 30 of oil, whilst Foster recommends 10 drops of ether to each table-spoonful of oil. Care should be taken not to use essences excessively, as they are apt to fatigue the stomach.

6. *Sufficiently Lengthy Preservation.*—To guarantee indefinite keeping properties, as manufacturers are in the habit of doing is useless, as such a condition of things can only be arrived at by the excessive addition of preservatives, such as glycerin, spirits, and essences. The use of glycerin is recommended by many authors and specialists in the quadruple capacity of emulsifying agent, by reasons of its viscosity, and of sweetening, preservative, and analeptic agent. The last effect does not seem certain, seeing that the nutrient properties of glycerin have been disputed. With regard to its emulsifying power, is not its viscosity balanced by its high density? I prefer to exclude it from a general formula. It will suffice for our purpose, since the preparation is made extemporaneously, if its keeping qualities can be guaranteed for the time necessary to use up such quantities as the pharmacist may be able to sell, say, one to two litres.

The formula which I propose fulfils the foregoing requirements satisfactorily, and the simplicity of the process in particular excels all others. Two forms of it have been worked out in response to the different tastes of patients and physicians: first, a creamy emulsion having a mixture of acacia and tragacanth as the emulsifying base, and a stable consistency which only allows of a very slight aqueous separation at the bottom, even after standing for a long time; secondly, a liquid emulsion, having a basis of acacia and liquid consistence, which soon separates into two layers, easily mixed by being shaken when taken.

A. Creamy Cod-liver Oil Emulsion.

Cod-liver oil	500 grammes
Finely sifted sugar	190 "
Powdered gum acacia	5 "
Powdered gum tragacanth	5 "
Coffee infusion	200 "
Rum or kirsch	100 "

Mix the sugar and gums in a mortar; weigh the oil and cold coffee infusion into the bottle which will contain the emulsion, and shake until mixed. Pour into the mortar, at the same time constantly stirring, sufficient of the mixture to make a semi-liquid; weigh the spirit and add it to the mixture of oil and coffee remaining in the bottle; shake and mix with the emulsion by degrees.

B. Liquid Cod-liver oil Emulsion.

The creamy emulsion can be modified so as to form the liquid emulsion by replacing the tragacanth by the same quantity of acacia. The corrective chosen in these typical formulæ imparts a colour of *café au lait* to the emulsions, in which the odour and especially the taste are conveniently disguised. But in this particular the formula can be modified *ad lib.* Various remedies can also be introduced.

7. *Change of Correctives.*—First, the spirit can be omitted and the quantity of coffee infusion increased to 300 grammes; in this case the coffee no longer suffices to cover the taste of the oil, and it becomes necessary to such an essence as bitter almonds dissolved in the oil to the extent of 20 or 30 drops per kilogramme. Secondly, one of the essences previously mentioned can be substituted for

the coffee itself, by dissolving previously in the cod-liver oil; the infusion of coffee is then replaced by water or an aromatic water. Thirdly, a more intense sweetness is obtained by mixing 30 grammes of glycerin with the aqueous vehicle.

8. *Addition of Other Remedies.*—First, in the aqueous vehicle, hypophosphite of sodium or calcium, phosphoglycerate of sodium or calcium (in the last instance the alcohol had better be omitted), alkaline, iodide, sodium arseniate, soluble salts of iron, etc., can be dissolved. Hypophosphites and iodides cause a disagreeable taste, in addition to that of the oil; the addition of a strongly flavoured corrective is then necessary, such as bitter almond, alone or associated with coffee, coffee or kirsch, eucalyptus essence, etc.

Secondly, 300 grammes of lime-water can be substituted for the aqueous vehicle; in this case the liquid emulsion formula will suffice, the lime-water itself having an emulsive action, which makes up for the absence of the tragacanth; still the stability of the emulsion will be increased by mixing the oil and lime-water in the mortar instead of in the bottle, the water being gradually mixed with the oil by trituration. A strong aromatic corrective will still be necessary.

Thirdly, such remedies as creosote, guaiacol, eucalyptol, iodine mercuric iodide, iodoform, etc., which are insoluble in water, can be dissolved in the cod-liver oil if the extent of the solubilities be remembered. In support of the foregoing I will give, in conclusion, an example of an emulsion to which commonly occurring remedies have been added:—

Creamy Emulsion of Cod-Liver Oil and Hypophosphites.

Cod-liver oil	500 grammes.
Essence of bitter almonds	20 drops.
Essence of wintergreen	20 "
Finely sifted sugar	190 grammes.
Powdered acacia	5 "
Powdered tragacanth	5 "
Distilled water.....	285 "
Calcium hypophosphite	10 "
Sodium hypophosphite	5 "

Dissolve the essences in the oil, the salts in the water, and proceed as before.

LATENT LIFE IN SEEDS.—In a very interesting paper in the *Archives des Sciences Physiques et Naturelles* (June 15), M. Casimir de Candolle records a series of experiments on seeds—chiefly wheat, oats, and fennel—with a view to ascertaining their power of resistance to unfavourable external conditions. He comes to the conclusion that seeds may pass through a period of completely suspended animation, during which all the functions of the protoplasm are quiescent, but from which they revive when again placed in conditions suitable for germination. The immunity from injury appears to depend on the protoplasm passing into a comparatively inert state, in which it is incapable either of assimilation or of respiration before being subjected to the unfavourable conditions. This period of suspended animation may extend over an indefinite time, probably through a long series of years, and the seeds may be subjected to very low temperatures without destroying their vitality. By the use of a refrigerator M. de Candolle obtained temperatures varying between -30° and -53° C.; seeds of wheat, oats, and fennel operated on in this way, 118 times in succession, still retained the power of germination; and previous experiments of M. Pictet indicate that the temperature may be reduced as low as -100° C. On the other hand, the greater number of the seeds of the sensitive plant and of *Lobelia erinus* succumbed to the experiment. These observations appear to open out most interesting possibilities with regard to the possible revival of species belonging to extinct floras, and entirely confirm the stories of the germination of long-buried seeds.

REVIEWS AND NOTICES OF BOOKS.

HAM'S INLAND REVENUE YEAR-BOOK, 1896. Edited by E. GRANT HOOPER, F.I.C., F.C.S., and other officers of H.M. Revenue Services. Pp. 376. Price 3s., or, with Warehousing Regulations, 4s. 6d. (London: Effingham Wilson and Co., 11, Royal Exchange, E.C. 1896)

It is generally recognised that the Inland Revenue Department virtually makes its own law, for few individuals care to risk the enormous expense involved in challenging its interpretations of the law. Therefore, as pointed out in the notice of last year's edition of this book (*Ph. J.* [3], xxv., 727), it is an advantage to be able to see many questions affecting the Inland Revenue from the official point of view, as the reader of the pages edited by Mr. Grant Hooper is enabled to do, the work being primarily intended for the use of Revenue officers. The present edition of this work shows that much of the more important matter introduced during recent years has been amplified; the tincture section has been re-written, certain articles have been extended, and pains have been taken to render the book even more useful than formerly.

The regulations affecting the manufacture of medicinal spirits, flavouring essences, and perfumes, and the use of methylated spirit and methylic alcohol, are given in a very concise form. Useful hints may also be obtained from the pages devoted to "patent medicines," wrongly so-called, a review being given of the principal provisions of the law under which liability to Stamp Duty is incurred, together with illustrations of dutiable labels, etc. Excise licences of different kinds receive their share of attention, and much useful information is given with regard to Income Tax, Death Duties, etc., etc. The general utility of the book is further enhanced by the inclusion of a handy calendar and diary, postal regulations, Inland Revenue directory, and other matters too numerous to specify. Readers of the Journal will find it of value in their business in many ways, and the slight cost incurred will be more than compensated by the aid afforded in avoiding difficulties.

THE TALLERMAN-SHEFFIELD LOCALISED HOT-AIR BATH. Patent. Baillièrè, Tyndall and Cox, London, 1895. Price 2s. Pp. 51.

This small book gives a description of a new invention for the local application of dry heat in the form of hot air. The value of dry heat in conditions such as neuralgia and chronic rheumatism has long been known to physicians. Hot air in the form of the ordinary hot air bath is a familiar method of obtaining diaphoresis in Bright's disease, but in none of the methods hitherto employed is the air kept in a state of dryness. Where a naked flame is used, the water generated by combustion is present, as well as that derived from the perspiration. The secret of the Tallerman-Sheffield apparatus is said to consist in an arrangement at the closed end of the cylindrical case in which the limb is placed for treatment. "The limb to be treated is passed into the open end of a cylinder through an air-tight curtain, which is afterwards secured in such a way as to close the chamber completely. The heat is applied by means of rows of gas jets, and a thermometer, the bulb of which lies in the air space, indicates the temperature. It is said that with dry air a temperature of 300° F. can be borne, whilst in a Turkish bath the limit in the hot room is 170° F. The method has been tried in many of the large London hospitals, and the evidence of unimpeachable witnesses proves that for suitable cases it works successfully. It is satisfactory to read that only such patients as are recommended by medical men are treated at the institution which has been established for the purpose, but for this restriction serious abuse of this ingenious therapeutic appliance would doubtless occur.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

DONATIONS.

At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 15th inst., the Librarian presented the following report of donations:—

To the Library (London).

- The Surgeon-General U.S. Army, Washington:
Index-Catalogue of Library, vol. 16.
Abbreviations of Titles of Journals.
- Whittaker and Co., London:
Thompson, The Chemist's Compendium, 1896.
- Chemists' Assistants' Association, London:
Proceedings, 1894-5, No. 11. Two copies.
- Dr. G. Dragendorff, Rostock:
Beiträge zur gerichtlichen Chemie, 1895. Two parts.
- Danmarks Apothekerforening:
Ny pharmaceutiske Tidende, Nos. 14-26, 1894.
Archiv for Pharmaci og Chemi, August, 1894, to February, 1895.
- Association belge des chimistes, Bruxelles:
Bulletin, 1894-95.
- F. M. Bailey, Esq., Colonial Botanist, Queensland:
Botany Bulletin, No. 12, 1895.
Bailey, Peculiarities of the Phanerogamic Flora of Queensland, 1895.
Lanterer, Queensland Native Astringent Medicines, 1895.
- British Pharmaceutical Conference:
Year-Book of Pharmacy, 1895. Two copies.
- University College, Nottingham:
Calendar, 1895.
- Colonial Pharmacy Board, Cape of Good Hope:
Medical and Pharmacy Register, 1895.
- George Watt, Esq., M.B., C.M., C.I.E., per Superintendent of Government Printing, Calcutta:
Agricultural Ledger, 1894, nos. 5, 12; 1895, nos. 5-7, 9, 10, 12, 13, 16, 17. Two copies.
- J. H. Maiden, Esq., Sydney (Corresponding Member):
Agricultural Gazette of N. S. Wales, Nov.-Dec., 1894; Jan., Mar.-Oct., 1895.

The Curator presented the following report of Donations:—

To the Museum (London).

- The Director, Royal Gardens, Kew :**
Specimens of the materials used in preparing the Uali poison in
British Guiana.
- Commendatore Thos. Hanbury, F.L.S., Ventimiglia :**
Specimens of the resins of *Pinus maritima*, *Pinus halepensis*,
and *Cupressus sempervirens*.
- Mr. F. C. J. Spurrell, Belvedere :**
Specimen of a resin found in an excavated shop at Tel el
Amarna, in Egypt, and dating from 1450 B.C.
- Sir F. von Mueller, K.C.M.G., M.D., etc., Melbourne :**
Specimens of the kinos from *Eucalyptus calophylla*, *E.*
corynocalyx, *E. diversicolor*, *E. melliodora*, and *E. viminalis*.
- Messrs. T. Christy and Co., London :**
Specimens of African kino recently imported.
- Mr. J. Ch. Sawyer, Brighton :**
Specimens of Patchouli leaves from Singapore, and of two
varieties of oil of patchouli.
- Mr. D. Hooper, Ootacamund :**
Specimens of the barks of *Ailanthus excelsa*, *Amoora rohituka*,
Schleichera trijuga, and *Terminalia arjuna*; of the roots of
Cylista scariosa, *Centaurea behen*, *Doronicum pardalianches*,
Gentiana kurroo, *Merendera persica*, an African dye root im-
ported into Bombay, and red behen; of the fruits of *Celosia*
argentea, *Phyllanthus emblica*, *Salvia plebeia* (?); and of the
seeds of *Antiaris toxicaria* and *Butea frondosa*.
- Messrs. Wright, Layman, and Umney :**
Specimen of ergot from the Canary Isles.

To the Museum (Edinburgh).

Messrs. Wright, Layman, and Umney, London :
Specimens of Ergot of Rye from the Canary Islands.

To the Herbarium.

Commendatore Thos. Hanbury, F.L.S., Ventimiglia :
Specimens of *Pilocarpus pennatifolius* in flower and fruit.

Mr. J. Ch. Sawyer, F.L.S., Brighton :
Specimens of Patchouli plants from Java.

EXAMINATIONS IN LONDON.

January, 1896.

MAJOR EXAMINATION—PASS LIST.

Candidates examined	24
„ failed	14
„ passed.....	10

Armitage, Nathaniel Newborn.	Dyson, Thomas Hatfield.
Arrowsmith, George Micklem.	Lucas, Harry.
Arundel, Edmund.	Taylor, Charles Ludlow.
Boorne, Herbert Edward.	Udale, George William.
Cocker, Lewis Alexander.	Walker, John Robert.

MINOR EXAMINATION—PASS LIST.

Candidates examined	187
„ failed	130
„ passed.....	57

Adams, John.	Hughes, Thomas Henry.
Alder, Sydney Frank.	Jones, William Parry.
Alexander, Ernest Glover.	Kellam, Edward Henry.
Atkinson, Thomas Cawood.	Kenney, George William.
Barnes, Victor Geo. Harry.	Knight, William Arthur.
Barritt, Alfred.	Leins, Heinrich.
Bell, Charles.	Lewis, Richard Rice.
Benney, John Herbert Leslie.	Mays, Sydney Walter.
Bramley, William Miles.	Meynell, Henry.
Cheshire, Geoffrey.	Morrell, John George.
Cowley, Thos. Norbert Bodnum.	Moseley, Geo. Robert M.
Dale, John Arthur.	Poole, Arthur Walter.
Davies, Lewis John Arthur.	Rees, John Melbourne.
Davies, Philip Percival.	Smith, Ernest Edward.
Davies, Thos. Edgar Owen.	Sykes, Richard Alfred.
Daybell, Samuel Maltby.	Tindale, Joseph Edward.
De Morgan, Frederick Filmer.	Tuffin, Alfred Henry.
Dewdney, Albert Victor.	Turner, Walter Frederick.
Fore, Walter Thomas.	Tute, James Scott.
Francis, John.	Veitch, William Cuthbert.
Green, Samuel Marston.	Walker, William Henry.
Hanson, Arthur.	Ward, Tom Goodrich.
Hawley, Thomas Herbert.	Wilkinson, Ernest Munkman.
Hemingway, George Garrett.	Wilson, Harold.
Hickman, Fredk. Stanley.	Wood, John Edward.
Holman, Henry.	Woodland, Walter Bayley.
Holt, William.	Woollen, John James.
Hopkins, William Edward.	Wright, Robert Edwin.
Howell, Ellen May.	

FIRST EXAMINATION.

Certificates by approved examining bodies were received from the
undermentioned in lieu of the Society's Examination:—

Bartlett, Henry Walsh	Brackley.
Casson, Frank	Birmingham.
Coulton, Arthur William	Southsea.
Coverdale, Arthur Edward	Kennington.
Crake, John William	Morpeth.
Fowler, Robert H.	Bishop's Stortford.
Francis, Herbert Stanley	London.
Grayson, Joseph	Whitehaven.
Greaves, Sydney Chater	Chesterfield.
Hewitt, Neville Charles	Cowes.
Jewell, Russell	Brixton.
Jewson, John Robert	Wisbech.
Johnson, George Sheriff	Ibstock.
Johnson, Robert Clitherow	Scawby.

Kennard, Lilian Sarah	Lambourn.
Knight, Thomas	Reading.
Leak, William	Buersil.
Pratt, Edward Adams.....	Bridgnorth.
Rawlins, Thomas.....	London.
Robinson, Richard Charles	Kendal.
Sandberg, Frederick James	Settle.
Simmons, Edward Harry	Birkenhead.
Stabler, Edgar	Levens.
Wells, John James	Harrogate.
Wilkinson, William J.....	Grantham.

FIRST EXAMINATION QUESTIONS.

January 14, 1896.

LATIN.

Time allowed—from 11 a.m. to 12.30 p.m.

I. For all Candidates. Translate into Latin :—

1. There were many citizens in the town.
2. A stone has been thrown into the wide river.
3. Between these two boys there has been a very great friendship.
4. I shall go back to my home in Italy.
5. This message being received, some were filled with joy, others with fear.

II. Translate into English either A (Caesar) or B (Virgil).

(Candidates must not attempt both authors.)

A.—CAESAR.

1. Id ea maxime ratione fecit, quod noluit eum locum, unde Helvetii discesserant, vacare, ne propter bonitatem agrorum Germani, qui trans Rhenum incolunt, e suis finibus in Helvetiorum fines transirent, et finitimi Galliae provinciae Allobrogibusque essent. Boios, petentibus Aeduis, quod egregia virtute erant cogniti, ut in finibus suis collocarent, concessit; quibus illi agros dederunt, quosque postea in parem juris libertatisque conditionem, atque ipsi erant, receperunt.

2. Dies colloquio dictus est, ex eo die quintus. Interim, saepe ultro citroque quum legati inter eos mitterentur, Ariovistus postulavit ne quem peditem ad colloquium Caesar adduceret: vereri se, ne per insidias ab eo circumveniretur; uterque cum equitatu veniret; alia ratione sese non esse venturum.

Grammatical Questions.

(For those only who take Caesar.)

1. Give the infinitive perfect and indicative present (third person singular only) of *noluit, incolunt, transirent, collocarent, concessit, dederunt, erant, receperunt* (Par. 1).

2. Give the comparative and superlative of *laetus, facilis, magnus, celer, malus, digne, graviter*.

3. Write in Latin :—16, 39, 106, 14th, 19th, 47th, twice, four times, three each.

4. How are questions expressed in *oratio obliqua*? Give two examples.

B.—VIRGIL.

1. Ac veluti magno in populo quum saepe coorta est Seditio, saevitque animis ignobile vulgus :
Jamque faces et saxa volant ; furor arma ministrat ;
Tum, pietate gravem ac meritis si forte virum quem
Conspexere, silent, arrectisque auribus adstant :
Ille regit dictis animos, et pectora mulcet.
Sic cunctus pelagi cecidit fragor, aequora postquam
Prospiciens genitor, coeloque investus aperto,
Flectit equos, curruque volans dat lora secundo.

2. Jam pater Aeneas et jam Trojana juvenus
Conveniunt, stratoque super discumbitur ostro.
Dant famuli manibus lymphas, Cereremque canistris
Expediunt, tonsisque ferunt mantilia villis.
Quinquaginta intus famulae, quibus ordine longam

Cura penum struere, et flammis adolere Penates ;
Centum aliae, totidemque pares aetate ministri,
Qui dapibus mensas onerent, et pocula ponant.

Grammatical Questions.

(For those only who take Virgil.)

1. Give the infinitive present and indicative perfect (third person singular only) of *coorta est, saevit, volant, silent, adstant, regit, mulcet, flectit* (Par. 1).

2. Give the comparative and superlative of *laetus, facilis, magnus, celer, malus, digne, graviter*.

3. Write in Latin :—16, 39, 106, 14th, 19th, 47th, twice, four times, three each.

4. How are questions expressed in *oratio obliqua*? Give two examples.

ARITHMETIC.

Time allowed—from 12.30 p.m. to 2 p.m.

[The working of these questions, as well as the answers, must be written out in full.]

1. A gallon of water weighs 10 lbs., and a cubic foot of water weighs 1000 ozs. How many gallons are there in a cubic foot?

2. Take $\frac{2}{31}$ of £4 0s. 1d. from $\frac{5}{43}$ of £7 14s. 1d.

3. If $\frac{1}{2}$ of an acre of land costs $\frac{156}{100}$ of £198, what ought $\frac{3746}{100}$ of an acre to cost at the same rate?

4. What will be the cost of painting the walls of a room 32 ft. long, 18 ft. wide, and 11 ft. high, at 1s. $1\frac{1}{2}d.$ per square yard, allowing for three windows each 6 ft. by 4 ft., and two fireplaces each 5 ft. by 6 ft.?

5. A house is insured for $\frac{3}{4}$ of its value at $1\frac{1}{2}$ per cent., and the premium is £18: what is the value of the house?

6. A tradesman advertises a reduction of 10 per cent. on the prices marked; at what price should he mark two articles for which he wishes to obtain 10s. 6d. and 19s. 6d. respectively?

The following question must be attempted by every candidate:—

7. Express 2 cwt. 3 qrs. 11 lbs. in kilograms, and 4 miles 3 fur. 30 pls. 9 yds. in metres.

ENGLISH.

Time allowed—from 3 p.m. to 4.30 p.m.

1. Analyse :—

“ My better parts

Are all thrown down, and that which here stands up
Is but a quintain, a mere lifeless block.”

2. Parse fully :—*are thrown, down, that, but, mere*.

3. Correct the following sentences, giving your reasons :—

(i.) I am neither a good actor in tragedy or comedy.

(ii.) The audience was divided; some of them were in favour of the speaker, and some of it against him.

(iii.) So frightened was he that he dare not move.

4. In the following passage supply the necessary capital letters, and put in the stops and inverted commas where necessary :—an elderly grey whiskered gentleman had been walking down the street glancing up at the numbers of the houses now as his eyes fell upon the old man he came straight for him hullo said he perhaps you are gregory brewster my name sir answered the veteran you are the same brewster as i understand who is on the roll of the scots guards as having been present at the battle of waterloo i am that man sir though we called it the third guards in those days

The following question must be attempted by every candidate.

5. Write a short composition on *one* of the following subjects :—

(i.) A visit to some large town.

(ii.) The lasting effect of early associations.

(iii.) “ It is not the tools that make the workman.”

(iv.) “ If you wish for peace, prepare for war.”

CORRESPONDENCE.

[Letters to the Editor should be written as concisely as possible, on one side of the paper only, and preferably with name and address for publication.]

"SCIENTIFIC" NONSENSE ABOUT VINEGAR, ETC.

Sir,—After more than fifty years' experience of the drug trade, I hold the opinion that acetum dest. is not white wine vinegar. Notwithstanding the similarity, long experience, and opposite conclusion held by my respected friend, Octavius Corder. Fifty years ago I was taught that vinegar, as the derivation of the word implies, was sour wine, but that custom and convenience sanctioned the extension of the term to sundry other liquors containing acetic acid obtained from malt, sugar, etc. It was also customary to speak of port wine as red wine, and sherry as white wine, and the special designation of white wine vinegar was necessary to discriminate between vinegar made from malt, and that resulting from the souring of pale coloured wines, which alone has the right to be called white wine vinegar. At the same time we sold malt vinegar under the names of malt or brown vinegar; the vinegar which we imported from Cognac as French or wine vinegar, and also dilute acetic acid as white or wood vinegar. I do not know that we were ever asked for distilled vinegar, but frequently for white wine vinegar. When white wine vinegar was demanded and the Cognac vinegar was offered, it was frequently objected to and the wood vinegar taken in preference.

Things have changed much during fifty years, and among other changes the sale of vinegar has gone very much out of our hands, a few gallons of malt, and a few gallons of wine vinegar per annum being all that now remains. I think that the so-called high qualities do not please the public so well as acetic acid of a purer kind well diluted. I do not think that is injurious to the health of the consumer nor in any sense to his prejudice, unless he pay a price out of proportion to the cost of the article and reasonable profit, a point upon which chemists do not need to say much. The difficulty lies mainly in the carelessness of the public, who do not know what they want, and will not take the trouble of asking for things by correct names. If I were a J.P. (I am thankful to say I am not) I would no more willingly fine a grocer for selling diluted acetic acid at 4*d.* per quart under the name of vinegar than I would fine Mr. Corder for selling acet. dest. (ex. P.L.) as white wine vinegar. I should require proof that the purchaser had suffered in health or in purse, and that the seller had been made to understand what the purchaser desired to have.

When malt vinegar is asked for we may reasonably say vinegar made from malt should be supplied; when white wine vinegar is asked for, vinegar made from light-coloured wines should be supplied. But when the term vinegar is used without qualification, and the purchaser does not suffer either in health or purse, he has no cause of complaint if he does not get the particular kind of weak acetic acid he desires. I daresay many of my righteous brethren will say I am very wicked to teach such doctrine. Perhaps I am very wicked. The Medical Council instructs us to mix squill root with dilute acetic acid, and call it vinegar of squills, and to mix cantharides with strong acetic acid, and call it vinegar of cantharides. Surely they are very wicked. A common custom of the trade is to mix acetic acid with spirit and perfumes, and sell it as toilet vinegar, and to mix very strong acetic acid with essential oils, and sell it as aromatic vinegar. Oh, brethren, are we not all very wicked?

Newcastle-on-Tyne.

BARNARD S. PROCTOR.

January 13, 1896.

THE POLICY OF 'THE ANTI-CUTTING RECORD.'

Sir,—As any reference in the *Pharmaceutical Journal* to the policy of the *Anti-Cutting Record* seems to command the attention of the editorial department of that publication, perhaps you will allow me to note the first paragraph under the heading of "Trade Notes" in the issue for January. The note refers to Jackson's febrifuge. In his advertisement (p. 16) the inventor tells us that the production of this almost perfect medicine constituted his sole study for over thirty years; that it possesses (!) a chemical action upon almost any diseased or deranged portion of the human system; and that it is an unfailing remedy for all kinds of fever, sore throat, headache, neuralgia, bronchitis, inflammation, pneumonia, influenza, quinsy, croup, feverish colds, weakness, debility, etc. Of course, the above is in line with the usual quack medicine advertisement, but surely it is out of place in an organ addressing the trade. Does Mr. Jackson expect chemists to use the article? Or does he expect chemists to endorse what he himself says about it?

The remainder—and probably the most important part—of the inventor's advertisement is left in the hands of the writer of the *Record's* "Trade Notes." We are told that the article is an invaluable febrifuge, and when "taken up" by the retailer it quickly makes for itself a rapid sale. Will the writer of the note kindly tell us exactly what is implied by the words "taken up," as used in this connection? On the same page of the *Record* it is stated that the demand for proprietaries is created, and has been created, not as the *Pharmaceutical Journal* states, by chemists and druggists themselves, but by persistent and colossal advertising. The *Record* may fitly supplement that statement by adding that in future such demand will be, or ought to be, created by chemists "taking up" the articles.

Further, "the article has been in use for over a quarter of a century, so that its reputation is not of recent origin." I cannot make out whether this statement is made by the inventor or by the writer of the note: in either case, what is its reputation? I have been in the retail trade for nearly a quarter of a century, and never before heard of the nostrum; nor can I find any trace of it in either London or Edinburgh catalogues of proprietaries.

January 13, 1896.

ANTI-HUMBUG.

ANALYTICAL NOTES.

A CRYSTALLINE COMPOUND OF FERROUS CHLORIDE AND NITRIC OXIDE has been obtained by V. Thomas by introducing the gas into an ethereal solution of ferrous chloride, when the liquid turns black and leaves a syrupy substance on evaporating off the ether. After this has stood for some time it becomes crystalline. The crystals have the following composition:— $\text{FeCl}_2 \cdot \text{NO} \cdot 2\text{H}_2\text{O}$. On evaporating the solution at 60° to 100° the compound is obtained free from water. The salt containing water of crystallisation occurs in well-formed black crystals; the anhydrous salt forms small yellow-coloured crystals. Ferrocyanide of potassium produces a white precipitate with the solution (*Apoth. Zeit. Jahr.*, x., 330).

PURITY OF ZINC OXIDE.—Schneegans has recently met with several samples of zinc oxide contaminated with sulphur—an impurity he considers due to the use of metallic zinc containing zinc sulphide in preparing the oxide. Part of the sulphide appears to be mechanically carried over undecomposed, and may be detected in the oxide by the action on lead-paper of the gas produced when dissolved in acid. Schneegans is of opinion that this test should be applied to zinc oxide (*Journ. f. Ph. v. Els. Lothr.*, and *Ph. Centralh.*).

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

FIFTY-FIFTH YEAR OF PUBLICATION.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, JANUARY 18, 1896.

COMMERCIALISM IN PHARMACY.

THE Editor of the *Apothecary* is nothing if not optimistic. In the latest number of his journal he expresses the opinion that slowly but surely true scientific pharmacy will assert itself and throw off the commercialism which has so long trodden it under foot. Possibly pharmacy in the United States may have made great progress of late in the direction indicated, but the prevailing impression in this country has been that the slowness of the movement referred to was more marked across the Atlantic than even here, where it is sufficiently pronounced to calm any fears on the part of the most fossilised ultra-conservative. Nevertheless, even though the wish be father to the thought so far as present appearances are concerned, many leading British pharmacists will join hands with Professor OLDBERG on the question, and hope with him that the parting of the roads where the mere merchant druggist and the real pharmacist will part may soon be reached. At the same time, it is difficult to conceive of pharmacy becoming purely professional in the exact sense of the term. The trade element seems bound to persist, and on the whole it will perhaps be better to accept this view with as much equanimity as may be forthcoming.

As an interesting sign of the times, it is stated that the purely commercial retail druggist in the States is now demanding that the colleges of pharmacy shall instruct their classes "in such purely commercial matters as the art of buying and selling, advertising, dressing show windows, 'handling' merchandise having no connection whatever with legitimate pharmacy, and other similar 'practical' means by which the sales and profits of the drug store may be increased." This, if carried into effect, would surely be technical education run mad, for it is difficult to credit that any intelligent individual honestly believes that such training, to be of any real value, can be obtained anywhere except in a shop. As Dr. OLDBERG justly insists, all of the purely mercantile special training which the druggist is expected to have must be gained in the shop, and it may be observed parenthetically that it is better obtained before than after entering upon a college course. On this point the opinion here expressed is not at one with that which at present finds favour in the States, but British experience fully endorses the statement that shop training should precede college instruction.

Compulsory preparatory general and special education for pharmacy; a complete system of registration for apprentices, assistants, and pharmacists; and a fixed period of shop experience precedent to registration and licence, are the chief desiderata stipulated for by our contemporary, and British pharmacists generally would view a law enforcing these with much equanimity and satisfaction. They ought also to approve of the suggestion that "when a boy or young man goes into a drug store to learn the business he ought to be told at the very beginning, and with authoritative finality, whether or not he can ever become anything more than an errand boy, a porter, or a mere salesman. If his general education is not sufficient to warrant his registration as a student, qualified to become an intelligent and competent pharmacist, he should be at once so informed, instead of being permitted to entertain the hope of being a registered pharmacist some day." It may be added that the onus of deciding with regard to the pupil's educational capacity should be left to competent examiners rather than the pharmacist, and the test ought to be imposed before he is allowed to enter the shop. Candidates for admission to the ranks of pharmacy undoubtedly require sifting out, but the sieve must be used at the right time and by the right persons, if the process is to be properly efficacious.

THE SALE OF POISONOUS WEED-KILLERS, ETC.

It is refreshing, after the storm of abuse levelled at the Pharmaceutical Society by different trade papers in connection with the proceedings taken against grocers, photographers, and seedsmen, for infringing the Pharmacy Act, to read the sensible remarks that appear on the subject in the *Gardeners' Chronicle*. The Editor of that paper is not disposed, as he says some of his correspondents are, to decry the action of the Pharmaceutical Society in undertaking the responsible duty of prosecuting persons who infringe the law by selling poisonous preparations when not expressly authorised so to do. It is pointed out that seedsmen and nurserymen incur great risks in dealing with poisonous substances, since, according to the Pharmacy Act of 1868, no person, not being a duly registered pharmaceutical chemist, or a chemist and druggist within the meaning of the Act, can legally sell certain poisonous substances, or preparations containing them.

"The object of this enactment," proceeds our contemporary, "is obvious enough—and every sane man will say it is reasonable. But the operation of the law is another matter." Certain correspondents, it appears, have complained bitterly against the action of the Pharmaceutical Society, urging that a poison is no less poisonous if sold by a druggist, and no more poisonous if retailed by a seedsman. "It must be remembered, however, that the pharmaceutical chemist has passed through a course of education to fit him for his duties, and has passed various examinations. He is therefore presumed to have a fuller and more intimate knowledge of poisonous substances than a grocer or a seedsman, who has given no such public pledges that he is a responsible person, and one competent to handle and dispense such dangerous ingredients." Aspersions against the Society—as being the possessor of a monopoly, and influenced by sordid motives in securing for its members exclusive privileges—are designated as not only in bad taste, but also untrue. "The Society would, we expect, gladly be relieved of what must be a very unprofitable and an extremely disagreeable duty. On the other

hand, the general public would have ample right to complain if the Society did not execute the commission entrusted to it by the State. So far from being too active in the matter, we are inclined to think it is not active enough."

Further, it is urged that if seedsmen were to be allowed to sell tins of weed-killer, they ought, for the public safety, to exercise their calling under the same sort of restriction as the druggist does. At present the druggist must keep a register detailing the amount of poison sold, the name and address of the person to whom it is supplied, and other particulars, but the grocer, oilman, or seedsmen takes no such precautions. "As matters now stand, a child may purchase a packet of vermin-killer or fly paper from an oilman, enough to poison half a parish." It is appropriately observed that no one, druggist or otherwise, should be allowed to deal in these dangerous substances without in some way giving a voucher to the public that he is a responsible and a competent person, and, in conclusion, it is suggested that "surely the facts of the case demand not lessened but increased restriction."

THE PRESERVATION OF DRUGS.

WE have been favoured by the receipt of an advance proof of a paper on a method for preserving organic products and protecting them from insect attacks, read before the Agri-Horticultural Society of India, at Calcutta, by Mr. J. CLEGHORN, of the Public Works Department. The paper is too long for reproduction in the *Pharmaceutical Journal*, but a brief summary of its salient points will probably be found interesting. The process has been used with good effects in the case of cassia pods, cigars, and cigarettes. Out of one hundred and five bales of cassia sent by one firm to London, five were treated by this sterilising process, and those five realised prices about seventy per cent. better than the rest.

The apparatus used in the experiments, which is somewhat vaguely described, consists of a large zinc box, raised on supports to a convenient height from the ground. The box is divided into two compartments, each of ten cubic feet capacity, "with an annular space on the bottom and sides." At diagonally opposite corners there are apertures in the "outside compartment," through either of which water is poured until a depth of about two inches is registered. Thermometers are attached to the caps closing these apertures, so that the temperature can be observed. There are two closely-fitting lids to each compartment, both resting on felt linings, and there is a space of about eight inches between the upper and lower lids to keep the temperature uniform. Over the whole apparatus two covers are placed, one of "gunny" and the other of blanket.

The articles to be treated are arranged in the compartments, tier upon tier, with battens between. When full, the covers are placed in position, and three ordinary paraffin oil stoves are lighted and placed below the apparatus. As soon as the thermometers record 138° F., *i.e.*, in about three or four hours' time, one stove is removed and the others are adjusted so that the temperature can be maintained at that point for five hours. The apparatus is then allowed to cool gradually, so that any vapour given off by the drugs, etc., may be reabsorbed evenly. On removal, the contents are found to be thoroughly sterilised, and are stated to be even improved in flavour. The effects of the process are to coagulate albumin, rupture starch granules, preserve tissues, destroy insects and their eggs, and kill germs. It is also said to

enable the goods treated to be kept with impunity in a suitable climate for maturing, and finally to improve their condition.

THE 'INDEX KEWENSIS' AND BOTANICAL NOMENCLATURE.

Sir JOSEPH HOOKER and Mr. B. DAYDON JACKSON are to be congratulated on the completion of that stupendous compilation,—the 'Index Kewensis'—which should so greatly lighten and facilitate the labours of all working botanists. It is doubtful, however, whether the prohibitive price—ten guineas—placed on the work will not entirely frustrate the intentions of the late CHARLES DARWIN, and leave the copies to moulder in the publisher's stores. It may be well to explain that the work is primarily an index down to the end of 1885, leaving much for successive monographers to do in the matter of synonymy. Still, an immense amount has been done in this direction, and according to the *Kew Bulletin*, there is a good prospect of an early publication of a supplement embracing the decade 1885 to 1895, which has been a very busy one, not only for would-be reformers of botanical nomenclature, who have probably added some 50,000 names to the already appalling synonymy of previously described plants, but also for systematists who have described the numerous discoveries of collectors in all parts of the world, more especially in tropical Africa, Madagascar, and China. Names have also been largely increased by a class of botanists who see species in individual variations, as in *Hieracium* for example, of which there are now upwards of a hundred reputed British species! Genera are also liable to this disturbing influence. A distinguished French botanist has dismembered the genus *Loranthus* as ordinarily understood, and without finishing, has already segregated about ninety groups, which he has raised to the dignity of genera. With regard to the rule of priority in nomenclature, there is a growing feeling in Europe in favour of making 1753 the starting point, subject to certain exceptions of not reviving obscure names to replace familiar ones that have been in general use for half a century or more. The director of Kew has publicly announced his adhesion to the rule of retaining and employing current familiar names; and whatever view may be taken of the question, this course has the advantage of adding nothing to synonymy, and at present causes no inconvenience.

POISONING BY CARBOLIC ACID.

It is high time, says the *Aldershot News*, that attention should be given by the proper authorities to the medical view of the danger of the unrestricted sale of carbolic acid. An Aldershot medical man, who has recently had to attend two cases of suicide by its means, has expressed a strong opinion that carbolic acid should be included in the list of scheduled poisons, and the local paper comments upon his remarks in the following sensible and pertinent passage:—"No one, of course, will suppose that the mere fact of scheduling it will alone be sufficient materially to reduce the total number of suicides, but it is reasonable to believe that the more we curtail the facilities for purchasing poisons the less likely are persons who choose them to find them at hand during those temporary periods when the mind is so unhinged as to allow them deliberately to contemplate self-destruction. And who shall say that many a person has not been saved from death by his own hand by lack of opportunity at the critical moment?"

ANNOTATIONS.

MANCHESTER PHARMACY BALL.—The third annual ball and musical promenade in connection with the Manchester Pharmaceutical Association, will be held at the Hulme Town Hall, Manchester, on Wednesday next, January 22. Inclusive tickets (double, 12s. 6d.; ladies', 5s. each, gentlemen's, 8s. 6d.) may be obtained of Mr. A. Blackburn, 7, Exchange Street, Manchester, and should be applied for without delay. Mr. T. B. Blyton will officiate as M.C., and the music will be provided by Messrs. Forsyth Bros.' band. The musical promenade commences at 8 p.m., dancing will begin at 8.30 p.m., and carriages may be ordered for 2 a.m.

HELMHOLTZ MEMORIAL LECTURE.—The Helmholtz Memorial Lecture of the Chemical Society will be delivered by Professor G. F. Fitzgerald, F.R.S., of Dublin, at an extra meeting of the Society, to be held at Burlington House on Thursday next, January 23, at 8 p.m.

TARAXACIN: A CRYSTALLINE BITTER PRINCIPLE FROM DANDELION ROOT.—According to Sayre (*Am. Journ. Pharm.*, lxxviii., 465), taraxacum root contains, in addition to an amorphous bitter substance, a crystalline bitter principle which he calls taraxacin. It is obtained from a diluted fluid extract of taraxacum obtained by displacement, by precipitating with solution of basic lead acetate. The filtrate from this is treated with sulphuretted hydrogen, the lead sulphide filtered off, and the liquid evaporated to near dryness. The pasty mass is mixed with sand and dried at 55° for three days; it is then exhausted with chloroform. This solvent, on evaporation, leaves the taraxacin in the form of crystals. The yield is about 0.05 per cent.

ARROW POISON OF NAMAQUALAND.—According to the *Scientific African*, the bushmen of Namaqualand poison their arrows with the venom of the "ring-halse," or black night-adder. This is forced from the poison glands by violent compression with a two-pronged stick, and mixed with a resinous extract from the root of *Buphane toxicaria*, being then ready for use. Formerly the head of the puff-adder was stewed with this resinous extract, together with beetles and noxious herbs, the incantations of a witch-doctor being also considered essential to ensure efficacy.

THE FIRST ARTICULATED SKELETON.—Andreas Vesalius—who is the first subject in an attractive series of articles promised by the *Practitioner*—is distinguished as being the first person recorded to have produced an articulated skeleton. With the help of a friend he stole the skeleton, which attracted his attention owing to the fact that vultures had picked it particularly clean, from the gallows erected near Louvain in 1536. He was also probably the pioneer "resurrection man," and made recognition of smuggled bodies impossible by removing the skin as soon as they arrived in the dissecting room.

THE FATE OF MICROBES IN INSPIRED AIR.—The desirability of inspiring air through the nostrils only is further emphasised by the results obtained by Drs. St. Clair Thomson and Hewlett. They have previously shown that the mucous membrane of the healthy nose only exceptionally shows any micro-organisms whatsoever, the interior of the great majority of normal nasal cavities being perfectly aseptic. They now find that nasal mucus is capable of exerting an inhibitory action on the growth of micro-organisms, though they have not been able to obtain any proof that it possesses bactericidal qualities.

THE CHEMISTS' BALL.—No more successful Chemists' Ball has been held than that on Wednesday last at the Portman Rooms, London. More than three hundred tickets had been sold, and supper was laid for two hundred and ninety persons. Mr. T. C. W. Martin filled his usual office as M.C., with as much tact and success as ever. The perennial Chairman, too—Mr. Michael Carteighe—was in his accustomed good form. His complimentary allusions to the manner in which the members of the Committee had fulfilled their self-imposed duties—and especially the Honorary Secretary, Mr. John C. Umney—were acclaimed with a heartiness that proved they were fully endorsed by all present. Mr. Carteighe also read a telegram received from Stonehouse, in which the chemists of the Three Towns and district, who were holding a ball at the same time, sent hearty greetings to their associates and friends assembled at the Portman Rooms. The whole of the proceedings passed off without a hitch, and the new Honorary Secretary is cordially congratulated on the results of his efforts. Amongst others present were Messrs. Butt, Bowen, Martindale, Cooper, White, Tanner, Taylor, Mathews, Wright, Bremridge, Francis, Greenish, Umney, Warren, and other prominent pharmacists too numerous to mention, accompanied in practically all cases by the lady members of their families.

WOMEN AS SURGEONS.—At a recent meeting of the Fellows of the Royal College of Surgeons, a resolution was carried to the effect "that, in the opinion of the Fellows of this College, women should be admitted to the diplomas of the College."

BLINDNESS CAUSED BY EXTRACT OF MALE FERN.—According to the *Journal de Médecine et de Chirurgie Pratiques*, Masiers has reported a couple of cases of amaurosis produced by extract of male fern. In one case a carpenter, after taking thirty-two capsules of extract of male fern and extract of pomegranate, and also a dose of castor oil, rapidly lost consciousness, and the next day his eyes showed total mydriasis and complete amaurosis. A week afterwards atrophy of the optic nerves supervened, and the patient became stone blind. The toxic effect of oil of male fern has been shown to be due to filicic acid, which is soluble in castor oil and other fatty bodies, and so more readily absorbed. Toxic symptoms are always more grave where a dose of oil has followed the ingestion of the male fern extract.

OESTERREICH. ZEITSCHRIFT FÜR PHARMACIE.—The official organ of the Austrian Apotheker-Verein has just published its jubilee number, having been commenced in 1846. This special number contains an article on jaborandi leaves and their structure, by Professor A. Vogl; a paper on columbin and columbic acid, by Professor A. Hilger; one on the source of dammar resins, by Professor J. Wiesner; and the first part of an elaborate illustrated paper on storax, by Professor J. Moeller. Communications on the assay of *Secale cornutum* by Professor H. Beckurts, and the histology of cinnamon chips, by Dr. T. F. Hanausek, are also amongst the contents of this excellent number of the *Zeitschrift*.

DISTRIBUTION OF FUNGI BY SNAILS AND TOADS.—Vogolino communicates a suggestive paper to the *Nuovo Giornale bot. Ital.* (1895 181), in which he demonstrates that certain fungi (Agaricineæ) are distributed by snails and toads. An examination of the stomach of the snails showed the presence of spores of various species of fungi which were seen to have begun their germination, and culture experiments with the excrements of various snails produced a large number of germinating spores of fungi. The same was observed on examining the stomachs of toads, in which the spores of *Russula* and *Lactarius* were specially abundant.

PROCEEDINGS OF SOCIETIES.

CHEMISTS' ASSISTANTS' ASSOCIATION.—The Chemists' Assistants' Association inaugurated the second half of the session by a smoking concert, which was held in the large hall of the Frascati Restaurant on Thursday, the 9th inst. When Professor J. Reynolds Green took the chair there was already a representative gathering present of pharmacists and their friends, and this was largely augmented in the course of the evening. Amongst those who attended were Mr. C. B. Allen, who occupied the vice-chair, Professor H. G. Greenish, Messrs. John Harrison, Joseph Ince, R. Bremridge, G. Claridge Druce, F. Ransom, C. Umney, J. C. Umney, Clarke, W. Watson Will, P. MacEwan, and T. C. W. Martin. An admirable programme had been drawn up by Messrs. T. Morley Taylor, and W. S. Crouch (Hon. Secs. to the Smoking Concert Committee), and amongst the items may be mentioned Mr. Frederick Russell's "Ventriloquism up to Date," which proved quite as successful a feature as at the School of Pharmacy Cricket Club "smoker." Mr. G. T. Miles' harp solos and Mr. Walter Churcher's recitations evoked hearty applause. It only remains to be added that Professor Green made a most acceptable Chairman, the same remark applying to Mr. Allen in his capacity as "vice," and that the general arrangements reflected credit upon all concerned.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.—A meeting was held on January 9, Mr. H. A. D. Jowett, B.Sc., in the chair. A paper was read by Mr. R. Payne entitled the "Antiquity of Man." In the first part of the paper, after treating of the monuments of Egypt and Chaldæa, and the most important early records, the author summed up by saying that over 7000 years ago there existed in Egypt a united nation, in a very high state of civilisation, in some respects equal to that of the nineteenth century. Chaldæa, he said, tells us practically the same tale, although we cannot go quite so far back as in the case of Egypt, and have not such a complete historical record. In the second part of the paper the author described the various geological periods, and discussed the probable length of their duration, expressing the opinion that the recent period had lasted about 20,000 years, the Quaternary about 200,000 years, and the Tertiary about 2,000,000 years. In conclusion, the opinion was expressed that we should have to go back into the Eocene or earliest Tertiary stage for the origin of man, and, further, judging from the present state of our knowledge of the antiquity of man, he said that he felt quite safe in saying that the probable date of man's origin was at least one million years ago, and that many facts pointed to a much greater antiquity. A discussion followed, in which Messrs. Eastes, Grier, Senter, Spurge, and Umney took part. The Chairman then gave notice of motion in connection with the proposals of the Executive Committee to amend the rules of the Association. These amendments will be discussed and voted upon at the next meeting, on Thursday, January 23.

LINNEAN SOCIETY OF LONDON.—At the meeting on December 19, Mr. W. P. SLADEN, Vice-President, in the chair, Mr. William Scott was elected a Fellow of the Society, and the Rev. T. R. Stebbing, Rev. H. P. Fitzgerald, and Mr. A. W. Geffcken were admitted.

Mr. W. B. Hemsley exhibited specimens and photographs of *Cactææ* from the Galapagos Islands, and gave an account of some of the more remarkable species.

Mr. George Brebner exhibited and described, with the aid of microscope and lantern-slides, the following new and rare algæ:—*Colaconema bonnemaisonia*, Batters, *C. chylocladia*, Batters, *Trailliella intricata*, Batters (*Spermothamnion turneri*, var. *intricata*, Holmes and Batters, 'Revised List Brit. Algæ'), *Ectocarpus velutinus*, Kütz., var. *laterifructus*, Batters, and *Hymenoclonium serpens*, Batters (*Callithamnion serpens*, Crouan). These were found by Mr. Brebner while studying the marine algæ of Plymouth and the neighbourhood. The first two are endophytic and new to science; the discovery of the tetraspores of the third (which in regard to position and development are unique in the group to which it belongs) justified the creation of a new genus for its reception (*cf. Journ. Bot.*, 1896, p. 8). The fourth is a variety of a well-known parasitic on *Himanthalia lorea*, Lyngbye, probably only a late autumn and winter form not hitherto described. The fifth was a young specimen of a rare Alga first discovered in this country by Mr. Holmes, and found, like the others, in Plymouth Sound.

Mr. J. E. Harting exhibited a living specimen of the Snow-Bunting (*Emberiza nivalis*), which had been captured with several others off Cape Race on board the s.s. "Ottoman" in October last, during the voyage from Boston to Liverpool, as mentioned at a former meeting (November 7).

Mr. R. A. Rolfe gave an abstract of a paper entitled "A Revision of the Genus *Vanilla*," in which some fifty species were enumerated, seventeen of which were described as new, though five of them had been previously confused with older forms. The plants in this genus were described as tall forest climbers, some of them leafless, found almost throughout the Tropics, though generally somewhat local in their distribution. Of the species described, twenty-nine were American, eleven Asiatic, and ten African. Six of the American species were stated to have aromatic fruits, and three are well known in commerce, although only one of them, *Vanilla planifolia* (often confused with other species), is largely cultivated as an economic plant. Mr. Rolfe gave an account of the morphology and mode of fertilisation of the genus, its affinities and geographical distribution, and an enumeration of the species with descriptions. As indicating a still imperfect knowledge of the genus, he remarked that it was even now uncertain to what species the Peruvian plant with aromatic fruits belonged, which was noticed by Humboldt more than eighty years ago. The paper was illustrated by a series of carefully made drawings.

Mr. E. S. Goodrich communicated a report on the collection of Cephalopoda in the Calcutta Museum. He explained that this collection had been forwarded from Calcutta to Professor Ray Lankester, at whose request he had undertaken to examine and report upon the species. It contained 162 specimens, almost all of which were collected in the Indian Seas from the Persian Gulf to the coast of Australia during the cruise of H.M.S. "Investigator." Fifteen genera were represented, and several new species were described belonging to the genera *Cheiroteuthis*, *Histiopsis*, *Abraha*, *Doliolus*, and *Faonius*. The paper was illustrated by original drawings.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.—Perhaps the most successful of the annual dinners in the history of this Society was the latest—the sixth—held at the Alexandra Hotel, Liverpool, on the 9th inst., under the presidency of Mr. T. S. Wokes. The arrangements were perfect, the after-dinner programme of music, vocal and instrumental, ran without a hitch, and last, but not least, the gentlemen to whom the task of proposing the various toasts was confided were commendably concise in their remarks, the replies being of a like nature. In response to the toast of the "Medical Profession," proposed by Mr. R. H. Mitchell, an exceedingly happy and well-turned speech was delivered by the doyen of the Liverpool medical faculty, Dr. J. B. Nevins, M.D., F.R.C.S., who has from the first exhibited an interest in the affairs of the Liverpool Pharmaceutical Students' Society, much valued by the members.

The menu card this year was a novelty in its way, being adorned with punning illustrations of the subjects in the syllabus of the Society's lectures. Fermentation showed two disciples of the "fistic art" having a "set-to"; "supporting the Pharmaceutical Society" was a modern Atlas with the Society's arms on his brawny shoulders; aquatic plants gave a huntsman taking an impromptu header into a ditch, whilst a bony and broken-down Rosinante was deemed a fit illustration of "weak points," etc. It seemed uncomplimentary, by the way, on the part of one of the musical friends, to herald the toast of the medical profession by the song "The Goblins in the Churchyard"! The visitors included Drs. Nevins, Larkin and Logan, Charles Sharp, Esq., F.L.S., Charles Symes, Esq., Ph.D. (who replied to the toast of the Pharmaceutical Society), and Professor R. J. Harvey-Gibson, F.L.S., F.R.S.E., of University College, as well as many members of the Liverpool Chemists' Association.

PLYMOUTH, DEVONPORT, STONEHOUSE, AND DISTRICT CHEMISTS' ASSOCIATION.—The quarterly meeting of the members of this Association was held at the Foresters' Hall, Union Street, Plymouth, on Wednesday, January 8, the President, Mr. C. J. Paik, in the chair. After the general business had been transacted, the Secretary announced the receipt of three books, kindly presented to the Association by Mr. E. M. Holmes, of the Museum Department, Bloomsbury Square, viz., Remington's 'Pharmacy' and two copies of Attfield's 'Chemistry.' A vote of thanks was unanimously passed to Mr. Holmes for his generous gift.—Mr. J. Kinton Bond, B.A., B.Sc. (hon. member), was to have delivered a lecture on "The Metric System," but owing to an urgent engagement out of town Mr. Bond was prevented from attending, and the lecture was consequently postponed to another date.

The final meeting of the Pharmacy Ball Committee was afterwards held, and reports presented by the Hon. Secs. (Messrs. F. Maitland and H. O. Westcott). Details of decorating the Town Hall, Stonehouse, and various other matters concerning the ball on the following Wednesday were agreed to. It was stated that this would be the first Pharmacy Ball ever held in the West of England, and there were many expressions of pleasure at the successful arrangements which were being made. The Secretary announced that no more tickets could be issued, as nearly 250 persons, including the Mayor of Devonport and the Chairman of the Stonehouse District Council, had intimated their intention of being present.

The Junior Section of the Association held its monthly meeting at the Foresters' Hall, Octagon, on Thursday, January 9, when an interesting paper on "The Microscope" was read by Mr. W. S. Favener (Plymouth), and much appreciated by those present. The early history of the microscope was traced, and its various developments and improvements up to the present day explained. Its uses in the study of botany and chemistry were enlarged upon, especially as it affects the pharmaceutical student. The bacteriologist found this instrument of great value in his researches, and it was the indispensable companion of the true scientist. Stress was laid upon the fact that it was advantageous to commence the use of the microscope as early as possible in student days, it being of great aid in the sciences. At the close of the paper a short discussion took place, after which a cordial vote of thanks was passed to the essayist, proposed by Mr. Darke (Stonehouse), and seconded by Mr. E. A. Hodge (Devonport).

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.—On Wednesday, January 8, the following paper was read by F. Casson, of which the following is an abstract:—

"Ferments," by F. Casson.

The word "ferment" is derived from *fervere*, to boil, and was formerly applied to those cases in which a liquid or semi-liquid mass was seen to become puffed up and disengage gas without any apparent cause, that is, without any cause that could be understood and explained.

The meaning of the term has been much extended, until at the present day we mean by fermentation those chemical changes which take place in a substance through the agency of a body derived either from the animal or vegetable kingdom, termed a ferment. This ferment remains the same, qualitatively, both before and after the reaction. Hence we class many bodies as ferments, to which the word ferment, as meaning a "boiling," is misapplied. All ferments possess three properties:—

1. They are nitrogenous organic substances.
2. They are unstable—heat, acids, etc., readily destroying them.
3. A relatively small quantity is capable of producing great changes in the body acted upon, especially if the products of the change be removed.

Ferments can naturally be divided into two great classes:—

1. *The Formed or Organised Ferments.*—These have a definite organised structure, and are capable of independent growth and multiplication. They include:—

- (a) The Moulds.
- (b) The Saccharomycetes or Yeasts.
- (c) The Schizomycetes or Bacteria.

2. *The Un-formed or Soluble Ferments.*—These have no organised structure or power of multiplication. They include amongst others—

- | | |
|----------------------------|------------------------------|
| (a) The Diastatic Ferment. | (c) The Rennet Ferment. |
| (b) The Peptic Ferment. | (d) The Pancreatic Ferments. |

The action of the first class appears to be due to the presence of one or more living cells in a body; the action of the second may be traced to the molecules of which they are composed, and which are the carriers of the chemical force that causes the changes. The second class of ferments will only be dealt with here.

1. *Diastatic Fermentation.*—The best known instance of this occurs in extract of malt. If a solution of extract of malt be heated to about 30° C. with its own weight of starch in solution, the starch is completely converted in a few minutes into maltose and dextrine, and ceases to answer the iodine reaction (experiment shown). The diastatic fermentation occurs to a small extent in the saliva. The diastatic body may be obtained by filtering saliva, and mixing with five or six times its weight of alcohol. The very slight precipitate which falls is dried at the temperature of the air. It has a strong diastatic action.

2. *Peptic Fermentation.*—This fermentation takes place in the stomachs of animals when food is digested, and the stomachs are the sole source of pepsin.

Various theories of digestion have been advanced from time to time that the changes were due to heat only, to grinding only, or to the action of strong acids, etc.

Gastric Juice exudes when the surface of the stomach is touched. It is usually colourless, and always acid in reaction. Human juice has a sp. gr. from 1.001 to 1.010, and contains less than 1 per cent. of solid matter. On boiling, it is not coagulated, but its power is totally destroyed. It may be kept for months unchanged.

The power of gastric juice in dissolving proteids may be traced to the pepsin it contains, which can only act in the presence of an acid, preferably hydrochloric.

The Preparation of Pepsin.—The B.P. directs that the mucous membrane of the stomach be, after washing, simply scraped off and dried. Pepsin can readily be obtained purer, and therefore stronger, than by this method. Wassman dissects off the mucous membrane and treats repeatedly with water at 30° to 40° C. The liquors are mixed, precipitated with lead acetate, the precipitate collected, suspended in water, and sulphuretted hydrogen passed through. The filtrate is concentrated and alcohol added to precipitate pepsin.

Another method is to exhaust the stomach and mucous membrane with weak acid, and saturate the solution with salt. A scum rich in pepsin rises to the surface and may be skimmed off. It is either dried and powdered at once, or mixed whilst still wet with sugar of milk.

Pepsin may also be obtained by digesting the membranes in glycerin, in which the pepsin is soluble, and precipitating with alcohol.

Pepsin is absolutely indiffusible through parchment paper, and advantage may be taken of this to purify it by dialysis.

3. *The Rennet Ferment.*—The fourth stomach of the calf has been long known for its milk-curdling properties, due to a ferment termed chymosin. This ferment is invariably present in the healthy human stomach, and is present in many animals. The chymosin may be extracted from the calf's stomach with water, but a better way is to digest with weak acid for twenty-four hours and carefully neutralise. Aqueous solutions of salicylic acid extract the ferment well, and will keep. Alcohol precipitates the ferment in an impure form. Prolonged contact with alcohol, especially if strong, is said to destroy the ferment. Fixed caustic alkalies have a powerful destructive action upon it, even in very small quantities, and carbonate of sodium, calcined magnesia, etc., act the same, though in a lesser degree. Heat readily destroys chymosin, especially if acid.

The Ferments of the Pancreas.—Pancreatic juice is a more or less viscid liquid, invariably alkaline and readily putrefying. Alcohol causes an abundant precipitate, which carries down the ferments it contains. These are at least three:—

- (1) A proteolytic ferment acting in neutral or alkaline solutions.
- (2) A diastatic ferment, similar to that in the saliva.
- (3) A fat-decomposing ferment which emulsifies and decomposes fats into glycerin and fat acids.

The proteolytic ferment (trypsin) does not exist in the perfectly fresh pancreas, but is formed in an hour or two's time. It may be extracted by digesting with water, precipitating with alcohol, re-dissolving, re-precipitating, and digesting in absolute alcohol. The precipitate is treated with water, acetic acid added, filtered, sodium hydrate added to slight alkalinity, filtered, concentrated at 40° C., filtered, and precipitated with alcohol. If necessary, it is purified by dialysis.

Trypsin acts most readily in a solution containing about 1 per cent. of Na_2CO_3 , that being the strength of the juice. It acts in neutral and in very slightly acid solutions, but contact with warm acid fluids gradually decomposes it.

The Diastatic Ferment is obtained by treating the pancreas by extracting with glycerin, chloroform water, solution of borax with boracic acid, brine, etc. By these methods solutions of the two ferments are obtained, which may be precipitated by alcohol. The ferment acts most readily on starch at from 30° to 45° C. One part of the diastase is said to be able to convert 40,000 parts of starch into sugar and dextrin.

The Fat Decomposing Ferment cannot be extracted or kept so readily as the others. If 2 parts of juice be agitated with 1 of olive oil, or of some fat melting below 40° C., a perfect and persistent emulsion is formed immediately. The fat globules are said to be finer than those in milk. Both the pancreas and its juice possess the power of decomposing fats. If a particle of the pancreas be dehydrated by means of alcohol, well teased out in an ethereal

solution of butter-fat, and afterwards transferred to a drop of tincture of litmus, a cover-glass being placed above it, the litmus is seen to be reddened all round the particle, due to the action of the fat-acids separated from the butter.

Eight samples of pepsin were tested by the B.P. test, and the results were shown. Six answered the test, two left much albumin undissolved. Five samples tested by the U.S.P. method were shown, of which three were satisfactory.

Thanks are due to Messrs. Southall, Bros. and Barclay, in whose laboratories the experiments were performed.

In the discussion which followed, the President thought the paper, which might have been termed "Digestive Ferments," was one of exceptional interest to pharmacists. He had listened with the keenest pleasure to every word and had learned much.

Mr. H. S. Lawton, having in view the samples which had been tested, asked if the price was any guide to the quality of pepsin.

Mr. H. Jessop said that as pepsin was only active in the presence of an acid, would it not be advisable to use pig pepsin less and human pepsin more, by administering hydrochloric acid when pepsin was indicated?

In replying, Mr. Casson said it was satisfactory to learn that those samples of pepsin which had proved themselves the best, were, with few exceptions, the highest priced. Regarding the question of administering acid for digestive purposes, he believed this was a common practice, but it must be left to medical men to decide whether the stomach of a patient is deficient in pepsin or acid.

A vote of thanks was passed and proceedings closed.

SHEFFIELD MICROSCOPICAL SOCIETY.—A general meeting of this Society was held on Friday, January 10, at the Rutland Institute, Fargate, the President, Mr. A. H. Allen, F.I.C., F.C.S., in the chair. There was a fair attendance. The paper for the evening was on the filamentous algæ, by Mr. R. B. Greaves, Ph.C., F.C.S., of the Sheffield College of Pharmacy. Mr. John Austen read the paper and explained the diagrams and specimens in the unavoidable absence of the author. At the close a hearty vote of thanks was accorded to Mr. Greaves for his admirable paper, on the motion of Mr. J. Newton Coombe, seconded by Rev. C. R. Killick, M.A.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.—On Thursday, January 9, a smoking concert under the auspices of this Association was held in the Alexander Hotel, Bath Street, Glasgow. Mr. W. L. Currie, president, occupied the chair, and almost eighty gentlemen were present. A most enjoyable evening was spent in song and recitation. Amongst the contributors to the night's amusement were Messrs. Gideon, Duncan, Currie, Laing, Irvine, A. F. Leifer, and Thomson. A violin solo was played by Mr. W. L. Bowman, and an instrumental trio, under Mr. Bruce, gave some selections. The most marked feature of the evening was the enthusiastic manner in which some patriotic songs were received, "Van Tromp and His Broom" in particular being vociferously cheered. The concert on the whole was a great success.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.—The third meeting of the eighteenth session was held in the Pharmaceutical Society's Hall, 36, York Place, Edinburgh, on Friday, January 10, at 9.15 p.m., Mr. J. Mackintosh Cameron, President, in the chair. The minutes of the last meeting having been read and approved, the following communications were read:—

"Note on *Pilula Ferri, B.P.*," by William Lyon.

During the past summer I made a series of experiments with the view of reducing the size of Bland's Pills. The official formula is a very satisfactory one, so far as massing and keeping properties are concerned, and it has been taken as a standard during the experiments. After many trials the following formula was found to be equal to the B.P. pill in every respect, and the bulk is a fifth less.

Take of—

Dried carbonate of potassium	30 grains
„ Sulphate of iron	36 „
Powdered sugar	15 „
Powdered tragacanth	3 „
Glycerin	2 minims
Syrup	10 minims
	or a sufficiency.

* By using carefully-dried sulphate of iron pharmacists may rely on this formula, giving a pill mass which will meet every test that

can be applied to the B.P. mass. Pills made as above can be readily varnished with ethereal solution of tolu residue. Another method which gives a nice result is to moisten the surface of them in finely powdered wood charcoal, and when dry varnish with tolu solution. Thus treated they have a nice glossy black appearance, and the gradual oxidation of the pill is not observed by the patient.

"Note on Compound Colocynth Pills," by William Lyon.

So much has been written about this pill at one time or another that it seems superfluous to deal with it again. This note, however, is merely to draw attention to the suitability of aromatic spirit of ammonia as a massing agent. During the summer months I subjected it to prolonged trials, and came to the conclusion that it was far superior to any agent I had tried. After being kept for nearly six months the pitting was scarcely perceptible, a big contrast compared with the present B.P. pill. Unfortunately, however, for the adoption of sal volatile as a massing agent, the B.P. pill is very frequently prescribed along with calomel, which undergoes decomposition in the presence of salt of ammonia, and this constitutes a strong argument against it being included in a new pharmacopœia, and restricts its usefulness at the dispensing counter.

"Note on Oleate of Mercury and Ointment of Potassium Iodide," by William Lyon.

Some time ago the following prescription was handed in to be dispensed.

I. R. Hydrarg. oleatis. ʒi.
Ung. potass. iodid. ʒvii.
Sig. The ointment. Misce.

On mixing this, it assumes a bluish colour, which quickly changes to dirty brown, but on standing for a day or two the colour gradually disappears, and it remains yellowish white. The reaction is, of course, a well-known one, but I thought it might be of some interest to the younger members of the Association if a few experiments were made by way of explaining to them what takes place.

In the first place, when oleate of mercury and iodide of potassium come together, double composition takes place, as indicated in the following equation:—

If the oleate and the ointment are slowly mixed, the greenish yellow colour of the mercurous iodide may be readily noticed.

In the second place mercurous iodide in the presence of potassium iodide (and the above proportions give an excess of potassium iodide) undergoes decomposition, the double iodide of mercury and potassium being formed and mercury liberated—

If the fat is washed out of the ointment the mercury will be formed. The next reaction that takes place results in the disappearance of the mercury in the free state. Though the few experiments I have had time to carry out are not conclusive on the point, still they indicate that the final change that takes place in the ointment is probably shown in the following equation:—

When the proportions of the oleate of mercury and the ointment of iodide of potassium are altered the reactions are gradually lessened as the proportions approach equality. Thus:—

II. Hydrarg. oleat. ʒii.
Ung. potass. iodid. ʒvi.

On mixing it assumes a bluish colour darker than the former. After a day or two yellowish green spots are seen on its surface. On further keeping it becomes yellowish white, darker than the former.

III. Hyd. oleatis. ʒiii.
Ung. potass. iodid. ʒv.

In this case the reaction is somewhat similar to II., except that the final colour is not yellowish white, but reddish yellow (a mixture of mercurous and mercuric iodides).

IV. Hydrarg. oleat.
Ung. potas. iodid. aa. ʒiv.

The bluish colour which is found on partially mixing is quickly changed to bluish green and finally to yellowish green (mercurous

iodide). The samples shown have been kept for nearly three months.

Mr. James McBain then read some "Random Notes from 'Macquer's Chemistry,'" which had been suggested to him when reading this old text book published in 1758. The notes dealt with many of the curious notions and explanations of chemical phenomena which prevailed at this early period, and cast an interesting light on some of the processes and names still familiar to pharmacists, such as liver of sulphur, salt of tartar, milk of sulphur, butter of antimony, sweet spirit of nitre, corrosive sublimate, red precipitate, etc.

The reading of the papers was followed by a discussion taken part in by Messrs. Cameron, Hay, Hill, McBain, and Sinclair, and on the motion of the Chairman a vote of thanks was awarded to the authors.

ENGLISH NEWS.

CASE OF COVERING BY A CHEMIST.—On Saturday the 11th inst. Mr. Justice Kennedy, in the Queen's Bench Division, gave judgment in the two actions *Butler and Crispe v. G. H. Doveton*, and *Idris Water Co. v. same*, which were argued before him on the last day the court sat before Christmas, as reported in the *Pharmaceutical Journal* for January 4 (p. 19). The plaintiffs in each case sued for a balance of account for goods supplied to a chemist's business carried on under the name of Christmas and Co., at 818, Holloway Road. The facts of the case were that the defendant, Mr. Doveton, was a mortgagee of Mr. Christmas, and on the death of the latter he took over the business in satisfaction of his mortgage, but, not being a registered chemist and druggist, he entered into an agreement with a Mr. Worfolk, a duly qualified man. By this Mr. Worfolk was to carry on the business under the name of Christmas and Co., he was to receive £2 2s. a week for his personal services, Mr. Doveton was to receive £2 10s. a week as interest on his capital, and then after the payment of all necessary expenses, including rates and taxes, the profits of the business were to be divided equally between Doveton and Worfolk. Mr. Worfolk's engagement was to be determinable on one month's notice, except in the event of certain favourable results in the way of profits being obtained, when it was only to be determined by Mr. Worfolk's consent. Whenever the agreement did come to an end, Mr. Worfolk was to leave on the premises stock to the value of £180. In his Lordship's opinion, Mr. Doveton was liable to pay for the goods supplied to Christmas and Co., the relation of the defendant to Mr. Worfolk being that of principal and agent. Under these circumstances, judgment would be entered for the plaintiffs in both cases. It was stated by Counsel that there were several other cases against the defendant, the total amount claimed amounting to some £160.

ALCOHOL IN HERB BEER.—On January 3, at Preston Police Court, John Hummersley, shopkeeper, of Marsh Lane, Preston, appeared to answer a summons for selling beer without having a retail licence.—Mr. Wallace Child, inspector of Inland Revenue, said the beer in question was herb beer, but when analysed it was found to contain 4½ per cent. of spirit, whereas it ought not to contain above 2 per cent. Defendant had previously been warned on an occasion when his beer had been found to contain close on 6 per cent. of spirit.—James Robbins, analyst from Somerset House, corroborated, and in answer to the Bench said an ignorant person might, in manufacturing these teetotal beverages, easily get 4½ per cent. of alcohol without having any guilty intention whatever.—Defendant was fined £2 10s., including all costs.

THE SALE OF CARBOLIC ACID.—An inquest was held on Friday afternoon, January 10, by Mr. J. A. Pearce (Borough coroner) at Burt's Falcon Hotel, Stoke, Devonport, into the circumstances attending the death of Charles Albert Budd Palmer, aged 47 years, a gunner serving on H.M.S. "Gorgon," coast defence ship at Devonport, who had died at 11, Higher Portland Road, Stoke, on the previous evening, after taking carbolic acid. The act was attributed to weakness of mind, caused by the effects of a sunstroke the deceased had two years ago at Bermuda, and the worry of his wife's long illness and recent death. The coroner, in summing up the evidence, said with regard to the poison it seemed a very absurd thing that some poisons should be scheduled according to Act of Parliament, and various other poisons, which anyone could get simply by asking, and would cause death quite as quickly as

those, were not scheduled at all. He was of opinion that all poisons or anything that would cause the death of a person, should be scheduled, so that there might be better precautions taken with regard to their sale. The jury returned a verdict of suicide by poisoning whilst temporarily insane.

SCOTTISH NEWS.

DEATH OF LORD BLACKBURN.—The death is announced on the 8th instant, at Doonholme, of Lord Blackburn, who was a Lord of Appeal from 1876 to 1886. The deceased judge will be known to pharmacists as one of the three law Lords before whom the case of the Pharmaceutical Society *versus* The London and Provincial Supply Association, Limited, was argued in 1880. It may be of interest now that the question of company trading is engaging the attention of the powers that be, to recall one or two passages in Lord Blackburn's judgment in the above *cause célèbre*. He held that "There could be no sale, whether a corporation be the ultimate vendor or not, unless a person—a natural person—manages the sale, and that natural person, if unqualified, would clearly become liable to the penalty under the Act." But he went further, and expressed himself as "strongly inclined to think" that the principle of *qui facit per alium facit per se*, might render a corporation liable to penalties under Section 15, if it caused an unregistered servant to conduct sales contrary to the Act. That is to say, that although a corporation cannot in its corporate capacity do an illegal act, it may be made liable for the performance of illegal acts by natural persons acting under instructions. It would be interesting to registered persons to see a case on these lines submitted to the courts. Lord Blackburn was in his eighty-third year.

IRISH NEWS.

BELLADONNA LINIMENT FOR WHISKY.—Mr. C. Friery, County Coroner, held an inquest at Coolock Police Barracks on January 7, regarding the mishap to Constable Sweeny, who came by his death by drinking a belladonna preparation in mistake for whisky. Constable Doherty deposed that he had used the liniment for lumbago, and left it on the mantelpiece in the day room on Saturday night, where deceased was sitting. Having occasion to leave the room for a little time he was alarmed on his return by finding Sweeny spitting in the hall and declaring he had taken poison. Witness immediately administered mustard and water, which caused copious vomiting. In about three-quarters of an hour later, finding Sweeny becoming unconscious he went for Father Mulqueen and immediately despatched another constable for a doctor. Dr. C. M. O'Brien deposed that on examination he found the deceased quite unconscious and breathing heavily, the breath smelling of belladonna, and the general aspect of deceased suggestive of acute poisoning from this drug. He administered emetics, antidotes, and stimulants, both by hypodermic needle and by the mouth. But the patient, though he recovered consciousness and rallied considerably for a time, ultimately succumbed. The jury found a verdict in accordance with the medical testimony, and expressed their satisfaction with the prompt measures taken by the police for the relief of their unfortunate comrade.

PHARMACEUTICAL SOCIETY OF IRELAND.—At the recent Pharmaceutical Licence Examination the following have passed:—Messrs. W. H. C. Baskin, D. O'Sullivan, C. Crowley, A. W. Mann, J. A. Doyle, J. Walsh, R. A. L. Wilson. Five were rejected. At the Preliminary examination the following candidates passed:—Miss C. M. Jessop, Messrs. T. W. Campion, J. D. Hunt; M. B. Widdess and J. P. E. Wright, equal; Miss M. K. McKnight; Messrs. J. Jennings and F. W. Warren, equal; T. Johnston; T. J. Anderson and M. Campbell, equal; W. Baxter, M. J. Monaghan, and E. B. Palmer. Nine were rejected. At the quarterly examination for the licence to act as registered druggist, held at Dublin, two candidates presented themselves, of whom one, Mr. R. J. Gore, passed. At an examination for the licence to act as registered druggist, held at Queen's College, Belfast, on Tuesday, the 14th instant, the following candidates passed:—Messrs. S. E. Alexander, D. Forde, I. Kirker, T. K. Scott. One candidate was rejected.

FOREIGN NEWS.

A REVOLUTION IN PHOTOGRAPHY.—According to the Vienna Correspondent of the *Standard*, the *Presse* for January 7, gives further details of the remarkable scientific discovery made by Professor Röntgen, of Würzburg University. "The Professor came upon his discovery quite by accident. He was experimenting in the dark with a Crookes' vacuum tube, which was covered with some sort of cloth. A strong electric current was passed through it, while close by there was some prepared photographic paper but no camera. On this paper the professor noticed next day several lines for which he could not account. By restoring exactly the circumstances as they existed on the preceding day, he was able to ascertain the real origin of these mysterious marks. He continued his experiments with the Crookes' tube and photographic paper, and found, in the first place, that not only may a camera be dispensed with, but that the image from the light rays of the Crookes' tubes is not obtained if it has to pass through lenses.

"By the use of these rays photographing is immensely simplified. There is the vacuum tube; in front of it is the object to be photographed, and immediately behind it is the prepared paper, in a wooden case, wood being transparent to these rays. An ordinary plate, whether wet or dry, must not be exposed to daylight until after fixing, because the ordinary light rays would act upon the silver or other compounds. But in the case of the Crookes' rays this difficulty does not exist, because the sensitised paper can be left in the wooden case, and, therefore, in complete darkness.

"That, however, is not all. The Professor found that these peculiar rays are not refracted, which is the reason for the inapplicability of lenses or the camera, and he further found by experimenting that they develop no heat, and that they are without any influence upon the most sensitive magnetic instruments. He also discovered that these rays possess this extraordinary peculiarity, that they do not travel in undulating waves, but by moving forward in a direct line. The theoretical interest attaching to this last peculiarity, if it be confirmed, is enormous. The first photograph of a human hand, showing only the bones and the rings on the fingers, was obtained by the Professor placing his own hand on the wooden case with the prepared paper, and allowing the rays from the Crookes' tube to fall directly upon it.

"There are already nine different Crookes' tube photographs in Vienna, the majority in the keeping of Professor R. Boltzmann, of Vienna University. This eminent Professor of Physics declares that the discovery of this "new light," as he terms it, will form an epoch in the history of science. He says that there are still certain obscure points that require clearing up; but, on the whole, he is not sceptical. The repetition of the experiment, however, has not yet been successful in Vienna; but this, it is said, is because the Crookes' tubes at the disposal of the experimenters here were not sufficiently large."

A correspondent of the *Standard* observes, in confirmation of Professor Röntgen's discovery, that he and a friend "have obtained distinct proof that the radiations in question do pass easily through various substances that are quite opaque to ordinary light, and do produce strong impressions upon ordinary photographic plates entirely incased in light-proof material. Indeed, all substances that we have so far experimented on in this laboratory appear to be transparent to these radiations, even sheets of ebonite, carbon, vulcanised fibre, copper, aluminium, and iron, though there is considerable variation in degree."

A later report states that Professor Klupathy, of the Physical Institute at the University of Pesth, has repeated, with very satisfactory results, the experiments made by Professor Röntgen. He was able to obtain pictures on a photographic dry plate enclosed in a wooden case, and has likewise photographed a larger part of the human body than the hand, obtaining pictures of the bones only, without their fleshy covering.

"Professor Röntgen has sent rays of the new chemical light through aluminium plates of one and a half centimetre in thickness, and they went as clean through as if the substance had been wood. The same was the case with two sets of books, including many volumes. These he placed between the Crookes' tube and an ordinary compass; behind them was the wooden case with the dry plate, and the result was as complete a photograph of the compass as possible. It is, perhaps, not strictly a photograph in the ordinary sense, because no lenses are used; it is not a negative, but a positive plate that is obtained. Hence some people are inclined to call such

a figure simply the shade of the object. It has not, however, up to the present, been found possible to get such a shade fixed."

THE "SOCIÉTÉ MUTUELLE D'ASSURANCE CONTRE LES ACCIDENTS DE PHARMACIE" has just published its annual report. This Society is under the patronage of the General Association of French Pharmaciens, and was founded in order to guarantee its members against pecuniary losses resulting from accidents caused by errors committed by members or their employés in the pursuit of their business. The entrance fee is twenty francs, and annual subscription five francs, these amounts constituting the reserve fund, from which all charges are paid. These charges (compensation, law costs, etc.) are totalled at the end of each year, and the amount levied in equal shares upon the members. During the past year only one case has occurred involving compensation. One of the members of the Society was prosecuted for having supplied salt of sorrel instead of Epsom salts, causing the death of a widow, who left four children without resources. He was condemned by the Tribunal to pay an annuity of 150 francs to each of the children until they attain their majority.

PRESENCE OF CUCUTINE IN THE ELDER.—The *Gazetta Chimica Italiana* says that .005 per cent. of cicutine has been extracted from the branches and leaves of the elder, by exhausting with acidulated water, precipitating with lead acetate, removing excess of lead by sulphuric acid, and then obtaining the alkaloid by means of Dragendorff's bismuth iodide reagent.

PROCEEDINGS UNDER THE PHARMACY ACTS.

SALE OF POISON BY AN UNREGISTERED PERSON.

The case of the Pharmaceutical Society v. E. C. Peacock was heard before His Honour Judge Bedwell, at the Hull County Court, on Wednesday. Mr. T. R. Grey, barrister, represented the plaintiff Society, and Mr. H. C. Hare appeared for the defendant.

Mr. Gray, in opening the case, said the defendant carried on business at 13, Barmston Street, Hull. On October 26, he sold a bottle of a preparation containing morphine. That bottle was labelled "The Mother's True Friend: for mothers and children." Then come instructions giving the amount to be taken, and following were the words "Prepared at Peacock's Drug Stores, 13, Barmston Street."

His Honour: "A blessing to mothers for infants and teething."

Mr. Grey (continuing) said the bottle contained a syrup in which there were morphine, Epsom salts, and dill water, the whole being coloured. It was most pleasing to the smell.

His Honour: You say it has a persuasive smell. Well (smelling it), there is a tone of dill water about it.

Mr. Grey said the syrup was carefully analysed, and found to contain as much as one-third of a grain of morphine in an ounce of fluid. There was 5½ ounces of fluid, and in that there was 17 grain of morphine. That amount of morphine was highly dangerous, and would certainly be fatal to infants. The dose for infants, mentioned on the label, ought really to be given, if at all, to adults, and would probably be fatal were infants to take it.

His Honour: Then if thirty drops is enough for an adult, two teaspoonfuls must be too much.

Mr. Grey: The analyst we will call will give you a scientific opinion on that.

His Honour: It may be important to ask what you have got to prove. Have you to prove the mere existence of morphine in the bottle? If you have to prove that the existence of the morphine would be fatal, that seems a different matter altogether. On all previous occasions I have had simply to decide on the aye or nay: is the stuff in the bottle a poison?

Mr. Grey: What I contend is we have only to prove that it is harmful.

Ida Mitchinson, fourteen years old, proved going with her father to Peacock's Drug Stores on October 26 last and purchasing a 1s. bottle of "Mother's True Friend."

John Mitchinson said that in consequence of instructions from the Pharmaceutical Society he got his daughter to purchase a bottle of "Mother's True Friend" from Peacock's Stores. She handed the bottle and its contents to him when she came out of the shop, and he then sealed it.

Harry Moon, clerk in the office of the Registrar of the Pharmaceutical Society, said he received the bottle and its contents from

the last witness on. October 28 and retained it in his possession until November 7, when he handed it to the analyst.

Ernest John Eastes, Fellow of the Institute of Chemistry and Demonstrator of Practical Chemistry to the Pharmaceutical Society, said he received the bottle (produced) from the last witness. It was then sealed up. He made a careful analysis of the contents of the bottle, and found it to contain a syrup containing morphine and Epsom salts, flavoured with dill water. The bottle contained $5\frac{1}{2}$ fluid ounces. It was full. There was nearly a third of a grain of morphine to each ounce of fluid, and in the whole mixture $1\frac{7}{10}$ ths of a grain. As to the risk of danger from the contents of the bottle it would depend on the quantity taken. If the whole were taken the results would be very serious. The result of a child taking the whole would undoubtedly be death. If it took half the result would be the same. There was enough in the bottle to kill two grown-up persons. A very much less quantity than a quarter of the contents would kill a child.

Cross-examined, witness said he made a careful analysis of the contents of the bottle. There was very much more than an eighth of a grain per fluid ounce in the mixture. If the whole contents were taken it would be death even to an adult. That he said seriously. He based his opinion on this, that $\frac{3}{4}$ of a grain of morphine was the smallest fatal dose for an adult. If there was an amount of antimony wine mixed with the morphine it would not have the effect of destroying the action of the morphine. A large dose would act as an emetic. He would not say there was no antimony wine in the bottle. He should be very much surprised to hear that, although thousands of bottles have been sold, there had never been any complaint of injury received.

Mr. Grey here put in the Register of Chemists and Druggists to prove that the defendant's name did not appear on the Register.

Mr. Hare asked His Honour to non-suit the Society on the ground that Mr. Grey had not proved sale by the defendant.

Mr. Grey: My case is for selling or keeping open a shop.

Mr. Hare: I contend that if sold by an assistant the assistant would be liable, and not the defendant.

Mr. Grey: The assistant is liable, and also the owner of the shop.

His Honour: I rule against the non-suit.

Mr. Hare said that although the defendant admitted there was a quantity of morphine in the mixture, there was not the quantity mentioned by Mr. Eastes—nearly one-third of a grain to a fluid ounce. Mr. Peacock in the measuring and mixing was careful not to put more than one-eighth of a grain to a fluid ounce in the mixture, though the mixture contained antimony wine, which would, in the event of an overdose or an attempt at poison, prevent ill effects, because it would act as an emetic. Then there was the fact that the defendant had been trading in this particular syrup for a considerable time, and had sold some thousands of bottles; and it was somewhat singular that during the whole of the time there had been no complaint or suggestion that any injury ever occurred to any patient—adult or juvenile—who had been in the habit of taking it. Under these circumstances His Honour had the discretionary power to say whether the poison was in such a limited quantity as to be safely administered to adults and infants.

E. C. Peacock then gave evidence bearing out Mr. Hare's statement of the defence, and added that on an average he sold two gallons per week, and he had sold it for twelve years. He sold it loose, and he sold it in bottles. He had never had any complaint. It was impossible for it to kill.

By Mr. Grey: He had no profession; he kept a drug store. He had a little knowledge with regard to drugs. He had never heard of Dr. Stevenson, the celebrated analyst, and did not think it possible for a hundredth part of a grain of morphine to kill an infant. For selling "Mother's True Friend" on December 13, 1894, he paid a penalty of £5 to the Pharmaceutical Society. He remembered paying penalties for two bottles—one sold on February 16, and one on March 2, 1895. He called morphine "Mother's True Friend." On May 29 and June 22, 1895, he again sold two bottles of the same mixture, and was again proceeded against in the Hull Court, and again he paid the two penalties without going into Court. Altogether he had paid £25. He was induced to test this case by seeing a report of a case heard in Scotland, and because he saw that the President of the Pharmaceutical Society had said that less than an eighth of a grain of morphine was not poison. He was, however, unable to produce any corroboration.

Mr. Grey: I am instructed that the President of the Society never made such a statement.

His Honour gave judgment for the plaintiffs, and said the penalty must be £5 with costs.

LEGAL REPORTS.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT.

THE COLOURING OF GREEN PEAS.

At Southwark Police Court, on Wednesday afternoon, a case was part heard before Mr. Fenwick, with regard to the alleged injurious effects of the use of copper sulphate in the preservation of vegetables. The case was that of A. A. Grist, Sanitary Inspector of St. Saviour's District Board of Works, against Mr. H. C. Summers, trading as George Mence Smith, at High Street, Borough, and also many other places, for selling preserved peas mixed or coloured with an ingredient injurious to health, viz., $\frac{8}{10}$ ths of a grain of copper per pound of peas, whereby the defendant became liable to a penalty of £50.

Mr. Frank Dodd, barrister, who appeared for the parish, stated that the summons was taken out under Section 3 of the Adulteration of Food and Drugs Act, 1875. The question to be decided was whether or not some preserved peas sold by the defendants were so coloured or stained as to render the article injurious. From the analyst's certificate it appeared that the quantity of metallic copper found in the peas was equal to 3.16 grains of sulphate of copper per pound of peas. He contended that chronic poisoning might result from a constant use of the peas. The chief object in introducing the copper into the peas was to give them their original green colour.

Mr. A. A. Grist was called, and stated he was the Sanitary Inspector for the St. Saviour's District Board of Works. On September 4 he sent his daughter into the defendant's shop for a bottle of preserved peas. When he had received them he returned to the shop and informed the defendant that they were for the purposes of analysis, and divided them in the usual way. He produced the analyst's certificate.

Miss Margaret Grist, daughter of the first witness, gave evidence as to procuring the peas.

Mr. Bodmer, public analyst, stated that he had examined the peas and found copper to the extent of $\frac{8}{10}$ ths of a grain to a pound of peas. The $\frac{8}{10}$ ths of metallic copper would amount to 3.16 grains of sulphate of copper. Witness not being a medical man was unable to give an opinion that the copper would be injurious to health.

Mr. Bonsey, barrister, who appeared to defend, cross-examined at great length, and during the cross-examination it was stated that in Paris in 1882 the Board of Health put restrictions on the use of copper in preserving peas and other vegetables, but in 1889 the French Government took off the restrictions. The peas in question were called *petits pois Anglaise*. Mr. Bonsey also referred the witness to several authorities, all of whom consider that the small amount of copper introduced is not injurious to health.

Evidence was also given by Dr. Leonard Wylde, M.R.C.S., Medical Officer to the Bedfordshire County Council; Dr. F. J. Waldo, Medical Officer of Health, St. George the Martyr, Southwark, Dr. Somerville and Dr. Herron, Medical Officer of Health, St. Saviour's, all of whom expressed an opinion that the use of preserved peas coloured with sulphate of copper would be attended with injury to health. Mr. Bonsey, in cross-examination of the witnesses, produced several books written by eminent doctors, whose opinions differed from those of the witnesses. The case for the prosecution was then concluded.

Before counsel addressed the magistrate for the defence, it was agreed to take the evidence of Dr. Burney Yeo, Physician to King's College Hospital, who gave his opinion that the amount of copper present in the peas would not be injurious to health.

Reference was made in the course of the proceedings to a previous adjournment of the case which had been taken for the purpose of procuring an analysis at Somerset House. It appeared that the result of that analysis had now been received, and that it showed only .461 grain of copper as against the public analyst's certificate of $\frac{8}{10}$ ths of a grain. On inquiry, however, it appeared that this analysis might have been somewhat vitiated by the fact that the sanitary inspector conveyed the material to Somerset House in a tin vessel. The inquiry was again adjourned.

NOTICES TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally, must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

ANSWERS.

"V. L."—It is difficult to say with certainty, but probably *Veratrum viride*. There is reason to doubt whether much *V. album* is in the market, and *V. viride* is often substituted for it.

"S. A."—Why not use alcohol in the form of rectified spirit, the taste and odour of which are more easily masked?

"Bromo."—Full information on the subject will be supplied by the Registrar of the General Medical Council on application. Address your inquiry to the Medical Council Office, 299, Oxford Street, London, W.

L. B. PRAGNELL.—Your idea is a good one, but not absolutely novel, being already represented by the well-known method of producing so-called "Russian vignettes." Perhaps, however, if you were to re-write the article more fully, and on one side of the paper only, it would be accepted by the editor of the *Amateur Photographer* or some similar paper.

"BIENVENU."—You have omitted to add your name and address.

"STUDENT."—1. The best way of preparing for the examination in practical botany and materia medica is to learn practically how to cut sections by hand, and apply appropriate reagents to differentiate the various tissues, cell-contents, etc. Use Cross and Cole's 'Modern Microscopy' (Baillière, Tindall and Cox, 3s. 6d.) and Bower's 'Practical Botany for Beginners' (Macmillan and Co., 2s. 6d.). Also study the articles on practical pharmacognosy published in the *Pharmaceutical Journal*, volumes xxiv. and xxv. No particular book is used in the class you refer to. 2. Uncertain as yet. 3. The other matter you refer to does not rest with the Editor.

"LIN. SAPONIS."—The matter is receiving attention.

QUERIES.

"LAVENDER" asks for the formula for "Hay's Wash" or "Hay's Lotion." He also desires to know where it was originally published, and who was "Hay."

D. S. C. REID asks for the addresses of French makers of "screw feeders."

PUZZLED asks if any light can be thrown on the third ingredient of the following prescription:—

R. Tr. ferri sesquichl.	ʒiij.
Liq. strych.	ʒxxiv.
Solut. sodæ minor	ʒiij.
Aq. ad.	ʒvi.

OBITUARY.

HALL.—On December 30, at his residence, Queen's Road, Finsbury Park, Thomas Howard Hall, Pharmaceutical Chemist. (Aged 56.) Mr. Hall was a life member of the Society, with which he had been connected over thirty years, and in the work of which he manifested considerable interest. When, in 1889, the representation of the Society in London by divisional secretaries was decided upon, the Council selected Mr. Hall to take charge of the Parliamentary Division of East Islington, and he held the position until his death, though his long illness had necessarily precluded any active participation in pharmaceutical matters for some time previously. Those who knew the deceased gentleman will recall his unassuming manner and amiability of character, and will regret his somewhat untimely death. He was practically helpless for the last fifteen months of his life, and the progressive paralysis from which he suffered had for a long time before that put a period to his pharmaceutical work. Mr. Hall leaves a widow and two young children.

COCKSEGE.—On Friday, January 3, H. B. Cocksedge, Pharmaceutical Chemist, Sandown, Isle of Wight. (Aged 80.) Mr. Cocksedge was a candidate for the post of Secretary and Registrar of the Pharmaceutical Society, at the time Mr. Elias Bremridge was appointed, the latter gaining the appointment by a single vote.

BAINES.—On December 24, John Baines, Chemist and Druggist, late of Corsham. (Aged 73.)

APPLEGATE.—On January 1, Edwin Applegate, Pharmaceutical Chemist, Islington. (Aged 65.)

HUMPHRIES.—On January 6, Jacob Humphries, Chemist and Druggist, Bradford. (Aged 36.)

WHITE.—On January 7, Luke Pearson White, Pharmaceutical Chemist, Penistone. (Aged 72.)

LOWE.—On January 7, John Lowe, Chemist and Druggist, Woolwich. (Aged 80.)

GARBUTT.—On January 11, James Garbutt, Chemist and Druggist, Wellingborough. (Aged 80.)

DAVIDSON.—On January 13, T. R. Davidson, Chemist and Druggist, Morpeth.

POISONING CASES AND INQUESTS.

Chlorodyne.—Dr. Charles Palé, aged 52, of 38, Keppel Street, Russell Square, Bloomsbury, died on January 6, from the effects of an overdose of chlorodyne taken to assuage internal pain. Verdict: "Death by misadventure."

Laudanum.—Ellen Slack, aged 53, of Docking Hill Road, Doncaster, died on January 7, from the effects of drinking an overdose of laudanum. Verdict: "Died from opium poisoning," but as to the circumstances under which it was taken there was not sufficient evidence to show.

Paregoric.—Margaret Isabel Biddulph, aged 14 months, daughter of J. A. Biddulph, of 12, Red Lion Mews, Camberwell Gate, died on January 3, from the effects of an overdose of paregoric. Verdict: "The cause of death was congestion of the lungs probably accelerated by an overdose of opium."

Belladonna and Aconite.—Edith Padgett, aged 2, the daughter of William Padgett, 1, Mission Place, Grantham, died on January 2, from the effects of belladonna and aconite contained in a liniment administered by her mother in mistake for medicine. Verdict: "Death through misadventure."

Laudanum.—Rose Allen, a widow, of Buxton, died on January 3, from the effects of an overdose of laudanum, taken for neuralgia. Verdict: "Death from an overdose of laudanum taken accidentally."

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Annesley, Austen, Blackburn, Bindloss, Bentley, Bird, Burge, Brown, Channock, Cory, Davies, Davis, Fairley, Faraday, Ferral, Forret, Gadd, Griffin, Gayer, Howorth, Howard, Holloway, Jarvis, Jast, Morrells, Macdonald, Melckebeke, Mackenzie, Owles, Pragnell, Parke, Proctor, Rymer, Reid, Robinson, Russell, Ross, Smith, Sawyer, Salter, Stratton, Thompson, Walker, Wall, Williams, Wyatt, Wood, Wardleworth.

ARISTOLOCHIA ARGENTINA.*

BY DR. O. HESSE.

Some twenty years ago several varieties of *Aristolochia* were chemically examined, without any well-defined substance being obtained from them beyond a yellow bitter or acrid resin. Walz† gave to products of that nature from the root of *Aristolochia clematis* the names aristolochic acid ($C_{11}H_{16}O_3$) and clematitin ($C_9H_{10}O_6$), but did not obtain these substances in a state of purity or further study them. The latter substance was probably identical with the serpentarin or aristolochin, which Chevallier‡ obtained from the root of *Aristolochia serpentaria* as the poisonous constituent. Frickinger§ subsequently obtained from the young underground shoots of *Aristolochia clematis* a substance crystallising in small amber-yellow needles, which he named aristolochia yellow, but the individuality of the substance was not established. Not long ago Dymock and Warden|| examined *Aristolochia indica*, and obtained from it a yellowish or brown resin of a basic nature. The publication of their results induced me to make known my investigation of *Aristolochia argentina*¶ so far as it had gone, showing the presence of an ester, probably palmityl phytostearin, an alkaloid—aristolochine—and a yellow crystalline body—aristin. At that time I was unaware of the publication by Pohl of investigations of various species of aristolochia, describing a finely-crystalline yellow substance under the name of aristolochine. As that substance is, in fact, of an acid nature, it will be desirable to call it aristolochic acid, and thus avoid a confusion with the alkaloid to which the name is more properly applicable. Since that time I have continued my investigation with a larger supply of material, and now give the results obtained.

ARISTOLOCHINE.—On extracting the roots with alcohol after treatment with soda a considerable quantity of brown resin is obtained after distilling off the alcohol. This was treated with solution of sodic carbonate and extracted with ether. On shaking the ether solution with dilute tartaric acid, the alkaloid is separated and the yellow acid solution can be decolorised by charcoal without much loss. Addition of ammonia gives a flocculent precipitate of the base, which is readily soluble in ether, and on evaporation a colourless residue is obtained, which shows distinct crystallisation. In alcoholic solution aristolochine turns litmus paper blue; it completely neutralises acids, but the salts are amorphous. A solution of the hydrochloride gives amorphous precipitates with potassium iodide or sulphocyanide. The platinum salt is also amorphous. Strong sulphuric acid dissolves the base with dark green coloration passing into blue-green on addition of ferric chloride. An accident prevented me from making an analysis.

* Translated from the *Archiv der Pharmacie* for December, 1895.

VOL. LVI. (FOURTH SERIES, VOL. II.). No. 1335.

INDIFFERENT SUBSTANCE.—When atmospheric air containing ammonia is passed through an ether extract of the crushed roots, the liquid, after becoming yellow and turbid, deposits a red crystalline mass. When that is at an end the ether is shaken with acid to remove ammonia and any trace of aristolochine. On distillation an oily greenish-brown residue remains, which yields a copious crystallisation of palmityl phytostearin, $C_{42}H_{74}O_2$, melting at 82° C., and associated with it is a minute quantity of a crystalline body—aristolin—which has a composition represented by the formula $C_{15}H_{28}O_3$, and is probably an alcohol, though the quantity at my disposal did not admit of further examination.

ARISTINIC ACID ($C_{18}H_{13}NO_7$).—The red deposit from the ammoniacal ether extract consists for the most part of the ammonia salt of this acid. After purification the acid forms greenish-yellow laminae and needles, melting at 275° C. with decomposition. It has a disagreeable bitter taste, and reddens litmus paper. It is sparingly soluble in ether, chloroform, benzene, and hot alcohol, and almost insoluble in water. Strong sulphuric acid dissolves it slowly, with a fine green coloration increasing on the application of heat, especially in the presence of a trace of ferric acid or molybdic acid. When heated with strong caustic potash no ammonia is evolved, but as the solution becomes concentrated the potash salt separates as a carmine-coloured mass.

ARISTIDINIC ACID ($C_{18}H_{13}NO_7$).—This acid remains in the acetic acid solution from which aristinic acid has been separated in purification, being more soluble in hot glacial acetic acid than aristinic acid is. It is soluble in ether, and crystallises in small needles. In dilute caustic potash it dissolves with yellowish-brown colour, and on adding more potash the salt separates as a dark red amorphous precipitate.

ARISTOLIC ACID ($C_{15}H_{16}NO_7$ or $C_{15}H_{11}NO_7$).—The alkaline liquor from which the two previously described acids have been separated gives, on addition of hydrochloric acid, a yellow flocculent precipitate, which is shaken out with ether, and is obtained on evaporating the ether as an orange-yellow crystalline residue, soluble in hot alcohol, and crystallising in small yellow needles as the solution cools. The crystals darken at 220° , and melt between 260° and 270° C. The potash salt is more soluble than those of the acids above described. The acid dissolves in strong sulphuric acid with dark green colour, a character which indicates relation to the other acids and also to the aristolochin or aristolochic acid of Pohl, and probably these substances are related to each other as follows:—

Probably the clematin of Walz and the aristolochin or serpentarin of Chevallier were nothing more than impure aristolochic acid, though the crystalline aristolochia yellow of Frickinger forming amber-yellow prisms may be a different body from it and from the acids above named, as their yellow colour is more intense than the term amber-yellow denotes.

The substances above described probably exist to a greater or less extent in other varieties of the genus *Aristolochia*, as I have previously suggested (*Pharm. Journ.* [3], xxii., 551), but in the roots of *Aristolochia longa* I have not been able to detect either the alkaloid aristolochine or any other base, nor yet aristinic, aristidinic or aristolic acids.

PROCEEDINGS UNDER THE PHARMACY ACTS.

THE SALE OF ARSENICAL FLY-PAPERS.

Bloomsbury County Court, January 21.
BEFORE HIS HONOUR JUDGE BACON.

Pharmaceutical Society v. Walton, Hassell, and Port.

In this case Mr. Grey appeared for the plaintiff; Mr. Danckwerts for the defendants.

Mr. Grey, in opening the case, said: This action is for a penalty incurred by the defendants for selling or keeping open shop for the retailing, dispensing, or compounding poisons contrary to the Pharmacy Act, 1868. The defendants are in a large way of business, and amongst their other shops they have one at 244, Brixton Road; and there, on July 15 last, they sold twenty-five what are called fly-papers for the sum of 8*d.* Those fly-papers were analysed, and the result of the analysis is certainly most startling; because in one of those twenty-five papers—No. 2, I think—they are all numbered—there was as much, I believe, as 12·9 grains of arsenic, and on the average, in the twenty-five, I think I shall be right in saying there were 8 grains of arsenic in each. Besides being analysed by Dr. Paul, they were also analysed by Dr. Stevenson, and I understand there was a joint analysis, so that there will be hardly any, if any, question as to the amount of arsenic contained in these papers; therefore, the twenty-five papers which were sold for 8*d.* contained as much as 200 grains of this most deadly poison arsenic, and the question which will be before your Honour to-day is whether the sale of these fly-papers comes within the Pharmacy Act of 1868. I will draw your attention to the label. I hold in my hand now one of these fly-papers, and you will find printed on it these words—"Mather's chemical fly-paper for poisoning flies, wasps, ants, mosquitoes, etc. Directions for use for flies, wasps, ants, mosquitoes, etc.: Spread each paper on a dish or plate and keep moist with cold water two or three times a day; remove the tray or dish beyond reach of children and out of the way of domestic animals." The reason, as we will prove before you, why the papers should be moistened is that nine-tenths of the arsenic in the paper is extracted on the application of cold water. So that the fluid which is given off from the paper is of the most deadly and poisonous character, containing quite nine-tenths of the arsenic which is originally put into the fly-paper. The Act under which we are suing is the Act of 31 and 32 Vict, c. 121. There it sets out the object of the Act in the preamble. It is an Act to regulate the sale of poisons and to alter and amend the previous Pharmacy Act:—"Whereas it is expedient for the safety of the public that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists should possess a competent practical knowledge of their business, and to that end, that from and after the day herein named all persons not already engaged in such business should, before commencing such business, be duly examined as to their practical knowledge, and that a register should be kept as herein provided." Then Section 1 says:—"It shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title 'Chemist and Druggist' or Chemist or Druggist or pharmacist, or dispensing chemist or druggist, in any part of Great Britain, unless such person shall be a pharmaceutical chemist, or a chemist and druggist, within the meaning of this Act, and be registered under this Act." Then Section 2, which defines what poison is under the Act, says:—"The several articles named or described in the Schedule A shall be deemed to be poisons within the meaning of this Act. Arsenic—the article contained in these fly-papers—is one of the articles named in the Schedule.

The Judge: There is not the slightest doubt, if there is an appreciable quantity of arsenic, it is within the Act if arsenic comes within Part I. of Schedule A.

Mr. Grey: If it comes within Sections 1 and 15 of the Act. Then the only other section I need refer you to in this case is Section 13, which makes the Register—which I put in before you—evidence. The Section says, "the absence of the name of any person from such printed register shall be evidence, until the contrary shall be made to appear, that such person is not registered according to the provisions of the Pharmacy Act, or of this Act." I do not think in

this case that point will be contested. Section 15 is the important section, and it provides that "any person who shall sell—," etc.

Mr. Danckwerts: It may, perhaps, shorten the case very considerably if I say that, after it has been proved what this fly-paper contains—and of course I want to see the analyst in the box to prove that—I think the question will be for you to decide whether, sold in the shape in which it is sold, it comes within the provisions of the Act.

The Judge: Do you question the analysis, that it contains enough poison to kill anybody—a packet of these papers?

Mr. Danckwerts: A packet.

The Judge: You at any rate want to ask some questions.

Mr. Danckwerts: I want to ask the analyst certain questions, and I want to put certain evidence before you as to matters of common knowledge, which must be borne in mind in construing the Act. I think the action is really a test case in order to try a question which will affect not only fly-papers but the daily life of the British public to an unlimited degree.

The Judge: I am told that half the green colours in wall-papers and posters contain arsenic. Persons who sell wall-papers will not be chemists.

Mr. Danckwerts: I think we should both agree that we would like your Honour to take a note of the evidence.

The Judge: I assumed that. I had begun by writing down the heading of the case. I assumed you would want a note.

Mr. Danckwerts: It may perhaps save you trouble if I tell you that a shorthand note is being taken.

The Judge: No; that is no use to me at all. The Queen's Bench Division will not look at it.

Mr. Danckwerts: Yes, they do. They did so in a case which I argued quite recently before Commissioner Kerr.

The Judge: He is a little difficult to get to take a note, is he not?

Mr. Danckwerts: Not now. I think he has become perfectly amenable on that point.

The Judge: However accurate a shorthand writer's note is, I should have to go through it to be sure it is right. I will take a note. I never object to take a note, although I never do it unless I am asked.

Mr. Grey: That being the case the shortest way will be to refer you at once to cases which have been tried lately under the Act. I have drawn your attention to the Sections of the Act, and especially Section 15. There is only one other matter that I wish to draw attention to—with reference to Section 17—viz., that arsenic comes in Part I. of the Schedule. Therefore, even if it is sold by a chemist or druggist, he has to do certain things. It is unlawful for him to sell any arsenic "to any person unknown to the seller, unless introduced by some person known to the seller; and in every sale of any such article the seller shall, before delivery, make or cause to be made an entry in a book to be kept for that purpose, stating in the form set forth in Schedule F to this Act, the date of the sale, the name and address of the purchaser, the name and quantity of the article sold, and the purposes for which it is stated by the purchaser to be required," besides labelling it "poison." Therefore, of course, if arsenic can be sold in the shape of fly-papers, and the Act does not apply, these fly-papers can be sold by anybody and to anybody; no trace can be obtained of them, and arsenic can be sold in this large quantity, whereas if it comes within the Act all these things have to be done to safeguard the public from the sale of the poison arsenic. The last case I will refer you to as being the most important is *The Pharmaceutical Society v. Armon*, which, as you are aware, went up to the Court of Appeal, and I have the report of that case here.

The Judge: What was the medicine there?

Mr. Grey: In that case it was Powell's Balsam of Aniseed. The case is reported in 1894, II. Queen's Bench, p. 720. The headnote is "The prohibition in Section 15 of the Pharmacy Act, 1868, against the sale of poison by other than registered chemists, is not confined to the sale of the scheduled poisons in their simple state, or of preparations of such poisons, but extends to the sale of a compound containing a scheduled poison as one of its ingredients." That was the case of Powell's balsam of aniseed, which contained one-tenth of a grain of morphine. The Master of the Rolls, in his judgment, on page 723, makes use of this expression: "It is said that the defendant did not sell a poison mentioned in the Schedule, because, though nothing has been done to it which alters its chemical nature, it had been mixed with other things. Does that, in

ordinary language, make it not poison? Does poison put into a bottle of wine cease to be a poison? Or does poison put into a cup of tea cease to be a poison? It is clear that when poison is put into a medicine, and a person sells the medicine, he sells the poison that is in it. There is nothing in the Act of Parliament, that I can see, reading it in its ordinary language, which says that you may sell a poison mixed with other things, though you may not sell poison by itself." Then I will not read what was said about the argument with regard to *de minimus non curat lex*, because that cannot be raised in this case if my case is correct.

Mr. Danckwerts : I do not suggest that.

The Judge : If your analysis is right.

Mr. Grey : Well, 2 grains is a fatal dose for an adult, so that settles the point. I understand that my friend does not contend that point. The real point is, does the Act cover fly-papers? That is shortly the point. Then Lord Justice Kay says, on p. 725 : "Therefore, anybody who sells opium, or any preparation of opium or poppies, is selling that which by this Act no one can sell without incurring a penalty, except a pharmaceutical chemist or a chemist and druggist within the meaning of the Act." Lord Justice Smith also says : "But it is said, Oh, he did not sell the poison *per se*, for he sold it together with something else!" Supposing a man filled up a bottle half with chloroform, which is one of the prohibited poisons, and the other half with water, and sold it, does he not sell chloroform? Of course he does—he sells chloroform and he also sells water ; and the prohibition is that he is not to sell chloroform unless he be a chemist. It seems to me there is a direct prohibition in this Act against other than legalised persons selling poisons ; the present defendant has sold a poison, and is within the meshes of this Statute." Then, your Honour, there is also the case of the Pharmaceutical Society *v.* Piper ; but I do not think that carries the case any further. This, of course, is a higher authority.

The Judge : What was that—chlorodyne ?

Mr. Grey : That was the case tried before your Honour, and the Court approved your Honour's decision in that case. That went up to the Divisional Court, and was not pursued further. Then, as I understand, my friend Mr. Danckwerts who appears for the defendants, does not desire me to do anything beyond proving the analysis.

The Judge : If Mr. Danckwerts does not succeed, do you mean to appeal this and to take it to the highest Court ?

Mr. Danckwerts : Very likely. I admit that the fly-papers have been analysed by an analyst in conjunction with Mr. Bevan, and that they were bought at my clients'. I will admit that my clients have no qualification.

The Judge : Then you had better prove your analysis.

Mr. Grey : Then I understand the analysis is all I have to prove in this case at present ?

Evidence for the Plaintiff.

Dr. Benjamin Horatio Paul, sworn, examined by Mr. Grey.

The Judge : What University do you belong to?—Geissen.

Mr. Grey : Are you a consulting chemist and a commercial analyst?—Yes.

Did you on January 1 receive certain fly-papers?—Yes.

Whom did you receive them from?—Mr. Partridge.

The Judge : I understood Mr. Danckwerts to admit that the papers submitted to the doctor were bought at defendants' shop.

Mr. Grey : Yes, I should have saved your Honour's time by omitting this.

Mr. Danckwerts : It is perhaps better to have a short note on it.

The Judge : I will put down the admission that the defendants are not qualified to sell poisons ; that these papers which were submitted to Dr. Paul were sold by the defendants.

Mr. Danckwerts : I am obliged to your Honour.

Mr. Grey : How many fly-papers were originally handed to you?—Twenty-five.

How many have you got before you? You gave three, I believe, afterwards to Dr. Stevenson, did you not?—I have eleven.

Did you number those fly-papers?—Yes.

Did you make a careful analysis of those fly-papers?—Yes.

What was the result of the analysis? I understand there has been a joint analysis?—Yes.

As well?—Yes.

Whom did you make this joint analysis with?—Mr. Bevan.

Mr. Bevan, on behalf of the defendants?—Yes.

Did you agree as to that analysis?—We did.

Now, will you tell me the result?—The result of my own experiments?

How many fly-papers did you analyse in the joint analysis?—Four.

Which four were those?—Numbers 5 to 8.

First of all, with regard to 1 to 4, you made an analysis of your own, I understand?—I did.

What was the average? What did you find in those papers?—The average quantity of arsenic was 8 grains per paper.

Mr. Danckwerts : Per piece of paper?

Mr. Grey : Per fly-paper.

Mr. Danckwerts : Will you call it a sheet?

The Judge : It was a packet of so many fly-papers. It will be each paper.

The Witness : 8 grains ; that was the average.

Mr. Grey : This is 1 to 4 you are stating now, are you not?—I am giving you now the result of the analysis that I made myself.

One to 4, is that?—Yes ; 1 to 4.

What was the amount you found in any one paper of those four?—Nearly 13 grains.

Let us come to the ones that you analysed jointly with Mr. Bevan. What was the result of the analysis of those?—11 grains and a fraction.

Mr. Danckwerts : Nearly 13, did you say?—Yes.

Are you sure?—Yes.

Mr. Grey : These are the ones numbered, I understand, from 5 to 8?—These are 5 to 8.

You analysed them with Mr. Bevan?—Yes.

And you say the average amount of arsenic in those fly-papers was 11 grains?—11 grains.

The Judge : And a fraction?

Mr. Grey : And a fraction?—11.1 it really was.

What was the largest amount you found in any one of those papers?—Those were not analysed separately ; they were taken together, mixed.

What is that you have before you?—This is the remainder.

The Judge : Is that the arsenic?—No ; this is the remainder of the papers.

After the arsenic is taken from it?—Before the arsenic is taken from it. It contains such a large quantity of arsenic that it was necessary to take only a portion of the paper for an accurate analysis.

Mr. Grey : What is the result if you follow the directions on this fly-paper? I am referring to the words "keep moist in cold water two or three times a day."—The arsenic contained in the paper is dissolved by the water.

How much of the arsenic is extracted by cold water?—The greater part of it.

Cross-examined by Mr. Danckwerts :—

You are a commercial analyst, you say?—Yes.

You are, no doubt, therefore thoroughly well acquainted with the articles of commerce?—Yes.

In the first place you tell me the quantities that you have given have been obtained by means of the hot water test?—Yes.

Boiling water?—Warm water.

Answer the question, please. I suppose you only come here to give us information?—Yes.

Would you mind answering without waste of time?—Will you repeat the question?

Your quantities were obtained by means of the boiling water test?—No, they were not.

None of them?—No.

The Judge : Warm water?—Warm water.

Mr. Danckwerts : You, of course, as expert, would obtain more from fly-papers than somebody who was not an expert?—No.

You do not think so?—No.

The Judge : It depends on how the expert tests it.

Mr. Danckwert : Yes. I mean an uninstructed person would not obtain the same quantity of poison from the paper as you got?—I think they would.

That is to say if they pursued the same method you did?—I think he would anyhow, putting it in water.

The Judge : Did you only soak them in water, and so find the arsenic?—Merely water ; it is perfectly soluble in water.

In what form did you obtain the poison?—In the form of ammonium-magnesium-arsenate ; that is a compound of arsenic acid, ammonia, and magnesia.

How would you describe that with reference to arsenic?—I should

describe it as arsenic in reference to the terms of the Pharmacy Act.

I did not ask you that.—Will you put your question more definitely, and I will answer more definitely?

The Judge: Do you mean you got 11 grains of arsenic pure?—Arsenic pure.

Without having discharged or got rid of the ammonia and magnesia?—I will explain it to your Honour.

How much pure arsenic did you obtain on an average?—Eight grains for each paper.

Then the ammonia and magnesia were in addition?—Added on. The arsenic as it exists in the paper cannot be got out for the purposes of analysis with accuracy because there is colouring matter mixed with it which would interfere with that result. It has to be transformed into arsenate of ammonium and magnesium, a definite substance which represents the arsenic which is in the paper.

Is it possible by any process after that to separate the ammonia and magnesia from the arsenic?—It could be separated, but it is weighed in that state. That is the actual thing got out from one of the papers.

Mr. Danckwerts: As I understand, what you procured was a mixture—a chemical mixture or a mere physical mixture.—A chemical compound—a well-known, definite, chemical compound.

Was what you obtained a chemical compound or a mere physical mixture?—A definite chemical compound.

So that what you obtained was not arsenic?—Yes, it was arsenic.

You have just told me it was a chemical compound of arsenic, ammonia, and magnesia.—Properly called arsenic.

Pure arsenic?—Pure arsenic? I do not know what you mean by pure arsenic. Arsenic is a general term not only for this substance but for any compound of this substance.

Very well; if I get arsenic and mix it with flour the result, according to you, is arsenic?—No, it is a mixture.

Is every chemical substance arsenic, according to you, that contains arsenic?—Not every one, but specific ones.

Which are they?—Arsenous acid, arsenic acid, arsenites, and arsenates.

Under which of those heads did your chemical compound come?—Arsenate.

Did you try to separate the ammonia and the magnesia?—No. You did not?—I had no occasion to.

Why not?—Because I wanted it to remain there.

I just want to understand your evidence if I can?—I will endeavour to make it clear.

Did you say that all arsenic compounds are arsenic within the meaning of the Act?—Yes, the one that I have given you specifically.

What do you understand by a preparation of arsenic?—A preparation of arsenic I should understand to mean a medicinal preparation containing arsenic.

A mixture?—It might be a mixture; it might be a compound, but a medicinal article.

I suggest to you by a preparation of arsenic is meant a chemical preparation of arsenic?—Well, I do not agree with that.

You do not?—I do not.

You said you were educated at Geissen?—Yes.

That is a German University, is it not?—It is.

Are you a German?—No.

Are you English—you understand English?—Rather.

Having obtained this chemical compound of ammonia, arsenic and magnesia, did you from that calculate the quantity of pure arsenic?—I did.

How did you do that?—By figures.

Come: do not answer me like that. Cannot you explain to me how you did it?—I say again by figures—calculation.

The Judge: What was the formula?—The formula was that so much of the compound represented so much arsenous acid, called, in common language, arsenic.

Mr. Danckwerts: Is that a constant quantity?—A constant quantity—a very definite compound.

Does this chemical compound of magnesia, ammonia, and arsenic always present a constant quantity of arsenic?—It does; it is a very definite substance indeed.

The Judge: I do not follow it quite. If you mix together three things of that sort will they turn into something else if there is less arsenic or more arsenic, or more ammonia or more magnesia?

Surely it does not?—It is a compound, a definite compound, containing a definite proportion of arsenic.

I want to know if you put more arsenic would it become another compound?—There would be more of the compound.

Suppose you have 1 grain of ammonia and 1 grain of magnesia, and 2 grains of arsenic, that makes this compound you speak of?—Yes.

Then how do you know how much there is in it, because you would have made the same compound if you put 3 grains of arsenic?—The same compound, but more of it.

It would not be the same compound?—The same compound.

Surely if you put brandy and water and sugar, you cannot say there is so much brandy. You may have as much brandy as there is sugar. How can you tell, in a tumbler of water, how much brandy there is unless you ascertain the quantity of brandy?—With two tumblers there would be just twice as much as one.

There would not be twice as much sugar or brandy or water necessarily.

Mr. Danckwerts: I think the witness has given your Honour the explanation that I have been trying to get from him. I will explain it, and put him right too. It is not a mixture, but a chemical compound. These substances only combine in certain proportions?—That is what I told you.

That is what I have been trying to get from you.

The Judge: That is what I put to you. If there were more arsenic would it cease to be this chemical compound. You said no, there would be more of it?—There would be more of it.

Mr. Danckwerts: I presume there would be a certain proportion of arsenic not utilised in the formation of this compound?

The Judge: There would be more arsenic in a grain of the compound.

Mr. Danckwerts: It would be a mixture of arsenic then and the compound.

The Witness: May I explain?

The Judge: I wish you would help me?—It does not matter what quantity of arsenic you have to determine; the quantity of the compound formed will be proportionate to it. If there is 1 grain of arsenic to be found, you get, say, 2 grains of the compound; but if you have 2 grains of arsenic you will get 4 grains of the compound: that proportion of arsenic to ammonia and magnesia is constant in the compound, but the quantity of compound may be different. The relative proportion of one thing to the other is constant.

The Judge: I cannot follow you.

Mr. Danckwerts: What you say is that a certain quantity of magnesium has an affinity for a certain quantity of arsenic?—In definite chemical proportions.

So that if you mix a disproportionate quantity of the two you get a mixture which is partly your compound and partly something else?—No, nothing of the kind. You always get the definite compound, and it is that fact which enables you to deduce from the quantity of the magnesia compound the quantity of arsenic.

Will you tell me what becomes of the superabundant quantity of arsenic?—There is no superabundant quantity.

Assuming you have put in a superabundant quantity?—That is a foolish assumption.

The Judge: Surely I or Mr. Danckwerts might add to this which you say is a compound a little more arsenic. What would be the contents then?—Then you would have a mixture, but that is not what the chemist does in analysis. The object of analysis is to get a definite thing so that he can tell how much of the substance is in his hands; and if I get 10 grains in one case and 5 in another I know with perfect certainty from the definite nature of the compound weighed how much arsenic there is in it.

I suppose there are formulæ for that in some book?—There are formulæ, certainly.

In what book shall I find the formulæ?—Any book on analysis.

Will you mention one?—Thorpe's 'Analysis,' and Fresenius.

Will that formula show how much arsenic there is in that chemical compound?—Yes, you will find that it is very nearly half; it may be taken as a half roughly. Ten grains of that represents 5 grains of what is called arsenic, in common language—white arsenic.

Mr. Danckwerts: Do you still maintain that if you try to combine an insufficient quantity of magnesia and ammonia to absorb the whole of the arsenic that the arsenic disappears; it is not combined?—That would be bungling, that would not be analysis.

Can you for a moment put yourself in the situation of trying to

produce the compound artificially which you found in the fly-paper?
—Yes.

You find magnesia, ammonia, and arsenic?—Yes.

Supposing you put a disproportionate quantity of arsenic and try to combine that, what would become of the excess of arsenic?
—I say again that would be bungling, that would not be analysis.

Is that the only answer you can give?—That is the only answer that is to be given to your question.

Mr. Danckwerts: We can form an opinion on that.

The Judge: You say that would be bungling, that it is not analysing; but surely what Mr. Danckwerts asked you was compounding this, not analysing it. If you had to make this material somehow; suppose for a moment it is possible that you put too much arsenic, what would be the result?—You do not put in arsenic, you take what is there.

Yes, that is analysis. If it is possible to say to the Court this bottle contains ammonia, arsenic, and magnesia, surely you could compound it with those three drugs in your laboratory? You could make this compound from that, could you not?—These things compound themselves from their inherent nature.

If you put the things together with their inherent nature they will make a compound, will they not, in the proper proportions?—They do, and, analytically, in order to ascertain the quantity of the substance you are searching for you will put enough of the things to combine with it. If you do not put enough it is bungling.

Mr. Danckwerts: As I understand, "preparation" means a medicinal preparation in your view?—That is what I understand a preparation to mean.

The Judge: You say this compound contains half pure arsenic? How did you divide the other half—I mean the ammonia and magnesia?—There is ammonia, magnesia, and a very small proportion of moisture. A definite proportion of moisture.

How much ammonia?—26 parts to 115 of arsenic acid. I had better write it down.

Then it would be 122 of magnesia, 150 arsenic, and 28 of ammonia as the balance?—The arsenous acid amounts to nearly one half.

Yes, you said 150?—Taking it roughly, the arsenic is one half, the rest is made up of magnesia and ammonia.

And a little water?—A small proportion of water.

Mr. Danckwerts: Is it not the fact that many articles of commerce contain arsenic?—Yes, they do.

Of everyday commerce?—I believe some pigments contain arsenic.

Is that all?—Well, there are sheep washes.

And arsenic in a form, I put to you further, that could be as easily extracted as it is from the fly-papers?—Possibly it would.

Take, for example, this document into your hand. Is not that green full of arsenic?—It may be.

To be got at by simply dissolving it in water?—No, I do not think that.

If it has been done, what do you say then?—I do not think so.

I say if it has been done, what do you say then?—I say I do not think so.

Mr. Danckwerts: Perhaps you will be enlightened about that. Perhaps your Honour would like to see this? [Handing up a large green poster.] It is Sir Charles Hall's advertisement in Manchester.

The Judge: A war was waged on green papers and green dress materials at one time.

Mr. Danckwerts: Look at that; does not contain arsenic? [Handing up a piece of fabric.]—I cannot say.

Then that could be dissolved out by water?—I could not say.

Mr. Danckwerts: We will give you another one.

The Judge: Without trying it a doctor, a man of science, will not say it does; he has never analysed it, and he does not know that it does.

Mr. Danckwerts: Just test it.—I cannot say from its appearance.

Do you not think it likely that the arsenic can be got out of that cloth by simply putting it in water?—If arsenic is there in a soluble form water will take it out.

Look at that. Do you say the same as to that? [Handing up another piece of fabric.]—I should say if there is any arsenic there it is not soluble in water.

Will you give me your reason?—Because I should imagine that it is in a state of combination which is not soluble in water.

Very well, then you have a fine imagination?—No, it is not from imagination. It is my judgment and experience that I speak from.

Do not many coloured fabrics contain arsenic in a soluble form

that would be soluble in water?—I should say not when they are in a state fit for sale.

Do you deny that there are any cloths commonly sold which contain any arsenic in a soluble form?—When they are in a fit state for sale I should say they do not contain arsenic. Arsenic is used in the process of calico printing.

Then take the case of sheep dip?—Sheep dip of course you may take as containing arsenic.

In a soluble form?—In a soluble form.

Emerald green?—Emerald green.

As bought in paint shops?—Emerald green contains arsenic, but the arsenic in emerald green is not in a soluble form.

Commercial sulphuric and hydrochloric acid?—They may contain traces, infinitesimal traces.

Zinc?—Infinitesimal traces.

The Judge: Is that in a soluble form?—No, not in a soluble form there, and it is very infinitesimal.

Mr. Danckwerts: Lead!—Possibly, if it is not pure.

Is not arsenic often deliberately put into lead?—Yes, it may be for certain purposes.

Bronze?—Possibly also infinitesimal.

But arsenic put in deliberately?—It may be.

They like to get a nice green colour on it?—I do not think arsenic would make bronze green in colour.

Lacquer for brass work?—I cannot say.

Brass-work itself before it is lacquered?—Brass-work contains some infinitesimal proportion of arsenic.

Common gunshot?—Yes.

The Judge: That is lead, is it not?

Mr. Danckwerts: Yes.

The Judge: You have asked him lead. He says in an infinitesimal degree, but not in a soluble form.

Mr. Danckwerts: It is put into lead to increase the quantity, and I think shot is one of those?—No, it is never put in to increase the quantity.

To harden it?—Yes, that is another thing altogether.

That is to increase the natural quantity of arsenic there?—Well, it may increase it 1/100,000th part, or a millionth part perhaps.

It does increase it?—If you call that increasing it.

The Judge: I assume not in a soluble form. Could you extract the arsenic?—It has no relevance to this case.

We do not know yet, but you could not extract it by pouring water hot or cold upon the shot?—No.

Mr. Danckwerts: Suppose you were to go to a bird-stuffer, would you not buy a large quantity of soluble arsenic?—Possibly.

The same if you bought the stuffed head of an animal?—It is used for preserving animals.

Many wall-papers contain arsenic in soluble form?—No.

None?—I should say none now.

Might they?—No, I should say not.

Never?—I have very good reason for saying that they do not.

Bills, posters?—They may perhaps.

In white wall-papers is there not a large quantity of arsenic to produce the satin white?—I do not think so.

Supposing you were to buy one of those summer numbers or Christmas numbers of the *Graphic*, would you not buy an appreciable quantity of arsenic there in the pictures?—I should hope not.

You do not think you would—not in the green colours of the pictures?—No.

That you swear?—I simply tell you I should think there would not be arsenic there. I hope that is intelligible.

Have you tried?—I have not.

Do you apply the same answer with respect to all the things that you should think not—that you have not tried?—That is my opinion; the result of my experience.

Green paint on walls, does that contain arsenic?—No, green paint for wall-papers does not contain arsenic.

No, green paint on walls I asked you?—It may contain arsenic if it is an arsenical pigment.

White lead, I put to you, contains traces of arsenic?—Well, there may be an infinitesimal amount on account of the arsenic in the lead from which the white lead is made; beyond that there is none.

Dunging liquor, which is used in calico printing works for mixing mordants, does not that contain a large quantity?—It may contain a small quantity of arsenic.

It may contain a small quantity of arsenic?—That was formerly a liquor from cow dung.

I believe the origin of that is this, that they used the ordinary cow dung at one time, now they use arsenic?—Yes, that is it.

The Judge: That is to fix colours?—Yes.

Or to produce them?—It is a process used in calico printing.

Mr. Danckwerts: Do you know arsenite of glycerin?—No.

It is used for brightening colours in calico printing. Does it not contain arsenic?—Very likely. Which do you mean, arsenate or arsenite?

Arsenite.—Possibly that is a solution of arsenous acid and glycerin. Of course that would contain arsenic.

I am going to put another general question to you. Is it not a fact that a chemist will tell you that we are continually surrounded by arsenic in greater or smaller quantities in our daily life?—Well, we are surrounded by a great many things.

Do answer the question, please?—Arsenic is one of the elements existing in the universe, and of course that surrounds it as well as any other object.

Yes, but most things contain arsenic in some form or other?—No, I should not say that. That would be a very exaggerated statement.

Re-examined by Mr. Grey: Is there any difference in the amount of arsenic contained in one of these fly-papers, whether you use hot or cold water?—None whatever.

Why in this case was hot water used?—Because my object was to get the arsenic out, and to determine it as quickly as possible.

The Judge: Hot water is a more rapid process?—It is more rapid.

Mr. Danckwerts: And more effective, too?—Not at all more effectual in the long run.

Mr. Grey: With regard to these fly-papers. Is arsenic put into them in such a form that it is soluble in water?—I should say it is from the state in which I find it there.

You have examined, I believe, certain wall-papers, have you not?—I have examined within the last few days six different green wall-papers.

What was the result?—There was not a trace of arsenic.

The Judge: What is a fatal quantity of arsenic to a human being?—From half a grain to 2 grains is given in the authorities on toxicology. Two grains is looked upon as a very dangerous dose, I think.

How much can be safely prescribed?—It is given in quantities of 1-16th of a grain, and less.

I believe the habit increases, does it not?—*l'appétit vient en mangeant!* It is a cumulative poison, I think, is it not?—No, it is not, it acts too rapidly, there no time for accumulation.

Dr. Thomas Stevenson, sworn, examined by Mr. Grey: Are you a doctor of medicine?—Yes.

And analyst to the Home Office?—Yes.

On January 11 did you receive from the last witness three fly-papers?—Yes.

Did you carefully analyse those three fly-papers?—One of them.

No. 9?—No. 9 I completely analysed.

What was the result of your analysis?—It contained 11½ grains of arsenic expressed as white arsenic; the oxide.

Can arsenic be extracted by the application of water?—From these papers easily.

How much?—I could get nearly 11 grains by water; over 10.

You have the fly-papers before you?—I have.

What would be the result of applying water to this fly-paper as directed—keeping it moist?—The arsenic goes into solution and you get a coloured liquid which, according to the amount of water, varies from the colour of whisky up to that of dark brown sherry. It is almost tasteless; you might put it on the tongue and scarcely perceive any flavour; certainly nothing unpleasant.

Would most of the arsenic from the paper become extracted?—Yes, I extracted nearly 11 grains by water from this.

What is a fatal dose of arsenic?—2 grains is fatal—probably 1 grain.

And with regard to the solution obtained from the fly-paper with water, how many people would that be sufficient to poison?—A paper such as I have analysed would be capable of killing about six people.

The Judge: This is most dangerous knowledge.

Mr. Grey: It is, no doubt. Have fly-papers being used for the purposes of murder?—Yes. A few years ago there were eleven people killed by fly-papers in a northern city, and two people were convicted and executed for it.

Was there also a later case in which you yourself gave evidence?—Yes, in which fly-papers were steeped in water.

The Judge: Is that the Maybrick case?

Mr. Grey: Yes, your honour.

The Witness: I cannot say that arsenic was employed there.

Mr. Danckwerts: There is a doubt about it?

Cross-examined by Mr. Danckwerts: I am sure you will bear with my ignorance, Dr. Stevenson, and give me some information. Did you employ hot or cold water?—I employed cold water, and found the arsenic would come out; then I employed hot water to get a full extraction quickly.

You mean to say hot water is more effective and speedier?—It is more speedy. The end result is the same.

If you employ a sufficient quantity of cold water?—Or let it soak long enough.

How long did you soak your fly-paper?—To get the arsenic out I soaked it only a few minutes, but I extracted with hot water until I could get no more arsenic out.

How long did that take you?—Some hours, I think, to get the last traces.

I suppose you would agree that an expert like yourself would get more extract out of these fly-papers than a layman like myself?—I do not think so. If you simply soak it in water anyone could get it out—the bulk of it at all events.

In what form did you find it in this fly-paper?—Chiefly in the form of white arsenic; some of it in the form of arsenate; about 2 grains in the form of arsenate.

What is white arsenic?—The lower oxide, commonly called arsenic.

Will you tell me what you understand by a preparation of arsenic?—Something prepared with arsenic as a constituent otherwise than a chemical compound of definite proportions.

In other words a mixture?—It may be a mixture, or it may be the arsenate, and then you have a chemical compound perhaps mixed with something else.

The Judge: Tell me again what you call a preparation?—Something prepared with arsenic as an ingredient other than a definite chemical compound.

Mr. Danckwerts: Is the arsenate a preparation of arsenic?—The arsenate is a compound of arsenic.

Not a preparation?—A chemical compound.

Not a preparation?—I do not call that a preparation. I do not know what you would say legally, but that is my opinion.

What is arsenous acid?—It is the white arsenic I have spoken of, commonly called arsenic.

Is that a preparation of arsenic?—No, it is a definite compound of arsenic and oxygen in unvarying proportions.

Have you answered me about the arsenite?—Just now.

The Judge: Arsenite is a chemical compound?—Yes.

Mr. Danckwerts: It is not a preparation, I understand. Now, arsenous acid?—Yes, it is a definite chemical compound.

Not a preparation?—I do not call it, strictly speaking, a preparation.

Will you tell me also about arsenates?—They are definite chemical compounds.

And not preparations?—Not strictly speaking.

The Judge: Is there a difference between arsenite and arsenate?—The arsenates are compounds of arsenic acid, the arsenates are composed of arsenous acid, the arsenic acid and the arsenates contain more oxygen.

Mr. Danckwerts: These are all chemical compounds, I understand?—They are, in a state of purity, chemical compounds.

I assume a state of purity for my questions?—Yes.

In what form did the arsenic subsist in the paper before you dissolved it?—Chiefly in the form of arsenous acid or white arsenic.

How would you describe it; where is it, in the paper; is it absorbed into the matter of the paper?—If you look into the paper you can see it on the paper; some of it as a white substance.

With a microscope, you mean?—With the eye.

Whatever you see, is that arsenous acid or what?—I think it is chiefly.

That is not the soluble form of it, is it?—Oh, it is soluble.

In water?—Yes.

Not readily, is it?—It will dissolve; about a wine glass would contain more than the fatal dose.

Now tell me about something else; you know something about the things which are ordinarily sold in shops and elsewhere?—Yes, I am not much of a commercial analyst, but I know with reference to arsenic.

Are there not many substances sold daily in commercial life

which contain arsenic in a soluble form?—I do not think many are sold containing arsenic in a soluble form, except for special purposes in the manufactures and arts.

Take this poster, which has been put in; will you kindly look at that?—I should say that probably contains arsenic in an insoluble form.

Look at it again?—Of course I have not analysed it, but it looks to me like arsenical green, which would not be soluble in water if it is copper green—Scheele's green. I am merely expressing an opinion on the view of it. I think it would be insoluble in water.

What is the proportion of arsenic or the substance you have taken from the fly-paper which could be dissolved into the water?—Practically, the whole of it; or about 11 grains out of 11½.

In what quantity of water? What is the proportion of arsenic in water?—You can dissolve that in about 1 ounce of water—about 2 tablespoonfuls; about 40 parts; you could get it into rather more than 2 tablespoonfuls.

The Judge: Out of the 11½ grains you found 11 grains of arsenic soluble in water?—Nearly 11.

Soluble in 2 tablespoonfuls of water?—It might be got into solution by dissolving it in hot water and then cooling; you could get it into 2 tablespoonfuls.

Mr. Danckwerts: Do you know Dr. Alfred Swain Taylor's book?—I believe I am the editor.

This does not purport to be edited by you?—Then that is an old edition. If it is the one on "Poison," I have edited it.

It says the grain dissolves in 400 parts of its weight in water. The proportion in hot water dissolves about 1-400th part of its weight in arsenic?—That must be a mistake.

It is so here. It says you only find a very small quantity can be dissolved in tea or coffee. [Handing book to the witness.] This is not the one I edited. If you pour on hot water it would take up that amount, but you can get very much more. If you follow it on he says the water kept boiling with the poison and allowed to cool dissolves 1-40th part of its weight.

1-400th, I think; I read it?—You only read part of it.

The Judge: It begins with cold water?—If you pour hot boiling water on the poison it dissolves 1-400th part, but water boiled for an hour with the poison and allowed to cool, holds 12 grains per 1 ounce; that is 2 tablespoonfuls.—I said 11 grains. If you read on you will see it.

Mr. Danckwerts: I have Dr. Tidy here. He says, speaking of the solubility of arsenous acid, 1000 grains of cold distilled water after standing twenty-four hours dissolved 1.74 in a transparent form, 1.6 grains in the opaque form?—That is cold water standing on arsenic.

Yes, distilled fresh crystals, 2 grains, so that you see that is 1-500th?—That is simply standing water on the arsenic, arsenic in crystals. In this form in which it is in the paper it comes out much more readily than if you pour water on white arsenic. It does not mix well with water, it floats about in lumps.

One thousand grains of boiling water poured on the acid and allowed to stand twenty-four hours dissolved 10.12 grains, that is 1-100th part?—That is about 1 per cent. Most of the authorities that I know give 1 per cent., that is to say, 1-40th as the maximum.

What do you say about this poster?—It looks to me like copper arsenic insoluble in water.

Look at that. [Handing a piece of stuff.] Does that contain arsenic?—I cannot say, I should think it probably contains small quantities. Some of these fabrics contain small quantities which are left as an impurity in the dye.

You agree that this green paper, whatever your opinion about its solubility in water, is dangerous?—If you eat it. It is a poster.

Take this cloth. [Handing specimen to the witness.] What do you say to this?—I cannot say, but some of these dyes do contain arsenic, generally in small quantities.

You heard the list of things I put to Dr. Paul?—Yes, zinc, lead, white lead, brass, and so on.

Do you agree that they all contain arsenic in some form or other?—In the commercial form they contain traces in the metal, and such things, white lead prepared from lead, and so on; arsenic is insoluble, if you take the white lead itself it is poisonous.

It is insoluble in water, but contains arsenic in the concrete form?—If you take white lead the lead is much more poisonous than the arsenic, which is a minute impurity, and does not go into water at all.

In what form does it subsist in the white lead?—As arsenate of

lead; that would be the compound you would look for; the very insoluble compound.

The Judge: What you describe you found in this fly-paper was arsenic in its common form?—The chief portion of which was ordinary white arsenic—commonly called arsenic.

In a preparation in the sense that we have previously had?—I should say not; probably it was some waste arsenic.

Not arsenic?—Arsenic; probably some waste arsenic from some liquid or other. I do not know that it had been added as white arsenic. I should think probably it had been obtained from some manufacturing liquid.

Mr. Grey: I do not ask the witness anything more.

The Judge: Is that your case.

Mr. Grey: It is admitted, I understand, that I need not produce the Register.

The Judge: No.

Mr. Grey: Then I need not call any other witnesses. That is the plaintiff's case.

Mr. Danckwerts: Perhaps it will be shortest that I should call my evidence first, and then address you on the case afterwards.

The Judge: You may if you like.

Evidence for the Defence.

Mr. Edward John Bevan, sworn, examined by Mr. Danckwerts: What are your qualifications?—I am the analyst of the County of Middlesex.

What are your medical qualifications?—I have no medical qualifications.

You are county analyst?—County analyst. I am a Fellow of the Institute of Chemistry.

Did you, together with Dr. Paul, analyse these fly-papers?—Yes. Nos. 5, 6, 7, and 8.

Will you tell his Honour how you did it, and what you found?—We extracted the arsenic by means of water which was very nearly boiling—it was quite hot water—and we repeatedly washed the residue that was left in—that is, in the fly-paper. We repeatedly washed it and poured the washings through until we concluded that we had got all out by those means.

What did you find?—We found 10.92 per cent., or in grains, assuming the weight to be the same as the rest of Dr. Paul's samples, the total number of grains was 11.6. But his papers weighed considerably more than the papers that had been submitted to me, and on the basis of my average weight they were 9.9 grains per paper.

So that the papers vary in weight and substance?—Yes.

In what form did you find the 11 grains?—You mean in what form did I weigh it?

The Judge: What was the 11 grains?—That is calculated as arsenous oxide—white arsenic.

Mr. Danckwerts: Do you agree with Dr. Paul that it was a compound of ammonia and arsenic and magnesium?—Yes, that is the ordinary way of estimating it.

Just explain that? Do these substances only combine chemically in certain proportions?—Yes, if you take a certain quantity of the arsenic in solution, and you add to that a large quantity—an excess of a mixture of sulphate of magnesia and ammonia chloride, you then have precipitated this white crystalline compound, which is a perfectly definite composition, and which contains, roughly speaking, half of its weight of arsenic. It does not matter very much how much of the magnesia mixture you use so long as you put enough to precipitate the arsenic. Then you get only this definite compound. To ensure getting it all down you have an excess of this sulphate of magnesia mixture.

What becomes of the excess?—It passes away in the filtrate, and the rest goes away, and we wash until it is pure.

Do you think the ordinary common-place person would get as much from the fly-papers as you would?—No, I think an unskilled ordinary person would soak the fly-paper in cold water, and by that means, in my experience, only a small proportion dissolves out.

How does the substance exist in the fly-paper in its ordinary dry condition?—It is disseminated more or less equally throughout the paper.

I suppose the way in which it is put in is, it absorbs it in the moist form, then it is dried?—Yes, it is allowed to dry.

The Judge: This is only a surmise of yours?—No, I have very good reason to believe that it is put in as a solution and arsenite of soda. In fact, I know it is either that or potash.

Mr. Danckwerts: It is caustic soda?—The white arsenic is

boiled up with caustic soda, or caustic potash, and it then goes into solution, and it is that solution which is used for the purpose.

With some colouring matter?—Yes.

The Judge: Then you say it is a preparation of arsenic?—No, it is a compound of arsenic.

You say it is boiled up with so and so. Is not that a preparation?—It falls exactly under Dr. Stevenson's category of a compound. It is an arsenite. It is a compound.

Mr. Danckwerts: May I put a question which will elicit this point? When the caustic soda and the arsenic are mingled in this way, do you get a mixture, or does a chemical change go on, and you get a chemical compound?—You get a definite chemical compound.

A chemical change taking place?—Yes.

Is it in the fly-paper in the same form as you produce it by means of dissolving in water?—I am not quite sure I follow that.

You produce the oxide, you told us. Is that the shape in which it subsists in the fly-paper itself?—No; no doubt part of it is. The majority of it is there as an arsenite, together with some portion of arsenate.

Is this arsenate or arsenite in the fly-paper a preparation or a compound?—They are compounds.

So that in the fly-paper as it is in the dry state, what the purchaser gets is a fly-paper containing that arsenite or arsenate?—Yes.

The Judge: Which can be prepared as you say from arsenic?—Yes.

Mr. Danckwerts: Chemically compounded from arsenic?—Yes.

The Judge: Can be prepared? You gave me the process. You put together arsenic and caustic potash and you produce this. Is not that a preparation of arsenic?—I see what you mean.

Mr. Danckwerts: I should not say you produce it—they produce themselves.

The Judge: They would not unless you prepared for the production; unless you prepared for the production they would not be produced.

Mr. Danckwerts: I agree. The point is, would you, as an expert, call that a preparation of arsenic?

I agree with Dr. Stevenson's definition. Of course every compound is prepared as his Honour says, there is no getting over that fact.

Mr. Danckwerts: But using the word preparation, supposing you were speaking of arsenic and its preparations would you include in that the arsenates and the arsenites?—Yes, I should have done so; it is done in text-books sometimes.

Did you have these posters; have you analysed any of them?—No, not these.

But similar ones?—Yes.

What did they contain?—They contained considerable quantities of arsenic.

In a soluble form?—In a form which can be readily removed by means of water.

The Judge: The consequences of the decision one way or the other can hardly enter into the consideration of any court that has to decide upon this Act of Parliament, can they? As time goes on other things are found out. That was used as an argument, was it not, against the chlorodyne, and used as an argument in Powell's balsam of aniseed. If you once get to that you would prosecute every village grocer who is selling a box of cough lozenges. I do not think that was laid the way that the Courts had to decide.

Mr. Danckwerts: But I think that you will find when you consider the arguments I have to address to you, at all events, that we propose to raise again, possibly in the ultimate tribunal, that this becomes material.

The Judge: Of course. But what I wanted to persuade was this. Suppose you prove that, you ruin half the shops, or make it very inconvenient for old women to get a pill.

Mr. Danckwerts: To put it shortly to you; can you tell me whether or not, assuming this fly-paper to be prohibited by the Act, there are a number of other commercial articles which are commonly sold which are in the same position?—Yes.

Mr. Danckwerts: That will shorten it if I put it in that way.

Cross-examined by Mr. Grey: There is only one question I want to ask you. Do you agree with what Dr. Stevenson says, that white arsenic is introduced into these fly-papers in a soluble form?—It is purely relative matter; it is introduced in a soluble form.

It is introduced into these fly-papers in a soluble form?—I did not understand Dr. Stevenson to say that, but it is so.

And the chief part is not arsenic at all, is it; it is arsenous acid?—No; I do not agree with that at all.

You do not agree with Dr. Stevenson there?—No.

On the application of water as you are directed to apply, do you obtain white arsenic again?—No; you obtain a solution of arsenite of soda. As a matter of fact, it is not there as arsenous acid at all, or only in small quantities. It is there as arsenite.

The Judge: What is that little bottle there that Dr. Paul produced as that result?—I think that was the ammonia magnesia arseniate that he produced.

Mr. Danckwerts: Yes; that was so.

Mr. Grey: Do you agree, then, with Dr. Stevenson when he says that he found 9.51 grains in the form of white arsenic?—I cannot either disagree or agree with him, because I did not analyse it with him. I agree with Dr. Paul.

Dr. Paul is, I think, to the same effect?—Dr. Stevenson did not find it in that form. I do not know that it very much matters.

Mr. William Thomson, sworn, examined by Mr. Danckwerts: Are you a member of the Council of the Institute of Chemistry of Great Britain and Ireland?—Yes.

A Fellow of the Royal Society of Edinburgh?—Yes.

Fellow of the Chemical Society and a Fellow of the Royal Microscopical Society?—Yes.

Were you in partnership with the late Dr. Crace Calvert?—Yes.

You have carried on the profession of consulting and analytical chemist for the last twenty-five years?—About that time.

Have you had great experience in analysis?—Yes.

And particularly, I believe, in commercial analysis?—Yes.

You have analysed some of these fly-papers, I believe, but not the fly-papers in question in this case?—That is so.

I believe you brought out a considerably lower result?—Yes.

Mr. Grey: I object to this.

The Judge: He has not analysed any the defendant has sold?

Mr. Danckwerts: No.

Mr. Grey: I do not know at all what has happened with regard to other fly-papers. This case is merely with regard to the twenty-five fly-papers sold by the defendants.

Mr. Danckwerts: Have you analysed these placards and cloths that I have produced here?—Yes.

What did you find in Sir Charles Hallé's green placard?—Equal to 6.4 of arsenous acid.

Mr. Grey: With regard to those wall-papers, I understand now their being put in evidence. I must object to them.

The Judge: I do not see how you can put them in evidence. As I said to you just now when the chlorodyne case was being discussed, it could not be proved to any useful purpose that Powell's balsam of aniseed was as bad. That is what you are doing.

Mr. Danckwerts: What I am trying to prove is that there are many commercial articles now sold in this country.

The Judge: That may be, but your reason for repealing the Act cannot help me to construe the Act.

Mr. Danckwerts: I submit that it is important.

The Judge: I do not see that you ought to put it in evidence.

Mr. Danckwerts: It is with reference to the argument I shall have to address to you upon the construction of the Act.

The Judge: I cannot see the relevancy. These other things are not fly-papers.

Mr. Danckwerts: That is true.

The Judge: I do not see how you can put it in evidence in this case, because your argument must surely be that there are other articles of commerce as bad as fly-papers or as noxious as fly-papers.

Mr. Danckwerts: I will state the point shortly.

The Judge: What is the argument you want to found upon it.

Mr. Danckwerts: My argument is this, that the Statute uses popular language, and you must construe it with reference to the state of things existing in the country just like any other document. The Courts have often said there is no mystery about a Statute. It is to be construed like any other document in popular language, unless technical language be employed, and with reference to the state of things which one knows to be in existence. If I prove to your Honour that in the ordinary life of the country there are many commercial articles, sold in a form which cannot possibly be covered by the Statute, and containing as much of the poison as this fly-paper, then I say that the Statute must be construed in such a way as not to cover any of these things.

The Judge: I could not accede to any such proposition. I thought you were going to argue that the Act was to be construed in the ordinary sense of the word, but the Act was passed to prevent these things, and if your contention is right, the first prosecution under

the Act would have failed. I will decide at once upon that argument. If that is the argument in support of which you wish to submit this evidence, I will not allow you to put this in evidence, because I am against you upon that argument, and this cannot be evidence. I will not allow you to give it in evidence.

Mr. Danckwerts: Well, perhaps not, but I will suggest for your consideration—as this case must go further—that in order to avoid it being sent down again, the evidence should be taken, subject to any objection.

The Judge: *De bene esse?*

Mr. Danckwerts: Yes.

The Judge: Very well. I think it is only a waste of time.

Mr. Danckwerts: So far as you are concerned, now you have ruled in that particular way, it may be.

The Judge: I do not mind if you are agreed.

Mr. Grey: I do object to the evidence with regard to those things.

The Judge: I do so constantly—in cases where I think perhaps a nonsuit may be the right course to adopt—rather than put the suitors to the expense of coming back again should the Queen's Bench Division take a different view of it. I do very often allow evidence to be adduced in employers liability cases, reserving to myself the right—

Mr. Danckwerts: To disregard it of course.

Mr. Grey: I cannot agree.

Mr. Danckwerts: I shall not be entitled to refer to the evidence upon the argument which you have only admitted *de bene esse* in this way.

Mr. Grey: If it were in any way relevant, of course I would not say one word, but what I submit to you is that it has absolutely nothing whatever to do with this case.

The Judge: No. I think in this case there is no question of expense, as there is sometimes under the Employers Liability Act, Expense is no object.

Mr. Grey: The question of costs cannot arise, and I do object.

The Judge: No, I do not think you ought to give such evidence, I think it is irrelevant to the issue I am trying.

Mr. Danckwerts: I submit to your Honour that this is not within the meaning of the Act. All the cases which have been referred to by my learned friend were cases of selling medicinal preparations. Not one of them was the sale of anything, but a medicinal article which contained as one of the ingredients poison in some form or other, and in its natural condition. Here in this case you have had described to you the process by which the fly-paper is made, and the arsenic is mixed with caustic soda, and a chemical change takes place. A chemical compound is formed, which, according to the witnesses for the prosecution, without exception, is not a preparation of arsenic, but a chemical compound and a different substance. I submit the proper meaning of the word "preparation" is something prepared in the ordinary way—mixed in such a way that a new substance is not obtained. That is what Lord Esher pointed to in the judgment which he gave in the case of *Armson*. You will find there that it was distinctly found that the poison was put into the *Powell's* balsam or whatever the case was (it does not much matter), and it remained there in the shape in which it was originally, and no chemical change at all took place. You will find that is specifically pointed out by Lord Esher. "It is said that the defendant did not sell a poison mentioned in the Schedule, because, though nothing has been done to it which alters its chemical nature, it has been mixed with other things." Then he says, "Do you sell it the less because you sell it mixed with other things." I submit to you here, in the first place, that it has been proved to you that what has been put in the fly-paper and what exists there, although something else is dissolved out of it, is the chemical substance known as arsenate or arsenite, and that those are chemical compounds, and not preparations. The language both of Dr. Paul and Dr. Stevenson is particularly clear upon that point, that the word preparation is understood to mean something other than a compound, namely, a medicinal mixture of some sort or other. Therefore, I put it first upon the ground that in the fly-papers nothing is sold except a chemical compound, which is neither arsenic nor one of those preparations. Therefore, in the fly-papers you do not sell any poison within the meaning of the Act. That is my first argument. In the next placemy submission to you is that those things are only within the Act which can be sold in the shape in which the Act permits them to be sold. Take Section 17 of the Act: "It shall be unlawful to sell any poison either by wholesale or retail, unless the box, bottle, vessel, wrapper or cover in which such poison is contained be distinctly labelled with the name of the article and

the word 'poison,' and with the name and address of the seller of the poison" and so on. Seeing that you can only sell these things in that way, it was not the intention of the Act to include within the prohibition any commercial articles which could not be sold ordinarily in the form permitted by the Act. It is absurd to suppose that the Act intended to lay down that wall-paper or printed calico or things of that sort, all of which contain poison in one form or another, should only be sold by qualified chemists. The commerce of the country would be absolutely impossible to be carried on, and you must give the Act of Parliament a reasonable construction just as you do any other document. I remember Mr. Justice Day, in many a case, to have said that the proper way in which to look at an Act of Parliament is to look at the whole of it and see what is the scope of it, and if you find that unreasonable consequences result, then you throw overboard and abandon the interpretation which produces unreasonable consequences.

The Judge: Yes; when those cases come before the court you need not apply the Act to unreasonable cases.

Mr. Danckwerts: Exactly; that is just what I am putting to you.

The Judge: Is it unreasonable with regard to the fly-papers here?

Mr. Danckwerts: If you say fly-papers, why stop at fly-papers? Why should you not go to wall-papers? Why should you not go to cloths and these things, which all contain, as I was prepared to prove to you, this very same poison in an equally soluble form? That is what I wanted the evidence for. In fact, it has been substantially admitted that it is so.

The Judge: You mean if a nurseryman sells a laurel bush that he can be brought under the Act.

Mr. Danckwerts: I do not know what a laurel bush is supposed to contain.

The Judge: Was not Sir Theodosius Broughton supposed to have been poisoned by prussic acid extracted from a laurel bush.

Mr. Danckwerts: I do not know whether that contains prussic acid or not. I think you could not say the nurseryman was not entitled to sell laurel bush because it contained prussic acid in some shape or other, which could be extracted from it. That is only another illustration of the argument I was putting before your Honour. It is ridiculous to say that all these commercial articles shall only be sold by qualified persons, because that is really what the contention of the prosecution would result in. You will have to make the ordinary draper become a qualified chemist, and be registered by the Pharmaceutical Society before he can sell any of these cloths, if the decision which your Honour is asked to give is consequent upon the Act. I submit that that is a perfectly absurd contention, and that the intention of the Act which has been suggested must be wrong. I submit it was intended to cover things which are usually sold by chemists—chemical goods and medicines, and things of that sort—preparations in that sense, containing a poison in its original condition, and preparations in a medicinal shape. All those cases which have been cited to your Honour are purely cases of medical preparations—*Powell's* balsam of aniseed and chlorodyne—which are ordinarily sold by chemists. Therefore with regard to those things, it was not unreasonable to hold that they were within the Act. But what you are asked to do now is to hold that a dry article of this kind, which is not used as a medicine but which is an ordinary commercial article, which has been sold for years, ever since the Pharmacy Act was passed, in every grocer's shop in the United Kingdom for fifty years and more, shall now suddenly be held to be illegally sold if sold by anybody but a qualified person, and sold with all the ceremonies which are attendant upon the sales of poisons. Take for example this well-known fact, that ordinary wall-papers contain arsenic in quantity; stockings contain arsenic in quantity—people have been poisoned by wearing them: people have been poisoned through living in rooms where the walls were papered with paper containing arsenic. They have had severe colds, and that is only another form of poisoning. Is it to be said that all these matters are to be within the Act? Take the 17th Section. Are you only to sell wall-papers if you put them into a box, or bottle, or vessel, or wrapper, or cover, and labelled poison; and you are not to sell it to anybody except to a person you know, and all the ridiculous minutiae which are utterly inapplicable to the sale of wall-papers and commercial articles of that sort. And similarly you must say that wall-paper shall only be sold by chemists. It will be a very fine thing indeed for chemists, and it will be an excellent thing for the Pharmaceutical Society, because I suppose the commercial people of this country will all have to be qualified chemists. It is a ridiculous result, I submit, and therefore the Act could never have been intended to apply to this case. There is no decision which warrants your Honour in so extending the words

of the Act to the sale of ordinary articles sold every day in commerce, and I submit that therefore your Honour ought to dismiss this action.

Mr. Grey: In the first place I submit that in a case of this kind we ought to look at what the Act was intended to put a stop to. Now, I will just quote a few words of Mr. Justice Hawkins in the well-known case of the *Pharmaceutical Society v. Wheeldon*, which is reported in the 24th Queen's Bench Division, page 683. He says: "Nothing to our understandings can be clearer than that the object of the Act was beyond all other considerations to provide for the safety of the public, and to guard, as far as possible, all members of the community from the disastrous consequences, so frequent in occurrence, arising from the sale of poisons by persons inadequately acquainted with their baneful properties, and the whole object of the Act would be frittered away, and the Act itself become a dead letter were we to declare by our judgment that an unqualified assistant can lawfully and with impunity sell any of the poisons to which the Act applies, unless upon each occasion of such sale he acts under personal superintendence of a qualified employer or a qualified assistant." He further says: "The object of the Act under discussion is, however, to prevent the occurrence of such mischief, and that can only be done by rigidly enforcing its provisions. Our judgment, for the reasons above given, is for the respondents." In that case the poison was contained in "Battle's vermin-killer," not a medicine at all. With regard to my learned friend's first argument as to compounds, he seems to base his argument on the fact that only arsenite—

The Judge: I do not think you need labour that. I think it was elicited from Mr. Thompson and Mr. Bevan that this really was a preparation of arsenic.

Mr. Grey: Clearly.

Judgment.

The Judge: As this case is not to rest here, I do not think it really necessary to wait to deliver a considered judgment in this matter. If I thought that would help at all I would have done so, but it seems to me the case is so absolutely clear upon authority that it is unnecessary to do more than decide it without any reservation of judgment at all.

As to the first objection, that the Act does not apply to things unless they are preparations and are dealt with as medicines, that is disposed of by the case that was decided by Mr. Justice Hawkins with regard to the vermin-killer. The vermin-killer case is on all fours with this. If that is so, that disposes of that part of the argument.

Then as to whether it is reasonable or not, and whether or not difficulties may some day arise I really have nothing to do with that. As the world progresses, as the Pharmaceutical Society gets on, and as the trade of the country increases, possibly other preparations will come under the penalties of this Act. I have nothing to do with that or with the possibility that wall-paper may be sold containing poison. First, I have not in evidence that these wall-papers do contain anything, because I would not allow that to be given in evidence. I have quite enough to do to deal with these fly-papers. Well, it is proved to me abundantly with regard to these fly-papers that the pores of these papers are filled up with arsenic, or a preparation of arsenic. One gentleman calls it by one name, and another calls it by another, but what it comes to is, that it is arsenic—what is commonly called white arsenic—and that it is a preparation of arsenic is clear from the fact that one of the chemists told me how he could make it. You boil arsenic in caustic soda, and you get this compound, which is in effect a preparation, or I do not know what it is. To say that Nature may do it sometimes does not take it out of the Schedule of the Act; it is a preparation of arsenic. It is sold by an unqualified person, and I think he comes under the penalty of the Act. Judgment for the plaintiffs, that is, for one penalty.

Mr. Grey: One penalty. This is, as your Honour has heard, a test case.

Mr. Danckwerts: I must ask for leave to appeal.

The Judge: Certainly. I think the authorities lead me to that conclusion. What do you ask for Mr. Grey?

Mr. Grey: As the defendant put it, it is a question of great importance, not only to one class of persons, but to the whole world, and it is a case of great public interest. I would ask you to allow us higher costs in this case, owing to the evidence it has been found necessary to bring.

The Judge: Do you say anything about that, Mr. Danckwerts? Is it difficult in law, or of interest to any class of the community; it is both, I think?

Mr. Danckwerts: It is of interest to the whole of the commercial community, because the consequences of your Honour's decision will be that we shall have to be chemists if we have to sell anything in future.

The Judge: I think you must have costs on the higher scale on the ground that it is a case of public interest.

Mr. Danckwerts: It is a case of a penalty, your Honour, and I think a person who prosecutes for a penalty is not to be considered. He must take what the law gives him, and no more. It is a mere penalty.

Mr. Grey: I submit we are entitled to the full costs.

The Judge: What have I done on a former case?

The Registrar: Given the costs on the amount recovered.

The Judge: Then I will follow that course. There will be costs of counsel and three witnesses.

THE ILLEGAL SALE OF PAREGORIC.

The Pharmaceutical Society v. Ager.

This case also came before the Judge of the Bloomsbury County Court on Tuesday, January 21, Mr. Grey appearing for the plaintiff.

When the case was called, Mr. Moore, solicitor, representing the defendant, said he could not contend, after the decision just given, that paregoric, which his client was charged with selling, was not a preparation of opium, but he was a man who had held positions in two hospitals, and he would have been entitled if he had been in business at the time of passing the Pharmacy Act, to have registered himself as a chemist, and he was an old man.

The Judge said the defendant had either contravened the Act, or he had not. If he had he (the Judge) had no dispensing power, he must give judgment against him notwithstanding he was an old gentleman and had been in two hospitals.

Mr. Moore went on to complain of the defendant being sued for two penalties, and after a little further discussion asked leave to withdraw his consent to the judgment.

Mr. Grey thereupon opened the case. The defendant, who is not on the Register, keeps a shop at St. James's Road, Holloway, where on July 8 and 29 last purchases were made of paregoric elixir, which were analysed and found to contain in one case one-fifth of a grain, and in the other one-sixth of a grain of morphine.

The defendant admitted the sale, and Mr. E. J. Eastes proved the analysis. There was practically no defence, and judgment was given for two penalties and costs, including counsel's fee.

THE ALLEGED NECESSITY OF LATIN IN PHARMACY.

Again and again is it asserted that a thorough knowledge of Latin is essential to a proper pharmaceutical education. This is but another striking illustration of the remarkable power of rooted habit contrary to reason. If it were claimed that the study of the Latin language is a necessary part of the course of mental training which should constitute the preparation for the pharmaceutical education, we might answer that while it is not necessary it is one of the very effective and useful means available for that purpose. But that is not the argument advanced in support of the claim that pharmaceutical students should have a good knowledge of Latin; it is, instead, insisted that the knowledge of Latin is necessary to the understanding of the Latin names used in pharmacy. The answer to that statement is that very few of the latinic names of drugs, chemicals, and preparations, in the pharmacopœias or out of them, are really Latin, and that the most intimate knowledge of the Latin language and literature affords no material aid to their proper interpretation. Less than one-third of all the latinic titles in our Pharmacopœia are of Latin derivation, and a great majority of those that are cannot be understood from any knowledge of the meaning of the words from which they are derived. Prospective students of pharmacy should know that a reading acquaintance with German will be of far greater value to them than any Latin, because our most valuable reference works in chemistry, pharmacy, and pharmacognosy are in the German language. They should know, further, that the study of English, German and mathematics will afford as thorough preparation for the special courses in pharmacy, chemistry and materia medica as can be derived from the study of Latin, and that the correct use of the latinic terms employed in pharmaceutical nomenclature can be easily mastered in a very short time without any previous knowledge of the Latin language or grammar, for all there is of Latin in these terms consists of their terminations, which are latinic in form and declined accordingly.—*Bulletin of Pharmacy.*

THE SALE OF POISONOUS FLY-PAPERS.

A VERY important point under the Pharmacy Act, 1868, was decided by his Honour Judge BACON at Bloomsbury County Court last Tuesday, viz., that fly-papers containing arsenic must be regarded as poison within the meaning of the Act. As notice of appeal against this decision has been given, it would not be fitting to comment upon the matter at the present stage. It may be well, however, to point out that the effect of this decision is that arsenical fly-papers can only be sold in accordance with the provisions of the Pharmacy Act, 1868, and consequently chemists and druggists selling them must carry out all the formalities prescribed in regard to poisons contained in Part I. of Schedule "A."

THE SALE OF SEIDLITZ POWDERS.

A FULL report appears in this week's Journal (p. 77) of a case under the Sale of Food and Drugs Act, in which the defendant was fined for supplying seidlitz powders "not of the nature, substance, and quality of the article demanded," the argument for the prosecution being that such powders are official in the British Pharmacopœia, and must therefore invariably be compounded in accordance with the formula therein provided. The real position of affairs is that "effervescent tartarated soda powder" was rendered official in the additions to the British Pharmacopœia (1890), a footnote stating that "Effervescent Tartarated Soda Powder is commonly known as 'Seidlitz Powder.'" But seidlitz powders were not in any sense rendered official preparations thereby. Neither the formula nor the footnote have any value whatever as a definition of a legal standard for anything else than the official preparation above mentioned. When that is asked for by the designations adopted in the Pharmacopœia, it must be supplied in accordance with the formula given as in all similar instances. But the theory apparently guiding the prosecution is that in regard to seidlitz powders nothing else than those prescribed in the Pharmacopœia can be lawfully sold. This is an extreme view that can scarcely be supported, whatever other reasons there may have been for the charge that the seidlitz powders were not correctly prepared. As the defendant will probably not allow the case to rest where it is, those circumstances need not be referred to here, and our remarks may be confined to the more general question

whether chemists should be debarred from selling seidlitz powders differing from those of the Pharmacopœia.

It is probably not far short of a century since seidlitz powders came into use, and the following formula for them occurs in the edition of GRAY'S 'Supplement to the Pharmacopœia,' published in 1821: "Soda tartar, ʒij.; sodæ carb., ʒij., in one paper; acid. tart., gr. xxxv., in the other. For half a pint of water." Assuming that this is the original formula, and it was certainly widely followed until quite recently for ordinary seidlitz powders, the B.P. formula for effervescent tartarated soda powder does not exactly represent what many pharmacists have been accustomed to dispense as seidlitz powders. But apart from that aspect of the question, it would be manifestly absurd to make the actual quantity of powder employed for a single dose a standard under the Sale of Food and Drugs Act, yet, as one correspondent points out, the result of the case now recorded is tantamount to a decision that not only must chemicals be pure, but no one must take any but a B.P. dose. He says chemists frequently sell seidlitz powders stronger than the B.P. form, and some customers will not have the mild ones. The quantities of active ingredients are accordingly increased, in relative proportions, to meet a demand which the public is entitled to have satisfied.

Whilst not granting, therefore, that the Pharmacopœia is a general standard for seidlitz powders, it may be added that it would be distinctly inadvisable to make it an offence against the law to supply any medicament in other than one fixed dose. It may, at some future date, be found desirable to introduce the term "Seidlitz Powder" into the B.P. as a synonym, and to fix the relative proportions of the ingredients used, but even then it would be unreasonable to punish chemists and druggists for supplying what their customers desire when they ask for extra strong powders. If the B.P. formula, as it stands, were a legal standard for seidlitz powder, it must be so in its entirety, and penalties should await any heterodox dispenser wrapping the separate powders in other than blue and white papers respectively. Parchment paper or waxed paper, for protecting the powders from damp, would equally be debarred. The next step might then be to fine the purchaser if he dissolved his dose in more or less than "half a pint of cold or warm water." But the contention is altogether too absurd on the face of it. "Seidlitz powder" has been a well-understood term for a hundred years; the preparation is not official, and customers must be free to purchase whatever quantity of it they deem necessary or desirable. Public authorities should suggest to their inspectors and analysts the exercise of a little more discretion and "sweet reasonableness," else they may find themselves a general laughing-stock. Magistrates, too, may find it advantageous to know something of the laws they are required to administer.

MORE ABOUT ARGON.

ON page 74 will be found a report of Lord RAYLEIGH'S lecture at the Royal Institution on Friday, January 17, when he related to a highly interested and fashionable audience the latest information about argon. There was little that is absolutely new to relate, but the facts already known were marshalled in somewhat better order than was formerly possible. The investigation serves as a striking example of the infinitely greater difficulties that now accompany researches into the exact composition of the atmosphere than in the days of PRIESTLEY and LAVOISIER. At the same time, the early investigators

whilst satisfactorily determining the nature and proportions of the more prominent constituents of the air, gave little or no attention to the minute residues which have served to make the work of RAYLEIGH and RAMSAY famous.

OPINION V. LAW IN SCOTLAND.

IN studying the reports of several cases under the Pharmacy Act, heard recently in Scotland, it is difficult to avoid the impression that certain judges are strongly prepossessed in favour of law breakers who infringe Statutes involving the status of professional men. Another instance of this kind is afforded by the proceedings at Dundee Sheriff Court, on Monday last, when an individual was proceeded against for a breach of the Dentists' Act, in that he had unlawfully called himself a dentist. The sheriff appeared to consider it necessary to betray a strong animus against what he was pleased to term the fencing-in of monopolies, other than those of law and of medicine. He was ready to admit that the practice of law and medicine should be restricted, "because a special education and standard of attainment are expedient in the public interest to protect bodily health and organic structure from the experiments of rashness and of ignorance."

He expressed himself, however, as being less certain that the teeth of human beings should be so protected, and thought that the statutory "consecration" of a word like "dentist" to the exclusive use of "the institute of registered dentists or any other trade union, however educated and genteel its membership, was an interference with the free use of the English language, which had no proper justification." The result of such legislation as the Dentists Act, he continued, was to set aside certain professions for certain people, and just as the word "dentist" was "rendered sacred" and reserved for the use of the members of a registered body, a man might be qualified to act as a professor of chemistry, and yet be liable to prosecution if he were to sell goods upon the representation that he was a chemist. Such legislation had for its purpose the preservation of innocent and gullible members of the public from believing misrepresentations that were made, and from trusting themselves to the skill (?) of persons who pretended to be doctors, chemists, and dentists, but who had no proper skill or qualification, and might do a great amount of mischief.

The arguments employed by the Sheriff, when thus divested of extraneous remarks, seem almost to lead him in the opposite direction to that he inclines to. Moreover, the lack of sound logic displayed in the assumption that, though the acquirement of a special education by lawyers and medical men tends to secure the safety of the public, it counts for nothing in the case of dentists and pharmacists, is nothing short of marvellous. The expressions of opinion, too, were quite irrelevant, and the reader is constrained to wonder whether the frequent recurrence of such "preachments" may be taken to indicate that some, at least, of the Scottish judges have missed their true vocation. The ethical displays on such occasions are brilliant to confusion, and one wonders whether the "kirk" has suffered or gained by the loss of such ardent propagandists and advocates of individual freedom. Fortunately, even judges are bound by the law, and must administer it; if not always quite as it ought to be administered, at any rate to the detriment of offenders, though it is remarkable how Scottish caution and economic principles tend to minimise penalties.

ANNOTATIONS.

THE PHOTOGRAPHY OF THE INVISIBLE.—Thus, the *Daily News* styles Professor Röntgen's work, in referring to some confirmatory experiments performed by Dr. Spiess in the "Urania," Berlin, before a large audience. A key and some coins were enclosed in a purse, which was then wrapped up in black paper and laid on a photographic plate. A thick board was placed on top, yet after fifteen minutes' exposure to the so-called "x" rays, the plate on development bore clear representations of the keys and coins. A photograph of a man's hand revealed the presence of a piece of glass that had been imbedded in the flesh for years, and a metal plate that had been broken and welded so that the join was not apparent gave an impression that showed the fracture quite distinctly. M. Poincaré has informed the Paris Academy of Sciences that photographs received by him from Professor Röntgen appeared to afford palpable proof of a theory that traverses present idea on the propagation of light. At Vienna, again, Professor Mosetig is said to have utilised the new process with success in operations. One photograph showed with the greatest clearness and precision the injuries caused by a revolver shot in a man's hand, and the position of the projectile. Another enabled him to ascertain definitely the position and nature of a malformation in a girl's foot. Finally, Mr. J. W. Gifford, of Chard, has exhibited to the Royal Photographic Society a number of photographs taken by Röntgen's process, and these may be seen at the Society's rooms, 12, Hanover Square, London.

ASBESTOS IN THE MANUFACTURE OF BOOTS.—It is proposed to use asbestos in the soles of boots, a preparation of asbestos wool being compressed into thin sheets by hydraulic pressure, the sheets waterproofed on one side by a special solution, and portions inserted into the boots as middle soles. It is assumed that asbestos being a non-conductor of heat, its interpolation into the fabric of boots and shoes, in conjunction with a waterproof material, will have the effect of counteracting the influences of heat, cold, and moisture. It is said also that asbestos-lined boots cannot creak in wear, and are, besides, many times more flexible than boots made in the ordinary manner. In addition, asbestos being a non-conductor of electricity, persons wearing boots thus made may possibly be able to walk over live electric wires in perfect safety.

THE BURNING TREE OF BURMAH.—There has lately been added to the collection of plants at the Botanic Gardens, Madras, a tree, bearing on the under side of its leaves, stings which leave no outward sign when they pierce the skin, though the sensation of pain persists sometimes for months, and is especially keen on damp days, or when the place which has been wounded is plunged in water. The natives in the parts of Burmah where this tree grows are said to be in such terror of it that they fly in haste when they perceive the peculiar odour which it exhales, and if they happen to touch the tree they fall on the ground and roll over and over on the earth shrieking meanwhile. Dogs and horses touched by it run wildly about, biting and tearing the parts of their bodies that have been touched.

SCIENTIFIC ADVISER TO THE TRINITY HOUSE.—Readers of the biographies of the immortal Faraday will remember how much valuable scientific work was performed by him in connection with his duties as scientific adviser to the Trinity House. The post was subsequently held by his successor in other fields, Professor Tyndall, but has been in abeyance since his resignation. It is now, however, to be revived, and the announcement is made that the appointment has been accepted by Lord Rayleigh, of argon fame.

NEW METRIC STANDARDS.—The three new metric standards deposited at the Standards Office, 7, Old Palace Yard, Westminster (see *Ph. J.*, March 9, 1895), are now available for use in the verification of ordinary metric standards, or for the purpose of science or manufacture. They are a "line" standard metre measure (*mètre-à-trait*), a kilogramme weight, and an "end" standard metre (*mètre-à-bouts*). The standards were verified at the Bureau International des Poids et Mesures (Sèvres, near Paris), which was established under a metric convention now maintained by twenty-one different states, including Great Britain. The English representative on the committee which is responsible for the maintenance of the international accuracy of metric standards throughout the world is Mr. H. J. Chaney, Superintendent of the British Standards Department.

SUGAR AND THE TEETH.—In his paper on "Sugar as a Food," read before the British Medical Association, Dr. Vaughan Harley opposes the popular view that sugar ruins the teeth; this, he states, is not borne out by observation. He finds that people who take large quantities of sugar are not more liable to bad teeth, but, on the contrary, have in many cases exceptionally fine ones. He quotes the case of the negroes of the West Indies, who are in the habit of taking large quantities of sugar.

DISTRIBUTION OF SEEDS BY THE WIND.—Bolley records some interesting facts on the distribution of seeds by the wind (*Pop. Sci. News*, xxx., 18). In two square feet of a three-week old and three-inch deep snowdrift, on the ice of a pond ten yards from any weeds, he found nineteen weed seeds, and, in another drift, similarly situated, thirty-two seeds representing nine distinct species. While the wind was blowing twenty miles an hour he poured out a peck of seeds upon the snow crust, and ten minutes after one hundred and ninety-one wheat grains, fifty-six flax seeds, forty-three buckwheat seeds, and ninety-one (American) ragweed seeds were found in a trench thirty rods distant from where they had been poured out.

TITLE FOR MR. THOMAS HANBURY.—Mr. Thomas Hanbury, of La Mortola, Italy, who has formerly borne the title in that country of Commendatore (Commander), has recently been further honoured by the King of Italy, who has conferred upon him the title of Marchese (Marquis). The *Gardeners' Chronicle*, which announces this fact, publishes in the same issue (January 11) a list of plants in flower at the Hanbury Garden, La Mortola, on New Year's Day. This list numbers about four hundred distinct plants.

THE NECESSITY OF PHARMACEUTICAL RESEARCH.—Professor Henry Trimble hits the nail on the head when he suggests in the *American Journal of Pharmacy* that if the time wasted in writing long articles on "Pharmaceutical Education—Degrees and Requirements," and the "Past, Present, and Future of Pharmacy," were turned into the proper channel, and the time lost by pharmaceutical bodies in listening to such "stuff" were otherwise occupied, "the cause of pharmacy would be materially advanced." As he points out, it is quite certain that there is as much necessity for pharmaceutical research work as ever there was. Education is a suitable topic for short papers and brief discussions, but with regard to long dissertations on the past, present, and future of pharmacy, they are distinctly out of place. "Of the past, it may be said, let it be past; of the present we know; and of the future we know nothing, and volumes of theory about improbable possibilities will not help us to know it any better. More laboratory facts and less writing-table theories are the crying necessities of the hour in pharmaceutical science."

ELECTRICITY FOR DENTISTS.—As a source of electricity for motive power and illumination, W. A. Bryson and H. B. Ezard (*Journ. Brit. Dent. Assoc.*) recommend the Poggendorff battery, which shows 2827.5 British thermal units for the consumption of 1 lb. of zinc, as against the Daniell, 1419 B.T.U., and the Grove or Bunsen, 2772.4 B.T.U. Each cell should contain two cut (not compressed) carbon plates, each 5 in. by 1½ in. by ¼ in., and one rolled (not cast) zinc plate, 5 in. by 3 in. by ⅜ in. The zinc should be amalgamated by rubbing with diluted sulphuric acid (1 in 10) and mercury until bright. The solution should be prepared as follows:—Dissolve potassium bichromate, 8 ozs., in water, 120 ozs., and add strong sulphuric acid, 6 fl. ozs. A battery of 10 cells in series will give 15 to 20 volts, but it is more economical to make up a battery of 30 cells—3 in parallel and 10 in series—and alter the connections at the switchboard according as motive power or light is required. It is estimated that such a battery will last without re-charging for 320 to 350 hours, at a cost of about one halfpenny per hour. The initial cost of ten home-made cells is given as fifty shillings. The carbons are, of course, permanent, and the zinc plates will last nine months with ordinary wear and tear.

'ANNALES DE L'INSTITUT COLONIAL DE MARSEILLE.'—A second volume of this work has just been issued, and contains detailed accounts of the natural history, chemistry, and physiological action of the following plants:—*Robinia nicou*, *Adansonia gregorii*, *Quassia africana*, *Pancovia heckelii*, *Tinospora bakis*, *Cocculus leæba*, and *Psidium guava*. These papers are, indeed, monographs upon each plant, and form valuable contributions to the science of medicine, as well as to that of botany. They are, in fact investigations that have been carried out in imitation of the valuable contributions by Dr. Greshoff from the botanical and research laboratories of the Buitenzorg Botanical Gardens in Java, but are even more full in detail.

PHARMACEUTICAL EXAMINATION FIGURES.—At the last examination for chemists and druggists in Great Britain, out of 352 candidates who presented themselves, 122 passed, that is, 34.65 per cent. It is interesting to compare with these figures those recording the results of recent examinations for registered pharmacists at Philadelphia and Pittsburg, Pa., U.S.A. At Philadelphia 11 only out of 87 passed (12.64 per cent.), whilst at Pittsburg the proportion was slightly higher, 9 candidates out of 56 being successful (16.07 per cent.). At this rate, as the Editor of the *American Journal of Pharmacy* remarks, the State of Pennsylvania will not very soon be overrun with registered pharmacists.

GINGER OR ACONITE?—A somewhat remarkable poisoning case, which points the moral that medical practitioners would do well to depute their dispensing to pharmacists, is reported on page 75. Apparently the surgery bottle, supposed to contain essence of ginger, had been filled with a preparation of aconite, and the individual primarily responsible for the error has suffered for the inadvertence of himself or his servant. It may be suggested that another lesson enforced by this melancholy incident is that one should never experiment upon one's self. From the patient's point of view, however, the nemesis in this case was probably both just and complete. It is a distinct misfortune that the accident should have occurred, but the results would have been infinitely more disastrous if a number of patients had died from the effects of similar medicine. In this particular instance the patient was almost as well served as those Eastern monarchs who insist on their medical attendants being the first to try their own remedies.

PROCEEDINGS OF SOCIETIES.

ROYAL INSTITUTION.—The Friday night lectures of the Royal Institution recommenced on the 17th inst., when Lord Rayleigh's lecture "More About Argon" drew a large audience. At the outset the lecturer reminded his hearers that when dealing with the same subject last year, special reference was made only to the isolation of argon by passing "atmospheric" nitrogen over red hot magnesium, which absorbs the nitrogen and leaves a residue of argon. Afterwards, when a modification of Cavendish's old method had yielded a gas which seemed to be identical with the former, it was thought a further step in advance could be taken, which would enable the isolated gas to be directly weighed. This was not done, although mixtures of oxygen and argon had been so treated, which enabled him to get at the weight of the argon by difference, but it was considered advisable, in order to conclusively prove the identity of the two gases, to devise some method of weighing them, and by that means to confirm the conclusions which had already been arrived at by means of spectrum analysis and other methods in this country and abroad. When it was considered that there is only 1 per cent. of argon present in "atmospheric" nitrogen, it would be readily seen that the isolation of the three litres of argon necessary for the research was a serious matter, involving as it did the absorption of 800 litres of the mixture.

Last summer Lord Rayleigh succeeded in reducing this 800 litres of the mixed gases to 10 litres in the laboratory of the Royal Institution, and then took the residue with him to his country house for the purpose of purification. This was found to be very difficult, and many delays were caused by breakage and leakage of the apparatus, and ultimately a modification was rendered necessary, in order to get satisfactory results. It will be remembered that the process described last year consisted in passing alternating currents through a Ruhmkorff's coil, high potential transformers being used, and thence through bent glass tubes filled with mercury and fitted with platinum points, into a large glass globe which contained the mixed gases. Here arrangements were made by which absorption takes place by strong caustic alkali after sparking, until the residue resists the prolonged action of the current, but it was found that it was necessary to use a spray of alkali, instead of a jet as before, so that a thin layer of liquid was formed over the whole inner surface of the globe, which, by intervening between the light of the electric arc and the glass, obviates the liability to fracture. This modification was found to work satisfactorily so long as care was taken to keep the fountain of alkali working steadily clear of the flame, which otherwise became coloured for several minutes. It had been proposed that space might be economised by working with a large arc light in a small globe, but experience showed that under that condition the rate of absorption was very inferior. After working for about two months continuously, the sparking being carried on for six hours daily, it was found that the weights of the gas were practically constant. Calculation of the density then gave 19.940, as compared with 19.941, the figures obtained by Professor Ramsay by means of the magnesium process. The absolute weights and dates of Lord Rayleigh's research are given below:—

May 22	3.2710	
June 4	3.2617	
" 7	3.2727	
" 13	3.2652	
" 18	3.2750	} mean = 3.2746
July 2	3.2741	
" 25	3.2748	
Oxygen = 16		Argon (Rayleigh) 19.940
		Argon (Ramsay) 19.941

The remarkable identity of these figures, obtained by methods which are entirely dissimilar, goes a long way towards proving that the theory of argon being a compound gas is not tenable.

Lord Rayleigh then made some allusion to a process which has recently been described in the *Comptes rendus*, by means of which argon is isolated by heating magnesium and lime together, and passing "atmospheric" nitrogen over the red hot mixture. The advantage claimed for this method is that the calcium attacks the nitrogen more easily than magnesium does, and experience has shown that it may prove more satisfactory than that originally described by Professor Ramsay.

The form of apparatus used for determining the refractive index of argon and helium is a modification of Michaelson's, and consists

of a telescope, in front of which is placed a screen perforated by slits. In order to see the band an eye-piece of very high power is necessary, and in this case a compound microscope was used. The results obtained by the method, which answered very well after some practice, showed that, taking the refractive index of air as 1.000, argon is .961 and helium .146, and from these it has been deduced that the theory of argon being simply an allotropic modification of nitrogen as N_3 cannot be sustained, seeing how nearly the figures for air and argon coincide. Professor Gladstone goes further, and is of opinion that it points to argon being diatomic rather than monatomic, but this suggestion is by no means proved.

Helium is remarkable in being less refractive than hydrogen, although its density is higher, and in the course of his lecture Lord Rayleigh made several statements in regard to the occurrence of this element which are of considerable interest. For some time it had been noticed that after the removal of oxygen from Bath springs there was less argon left in the residue than in "atmospheric" nitrogen, and it was thought possible that this fact was due to the presence of helium in considerable proportion, and recently this idea has been entirely confirmed. To a certain extent the result came as a surprise, seeing that Bath gas which had been previously examined had yielded no trace of helium, but the discrepancy was attributed to the fact that the previous sample had been kept for a year before being examined, and hence the helium might have escaped. Gases from the "thermal" springs at Buxton have also been examined, and it has been shown that they contain as much as 2 per cent. of argon, but the proportion of helium is less than in Bath gas. The experiments demonstrating the spectrum of argon and helium were very striking, the former consisting of an alternating change of blue to red and red to blue, which is characteristic of the substance, whilst that of helium shows a brilliant line D. Efforts have been made to determine the presence of helium in the atmosphere, of which one would expect to find traces, seeing that it must bubble up and escape from some of the hot springs, but, so far, it has not been detected even to the extent of 1 part in 20,000. In this portion of the research Lord Rayleigh's son had done a large amount of work, the method being to work with 60 C.c. of the supposed argon by boiling it down with water to 1.5 C.c., which is then examined by means of the spectroscope after enclosure in vacuum tubes. Determinations of the viscosity of argon and helium have also been made by allowing the gases to flow through capillary tubes under pressure, the relative time occupied being noted, the results obtained showing that argon has a viscosity of 1.21, helium of .96, as compared with air as 1.

A large number of experiments were conducted, and models of the physical and chemical apparatus by which the researches have been conducted were exhibited.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.—On Wednesday, January 15, at Exchange Rooms, Birmingham, the first half of a paper on "Coal in Relation to Pharmacy" was read by H. Jessop. The paper, which dealt more especially with the manufacture of coal gas, and described minutely the principles involved and the apparatus used, was of a most interesting nature. The second portion of the paper, which will have a more direct bearing upon pharmacy, will be read on February 19.

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).—A smoking concert was held at the Westbourne Restaurant, Craven Road, W., by the members of this Association and friends, on Wednesday last. The chair was taken by the President, Mr. J. C. Hyslop, and an attractive programme was offered. A humorous sketch was contributed by the President, and songs, etc., were ably rendered by Messrs. Richardson, Andrews, Clarke, and Trueman. Mr. E. J. Eastes, Secretary to the School of Pharmacy, officiated at the piano.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.—The chemists of the Three Towns and their friends to the number of two hundred and sixty took part in the annual ball held in the Town Hall, Stonehouse, on Wednesday, January 15. Dancing took place in the large hall, where exotics, fairy lamps, and other examples of the decorative art were set off to good advantage. The staircases were draped with crimson cloth and shrubs, and these, commingling with flowers and electric lights, presented a fine effect. Supper was laid in the small hall, Messrs. Risdon and Sons, of George and Bedford Streets, catering with even more than accustomed satisfaction. To Mr. F. W. Pascoe, of Chapel Street, Stonehouse, was entrusted the main idea of decoration, and music was supplied by Mr. Acland's band. At 2 a.m. the company dis-

persed, and all agreed that the hosts had done all things exceptionally well. During the evening there was an interchange of compliments between the local executive and Mr. Michael Carteighe, the President of the Pharmaceutical Society and Chairman of the Committee of the Chemists' Ball, which was being held in London at the same time.

MANCHESTER PHARMACEUTICAL ASSOCIATION.—At the meeting held on January 15, a paper was read by Mr. Wm. Lane on the sale of poisons and of poisonous preparations. He explained how the Pharmaceutical Society came to be entrusted with authority to control the sale and dispensing of certain poisons, and also how many difficulties and trade prejudices had tended to prevent the carrying out of the Pharmacy Act, 1868, in its entirety. It was pointed out, however, that of late the Society has not hesitated to perform fully the duties imposed upon it by the Legislature. The following extract from a recent number of the *British Medical Journal*, on the "Negligent Sale of Poisons," was read with approval:—

"The steps taken during the last two or three years by the Pharmaceutical Society, and also by the police authorities, to enforce observance of the law relating to the sale of poisons cannot fail to be productive of benefit to the public by lessening the danger of accidental poisoning, and even helping to prevent the misuse of poisons for suicidal or other unlawful purposes. The propriety of restricting the sale of poisons, and even of potent medicinal preparations to the hands of persons possessing special knowledge of their dangerous nature is so obvious that the argument against this restriction on the ground that it confers a monopoly of the supply of poisonous articles is not worth consideration. It is not for the benefit of chemists and druggists that the sale of poisons has been placed exclusively in their hands, but solely for the public good. At the same time it is essential that the persons who are authorised by law to sell poisons should be scrupulously observant of the precautions which the Legislature has held to be requisite in dealing with poisons. Labelling and the registration of sales in the poison book ought always to be strictly carried out by them. That this is not always done appears from the evidence given at two recent inquests held by Dr. Danford Thomas and Mr. Braxton Hicks. In one case cyanide of potassium was sold, and in the other a vermin-killer containing strychnine, but neither of the sellers kept a poison book or registered the sales in the manner directed in the Pharmacy Act. This is negligence of a kind that the Pharmaceutical Society would do well to take cognisance of, not only because of the danger attending it, but also because it might be made use of as an argument against the restriction of the sale of poisons to chemists and druggists. Fortunately neglect of this kind constitutes an offence which can be dealt with by the police authorities independently of the Pharmaceutical Society, and it is highly desirable that the provisions of Section 17 of the Pharmacy Act should be made use of when occasion arises."

In conclusion, it was pointed out that the recent decisions in Edinburgh under the Pharmacy Act are of great importance. They bear upon the title of "Chemist," it being decided that this title cannot be used in any retail way of trading or keeping open shop unless the holder of the title be qualified under the Act. The prefixing of a qualifying adjective, as for instance, "Technical" chemist, or "Photographic" chemist does not take the person using such title out of the statutory prohibition. It was also decided that no one but a qualified chemist under the Pharmacy Act may legally sell scheduled poisons. The poisons sold by the defendants in these cases were poisonous chemicals used in photography and included in the schedule of poisons under the Pharmacy Act. Chemists should, therefore, see that in supplying any of these chemicals, which for the safety of the public are under their sole control, that all the regulations as to Part I. or Part II. of Schedule "A," as the case may be, are strictly and regularly carried out. This applies to the poisons in their simple state, in solutions, and in combination with other chemicals.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.—The annual dinner of the above Association took place on Friday, January 10, as announced, and the assistant honorary secretary, Mr. S. F. Barker, intimates that it was a great success.

ENGLISH NEWS.

POISONING BY HYOSCYAMUS.—The Bournemouth coroner on Monday, January 13, held an inquest on the body of Bessie Jane Childs, 20 years of age, lately in the service of Dr. Turner, of Poole, who died at Role's Hotel on the previous Saturday. Dr. Alfred James Turner, Lynden House, St. John's Wood Road, deposed that he found deceased in bed apparently in a deep sleep. There was no positive sign of poisoning except the partial dilation of the pupils, which might either be caused by a blow or by a drug. He found no trace of poison in the room. He administered restoratives, and deceased apparently revived. The heart recovered its tone, and she breathed much more easily. This continued till six o'clock in the evening, when a change for the worse in her breathing took place. He sent for Dr. Moynan, who could suggest no different treatment. He gave hypodermic injections when he could not administer restoratives between her clenched teeth, and saw her every hour until she died. He made a post-mortem examination with the assistance of Dr. Moynan. The body was fairly nourished, and thoroughly healthy except the general anæmia. There was no trace of pregnancy, nor apparently any cause for natural death. They discovered in the intestines a mass of substance which was either belladonna (deadly nightshade) or hyoscyamus (henbane). He himself thought it was most probably hyoscyamus. The poison must have been self-administered. It could not have been taken at one mouthful. It was probably swallowed in separate lumps. It would take two or three hours before it took any effect. Hyoscyamus or belladonna was sometimes given in small doses to relieve pain or produce sleep, but deceased had taken enough to kill several people. He did not administer an emetic because there was no symptom of poisoning. Had he suspected poisoning he would have given an emetic. The jury returned a verdict that the deceased died from taking a poison, which she knew to be a narcotic poison, but how that poison came into her possession there was no evidence to show. The coroner said that the verdict must read, "That the deceased died from the effect of poison administered to herself as narcotic."

CURIOUS POISONING CASE.—The *Yorkshire Post* reports an inquest held at the Bridlington Police Station on January 17—before Mr. J. M. Jennings—relative to the death of Mr. John Robinson, surgeon, which took place at his residence, Quay Road, on Wednesday. It appeared from the evidence that deceased, who had been in practice at Bridlington for about forty years, left home on Wednesday morning and visited some of his patients, one of these being a young man named Proctor, at Hilderthorpe. This patient he had on Monday supplied with a bottle of medicine, but owing to the agonising effect produced after taking one dose he declined to take any more, and deceased, being sent for, said he would take it away and supply him with some weaker medicine. He sent a second bottle, and, on taking a small dose on Tuesday night, Proctor was again similarly affected, and again declined to take any more. Calling on Wednesday morning, deceased expressed his surprise, as he said the prescription was one he made up every day, and he dare take the whole bottle. As a proof he asked for some water, and took a dose, asking Mr. Priestley (Proctor's father-in-law) to taste it also. They had not taken it long before it became evident that something was wrong with the medicine. Deceased hastened home, and, calling to his housekeeper for some hot water, said, "I have been tasting some medicine outside, and taken poison by mistake." Mr. Webster (next-door neighbour) and Doctors Kirby and Magoris were speedily in attendance, and everything possible was done, but after suffering severe paroxysms for upwards of two hours, Mr. Robinson died. At first deceased told the medical men that it was an extra strong essence of ginger that was in the medicine, but as the symptoms became more marked, his professional knowledge evidently indicated to him what the poison was, as he said, "It was aconite. I am dying." A verdict of "Death from misadventure" was returned. Deceased was 64 years of age, and unmarried.

TO REMOVE INK AND RUST STAINS.—Ink stains: Tartaric acid, 10 parts; alum, 10 parts; water, *q. s.* to dissolve. Rust Stains: A mixture of 2 parts of powdered cream of tartar with 1 part of powdered oxalic acid will remove stains from cotton and linen. The poisonous character of the acid must be noted to avoid accidents in using (*Pharm. Era*, xiv., 174).

IRISH NEWS.

THE DECISION IN THE CLELAND CASE. — Intending chemists, says the *Cork Constitution*, are specially interested in the case of Cleland v. the Pharmaceutical Society, which was decided by the Court of Appeal (see *Ph. J. Supplement*, January 18, p. ix.). "It illustrates at once the technicalities and the anomalies of the law. The appellant had served his full time as an apprentice and assistant to the well-known firm of Gratton and Co., chemists, of Belfast, and complied with the requirements of the Society as regards certificates and other forms in applying to be admitted to a preliminary examination in order to obtain his licence. The Council, however, who seem to keep a sharp look-out for technical flaws, objected to his being admitted on the ground that the establishment was a limited company, whereas the regulations of the Society required that the term should be 'in the sole employment of a firm of legally qualified pharmaceutical chemists.' The court upheld the legal view and dismissed the appeal. This is very hard upon the applicant, who is not charged with being incompetent, and he most probably is as well taught an apprentice as any to be found in the country. But an establishment which is allowed to supply chemicals to the public, through the hands of assistants, is held to be incompetent to grant a certificate which the Society will recognise, although we have no doubt that it employs a qualified chemist to conduct its business. The law as now interpreted amounts to a practical prohibition of limited companies, although, as far as the protection of the public is concerned—and this is the ostensible object of the Pharmaceutical Act—it is more likely to be secured in such an establishment than in a very large number of chemists' shops in the country which are owned by individuals."

MR. JAMES NORTH HARDY, M.P.S.I., had a fire last week in his establishment, known as Beater and Company, 17, Lower Sackville Street, Dublin. It broke out in the oil and colour department, but having been discovered before it had laid a firm hold on the inflammable materials about, it was extinguished before any great injury was done.

THE PRELIMINARY EXAMINATION under the dual examinership was an interesting feature in Irish pharmaceutical affairs this month. The number of candidates, twenty-three, was not as large as usual, many, no doubt, being desirous of seeing the style of questions set before venturing. The feeling about new examiners being more searching than the old, curiously enough appears to have received justification by the result, nine, or about 39 per cent., having been rejected, compared with 23 per cent., according to Dr. Duffey, rejected last year. As in October last, a lady again took first place, while another was also high in the list. It is noteworthy that in each of these cases the candidate was the sister of a pharmaceutical chemist.

FOREIGN NEWS.

ILLEGAL SALE OF MEDICINES.—During the annual tour of the Government Inspectors of Foods, they found, on visiting a grocer's shop at Mezières (Ardennes), a quantity of pharmaceutical preparations, the right of sale of which is solely restricted to pharmacists. The offender was prosecuted, and his plea that the medicines were kept for the convenience of the public (there being no pharmacy in the vicinity) was not considered sufficient justification. A fine of 500 francs was imposed for usurping the privileges of pharmaciens.

THEOBROMINE IN LARGE DOSES.—At the last meeting of the Société de Thérapeutique, Dr. Huchard gave a lengthy account of his experience of theobromine, which he considers has a diuretic action far superior to caffeine in the treatment of cardiac affections. His observations were based on the use of over 2 kilogrammes of the substance, administered without any admixture in the course of his clinical practice at the Hospital Necker, to more than 200 patients. He found that the diuresis was more rapidly produced than with digitalis, commencing after the first few doses, and lasting for three days after the last dose. According to Dr. Huchard, it is not cumulative, does not cause any accidents, not being toxic its use can be prolonged with safety, and it frequently succeeds when all other diuretics have been unsatisfactory. In only a very few cases of albuminuria was the amount of albumin increased. The mode of

administration recommended is in cachets, commencing at 3 grammes daily and increased to 5 grammes. Sometimes a larger quantity (8 grammes) has been given without bad effects. The intolerance occasionally observed can be overcome by beginning with smaller doses and gradually augmenting. It was also found of great service in eliminating the toxic principles by the kidneys in pneumonia and hepatic cirrhosis. In the course of his communication Dr. Huchard expressed his condemnation of the natio-salicylate of theobromine (known as diuretin), which he said is liable to cause serious complications, and possesses toxic properties not to be ascribed to the theobromine. The discussion on this subject, which the members esteemed of great importance, was deferred until the next *séance*.

BETWEEN SCYLLA AND CHARYBDIS!—A pharmacist of a market town in Calabria in the Gerace district has lately had a hard time in trying to fulfil the demands made upon him in his capacity as a pharmacist and as a citizen. He was summoned to the chief town to attend the assizes in the rôle of jurymen, and this causing his absence for some fifteen days, he had to close his pharmacy, as the services of a qualified assistant could not be obtained, and if he had left an unqualified man in his place he would have been liable to a penalty under Article 67 of the Sanitary Law. The chief justice declined to excuse him when appealed to, because there were two other chemists in his native town who could look after the interests of the people in his absence. On his return home, at the close of the Assizes, the pharmacist found that the doctor charged with the inspection of pharmacies had visited his pharmacy, and finding it shut up had sent him a summons to appear before the magistrates on the charge of contravening article 26 of the Sanitary Law, which requires every holder of a pharmacy "to remain in it continuously," and article 67, the latter portion of which says that "anyone who has opened a pharmacy must not shut it without fifteen days' previous notice to the Prefect." Fortunately for him the magistrates were possessed of more common-sense and justice than the pharmacy inspector, and remitted the fine of 100 lire to which the pharmacist had made himself liable in his attempt to satisfy the requirements of Italian justice.

COMPULSORY INSPECTION OF PRESCRIPTION REGISTERS IN SPAIN.—The recent order that pharmacists were to submit their prescription books to the Revenue officials so that it could be ascertained whether the medical men had complied with the law making them write their "recetas" on 10 centimos stamped paper, has been recalled, thanks to a very vigorous agitation instituted by our contemporary, *El Memorandum*, of Barcelona, against inflicting upon pharmacists such an indignity. Most of the other pharmaceutical papers of the Peninsula supported the *Memorandum* in bringing this to pass, amongst others *La Farmacia Española*, *El Boletín-Médico-Farmacéutico*, and *El Restaurador Farmacéutico*.

A NEW MINERAL WATER.—A Royal Decree in the *Gaceta* recognises as of public utility the sulphurous water rich in chlorides, issuing from the spring of Don José Roquetas, in San Andrés de Tona.

A PRINCELY SALARY!—The Municipal authorities of Sitges have thrown open to competition the post of Municipal Pharmacist, whose by no means light or well-defined duties are to be paid for at the munificent rate of 1000 pesetas (£38) per annum, payable in quarterly instalments.

MARAGLIANO'S ANTI-TUBERCULAR SERUM.—The *Gazetta Ufficiale* announces that as Maragliano's serum cannot be freely sold or used until it has received the official sanction of the Superior Council of Health, and as the experiments with it are as yet not completed by the Council, permission is granted in the meantime for its employment and sale, provided that these are under the direct control of Professor Maragliano himself, who is responsible for the correct distribution and employment of the remedy.

NEW DENTIFRICE.—A new paste and powder for the teeth is recommended by the professor of dentistry at Geneva, in cases when the gums recede. The formulæ are, for the powder, strontium carbonate, 15.0 Gm.; flowers of sulphur, 15.0 Gm.; otto of rose, 4 drops; for the paste, strontium carbonate, 6.0 Gm.; flowers of sulphur, 3.0 Gm.; powdered soap, 13.50 Gm.; mucilage or glycerin, *q.s.* to make a paste.

TRICHLOR-ACETIC ACID IN CHRONIC CYSTITIS.—The *Gazzetta Medico di Torino* prescribes 5 or 6 drops thrice daily of a 1 in 5 solution of trichlor-acetic acid to counteract the alkalinity of the urine in chronic cystitis.

IMPURE ICE AND INFECTION.—Another instance of infection conveyed by means of ice has lately been reported from the garrison town of Rennes. It appears that at a regimental banquet the officers seated at one only of the tables partook of ice with their wine, and all of these were subsequently attacked by typhoid fever, resulting fatally in two cases. A journal, the *Bulletin Medical*, investigated the causes of the outbreak, and it now transpires that the ice was procured from a river polluted with a considerable quantity of sewage. Formerly, when the town derived its water supply from this river, enteric fever was very prevalent, but since the introduction of a source of pure water from a neighbouring stream, no epidemic has been recorded.

A SIMPLE PROCESS FOR THE DETERMINATION OF URIC ACID.—The urine to be examined is first treated with excess of carbonate of soda, and filtered to get rid of phosphates. Any quantity (say 20 grammes) of the filtered liquid is then taken and titrated with the following solution:—sulphate of copper, 1.484 gramme; Rochelle salt, 40.0 grammes; hyposulphite soda, 20.0 grammes; distilled water to 1 litre. One C.c. of this solution precipitates 1 milligramme of uric acid, which falls as a white flocculent powder. Care should be taken to add the solution drop by drop, and to stop immediately no further precipitate forms.

THE KEEPING PROPERTIES OF ANTI-DIPHTHERITIC SERUM.—Some hesitation having been lately shown by medical men in using the anti-diphtheritic serum, on account of doubts arising as to its possible deterioration, an application has been made to Dr. Roux by the French Pharmaceutical Association, in order to obtain the inscription of the date of fabrication on each phial of fluid supplied by the Institut Pasteur. Dr. Roux has informed the Association that although no difficulty will be made for exchanging doubtful specimens, he is in a position to state that, as an outcome of recent experiments, the serum now prepared will keep indefinitely, and a notice to this effect will be enclosed with each bottle.

LEGAL REPORTS.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT.

THE SALE OF SEIDLITZ POWDERS.

On Saturday last, at Brentford Petty Sessions, before General Tremeneere, in the chair, and other justices, a long hearing took place of a case involving an important point with regard to the preparation of seidlitz powders.—Mr. Ernest Frank Strickland, chemist and druggist, of the Broadway, Ealing, trading as "Bruce's Drug Stores," was summoned under the Food and Drugs Act for having sold to Walter Tyler, an inspector under the Act, seidlitz powders not of the nature and substance demanded.—Mr. F. Walker, solicitor, defended.

On the 18th ult., Wm. Randall, an assistant to the inspector, asked for and was served with seidlitz powders, for which he was charged 10½d. He handed them to the inspector, who put the usual questions to the defendant as to division of the sample. Defendant refused to have it divided, and it was sent in its entire state to the analyst, who certified that the blue packet analysed contained 204 grains of a mixture of Rochelle salt and bicarbonate of soda, while the proper quantity, by the formula of the British Pharmacopœia, should be 160 grains. One packet contained 210 grains. The white packet contained an average of 46 grains of tartaric acid, the proper quantity being 38 grains.

For the prosecution it was urged by Inspector Tyler that the British Pharmacopœia was intended by law to contain the formulæ for all medicinal compounds, and was to be regarded by all chemists as the standard they must observe. He contended that the Pharmacopœia must be taken in conjunction with the Sale of Food and Drugs Act, and cited *White v. Bywaters*, 51 J.P., 821, as proving his contention.

Evidence of the purchase having been given,

Mr. Edward Bevan, official analyst to the County of Middlesex, was called to prove his certificate. He considered that any one

asking for seidlitz powders should have them prepared according to the formula of the British Pharmacopœia.

Cross-examined, he admitted the words "seidlitz powder" were not applied to the formula. The words "effervescent tartarated soda powder" were, and a foot-note in the Pharmacopœia stated this was commonly known as seidlitz powder. He considered any deviation from the formula would be wrong. He found the ingredients pure. There was nothing injurious, but if he were ordered to take a grain of anything, and a chemist gave him two grains, he should think that would be wrong, even if the substance were not injurious. He received the whole packet of powders, and divided it into two, taking six of those in blue papers and six of the others.

Mr. Robert Watts, of the Apothecaries' Hall, was also called. He considered the purchaser was prejudiced if he obtained the powders in question as seidlitz powders.

Cross-examined: If chemists sold two or three or more kinds of seidlitz powders that was wrong. He would not consider he was committing an offence in supplying stronger powders if asked for them. Nor would he regard it as an offence to supply seidlitz powders made up with flavourings of any kind. If, however, a man asked for seidlitz powders, he should get those in accordance with the British Pharmacopœia. If a man wanted extra strong seidlitz powders he would not regard it as an offence if the chemist went outside the formula.

Mr. Walker submitted that no criminal offence had been disclosed and that the prosecution was only an attempt to make the British Pharmacopœia a standard under the Sale of Food and Drugs Act, which was contrary to the recommendation of the Royal Commission. He submitted, further, that seidlitz powders were not mentioned in the Pharmacopœia. That term might mean the effervescent tartarated soda powders official in the Pharmacopœia, or something different, and unless the chemist were asked for this compound, he was not bound by the Pharmacopœia. His client, in common with other chemists, had two kinds of seidlitz powders, sold at 7d. and 10½d. per box, and he asked the inspector's assistant if he would have the best, to which an affirmative reply was received. He was therefore asked for a special article and got it, and it was in evidence that a chemist did no wrong in supplying a special article when asked to do so. Further, he submitted the analyst had not complied with the directions of the Act as to dividing the samples. He should have halved each separate packet, so that the defence might have had a chance of analysing the remaining half of the actual packet dealt with. As he did not reserve any of the contents of the blue and white papers analysed, the defence had no chance of checking the analyst's results.

The defendant, sworn, said he had two kinds of seidlitz powders one kind being labelled "Hygienic." Randall asked for the best, and witness concluded he wanted the higher-priced.

Mr. Sharpe (on the Bench): But how did he understand the word "best"? He might have thought it meant newest or freshest drugs?—All my drugs are fresh. It is usual to have two strengths.

Cross-examined: If a medical man sent to him for seidlitz powders he should send the strongest, because they were the most asked for.

Mr. Tyler: In the face of the British Pharmacopœia?—If a doctor wanted one of those he would use the official Latin term.

Evidence was given as to the different strengths of seidlitz powders made up to order by the Viking Food and Essence Company, who supplied the defendant.

Dr. Wm. Hy. Symonds, past examiner to the Pharmaceutical Society, stated that the term seidlitz powder was not an official one. He considered a variation of 5 grains would have no appreciable effect on a patient. An extra wineglass of water with a seidlitz powder would do as much.

Mr. Allen Brown (on the Bench): Do you consider an excess of 44 grains would make a difference in a young person?—It would then be less than a dose of tartaric acid.

Further evidence in support was given by Dr. Herbert Neville, and Mr. David Peters, chemist and druggist.

The witness Randall, re-called, swore no question was asked him as to the quality of the powders he wanted.

The Bench, after deliberation, found that the inspector's assistant did not ask for "best" powders. They had great doubt as to the meaning put on the word best, which need not necessarily mean the strongest, but might have implied the purest. On all the other points they agreed, and they fined the defendant 5s., and £2 2s. costs.

Mr. Walker asked for a case, and was directed to put his points into writing.

THE PRESENCE OF COPPER IN PRESERVED PEAS.

At Southwark Police Court, on Wednesday afternoon, the case of A. A. Grist, Sanitary Inspector of St. Savion's District Board of Works, against Mr. H. C. Summers, trading as George Mence Smith, at High Street, Borough, and also many other places, for selling preserved peas mixed or coloured with an ingredient injurious to health, viz., 8/10ths of a grain of copper per pound of peas, whereby the defendant became liable to a penalty of £50, again came on for hearing.

The previous hearing of this case was fully reported under the above heading in our last week's issue (see *ante*, p. 59).

Mr. Frank Dodd, barrister, again appeared to prosecute, and Mr. Bonsey, barrister, defended.

Dr. Fredk. John Smith, called for the defence, stated that he had had considerable experience in relation to the adulteration of food and toxicology. He had been informed of the quantity of copper in the peas. In the first place, it would not render the food injurious to health. He knew of no case of recorded poisoning through the constant use of such peas. He had looked up all the records of the London Hospital, where they get a large number of cases of lead poisoning, but had failed to find a single case of copper poisoning. Copper is used medicinally in cases of diarrhoea. It is used as an emetic. It has also been given as a tonic. He thought that $1\frac{1}{2}$ grains of copper sulphate per day, given in three doses of $1\frac{1}{2}$ grain each, could be taken without fear for a considerable period. Copper taken even in a soluble form would pass off by the bowels a good deal, and in a very short time. If a person took one-fifth of a grain in 4 ounces of peas, as in this case, a large portion of the copper would pass off and not get into the system.

Cross-examined by Mr. Dodd: Witness agreed that copper sulphate was poisonous, but only in large doses. He was aware that the United States Government prohibited preserved vegetables being sold containing copper equal to more than 3 grains of copper sulphate per pound, and that in such a case a printed label signifying the same was required to be attached on the bottle. Regarding the quantity of copper that would not be injurious to health, witness said what he meant was that the amount in these peas was certainly not injurious to health. He could not suggest any purpose of putting copper in preserved vegetables other than that of preserving their green colour.

Dr. Biss, Physician to the Middlesex Hospital, stated that in the whole of his experience he had never seen a case of chronic copper poisoning. He thought it quite possible that if a person were to eat a pound of the peas he might have feelings of discomfort afterwards, but not as the effect of the copper present. The witness had searched the *Lancet* and also the *British Medical Journal*, in which he had found a large number of cases of poisoning, but failed to find one single instance of chronic copper poisoning or of injury from preserved peas.

Dr. Hime, of Bradford, corroborated both the previous witnesses as to the non-poisonous qualities of the copper in preserved peas. During the whole of witness's experience he had neither heard, nor read of a case of injurious effects from such peas. He had examined the authorities with regard to chronic copper poisoning, but had found nothing whatever that was evidence to show there had been any such thing. He had also looked through several medical journals with the same result. With regard to the introduction of copper into preserved peas he was of opinion that it was merely done to fix the original green colour and not to give them the colour, but was, in any case, perfectly innocuous.

In cross-examination the witness was taken through a number of books written by gentlemen whom he admitted were eminent medical men, whose opinions were different from those of the witness, and he stated that the quotations were either copied from other books, or founded upon misconceptions.

Evidence was also given by Dr. Walter Winter, in corroboration of the evidence given by the previous witnesses, and by Mr. Rowson, an importer of preserved vegetables.

The inquiry was again adjourned until Wednesday next, Mr. Bonsey intimating that he had one further witness to call before addressing the Court for the defence.

WHITE FABRIC AND FRUIT STAINS.—For white cotton or linen use fumes of burning sulphur, warm chlorine water. For coloured cotton or woollens, wash with tepid soap-suds or ammonia. For silks the same with gentle rubbing (*Pharm. Era*, xiv., 174).

BOTANICAL NOTES.

FERMENTS IN THE MANUFACTURE OF ARRACK.—F. A. F. C. Went and H. C. Prinsen have investigated the nature of the organisms of the substance known as "raggi," which is used in Java for the fermentation of arrack from rice-starch. Among other microbes they find an interesting organism, which they name *Chlamydomucor oryzae*. It consists of a much branched but unseptated mycelium, and possesses the property of converting amylo-dextrin and ordinary dextrin into dextrose. It is aerobic, coagulates milk, does not invert saccharose, and does not ferment cogluse. It may be obtained either from rice-meal or from the sugar-cane. The authors suggest that it may be a stage in the cycle of development of *Rhizopus oryzae*. In the same material was found also another new organism, which they name *Monilia javanica*. It has the power of fermenting dextrose, saccharose (which it first inverts), raffinose, maltose, and levulose, but not lactose. A true *Saccharomyces*, to which they give the name *S. vordemannii*, was also found, and this appears to be the principal agent in the manufacture of arrack (*Med. van het Proofstat.*, in Snikerriet, West Java, 1894; from *Bot. Zeitung*, 1895, 2te. Abtheil, p. 143).

FORMATION OF CHLOROPHYLL AND STARCH.—A very extended series of observations on the mode of formation of starch grains and chlorophyll bodies in plants has led M. E. Belzung to the following general conclusions. The first process which takes place in the embryo is the formation of starch, the result of the activity of the protoplasm, the chlorophyll body being a secondary formation. With but few exceptions the chlorophyll pigment is diffused through the protoplasm of the young embryo. The substratum of the future chlorophyll body—leucite or plastid—is always fully formed by the time the seed arrives at maturity; the protoplasm has always a reticulate structure; it is the protoplasm of the amyloferons vacuoles which constitutes the chromatophore or leucite. Those starch grains which are destined to constitute the reserve food material in the ripe seed are an exception to this rule, and increase in the meshes where they are originally deposited. In proportion as the embryo becomes green and the mass of green corpuscles more abundant, the starch grains are resorbed; they form a part of the material for building up the green chlorophyll grains. In adult green organs, especially leaves, the starch grains which are formed in the light in the chlorophyll bodies are a result of the assimilating power of these latter, being one of the products of the substance itself of the chlorophyll bodies, a kind of secretion from the green substance. The resorption of the chlorophyll, which in leaves takes place only at the period of the autumnal fall, is, on fruits, effected almost entirely before they ripen. The two essential phases in the life of a plant—the embryonal phase, during which the green cell is built up at the expense of materials which it has not elaborated, and the adult phase, in which its formative activity is manifested by new embryonal conditions—constitute a remarkable example of organic reversibility (*Morot's Journal de Botanique*, vol. ix., 1895).

PROTEIDS OF WHEAT.—Miss M. O'Brien has an exhaustive paper in the *Annals of Botany* (vol. ix., 1895, p. 171) on the distribution and the functions of the aleurone-grains in wheat. She supports the theory of Weyl that gluten is formed by the action of a ferment on the myosin, which is the chief proteid of wheat. The aleurone-grains do not, in the Gramineæ, present that degree of differentiation in which the mineral matters are sharply separated off as a globoid from the proteid constituents of the grain, only the membrane is here differentiated. The theoretical view is advocated of there being in flour one mother-substance which readily undergoes hydration, giving rise to gluten.

THE GERMINATION OF OILY SEEDS.—According to M. Leclerc du Sablon, the reserve substances of oily seeds, whether they are stored up in the embryo or in the endosperm, consist chiefly of oil and aleurone; starch is but rarely found in them. In the species examined the proportion of oil decreases regularly during the period of germination. By the action of a diastase the oil is transformed into fatty acids without any separation of glycerin. During germination these fatty acids, instead of accumulating, are themselves transformed into carbo-hydrates, especially into those belonging to the group of saccharoses. This saccharose is again converted, by the action of a diastase, into glucose, which is directly assimilated by the plant. Starch is also temporarily present as an intermediate product between oil and glucose. Starch and oil, as reserve substances, give rise to the same assimilable products during the germination of the seed (*Bonnier's Revue Générale de Botanique*, vol. vii., 1895).

NEW REMEDIES.

[The notes given under this heading embody recent suggestions in therapeutics. They cover both new drugs and preparations, and old ones under new aspects. The word "parts" is used to represent parts by weight, both for solids and liquids.]

CREOSOTAL OR CREOSOTE CARBONATE.—Chaumier confirms the favourable reports of others on the non-irritant action of creosotal and its value in the treatment of the earlier stages of tubercule. He attributes the usefulness to the fact that, being deprived of irritant properties, it may be given in large doses, up to as much as 20 grammes per diem. He gives it mixed in milk or in cod-liver oil, or else in capsules (*Rev. de Thérap. Méd.-Chirurg.*, lxii., 768).

CUTOL IN SKIN AFFECTIONS.—Under the name of cutol, a combination of alumina, boric acid, and tannin, has been introduced for various affections of the skin. It forms a brownish insoluble powder, which, however, becomes soluble when combined with tartaric acid, and is then called "soluble cutol." Cutol is of great service in the treatment of moist eczema and pruriginous affections. It is prescribed in the form of an ointment; Cutol, 4 parts; olive oil, 10 parts; wool-fat to produce 40 parts. When the secretion has disappeared, the following dusting powder is substituted:—Cutol, zinc oxide, and talc, of each equal parts. Soluble cutol is useful in burns, and a 15 per cent. solution may be used in catarrhal metritis. Hæmorrhoids are treated with an ointment containing 15 per cent. of cutol, and for chilblains the following application is recommended. Cutol, 3 parts; oil of sweet almonds, lanolin, of each 15 parts; orange flower water, 10 parts (*Rev. de Thérap. Méd.-Chirurg.*, lxii., 769, after *Therap. Monatse.*).

EUROPHEN AS AN IODOFORM SUBSTITUTE.—Saalfeld finds that europphen is preferable to iodoform for the dressing of varicose ulcers; for this purpose he uses a mixture of 1 part europphen and 2 parts boric acid. In intertrigo of infants a powder of talc with 5 to 10 per cent. of europphen, and sometimes also 5 per cent. anhydrous wool-fat, effects a rapid cure, even where the usual remedies have failed. Excellent results also follow its application to soft chancres, the powder being applied three or four times a day. Ulcerated gummata are rapidly modified under the influence of the following ointment: Europphen, 3 to 6 parts; olive oil, 3 parts; wool-fat, 30 parts (*Rev. de Thérap. Méd.-Chirurg.*, lxii., 770, after *Therap. Woch.*).

TANNIGEN IN INFANTILE DIARRHŒA.—Tannigen is recommended as acting both as an astringent and as an intestinal antiseptic. Moncorve has given it in doses of from 25 centigrammes up to 2 grammes in twenty-four hours, divided into four or five doses. It has proved equally serviceable in chronic as in acute cases (*L'Union Pharm.*, xxxvi., 548).

PICRIC ACID COTTON AS A DRESSING FOR BURNS.—Delpech has prepared a picric acid cotton-wool for conveniently applying that body to the surface in the case of burns. It is simply made by steeping absorbent cotton in a saturated solution of picric acid and drying. In dressing burns the wool is damped with water and applied wet; the moist dressing should be renewed from time to time. As Thiery has previously recorded, solution of picric acid at once relieves the pain of a burn and promotes rapid healing (*L'Union Pharm.*, xxxvi., 552).

TRIFORMOL AS AN INTESTINAL ANTISEPTIC.—Under the name of triformol, trioxymethylene has been introduced as an intestinal antiseptic. It is a light white substance, soluble in boiling water, and in alkalis. It is stated to be as active an antiseptic as β -naphthol. It large doses of 3 to 4 grammes it has a purgative action, but in small doses it produces constipation (*L'Union Pharm.*, xxxvi., 534, after *Schw. Woch. fur chim., pharm.*).

BELLADONNA EXTRACT IN DENTAL NERVE PASTE.—Diack considers morphine in nerve paste ineffective, likewise tannin, aristol, cocaine, and clove oil. He uses extract of belladonna, 2 parts; arsenious acid, 1 part; made into a paste with glycerin. The belladonna acts on the sensitive nerves, and no pain follows the application of the paste (*Brit. Journ. Dent. Sci.*, xxxviii., 1089).

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulæ for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

BLEACHING BONES AND IVORY.

To make bones a good white colour, the process adopted for bleaching ivory should be adopted. First treat them with strong solution of washing soda to remove grease and open the pores. Then immerse in hydrogen peroxide solution, to which one-twentieth part of strong solution of ammonia has been added, and maintain at a moderate temperature for as long as may be found necessary (24 to 36 hours or more). On removal from the liquid be careful to dry slowly to prevent cracking. [*Reply to J. T. Davy.*]

HAY'S WASH.

The formula for this preparation is as follows:—R, Zinci sulph., gr. ij.; aq. rosæ, \mathfrak{z} i.; tinct. lavand. co., q.s. to colour. Mr. A. McKellar, who sends this information, does not know the origin of the preparation, but states that it is in common demand in Glasgow. [*Reply to Lavender.*]

DISPENSING DIFFICULTY.

Several correspondents point out that "Puzzled" has probably misread the prescription he wrote about (*ante*, p. 60). The third ingredient should probably read "Solut[io] solv[entis] miner[alis]." The dose ordered in the prescription should afford some corroboration if this solution of the problem be correct. [*Reply to Puzzled.*]

REMOVAL OF FACE WRINKLES.

You might try anointing the face with wool-fat, then holding for some time over the vapour given off from boiling water. Keep the head and vessel containing the water covered with a woollen blanket, and gently knead the muscles with the fingers during the operation of steaming. Finally, after wiping the face, apply the following wash:—Alum, 30 grains; glycerin, 2 ozs.; perfumed spirit, $\frac{1}{2}$ oz.; water to 10 oz. Subsequently employ this three times a day and always use a little after washing, applying before the skin is quite dry. [*Reply to Ajax.*]

TO SILVER GLASS.

The surface of the glass is thoroughly cleansed, and then rubbed with chamois skin and bole, all dust being afterwards removed. To 100 C.c. of a 10 per cent. solution of silver nitrate add, drop by drop, solution of ammonia until the precipitate is just dissolved, taking care to avoid a large excess of ammonia. Dilute this solution to 1 litre. Then a 10 per cent. solution of formaldehyde is prepared (the commercial formalin being about 40 per cent.), and one volume mixed with two volumes of the silver solution (*Pharm. Era*, xv., 14). The mixture is poured at once on the glass surface, which is kept at from 15° to 19° C. In from five to ten minutes the silver will be deposited in a bright metallic film. This may be protected by a transparent varnish.

TO CATCH EARTHWORMS.

According to *La Nature*, earthworms may be obtained in any quantity without the labour of digging, by watering the ground with a solution of sulphate of copper of a strength of 1 per cent. This will bring the worms to the surface almost immediately. Soap suds are said to produce the same effect.

ARSENIC FOR SUBCUTANEOUS INJECTION.

Von Ziemssen states that Fowler's solution is not suitable for hypodermic use, since it causes pain and inflammation. He recommends a 1 per cent. solution of arsenic in the form of sodium arsenite, prepared by boiling 1 gramme of arsenous acid with 5 C.c. of normal sodium hydrate solution until completely dissolved. The liquid is then diluted to 100 C.c., filtered, sterilised, and kept in small tubes with cotton-wool stoppers, each containing 2 C.c. The initial dose is 0.25 C.c., once daily; after a few days two injections are made daily, and the dose is gradually increased until the whole syringeful is injected twice daily (*Quart. Med. Journ.*, iv. 187, after *Deut. Arch. Klin. Med.*).

NOTICES TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally, must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

LETTERS.

WHITE WINE VINEGAR AND ACET. DEST.

MR. ARTHUR DECK, of Cambridge, writes as follows:—"Notwithstanding Mr. B. S. Proctor's scientific lecture on 'Vinegar' in the Journal, I still maintain Mr. Octavius Corder is quite correct in his remarks (*vide Ph. J.*, January 11). When white wine vinegar is asked for, diluted acetic acid (made by destructive distillation of wood) ought not to be sold for it, but distilled malt vinegar, or French wine vinegar, is the correct thing. There is an article distilled from malt vinegar sent out by the wholesale pickle makers, quite white, perfectly pure, free from wood acid, of a nice aroma, and an elegant ingredient in salad with only plain oil. White malt vinegar is certainly more of a vinous product than diluted pyroligneous acid, which is only fit for external use, and should not be used for dietetic purposes. I cannot help thinking the magistrate's decision in the white wine vinegar case was a very wise one."

COMPOUND COLOCYNTH PILLS AND PHARMACOPŒIA REVISION.

MR. THOMAS DUNLOP, of Glasgow, says Mr. Wm. Lyon, in his note on compound colocynth pills, published in the Journal of January 18, confirms the statement he made a year ago (*Ph. J.*, January 19, 1895) as to "the suitability of aromatic spirit of ammonia as a massing agent." He differs from him, however, in his opinion that because "the B.P. pill is very frequently (!) prescribed along with calomel," that "constitutes an argument against it"—"sal volatile as a massing agent"—"being included in a new Pharmacopœia." He continues, "The Pharmacopœia has to deal with official, not with private formulæ, and the pharmacist when called upon to dispense pil. coloc. co. c. calomel must show his intelligence by doing so *sec. art.* During the past twenty-five years I have not once dispensed this combination, so that if it is 'very frequently prescribed,' my experience must have been very exceptional. Moreover, the 'usefulness' of all pill excipients is restricted."

ANSWERS.

JAMES HOWORTH.—Please address all communications intended for publication in the Journal to the Editor, according to instructions printed every week at the head of this page.

W. J. DODRIDGE, JUNR.; H. LUCAS.—Ordinary advertisements must not be sent to the Editor. See instructions at head of page.

GRIMBLE AND KENT.—Paper received, with thanks.

W. SIMONSON.—The general indexes to the *Pharmaceutical Journal* that you possess are the only ones that have been published. The fact that there is no general index to the last seventeen volumes of the third series is felt by many to be an inconvenience, and though work is now being done in connection with the preparation of such an index for those volumes, no arrangements have been made for printing and publishing it. Possibly it might be published by subscription, but everything will depend upon the number of readers requiring it.

H. GOHRT.—See reply to J. T. Davy on page 79.

W. H. D.—Many thanks for your suggestion.

LIN. SAPONIS.—The "anti-ferment" for preserving cordials, etc., is a strong aqueous solution of sodium salicylate, containing a large proportion of acetic acid but no boric acid.

OBITUARY.

AMES.—On January 1, at Bloemfontein, O.F.S., South Africa, John Charles Ames, Pharmaceutical Chemist. (Aged 27.)

DAVIDSON.—On January 11, William Davidson, Chemist and Druggist, Aberdeen. (Aged 65.)

HOLLOWAY.—On January 13, Joseph Holloway, Chemist and Druggist, Sheepshed. (Aged 59.)

HOLMES.—On January 16, Joseph Holmes, Chemist and Druggist, Leeds, at his residence, Claremont, Garforth. (Aged 53.) Mr. Holmes devoted much time to public business, and for some years past had filled the office of Alderman in the West Riding County Council.

PUBLICATIONS RECEIVED.

THE POISONOUS PLANTS OF THE VICINITY OF NEW YORK CITY.

By PROFESSOR HENRY H. RUSBY, M.D. Being a report of a lecture delivered to the Alumni Association of the College of Pharmacy of the City of New York. Pp. 19. From the Author.

MINUTES OF THE GENERAL MEDICAL COUNCIL, AND OF ITS COMMITTEES, from November 25, 1895, to December 2, 1895, with thirteen appendices. Pp. 481. (London: Spottiswoode and Co., 54, Gracechurch Street, E.C., 1895.) From the Registrar.

THE PHYSIOLOGY OF THE CARBOHYDRATES. An Epicriticum. By F. W. PAVY, M.D., LL.D., F.R.S., F.R.C.P. Pp. 141. Price 3s. 6d. (London: J. and A. Churchill, 11, New Burlington Street, W., 1895.) From the Publishers.

TWENTY-SIXTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF MASSACHUSETTS. Pp. 892. From the State Board of Health, State House, Boston, Mass., U.S.A.

ESSENTIALS OF VEGETABLE PHARMACOGNOSY. By HENRY H. RUSBY, M.D., and SMITH ELY JELLIFFE, M.D. Pp. 149, with 560 illustrations. Price \$2.50. (New York: D. O. Haynes and Co., 1895.) From the Publishers.

POISONING CASES AND INQUESTS.

Cyanide of Potassium.—William Christison, aged 32, of 155, Eglinton Road, Plumstead, died from the effects of cyanide of potassium, supposed to have been taken by deceased in mistake for his medicine. At the inquest held on January 1, the jury returned a verdict to the effect "that deceased died from the effects of poison, but that how the poison was administered there was no evidence to show."

Laudanum.—Mary Tolley, aged 42, of 42, Newcastle Street, Nottingham, died on January 2, from the effects of inadvertently drinking an overdose of laudanum. Verdict: "Deceased died from an overdose of laudanum taken by misadventure."

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Allen, Alder, Adams, Ames, Bramley, Blythe, Browne, Barry, Bienvenu, Bindloss, Bayley, Bird, Burge, Blinkhorn, Bellamy, Blackburn, Bentley, Capit, Carter, Cracknell, Cooper, Clarke, Dunlop, Davy, Deck, Dyer, Davis, Dispenser, Elliott, Eastman, Ekins, Ellis, Forrester, Fragner, Fletcher, Gohrt, Hearn, Holmes, Hill, Henry, Johnston, Keech, Kerr, Line, McKellar, Maiden, Maish, Peck, Pryse, Randall, Reynolds, Stratton, Sedge, Smith, Thomas, Thompson, Tully, Williams, Westmacott.

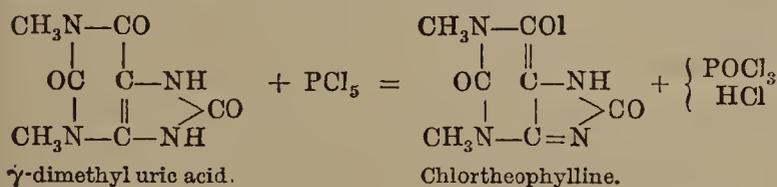

“THE MONTH”

Synthesis of Caffeine.

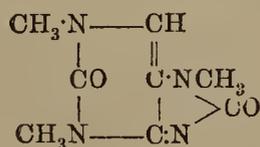

Since the discovery of caffeine in 1821 by Runge and Pelletier, its subsequent identification with theine by Berzelius and Dobet, and its analysis by Liebig, the relation of this substance to uric acid was indicated by Rochleder, and more recently Strecker showed its relation to theobromine. E. Fischer then established the relation between these two bases and xanthine. Since that time theobromine has been represented as dimethyl xanthine, and caffeine as trimethyl xanthine. But notwithstanding the evident close relation of uric acid to xanthine, all attempts to convert uric acid into that substance have been unsuccessful. Professor Fischer now points out that this is due to constitutional differences which are shown by the following formulæ:—

The difference between these two compounds consists not only in the number of oxygen atoms, but also in the situation of the double linkage and of the hydrogen atoms. In the methyl derivatives of uric acid hitherto known, the structure of the carbon chain has remained unaltered, while hydrogen and oxygen have been removed from the alloxan nucleus. Fischer and Ach have now succeeded in replacing both hydrogen atoms of the alloxan nucleus by methyl and have thus obtained γ -dimethyl uric acid, convertible by means of phosphorus oxychloride and pentachloride into the chlorine derivative of theophylline, as shown below:—

By reduction with hydriodic acid chlortheophylline is converted into theophylline, and this yields by methylation caffeine:—

At present this synthesis does not admit of practical application, as it involves too many operations. But if it should prove possible to methylate uric acid directly, so as to substitute two methyl groups in the alloxan nucleus, the case will be different, and the synthetic production of caffeine may become of technical value (*Berichte*, xxviii., 3135).

Action of Alkalies on Sugars.

Loboy de Bruyn and van Ehenstein, in studying the behaviour of glucose, fructose and invert sugar towards alkaline salts of weak acids, have found that very minute proportions of alkalies affect the rotation of several carbohydrates very materially. The influence thus exercised indicates a certain degree of transformation, for glucose

and fructose give as a result syrups which are almost inactive, and galactose one for which the value of $[\alpha]_D$ is about $+30^\circ$, while the respective normal values for $[\alpha]_D$ are $+53^\circ - 91^\circ$ and $+81^\circ$. As the general result of a large number of experiments, it has been ascertained that this change is due to a reciprocal transformation of the different sugars into each other. This has been established in the case of glucose, fructose, and mannose. Each of these sugars is changed under the influence of hydroxyl ions, alkalies, etc., into the other two (*Berichte*, xxviii., 3078).

Production of Ozone.

Brink has shown that oxygen prepared from potassium chlorate and manganese peroxide in the ordinary way contains ozone. When oxygen gas is passed over manganese peroxide heated to 400°C ., or even to redness, ozone is also formed and the oxides of cobalt, silver, nickel, mercury, lead, chromium, uranium, and gold, act more or less in the same way. Lead peroxide heated to 400°C . yields ozone even in a stream of carbonic acid gas (*Zeitsch. Anorg. Chem.*, 1895, 222).

Absorption of Nitrogen by Lithium.

In preparing argon by means of lithium, Deslandres observed that hydrogen was evolved, and he heated lithium in a vacuum in order to separate it. The metal became dark at the surface and showed fissures. After cooling, nitrogen gas was passed over the metal and was slowly absorbed, showing that lithium combines with nitrogen even at the ordinary temperature. The amount of the absorption depends upon the extent of bright metallic surface (*Comp. rend.*, cxxi., 886).

Determination of Albumin in Urine.

When albumin is associated with peptone or albumose in urine, asaprol or the calcium salt of β -naphthol-sulphonic acid precipitates all the albuminous substances from the acidified urine, but on boiling the peptone and albumose precipitates redissolve, while the albumin precipitate remains unaltered. This precipitate is soluble in dilute caustic potash, and Riegler finds that the albumin may be determined in such a solution by means of the refractometer (*Ph. Centrallh.*, xxxvii., 19).

Urine Testing.

Zeehuisen points out the importance of diluting urine, before applying tests, until its specific gravity is reduced to at least 1.005. In that condition most satisfactory results are obtainable with the nitric acid test for albumin, with Fehling's test for sugar, and in testing for the pigments of bile (*D. Med. Wochenschr.*, through *Ph. Zeit.*, xli., 22).

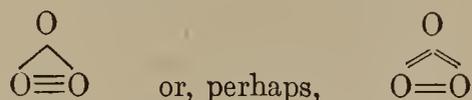

Hydrogen Peroxide.

By a series of chemical, physical, and especially spectrometric investigations, J. W. Brühl has been led to the conclusion that hydrogen peroxide must be looked upon as containing tetratomic oxygen, and that its constitutional formula is $\text{H}\cdot\text{O}\cdot\text{O}\cdot\text{H}$. The theory of the tetratomicity of oxygen is in accord with the views of H. Rose as to the compounds termed by him *quadrantoxides*, as Ag_4O , etc. The behaviour of the compound of HCl and methylic-ether, $\text{HCl}(\text{CH}_3)_2\text{O}$, lately discovered and studied by H. Friedel, furnishes further argument in support of the tetratomicity of oxygen in a free state. In support of his theory the author refers to the electrolytic formation of H_2O_2 from nascent hydrogen and molecular oxygen, and its instantaneous decomposition by nascent oxygen. Further evi-

dence is furnished by the easy decomposition of H_2O_2 into water and molecular oxygen, which may be represented as taking place in two phases.

The intense reducing property of H_2O_2 is especially characteristic, and is probably due to the very loose attachment of the atoms of hydrogen by means of supplementary valencies. It is also probable that ozone has a similar constitution. Its formula would then be—

A further hypothesis is suggested by the author in the case of carbonic oxide, the only compound in which uncombined carbon-valencies have had to be admitted hitherto. This would no longer be necessary if the tetratomicity of oxygen can be assumed. The old theory of uncombined carbon-valencies is inconsistent with the spectrometric behaviour of CO, as well as with its small faculty of combination with chlorine or with the other halogens. These facts are more in accord with the constitution, being $C : O$. Such an hypothesis involves, of course, the existence of unsaturated oxygen-atoms in all other organic compounds which contain an odd number of oxygen-atoms. There is no reason why this should not be admissible, as triatomic phosphorus, and nitrogen-atoms, and diatomic sulphur-atoms, which undoubtedly are unsaturated, are often met with in organic compounds (*Berichte*, xxviii., 2842).

Constitution of Water.

J. W. Brühl points out that, according to the constitutional formula suggested for hydrogen peroxide in the preceding note, the analogous formula of water would be $H \cdot \dot{O} \cdot H$. Water would thus be an unsaturated compound, and, in fact, no other chemical compound possesses the criteria of unsaturation in such a high degree as water. Most compounds combine easily with water and are hygroscopic, hydrates containing crystal water combinations are very numerous, and, finally, water is the most general and powerful solvent. Such a constitution of water would also agree with the high power dissociation which water exercises upon several organic compounds in separating their molecular aggregates. Alcohols, ethers, esters, ketones, phenols, and other solvents which are capable of causing dissociation, and are analogous to water in this respect, contain oxygen, whilst hydrocarbons, etc., which have not that capacity, do not contain oxygen. Water contains the largest amount of oxygen, and its dissociation power is the highest; then follows methyl-alcohol, and the dissociation power of the higher homologues of methyl-alcohol gradually decreases (*Berichte*, xxviii., 2866).

Solanine in Potatoes.

In various works statements have been published as to poisonous effects caused by the solanine present in potatoes, and, with the view of ascertaining the normal amount contained in potatoes before and during germination, a series of determinations have been carried out by G. Meyer in the pharmacological laboratory of Strassburg, under the

direction of Professor Schmiedeberg. Sound potatoes were found to contain 44 parts of solanine in a million parts. When peeled the amount was only half as much. Young potatoes contained, between July and August, from 201 to 236 parts in a million; Malta potatoes only 50 parts per million. During sprouting in a cellar, between March and July, the amount of solanine increased from 90 to 112 parts in the million, and the sprouts contained from 2.72 to 5 per cent. of solanine, according to their length. Shrivelled potatoes were found to contain 144 parts per million, and rotten potatoes covered with black fungus contained as much as 1340 parts per million. Schmiedeberg's experiments as to the toxic effects of solanine on rabbits showed that, when continuously administered in considerable doses insufficient to cause vomiting, the mucous membrane of the stomach and intestine may be affected without augmenting the tendency to acute poisoning. Consequently potatoes cannot have toxic effects unless the amount of solanine becomes unusually large under special conditions, but it is evident from the results above quoted that such an influence may possibly be exercised (*Arch. exp. Path. Pharmacol.*, 1895, xxxvi., through *Apoth. Zeit.*, xi., 11).

Chinosol.

This substance is described as a neutral compound of an oxyquinoline. Trials made at the hygienic institute in Munich have shown that it has a powerful antiseptic action, and is comparatively innocuous. Professor Kossmann, who has used it in place of sublimate and carbolic acid, confirms the antiseptic and non-poisonous action. Chinosol does not attack the hands, though it is said to be forty times as effective as carbolic acid, a solution containing 25 parts in a million being sufficient to hinder the development of staphylococcus pyogenes aureus, the most resistant of the pus-micro-organisms (*Ph. Centralh.*, xxxvii., 40).

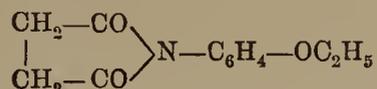

Mercury in Mercurous Tannate.

C. Glücksmann finds the methods usually recommended for determining the quantity of mercury in this preparation to be unreliable, and, guided by experiments made with the view of improving them, prefers to dissolve the preparation in nitro-hydrochloric acid, dilute with water, reduce with a solution of pure barium hypophosphite acidified with hydrochloric acid, and filter off the precipitated mercurous chloride. This is then dissolved in a measured quantity of $\frac{N}{10}$ solution of iodine with the aid of a little potassium iodide, and the excess of iodine removed by a measured quantity of $\frac{N}{10}$ solution of sodium hyposulphite, the excess of which is determined by titrating back with the iodine solution. This method is said by Glücksmann to yield quick and reliable results. (*Oesterr. Zeitschr.*, l., 147).

Pyrantin.

This name is given to a product of the reaction of succinic acid with derivatives of *p*-amidophenol, obtained by Professor A. Piutti and described by him as possessing properties analogous to phenacetin and methacetin, and as being free from the disadvantages of analogous antipyretics. It is prepared by melting together *p*-amidophenetol hydrochloride or phenacetin with succinic acid and extracting with alcohol. It is colourless, crystallises in needles melting at 155° C., is insoluble in ether, but soluble in 83.6 parts boiling water, and in 1317 parts of water at 17° C. Pyrantin has been found especially useful in rheumatic fever, by Professors Renzi, of

Naples, and De Giovanni, of Padua. It is said to be without action on the heart or respiratory organs, and not to cause disturbance of digestion. Pyrantin is *p*-ethoxyphenyl succinimide—

Alkalies convert it into salts of *p*-ethoxyphenyl succinamic acid, which are soluble in water. Both forms are manufactured by Messrs. Meister, Lucius, and Brüning, in Höchst (*Chemiker Zeitung*, xx., 54).

Glycerose or Glyceric Aldehyde.

Fonzes-Diacon has obtained this compound in considerable quantity by the action of mercuric chloride upon glycerin. A mixture of these substances gradually heated to 150° or 160° C. in a very capacious retort yields a distillate containing the aldehyde, acrolein and chlorinated products; this is neutralised with soda and shaken with benzene to remove some oily substances. The clear, yellowish liquid remaining consists for the most part of glyceric aldehyde. The substance has great reducing power, and is applicable for silvering glass, as well as for photographic purposes, as a developer. It forms with phenylhydrazine an osazone soluble in alcohol, very sparingly soluble in water, and melting at 131° C. (*Bul. Soc. Chim. de Paris*, xxiii., 862).

Detection of Nitrates in Water.

Alessandri and Guassini mix the evaporated residue of the water while warm with a few drops of a solution of carbolic acid in strong hydrochloric acid, and on heating an intense reddish-violet coloration is produced if the least trace of nitrates is present. On addition of ammonia the colour changes to emerald green. Water containing very minute traces of nitrates gives the violet colour, and the green colour is produced when the amount of nitrate is still smaller (*Bollet., Chim. Pharm.*, 1895, 490).

Lithium Sub-Chloride.

By heating a mixture of molecular weights of metallic lithium and lithium chloride to a red heat, a sub-chloride, Li₂Cl, is formed. It is described by M. Guntz as forming a greyish, very hard, and homogeneous mass, resembling fused sodium chloride. In the presence of water it decomposes energetically, hydrogen being evolved, and lithium chloride and hydrate formed (*Comp. rend.*, cxxi., 945).

Strontium and Calcium Iodides.

M. Tassilly has obtained strontium iodide in crystals, corresponding to the formula SrI₂·7H₂O, thus differing from those described by Croft, which contained a molecule of water less. Similarly, by slowly evaporating a concentrated solution of calcium iodide at the ordinary temperature, Tassilly has obtained crystals of the composition CaI₂·8H₂O (*Comp. rend.*, cxxii., 82).

Mydriatic Drugs.

The Australian correspondent of the *Lancet* reports that Dr. Joseph Lauterer, of Brisbane, has been investigating the active principles of *Duboisia myoporoides*, introduced into medical use by the late Dr. Bancroft, and some other mydriatic plants. He finds that the old leaves and twigs of *D. myoporoides* contain hyoscyamine, the fresh young leaves scopolamine. When the flowers commence to bud the leaves are richest in alkaloid, containing then 0.3 per cent. In

winter the amount is much smaller, and may fall to 0.03 per cent. Dry leaves contain 0.97 per cent. alkaloid, and are much stronger than belladonna leaves. *Duboisia leichardtii* is richer in alkaloid, and contains chiefly amorphous scopalamine. The leaves of *Brugmansia arborea*, and *B. knightii*, natives of South America acclimatised in Queensland, contain less alkaloid, consisting of two-thirds hyoscyamine and one-third atropine.

Characters of Spermaceti.

The United States Pharmacopœia requires spermaceti to possess a specific gravity "about 0.943, and a fusing point near 50° C.," but L. F. Kebler has obtained data on examining several samples which do not correspond with those stipulated by that authority. Reference to different publications showed that the figures recorded ranged from 41°·6 to 47°·7 C. for the melting point of spermaceti (cetin—48°·9 to 55°·5), whilst the specific gravity approximated generally to 0.943 at 15° C. A table is given, showing the result of the examination of seventeen specimens by Kebler, who concludes that the melting point of spermaceti varies from 42° to 47° C., and that of cetin from 48°·9 to 55°·5; the specific gravity of spermaceti ranges from 0.905 to 0.945 at 15°, and its saponification number from 125.8 to 134.6, whilst the acid number varies with the age of the sample. The requirements of the U.S.P. would appear, then, to correspond with the figures for cetin rather than for those of spermaceti (*Am. Journ. Pharm.*, lxxviii., 7).

Conversion of Casein into Albumose and Peptone.

The action of *Bacterium peptofaciens* in effecting this change has been applied to the treatment of milk by Alex. Bernstein under a patent for producing a liquid containing soluble albuminous substances, together with the milk sugar and salts of the milk. By subsequently fermenting with suitable ferments an alcoholic liquor containing peptone is also produced. The peptone bacterium is chiefly found in milk; it is rod-shaped, occurring generally in pairs, and shows very active motion (*Milchztg.*, 1895, 942, through *Ph. Centralh.*, xxxvii., 21).

Alteration of Milk by Boiling.

Professor Rubner points out that when milk is boiled the albumin is coagulated, but not the casein, and that the question whether sterilised milk has been boiled can be determined by separating the casein by addition of salt and warming to 30° or 40° C., then filtering and heating the clear filtrate to the boiling point. If the milk had been previously boiled this filtrate would not contain albumin, but otherwise it will coagulate on heating to the boiling point (*Hygien. Rundschau*, through *Ph. Centralh.*, xxxvii., 18).

Carissin.

A new glucoside, isolated from the bark of *Carissa ovata*, R. Br., var. *stolonifera*, by J. H. Maiden and H. G. Smith, has been provisionally named "carissin." It is described as very poisonous and exceedingly bitter, causing nausea and headache. The taste is also persistent. The purified glucoside is totally insoluble in petroleum spirit, ether, or chloroform; slightly soluble in absolute alcohol in the cold, much more on boiling. Dilute alcohol and hot water dissolve it readily, but it is not readily soluble in cold water. The substance could not be obtained in crystals, but formed an amorphous, slightly deliquescent mass when purified by treatment with amylic alcohol. It is readily decomposed by all acids, and somewhat resembles strophanthin, differing from that glucoside in

being precipitated by basic acetate of lead and by tannic acid. It also gives a precipitate with KI+I solution, and produces a yellow colour, changing to yellow-brown and then purple, when dissolved in concentrated sulphuric acid. The most characteristic reaction of carissin, however, is the beautiful emerald-green colour produced when a portion of the dry substance is dissolved in concentrated sulphuric acid, and a minute fragment of potassium bichromate added.

Assay of Ergot.

H. Beckurts has determined the percentage of alkaloid present in a variety of samples of Russian, Austrian, Spanish, and German ergot. It was found that by percolation with petroleum spirit the fixed oil but no alkaloid was removed. Twenty-five grammes of each sample were therefore freed from oil by that means, dried and shaken with 100 grammes of ether and 1 gramme of magnesia, previously suspended in 20 C.c. of water; 60 grammes of the ethereal solution are freed from alkaloid by repeated agitation with .5 per cent. hydrochloric acid, from which the alkaloid was then removed by ammonia and ether. The latter liquid on evaporation left a yellowish-white crystalline residue of alkaloid. The determinations agreed with those previously made by Keller. Russian and Austrian were the best, the richest samples containing .20 per cent., whilst the best German yielded only .15, and Spanish .14. Drying by artificial heat diminished the yield of alkaloid by about 10 per cent. (*Oesterr. Zeitschr.*, l., 31).

Urea as a Diuretic.

Dr. Klemperer draws attention to the solvent action of urea upon uric acid, and states that he has found urea very useful as a physiological diuretic and solvent of uric acid, even more efficacious than piperazine, lysidin, etc. It is given in solution (5 to 10 per cent.) in doses of a tablespoonful hourly. It is important that the urea should be pure, and the best criterion of this is the melting point, which is $132^{\circ}\cdot5$ C., and not 120° , as stated in most text-books. So far back as 1870 Lubavin showed that the melting point of artificially prepared urea was 132° C. (*Berlin Klin. Wochenschr.*, through *Pharm. Zeit.*, xli., 30).

Polygonin.

Full details of the examination of the root of *Polygonum cuspidatum*, a plant originally introduced into the Leeds district by Mr. Richard Reynolds, are now published by A. G. Perkin. The glucoside extracted, for which the name "cuspidatin" was formerly proposed (see *Ph. J.* [4], i., 445), is now termed "polygonin," $C_{21}H_{20}O_{10}$. It was obtained in the form of orange-yellow needles, which softened when heated to 200° , and melted at 202° - 203° . From its solution in boiling alcohol, in which it is but sparingly soluble, it is deposited in a gelatinous condition if rapidly cooled, but when the solution is left to cool slowly the glucoside separates as a mass of hair-like needles. It is only sparingly soluble in boiling water or ethylic acetate, and almost insoluble in ether. Orange-red liquids are formed by treating it with cold dilute alkalies or baryta water, and the potassium derivative occurs in the form of red, flat, microscopic needles. Polygonin yields emodin on hydrolysis, but the root also yields free emodin, an emodin monomethyl ether, and a wax, $C_{18}H_{28}O$, melting at 134° - 135° , and consisting of beautiful, colourless leaflets which resemble phenanthrene in appearance. The presence of emodin shows a chemical connection with rhubarb root, whilst the bark of *Rhamnus frangula* and root-bark of *Ventilago madraspatana* both contain emodin

methyl ether. There is also a connection with *Morinda umbellata*, which contains an identical wax (*Journ. Chem. Soc.*, lxvii., 1084).

Caffeine in Kola Nuts.

As the result of a comparative examination of African and West Indian kola nuts, Dohme and Engelhardt find that the former are richer in caffeine than the higher-priced Jamaica product. Two methods of extraction were employed. In the first the powdered nuts were exhausted with chloroform, and in the second, which extracted the caffeine more completely, $33\frac{1}{3}$ per cent. alcohol was used. The results were as follows:—

	African Nuts.	Jamaica Nuts.
Method I.—Caffeine.....	2.04 per cent.	1.75 per cent.
„ II.— „	2.24 „	1.93 „

The extract from the Jamaica nuts was lighter in colour than that obtained from the African nuts, the two resembling in colour tea and coffee infusions respectively (*Am. Journ. Pharm.*, lxviii., 5).

Production of Storax.

After much trouble J. Moeller has succeeded in following the secretion of storax in the stem of *Liquidambar orientalis*, and he has published a detailed account of his investigations, fully illustrated with drawings and photographic reproductions. Moeller shows that storax is a pathological, not a physiological product, and that it is formed after slight injury only to the stem; too extensive an injury appears to be followed by the production of but little storax. In the pith there occurs normally a circle of schizogenous ducts, the secretion in which, however, bears no resemblance in odour to storax. But if the stem is gently beaten, secretion-ducts are formed at the point of injury in the young wood and there only, though the secreted balsam may find its way to the exterior of the stem, through fissures, etc., and saturate portions of the bark. Extremely interesting is the fact that the secretion-ducts are of schizogenous origin, and subsequently only become lysigenous. In the production of storax, the probability is that the stems are hacked, and after some time, during which secretion of balsam takes place, the bark and young wood are removed, and the hacking is repeated on another portion of the stem. From the chips and bark thus obtained the balsam is separated by boiling in water. The secretion of sweet gum in the stem of the American *L. styraciflua* appears to have a similar origin (*Oesterr. Zeitschr.*, l., 19).

Cinnamon Chips.

T. F. Hanausck has lately observed in powdered cinnamon the presence of white particles, which proved to be due to admixture of the wood of the cinnamon tree; the powdered cinnamon consisted principally of powdered cinnamon "chips." To determine that point the wood of the cinnamon tree (*Cinnamomum zeylanicum*) was examined. The chief distinctive characters were found in the medullary rays, the vessels, and wood-parenchyma. The medullary rays are two-rowed, the cells usually radially elongated, but sometimes nearly square or axially elongated, in which case they frequently contain a dark brown mass; the walls are always thickened and porous. The vessels vary considerably; spiral vessels 30μ wide are occasionally found, which are derived from the primary wood and indicate that whole twigs have been powdered. The vessels of the secondary wood have sometimes large oval pores, sometimes oval or

hexagonal bordered pits, sometimes scalariform perforations. The cells of the wood parenchyma are frequently so thickened and lignified as to be true stone-cells, and not unfrequently contain a dark brown mass. All these characters must be identified before the wood can be pronounced to be that of the cinnamon tree (*Oesterr. Zeitschr.*, l., 34).

Source of Dammar.

J. Wiesner has investigated the source of the dammar resin of commerce. From the examination of specimens of the branches (without flowers or fruit) sent from Padang in Sumatra, Wiesner concludes that the tree yielding this resin does not belong to the natural order Coniferae at all, but to Dipterocarpaceae, and will in all probability prove to be an undescribed species of Burck's genus *Hopea*. *Dammara orientalis* (Coniferae) yields a resin totally distinct from commercial dammar, but closely resembling Australian dammar or kaurie gum (from *Dammara australis*, Lamb). Much confusion has apparently been introduced by the changes in the names of certain genera of the two orders (*Oesterr. Zeitschr.*, l., 14).

Powdered Allspice.

E. Spaeth has repeatedly observed in powdered allspice a foreign powder, which he has determined to be powdered pimento stalks. These are frequently present in the commercial drug in not inconsiderable quantity, and when powdered can easily be recognised microscopically by the small, thick, one-celled hairs, by the long colourless or pale yellow bast fibres, and by the sclerenchymatous cells, which are smaller and paler than those of the powdered fruits. Clove stalks, which are a common article of commerce, both whole and powdered, have no hairs, their bast fibres are thicker and more deeply coloured, the sclerenchymatous cells are yellow and more numerous, and portions of the epidermis are frequently discernible (*Forschungs-Berichte*, ii., 419).

Calumba Root.

A. Hilger contributes a review of the three active principles of calumba, viz., columbin, columbic acid, and berberine. Columbin is represented by the formula $C_{21}H_{24}O_7$, and is converted by dilute acids and alkalis into columbic acid, of which it is to be regarded as the anhydride. In calumba root it occurs in combination with berberine. During the conversion of columbin into columbic acid, especially by the action of 15 per cent. hydrochloric acid, the columbin is changed into a yellowish-brown mass, whilst the solution assumes a bluish-green fluorescence, and slightly reduces Fehling's solution. From the details given it would appear that this fluorescence is not due to columbic acid, but to some other body that has not yet been isolated (*Oesterr. Zeitschr.*, l., 8).

Structure of Bacterial Cells.

H. Wager is of opinion that in a bacterial cell there are two different substances to be recognised—a nuclear substance and a cytoplasmic substance. The nuclear substance has a definite structure, which is found in principle in all bacterial cells and plays an important part in the division of the cell, but it is simpler in structure and form than the nucleus of the higher plants and animals. In the protoplast of one short bacillus examined a central rod was distinguished, which stained

deeply in fuchsine and other aniline dyes, and fairly deeply in Delafield's hæmatoxylin. This rod was not digested by pepsin. In connection with it occurred a substance which stained but slightly. Division of the cell was found to be preceded always by division of the central rod. Other bacteria have a more complicated structure, though always referable to the above as a type. In *Spirillum undula* numerous deeply-stained bands were seen crossing the cell transversely, after treatment with fuchsine. They were in close contact with the cell wall, and connected with one another by a layer of less deeply stained substance (*Annals of Botany*, ix., 659).

Proteids of Wheat.

Wheat flour is derived entirely from the endosperm of the wheat grain, the germ or embryo being removed before the grain is ground. Dr. M. O'Brien has previously shown that the proteids of the flour are two globulins (coagulating at about 55° C. and 75°-80° respectively); proteose, not coagulated by heat; and the mother-substance of gluten. He is now able to show that the proteids of germ and of flour seem to correspond, so far as the globulins and proteoses are concerned, but in the remaining proteid-matter they differ widely—the insoluble gluten of the endosperm being replaced by albumin in the germ. The supposed albumin obtained from flour by Osborne and Voorhees, and named by them leucosin (see *Ph. J.* [3], xxv., 171), is thought by O'Brien to be rather a globulin (*Annals of Botany*, ix., 543).

Structure of Jaborandi Leaves.

A. Vogl has described the structure of the leaflets of *Pilocarpus trachylophus*, Holmes, and compared it with that of true jaborandi leaves derived from *P. jaborandi*, Holmes. The following are the principal differences observed:—In the leaflets of *P. trachylophus* the palisade cells are much more slender, and occupy about one-third of the mesophyll, whilst in *P. jaborandi* they occupy only one-fourth or one-fifth; the outer walls of the epidermal cells of the under surface are arched so as almost to form papillae; in nearly all the epidermal cells of the upper surface spherograins and aggregated crystals of hesperidin are of regular occurrence; on the under surface there are numerous hairs. The latter is also the case with a number of leaves that are always to be found amongst the jaborandi leaves of commerce, but the question whether these are derived from a different species, or from a variety produced by change in the environment, must for the present be left an open question (*Oesterr. Zeitschr.*, l., 1).

Proposed Substitute for Saffron.

Heim proposes to employ the dried perianth of *Tritonia aurea*, Poppe (*Crococoma aurea*, Pl.) as a substitute for saffron. In a preliminary note on the subject, he states that the dried petals give when boiled with water an intensely yellow solution of even finer colour than that obtained from the ordinary saffron. On prolonged boiling the infusion loses its characteristic odour, due probably to the loss of a trace of volatile oil. The yellow colouring matter is more soluble in dilute alcohol and in alkaline solutions than in water, but it is insoluble in absolute alcohol and in benzol. The partly dry aqueous extract gives with sulphuric acid a blue coloration, passing to violet, similar to that obtained from saffron. *Tritonia aurea* is a handsome bulbous plant, indigenous to

Southern and Tropical Africa, where it is roughly cultivated as a dye stuff. The fact that the whole flower, and not the stigmas only, contain the colouring matter, indicates that the plant might prove worthy of extended cultivation. Further chemical examination is promised (*Nouv. Rém.*, xii., 217).

Autumnixanthin. Staats finds that the yellow coloration of leaves in autumn is due to the presence of a substance soluble in alcohol, and differing from the phylloxanthin produced together with phyllocyanin from chlorophyll by the action of hydrochloric acid gas in not showing the red fluorescence of chlorophyll when dissolved in alcohol. Fremy, Hoppe-Seyler, and Schunck have attributed the yellow coloration of leaves in autumn altogether to the conversion of chlorophyll into phylloxanthin (*Berichte*, 1895, 2807).

Effects of Heat on Pepsin. F. A. Thompson finds that dry insoluble pepsin can stand more heat than the soluble form. The United States Pharmacopœia (1890) states that dry pepsin can be heated to 100° C. without injury, and this statement appears to be more than borne out by the following results of experiments, which show the respective digestive powers before and after heating for one hour to the temperatures indicated (*Bulletin of Pharmacy*, ix., 539):—

Variety of Pepsin.	Original Digestive Power.	D.P. Temp. 250° F. (121°·1 C.).	D.P. Temp. 280° F. (137°·7 C.).	D.P. Temp. 330° F. (154°·4 C.).
Insoluble.....	4000	4000	1000	200
Soluble (Scale)	4000	4000	200	—
„ (Powder) ...	Abt. 2000	Abt. 2000	No action	—

Superfatted Soap. F. Edel points out that whilst superfatted soaps have been recommended as ointment bases, they are not advisable for general use, though peculiarly adapted for ointments containing sulphur, ichthyol, tar, resorcin, etc. He finds, however, that the most carefully prepared superfatted soaps on the market are more or less irritating when applied to inflamed surfaces, and recommends the following formula as producing an excellent soap of the kind:—Dissolve caustic potash, 2 oz. in water 16 ozs.; melt together lard, 5 oz., and coco nut oil, 5 oz., and add the lye with constant stirring. Heat moderately and continuously until saponification is complete. The process may be hastened by adding alcohol, 3 ozs. Then add wool-fat, 3 ozs.; lard, 2½ ozs.; coco-nut oil, 2 ozs., and glycerin, 4 ozs. Mix thoroughly and heat for ten or fifteen minutes, afterwards stirring constantly until cold. If more glycerin be desired, replace part of the potash by soda (*Bulletin of Pharmacy*, x., 7).

Repairing Platinum Apparatus. Small holes in platinum laboratory apparatus may be stopped by melting a trifling amount of gold chloride around the edges by the application of gentle heat, then turning on the oxy-hydrogen blow-pipe flame. The reduction of the chloride causes a plug of gold, or an alloy of gold and platinum, to fill the hole. Larger openings may be closed by means of suitable pieces of platinum foil, using gold chloride as a flux, and soldering the foil to the vessel by the heat of the blow-pipe flame as before (*National Druggist*, xvi., 10).

SHORT NOTES ON THE PREPARATIONS AND FORMULÆ OF THE BRITISH PHARMACOPŒIA.

WINES.

The use of wine as a menstruum or vehicle for the administration of drugs is an old-fashioned custom, the origin of which is probably due to the fact that wine was formerly the most convenient, and generally available, alcoholic fluid. Preparations made with wine had therefore the character of permanence which the presence of alcohol imparted, beside the collateral advantage of pleasant taste and odour, which serves to mask the nauseous qualities of many drugs. At the present time the use of wine as a menstruum or vehicle for any particular drug requires to be justified by both the following conditions:—

1. The drug must be easily and thoroughly susceptible of exhaustion by weak alcohol.
2. The wine must have the property of masking the taste or modifying the character of the taste so as to make the preparation palatable.

Even the strongest wines, which contain about 18 per cent. of alcohol, are obviously unsuitable menstrea for certain drugs, and nothing further need be said under this head. If the second condition be not fulfilled, then the preparation of a "vinum" is not justified, because alcohol in the form of wine is more expensive than alcohol as plain rectified spirit. A further point which militates against the use of wine is the great variation in character to which a wine—sherry, for example—is liable. If the character of the wine serves to mask the taste and odour of the drug, then the variations of the wine will be reproduced in the "vina" prepared from it. The stimulant properties of wine tend to encourage its use particularly in connection with tonics.

Vinum Aloes.—This wine is very seldom used. The taste of the aloes is very imperfectly masked, and the proportion of aromatics—2 grains each of cardamoms and ginger in the fluid ounce—cannot be expected to exert an appreciable carminative action.

Vinum Antimoniale does not require any special reference.

Vinum Aurantii.—No mention is made in the Pharmacopœia of the necessity of removing tannin, particularly when the wine is used as a vehicle for iron preparations. A well-made orange wine is much to be preferred to the cheap sheries commonly used for pharmaceutical purposes, the latter costing even then about twice as much as the former.

Vinum Colchici.—This is a respectable old-fashioned preparation, which is extensively used. This probably indicates that its medical effects are satisfactory. The small quantity of wine contained in a medicinal dose cannot, however, have much influence on the flavour of a "mixture," in which form colchicum wine is nearly always administered.

Vinum Ferri.—This is a most unsatisfactory preparation. Published statistics show that it is liable to great variation in the quantity of iron contained in it, these variations being chiefly due to variations in the wine which do not easily admit of rectification. In short, the iron seems chiefly to serve the purpose of spoiling the sherry. The small quantity of iron it does contain probably exists in a form nearly related to the iron in ferrum tartaratum.

Vinum Ferri Citratis.—This is a very satisfactory preparation of iron for administration to children. It is pleasant, easily made and of definite strength.

Vinum Ipecacuanhæ.—A good deal of controversy has raged around this preparation, in which form ipecacuanha is chiefly administered as an expectorant. The "acetum" at present

contained in the Appendix of 1890 is no doubt a very active preparation, but ipecacuanha is so frequently prescribed with alkalis—ammonium carbonate, *e.g.*, that a neutral preparation is still required. The evaporation of the percolate in the official wine damages the alkaloidal contents, and unless it is carried down to dryness, acetic acid will be present in the finished product. It seems, therefore, desirable to modify the wine by adding to sherry a strong fluid extract, as has been suggested, or to replace it altogether by a fluid extract or some similar preparation. The retention of a "wine" of ipecacuanha can only be desired on sentimental grounds, since wine is not a suitable menstruum for the drug, and the small amount contained in an expectorant dose is not worth consideration either as a stimulant or flavouring agent. The solution of ipecacuanha alkaloids in wine could not be called vinum ipecacuanhæ any more than vinum quininæ could be regarded as vinum cinchonæ.

Vinum Opii.—This only requires mentioning to suggest its removal from the official formulæ. It is little used, and we already possess a tincture and fluid extract, the latter being also little used.

Vinum Quininæ.—This is a popular form for the administration of quinine as a tonic and appetiser, and no alteration is obviously required.

Vinum Rhei.—Another obsolete preparation. Its removal from the Pharmacopœia would cause the deletion of canella from the list of official drugs.

Vinum Xericum.—The Pharmacopœia simply describes this as "a Spanish wine." There is no doubt that a large proportion of the sherry used in pharmacy is quite innocent of the juice of the grape, and is made in Germany. The palate of an expert easily distinguishes the Spanish from the Hamburg variety, but it is not so easy to devise tests for the same purpose which could be introduced into the Pharmacopœia. The weaker sherry which is admitted under the 1s. duty is also unsuitable for pharmaceutical purposes, the percentage of alcohol not being high enough to render its preparations stable. The percentage of alcohol—seventeen—given in the B.P. characters of course excludes this weaker wine. Part of the extreme variability and unsatisfactory behaviour of vinum ferri is no doubt due to the use, in many cases, of Hamburg sherry or natural sherry of low alcoholic contents.

DISTRIBUTION OF MUCILAGES IN PLANTS.—J. A. Guiraud has investigated the distribution of the mucilages in the officinal Malvaceæ, especially in *Malva sylvestris* and *Althæa officinalis*. He states that the receptacles are not of lysigenous origin, as has usually been stated. The mucilage is formed in all the organs, and results from the gelatinisation of the walls of special cells found only in the secondary parenchyme. It may remain in enclosed cells, or may flow out into passages or receptacles formed by a dissociation of the tissues. In the root the formation of the mucilage coincides with that of the secondary structures. In the stem of *Malva* the mucilage cells appear first in the pith, then in the cortical parenchyme and the hypodermal parenchyme; it is most abundant in the periphery of the stem, where it arises partly in the cells, partly in the intercellular spaces. In the leaf its formation follows a similar course to that in the stem, occurring both in the cells and in special receptacles; it abounds especially in the leaf of *M. sylvestris*. Mucilage is very abundant in the flowers of *Malva* and *Althæa*, but its distribution very variable; in *M. sylvestris* it occurs in large quantities in the epiderm of the calyx and epicalyx, and in the fundamental parenchyme of the petals (*Du développement et de la localisation des mucilages chez les Malvacées officinales*, Toulouse, 1894. From *Bot. Centralblatt*, vol. lxi., 1895, p. 376).

FERMENTATION.*

BY JOHN WELSH, PH.CH.

Although for many years scientists have held various opinions regarding the nature of fermentation, nowadays they are almost unanimous in holding that it is caused by the living processes of minute bodies (micro-organisms), so minute as to require the most powerful microscopes, in order to investigate their structure, yet endowed with natural power, power which, when exercised, results in good or ill effects to every living being. These organisms live upon organic matter, and in so doing split up the organic matter into matter possessing entirely different properties.

The minuteness of these organisms is so excessive that their dimensions baffle description in the ordinary terms of measurement; thus we find, as a common length, one twenty-thousandth of an inch; and thus one writer remarks very popularly, "Four hundred millions of these organisms could be spread over one square inch in a single layer; and, therefore, we could have four times the population of London on an area of a square inch, without any complaint of overcrowding, the one four-hundred-millionth of a square inch being quite adequate for a citizen in the commonwealth of micro-organisms.

We must have all noticed the scum which appears on putrefying liquids; this scum is a colony of organisms held intact by mucus. These organisms are very often reproduced at this stage, known technically as the zooglea stage. The reproduction takes place by the formation of "spores," and it is to these spores I wish to draw your attention. They cling to life so tenaciously that the cold of an Arctic winter or the heat of tropical summer has little or no effect upon them. The organisms themselves would be destroyed, but their spores appear to be almost immortal; little wonder, then, that fermentative processes make their appearances almost everywhere, that the morning's milk is sour before nightfall, that the ointments in our pharmacies so readily become rancid.

I do not intend, in this brief abstract, to say anything regarding "yeast," the plant which causes that kind of fermentation known as alcoholic, so very much matter having already been written upon the subject. With regard to alcoholic fermentation itself, it is necessary to note that—

The *Saccharoses* (sugars of the grape sugar type) ferment immediately, whilst the "disaccharoses" (sugars of the cane sugar type) will not ferment with pure yeast, but with ordinary yeast, owing to its containing another ferment which first converts the "disaccharose" into a "saccharose," fermentation will take place. Upon these two points depends the fact that the production of beer involves two distinct fermentations: 1. Diastasic, *i.e.*, the converting of the starchy matter in the seed into "maltose" and "dextrin" by the ferment "diastase," which is formed in the seed during germination. 2. True alcoholic, *i.e.*, the converting of the "maltose" into alcohol and carbon dioxide.

We are not dependent entirely upon yeast for alcoholic fermentation, the spores of several fungi, notably "*Mucor mucedo*," and "*Penicillium glaucum*" having this power. It is said the presence of fousel oils in alcohol produced by yeast is due to these fungus spores.

Acetic fermentation, another well-known matter, I shall pass by, simply remarking that it differs entirely from "alcoholic," in that the "oxygen" of the air becomes a factor, as seen in the equation: $C_2H_5OH + O_2 = CH_3COOH + H_2O$.

It is also interesting to note that the organism which produces this fermentation appears to be the only one at all partial to alcohol,

* Abstract of a paper read before the Liverpool Pharmaceutical Students' Society on November 14, 1895.

this being quite an exception in members of the lower creation, and even this organism is so particular as to have absolutely nothing to do with solutions which contain more than 10 per cent. of alcohol; another writer very wittily remarking "that the wisdom of such an aversion could be developed in man, the sole consumer of alcohol, were indeed a consummation devoutly to be wished."

Lactic and Butyric Fermentation.—These two are so closely allied that I have grouped them together. "Lactic" is caused by a ferment contained in sour milk; free acid is formed during the process, which would destroy the ferment were it not that chalk is added to neutralise the acid as it is formed. "Butyric" fermentation takes place as a second stage if "sour cheese" be added to the sour milk, the "lactic acid" first formed being transformed into "butyric acid" by the ferment contained in the cheese.

The equation illustrating the formation of "lactic acid" also illustrates the fact that many of these organisms act as "hydrolytics," *i.e.*, they add water to the body acted upon, thus:—

Fermentation has been found to be the fact wanted for years to account for two very important agricultural questions. The one, how is nitric acid formed in the soil? The other, can the free nitrogen of the air be absorbed and assimilated as food by plants? I will conclude with very few remarks about the first.

Nitric acid is one of the most important of plant foods in the soil, if absent it is stated that, to grow even the apology of a crop of corn or roots, though all other conditions be perfect, would be impossible. In 1877 two French chemists found that the power of converting the nitrogen of nitrogenous substances was the property of micro-organisms, but since then it has been found that this organism only transformed the nitrogen into nitrous acid, an acid very rarely found in soils. How, then, is the nitric acid produced? This question has been answered by the discovery of another organism, whose special work is to convert the "nitrous" into "nitric" acid, and thus the "nitrification of soils," it is clear, depends upon fermentative processes set up by two distinct organisms, the one converting the nitrogen into nitrous acid, the other, the nitrous acid into nitric.

From this we find a solution to that strange fact over which many a thoughtful student must have wondered. I refer to the presence of those immense deposits of Chili saltpetre found in the rainless districts of Chili. One can scarcely credit that such minute organisms could produce such a vast amount of a commercial article. What countless ages ago? and what myriads of these minute organisms must have been at work? are two questions well worthy the exercise of our imagination. "There is romance in Science."

The uses of fermentation to pharmacy, as seen in the action of ferments upon glucosides and other organic bodies; the splitting up of complex organic bodies into entirely different and simpler bodies, helping investigators to arrive at correct conclusions as to the relations and formulæ, etc., of such bodies; the preparation of new compounds artificially, by means of ferments, as the result of Emil Fischer's work shows; the physiological effects of ferments are all most interesting and instructive. In fact, our knowledge of "fermentation" is in its infancy, as all other knowledge is, as compared to the vast districts of the unknown yet untraversed, and there is interest and romance saturating every point of this subject, a fairy tale, indeed, yet more reliable and, shall I say, more interesting and wonderful.

REVIEWS AND NOTICES OF BOOKS.

MACHINERY AND APPARATUS FOR MANUFACTURING CHEMISTS.

By JAMES C. SHEARS, Assoc.M.Inst.,C.E. Pp. 93. Price 3s. 6d. (London: E. Marlborough and Co., 51, Old Bailey, E.C. 1895.)

The author of this book has been for many years engaged in the manufacture of plant for pharmaceutical laboratories, and has now thought fit to record his experience in a permanent form. He describes and briefly explains the use of steam boilers, evaporating pans, vacuum pans, stills, stirrers, condensers, drug mills, emulsifiers, percolators, hydraulic presses, and other forms of apparatus used by manufacturing chemists. The matter is illustrated, and suggestions are given as to the best forms of apparatus to be used for special purposes.

A LABORATORY MANUAL OF ORGANIC CHEMISTRY. By Dr. LASSAR-

COHN, Professor of Chemistry in the University of Königsberg. Translated, with the author's sanction, by Alexander Smith B.Sc., Ph.D. (London: Macmillan and Co. 1895.)

This work is of a nature entirely different from other books on organic chemistry. Instead of the descriptions of individual compounds as to physical characters, composition, constitution, etc., which make up the bulk of most manuals dealing with this subject, the methods actually followed in the prosecution of laboratory work are described and illustrations given of their application so as to show their relative fitness for producing the results desired. By the adoption of this plan a very serviceable deviation has been made from ordinary routine, affording most valuable assistance to students and even to advanced workers. A vast mass of information has been gathered together in a concise form from the multitude of publications in which original communications have appeared, and copious references are given to the sources whence it has been taken, to provide for the possibility that the original papers may have to be consulted.

The matter is arranged in chapters with headings descriptive of the several operations, by means of which particular chemical changes are effected, and under sub-heads the relative applicability of different reagents made use of for that purpose is treated of. The general methods described in the nine chapters forming Part I. include the application of heat by means of baths, crystallisation, decoloration, distillation, drying, extraction, filtration, determination of melting points and molecular weights, operations with sealed tubes, and sublimation. Eleven chapters in Part II. describe special methods, including condensation, preparation of diazo-compounds and esters, fusion with caustic alkalies, preparation of halogen compounds, oxidation, reduction, saponification, and the preparation of sulphonic acids, while in the twelfth chapter the methods of determining the elementary constituents of organic compounds are briefly described.

The publication of an English translation of Professor Lassar-Cohn's work will serve a useful purpose in directing attention to the various methods by which the chemical transformation of organic compounds may be effected. Text-books very generally give little information on this point, and often convey an impression that there are no difficulties in the way of obtaining products in the full proportions indicated by the equations given. The preparation of an ester from an acid and an alcohol with elimination of water appears extremely simple from a theoretical point of view, but the student soon finds that the yield indicated by an equation cannot always be obtained in the laboratory unless certain definite conditions are observed. It is to assist students in overcoming such difficulties that this work is intended, and those who have not had

the opportunity of making extensive reference to chemical literature will find collected together for their guidance all that is essential without the necessity of having recourse to memoirs scattered through numerous chemical publications. On that account the work will be a most valuable companion to assist students engaged in the prosecution of organic chemistry.

FORMULAIRE DES MÉDICAMENTS NOUVEAUX FOR 1896. By H. BOCQUILLON-LIMOUSIN, with an introduction by Dr. H. Huchard. Pp. 306. Price 3 francs. (Paris: J. B. Baillière et fils, 19, rue Hautefeuille. 1896.)

The seventh annual edition of this most useful little compilation appears in its usual style, and contains detailed references to aïrol, apolysin, argonin, cannabindone, caseinate of iron, cotarmine, cuprohemol, eudoxin, ferripyrin, gallicin, glycerophosphates, hemo-gallol, hemol, lysidin, nosophen, phosphergot, pixol, salipyryne, salithymol, sublumo-phenol, tannigen, and numerous other remedies of comparatively recent introduction. It is almost needless to say that the book is cordially recommended to all English pharmacists who desire to have in a handy form the latest information concerning the novel medicaments that seem to invade pharmacy unceasingly.

A PHARMACOPŒIA FOR DISEASES OF THE SKIN. Edited by JAMES STARTIN, Senior Surgeon to the London Skin Hospital. Fourth edition. Pp. 53. Price 2s. 6d. (Bristol: John Wright and Co. London: Simpkin and Co., Ltd. 1896.)

In the words of the editor, this pharmacopœia is published for the use of students and medical practitioners engaged in active practice. It is small enough to go into the waistcoat pocket, yet besides containing concise directions for the preparation of numerous baths, mixtures, ointments, lotions, and caustics, space is found for rules of diet, a classification of skin diseases, and a therapeutical index.

ANATOMISCHER ATLAS DER PHARMAKOLOGIE UND NAHRUNGSMITTELKUNDE. By Dr. A. TSCHIRCH and Dr. O. OESTERLE. Parts VII. and VIII. Price 1s. 6d. each nett. (London: Williams and Norgate. 1895.)

These two parts of the anatomical atlas of Tschirch and Oesterle include the description of cassia, cinnamon, canella alba, taraxacum root, cardamoms, nux vomica, hemlock leaf and fruit, henbane and insect flowers. They complete the first volume of this excellent work, and in them, as in the previous parts, many new observations are recorded, to a few only of which attention may here be directed.

In the description of the anatomy of cassia bark the development of the oil cells and of the mucilage cells is of special interest. In early stages they cannot be distinguished from one another; in those destined to secrete oil either one of two things happens, either a resinogenous layer is formed from the inner layer of the cell wall, in which oil is produced, or several layers of mucilage are first deposited, and on the innermost of these the resinogenous layer is formed and secretion of oil takes place; in the mucilage cells no oil is formed, and in this manner Dr. Tschirch explains the occurrence of oil and mucilage in separate cells or in the same cell, a fact that has often been noticed in cassia and cinnamon bark. During the preparation of the drug from the fresh plant the cinnamic aldehyde which can be detected in the oil cells of the latter, diffuses almost completely into the surrounding tissue. According to the author, cinnamon bark is characterised by the formation of bast fibres at a much earlier period than cassia, but there is no reliable means of distinguishing powdered cinnamon from powdered cassia, a statement at direct variance from the

accepted utterances of other eminent histologists. In taraxacum root the development of an anastomosing network of laticiferous vessels is facilitated by the mucilaginous nature of the intercellular substance, by which branches can be pushed between cells at points where it would otherwise be impossible. Extremely interesting is the anatomy of the cardamom fruit and seed, which is illustrated by an excellent plate; in the form of powder, the pericarp is distinguished by its bast fibres, whilst Ceylon wild cardamoms are characterised by the thick walls of their epidermal cells. The development of the nux vomica seed from the ovule is closely followed. Here only one seed coat is present, the epidermal cells of which develop into the characteristic hairs; the remaining cells at first fill with reserve material, which, however, is subsequently absorbed, the cells collapsing to form a narrow layer under the epidermis. The micro-chemical detection of the alkaloid is best effected by sulpho-vanadic acid, which colours the oil-globules and proteld granules of all the endosperm cells deep violet.

In Part VIII., the anatomy of hemlock leaf and fruit first calls for attention. For the micro-chemical detection of the alkaloid coniine, sulpho-vanadic acid again appears to render good service. In the leaf the alkaloid is localised principally, if not entirely, in the epidermis; in the fruit, on the other hand, it is not confined to the layer known as the coniine layer, but occurs in the layer exterior to that, in the epidermis and in the intervening parenchyma. The plate illustrating the anatomy of the fruit is a masterpiece of clearness, to which the colour of the ink used for this, but not all plates, contributes not a little. In the description of insect flowers, attention is drawn to the difficulty of distinguishing the Persian from the Dalmatian powder; the detection of turmeric, mustard and other powders said to be used to impart the bright yellow colour demanded by pharmacists can be effected with facility.

The care that has evidently been bestowed on these two parts places them on the same high level as the previous parts, which have already been noticed in these columns.

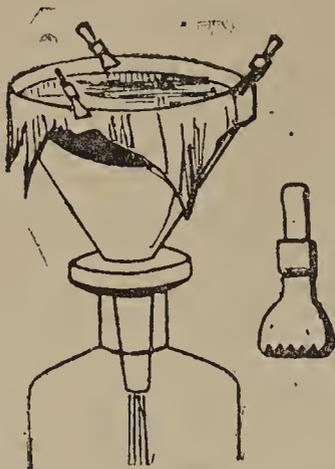

GUY'S HOSPITAL REPORTS. Vol. LI. 1894. Edited by E. C. PERRY, M.A., M.D., and W. H. A. JACOBSON, M.A., M.Ch. Pp. 272. Price 10s. 6d. (London: J. and A. Churchill. 1895.)

This volume as usual contains much useful information. The majority of the papers are surgical, and include an interesting communication from Mr. Thomas Bryant on temperature after operation. A valuable statistical paper, furnished by Mr. G. B. Smith, on the question of amputation in senile gangrene, based on a study of forty-eight cases. Mr Newland-Pedley contributes two articles, one on the treatment of suppuration of the maxillary antrum; the other is a very critical review of the treatment of congenital cleft palate, which well deserves attentive consideration. Dr. John Fawcett gives the results of an investigation of piperazin undertaken with the view of determining (1) the solvent power it possesses in urine upon uric acid calculi; (2) the value of it in gout; (3) the effect of the drug when given to birds, uric acid deposits having been produced in them by injections of potassium chromate. In regard to its effects in gout, Dr. Fawcett's conclusions are these: "The drug neither relieves the pain, nor does it increase the uric acid elimination. It is also very expensive, and so, as it does not appear to possess any greater value, but rather less, than the drugs already recognised in the treatment of gout, I can see no indication for continuing its use further." Dr. Silk gives a paper on the administration of gas and ether and Dr. Pye-Smith relates cases of bilateral paralysis of the facial and auditory nerves. The volume concludes with the customary information relating to the school, museum, and pupils.

NOVELTIES IN PHARMACEUTICAL APPLIANCES.

SIMPLE FUNNEL CLIP.

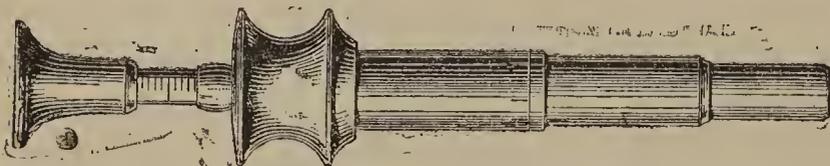

A very simple metal clip has been recommended for fastening a calico strainer on to a funnel so that the contents may, if

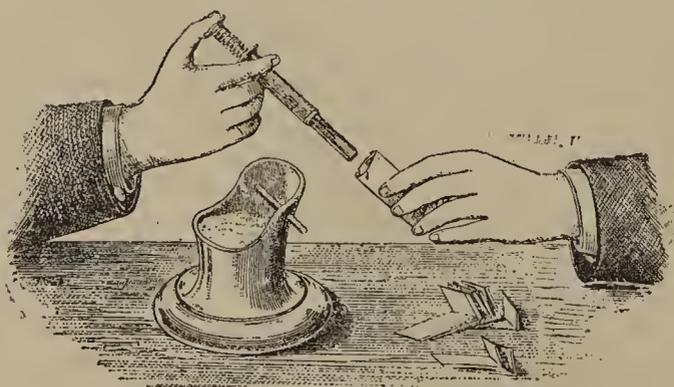

necessary, be stirred, or the strainer left without fear of its slipping; they are easily fixed in position, and should prove very useful (*Pharm. Zeit.*)

CONVENIENT POWDER MEASURING APPARATUS.

The immense amount of valuable time consumed by the tedious weighing of powders has led to the invention of various means by which powders can be measured instead of weighed. One of the most convenient appears to be that of Fr. Hausmann (*Pharm. Centralh.*), which consists of an adjustable piston working by a spring in a cylindrical tube. It is made in two sizes, the smaller for powders weighing about 0.1 to 0.5 gramme, the larger for those between 0.5 and 2.0 grammes. The quantity of powder taken up by the apparatus can be delicately regulated by a coarse

and fine adjustment, each of which carries a scale, so that a position once ascertained for any powder can be registered for future reference. A small porcelain cup contains the powder, and is provided with a glass rod by which excess is removed. A skilled workman is said to be able to weigh just 1000 powders from the

exact calculated quantity; in unskilled hands a difference of at most 10 powders in 1000 is to be expected, part of which is undoubtedly due to loss by dust, or increase of weight by absorption of moisture, according to the nature of the powder. This little piece of apparatus has been in daily use in the pharmacy of its inventor for many years.

CORRESPONDENCE.

[Letters to the Editor should be written as concisely as possible, on one side of the paper only, and preferably with name and address for publication.]

THE USE OF BORIC ACID AS A PRESERVATIVE.

Sir,—The possibilities of mischief ensuing upon the use of boric acid as a preservative of milk and other articles of food seem not to have received the attention they deserve. Since 1891, when the Kensington Vestry sought the advice of Sir A. Clark, Sir Henry Thompson, and Dr. Lauder Brunton on the subject, no further step appears to have been taken. The opinions of those eminent men were cautiously expressed, *vide Pharm. Journ.* [3], vol. xxi., p. 865, but they concurred in pronouncing the use of boric acid in large doses, or over prolonged periods, to be dangerous to health.

During the exceptionally hot weather which prevailed last September some milk was delivered to a household here, which is believed to have had boric acid added to it by the dairyman. In ignorance of this the cook used "glacialine" to preserve it, and ultimately it was made into blanc-mange.

The ladies to whom this was served up were attacked with vomiting and other symptoms of gastric irritation, and were for several days seriously ill. The remainder of the blanc-mange was given to the fowls, with the result that six out of the nine died, apparently from exhaustion, being unable to take food. An examination of the stomachs made by the medical officer of health, Dr. M. K. Robinson, revealed organic lesions, penetrating below the inner surface of the stomach, and apparently caused by an irritant poison.

If this was really caused by boric acid, such a result is strangely at variance with the generally accepted belief that it can be safely applied, not only as a dusting powder to the tender skin of an infant, but also to the eye, to mucous membranes generally, and even to open wounds.

Dr. Robinson referred to the experience gained in a public institution by using boric acid as a remedy for epilepsy in lieu of bromide of potassium; which pointed to the risk of serious injury to the kidneys, as well as to the stomach.

This should put the chemist on his guard against the possible evil effects of this preservative when used both by the dairyman and the consumer; although unfortunately it is more than probable that he will lack the opportunity of exercising his vigilance.

In the case I have described, the customer obtained the "glacialine" from the grocer; and too often the curious perversity of the public in seeking their supplies of drugs and chemicals from those who are necessarily ignorant of their properties, deprives them of a valuable safeguard. I may add that "glacialine" responds to the tests for boric acid.

Dover, January, 27, 1896.

J. F. BROWN.

RUSSIAN PETROLEUM may, according to Riche and Halpen, be distinguished from American by the relative solubility of fractions of the same density in a mixture of equal parts of chloroform and 93 per cent. alcohol. The specific gravity is taken, and then 4 grammes of the oil are weighed into a flask, and the chloroform-alcohol mixture added until the opalescence produced disappears. The result is compared with the figures obtained from genuine petroleum, and given by the authors. The lighter portions of both varieties of petroleum consist of derivatives of members of the methane series, and so do the medium and heavier portions of American oil, whilst in the Russian these latter are mostly isomers of olefines (*Monit. Scientif.*, and *Ph. Centralh.*, xxxvi., 313).

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

FIFTY-FIFTH YEAR OF PUBLICATION.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, FEBRUARY 1, 1896.

PROFESSIONAL UNIONISM.

THE lack of union amongst British pharmacists is notorious, and is being continually commented upon, various remedies being suggested from time to time, but the ideas of the promoters of the suggestions receiving little support generally from the rank and file of the craft. It is interesting, therefore, to observe that the medical profession in this country, which is a much better consolidated body, is afflicted by a similar trouble, not so marked in its effects perhaps, but yet tending to impede progress. The British Medical Association, a purely voluntary combination with sixteen thousand members, does not include half of the total number of practitioners on the Medical Register. Whilst, therefore, it compares favourably with the Pharmaceutical Society, which does not include quite one-third of those registered under the Pharmacy Acts, it is, nevertheless far from being in a position to pose as the representative of the whole medical profession. But even if such an almost impossible position were attained, either by the British Medical Association or the Pharmaceutical Society, so that the whole profession in either case could act as one individual, there would yet remain many problems which the action of the representative body would probably fail to solve, inasmuch as its organisation would prove too cumbersome, and its machinery be too difficult to set in motion, to deal satisfactorily with matters of comparative minor importance. Such matters, in fact, would require a devolution of authority, and they can be much more promptly and satisfactorily dealt with by local medical and pharmaceutical associations in the districts affected.

The necessity of some such differentiation of duties and division of labour is plainly manifest to leading medical practitioners, strong evidence of this being afforded by two addresses published in the *Lancet* for January 18 last, and by the editorial comments thereupon in the same number of that publication. The text of both addresses is the same, and, to paraphrase the words of our contemporary, in both cases is shown a personal grasp of the subject in all its bearings, with a thorough fulness of detail as to the evils under which the medical profession labours, and the remedies that must be applied to save it from degradation and possible destruction. In the address delivered by Mr. W. G. DICKINSON before the South-West London Medical Society,

he raises the question, What is meant by unionism in the profession? and proceeds to discriminate between trades-unionism and what he happily terms "professional unionism." Disclaiming all sympathy with the methods of trades-unionism, and insisting that all dissentients from the main body should be treated as gentlemen, he yet urges that moral pressure should be brought to bear upon those who incline to sacrifice the honour of their profession, and in cases where remonstrances have no effect the delinquents should be left severely alone. No man, it is pointed out, is altogether insensitive to the opinion of his fellows, but to bring a sufficient amount of moral pressure to bear, local professional unions should be established, which should be free from exclusiveness and place no limitations on individual freedom of action, unless this should be in violation of recognised ethical principles. Care must also be taken to protect the interests of the public. The objects of the unions would be to establish freedom of action in all questions between the members and the public, to render the profession more self-governing, and to cultivate that *esprit de corps* which is so frequently lacking. The address of Mr. FRANK STURGESS, to the Beckenham Medical Society, proceeded on similar lines, and whilst devoting greater attention to ways and means, the speaker insisted upon the paramount necessity of forming local unions all over the country, and by that means enforcing the principles of professional unionism.

The scheme of protection thus ably propounded by two equally skilful exponents of the merits of self-aid seems distinctly feasible, and there is little reason to doubt that in the present temper of the medical profession it may soon become an accomplished fact. Its chief recommendation is its simplicity. No special legislation is required, no unwieldy organisation, but simply the means available in every place where half-a-dozen or more members of a profession are established in practice. The special needs of every locality can be studied, and the procedure of the local union adapted accordingly. Nothing need be done that will clash with the interests of the public. Indeed, the unions would be likely to receive popular sympathy rather than censure, and in that would reside a great part of their strength. The question suggests itself, therefore, why should not pharmacists also seek to support this principle of professional unionism? In many instances the means are ready to hand in the local associations that have done such good work in the past, and may be expected to do still better in the future. Perhaps not to the same extent, but yet to some extent, the majority of the pharmacists in any particular district could bring moral pressure to bear upon unprofessional competitors in their own ranks. The results could not fail to be good, and would improve with the growth of experience, consequent upon the passing of years filled with records of useful work.

UNQUALIFIED ASSISTANTS.

MR. W. L. CURRIE, of Glasgow, has once more drawn attention to the employment of unqualified assistants in branch shops (*vide* p. 96), and pointed out that for pharmacists to raise themselves above suspicion "they must boldly face the question and give their dignified but united support to the Pharmaceutical Council." There is reason to believe that the practice referred to is surely, if slowly, dying out. Certainly the time that has elapsed since the matter first received attention ought to have sufficed to put an end to the practice of leaving pharmacies in charge of unregistered persons. Strictly, no pharmacy ought ever to be without a

registered individual in charge, and in the public interest, no less than in that of pharmacy, the application of this principle ought to be extended rather than restricted. The day of unqualified assistants is passing, in pharmacy as well as in medicine. In the latter connection it is noteworthy that a correspondent of the *British Medical Journal* suggests the issue by the General Medical Council to the profession of some warning to the effect that "the era of unqualified assistants must come to an end"; that after a given period (say three or four years) their employment will no longer be sanctioned, but regarded as "infamous conduct in a professional respect." Such a rule would work hardly, less so in medicine than in pharmacy, but it may at any time be found necessary in the public interest, and is best guarded against by fulfilling the requirements of the law with regard to qualification at the earliest possible opportunity.

ADVICE TO CONTRIBUTORS.

ONE of the greatest difficulties editors experience at the present day is to persuade contributors that, other things being equal, conciseness of expression conduces more than anything else to render articles and letters generally attractive. Nothing tends to destroy the interest of readers in a subject more than a diffuse style of writing, and the following advice from *Merck's Market Report* should be acted upon by everyone concerned:—"Life is short. Time is precious. We ask our contributors to write every paper as they would a telegram that they have to pay for by the word. Verbosity kills many a good article. Few care to take the pains to get the meaning of a verbose writer. Go over your papers again and again, cutting out every word and sentence that adds nothing to the meaning. Try and give in ten words the same idea that when first written took twenty. Every good writer is such because his finished sentences contain only the ten and not the twenty words. Do not string out your sentences with conjunctions. Make them all short and pithy. We ask you to do this for your own sake and the sake of your readers. They will the better understand and be more willing to render to you the meed of appreciation." Whilst, however, the advice of our contemporary is excellent, his style is somewhat too intermittent and aphoristic to suit the taste of English readers. Correspondents should therefore act upon the advice but not necessarily copy the style, for even the much-abused conjunction is useful and ornamental in its place.

PROFESSOR STANISLAS CANIZZARO.

It has been felt by Italian chemists that it would be a graceful act to present to Professor CANIZZARO some little recognition of his services to science on his 70th birthday, which occurs on July 12. To this end a committee has been formed, and a circular has been issued, which is being sent not only to Italian chemists, but also to those in foreign countries, who know what work has been done by Professor CANIZZARO and might possibly wish to thus join in recognising its value. Subscriptions should be sent to the treasurer, DOTT. VICTORIO VILLAVECHIA, Al Laboratorio, Centrale delle Gabelle, Piazza Mastai, Rome, before the end of April.

COLOUR PHOTOGRAPHY.

At a special meeting of the Royal Society of Edinburgh, on Monday last, Mr. F. E. IVES gave an interesting demonstration of his method of recording colour by photography. The reproduction of colours was beautifully illustrated by

throwing on the screen, by means of an electric light lantern, the three slides produced by three negatives, one of which had been exposed to the rays from that portion of the spectrum associated with the red, another with the green, and the third with the blue-violet colour sensations. The three slides consisted of three uncoloured photographs of a plate of fruit consisting of apples, oranges, bananas, and grapes, and they differed in no respect from one another in appearance. By introducing suitable coloured glass screens, one slide was illuminated with red light, another with green light, and the third with blue-violet light. Then by a simple mechanical adjustment the three pictures were exactly superimposed on the screen, with the result that the dish of fruit stood out on a perfectly white ground, and the different fruits showed brilliantly, each in its rich natural colours, these being reproduced so accurately as to make it difficult to believe one was not looking at the actual fruit. The stereo-photo-chromosome, as the novel apparatus employed is termed, is in appearance like an ordinary stereoscope. When a series of three pairs of uncoloured photographs similar to those shown on the screen are viewed in the stereo-photo-chromosome, the dish of fruit is seen as in a stereoscope, with the addition that it appears in all its natural colours, and the effect is extremely realistic. Several practical applications of this ingenious instrument have been suggested, one of which is that it might be valuable for preserving colour records of skin diseases, which would be useful to the physician for diagnostic purposes. The perfected stereo-photo-chromosome seems to bring this method of making colour records within the sphere of practical utility.

A NEW BLACK AND WHITE PROCESS.

PROFESSOR HUBERT HERKOMER, R.A., has invented a new method of preparing artistic printing surfaces, in which chemical and electrical means enable blocks to be prepared for printing without the intervention of the engraver. On Tuesday last, at the rooms of the Fine Art Society, London, he gave an exposition of the process, the details of which are as follows:—A picture is painted upon the surface of a copper plate, which is covered with a thin coating of silver cyanide, the medium employed being a special ink resembling printing ink. This ink practically never dries, however, and after using it for the sketch, a specially prepared copper-brown powder is shaken thickly over the picture, the surplus powder being afterwards removed. This powder granulates the ink and gives it the conductivity which is required for the next stage—electro-plating. An electrotype negative is then prepared in the ordinary way, and from the negative copies can be struck off by the press. The inventor claims for his process that it enables a painter to come before the public in black and white without the intervention of the engraver, without having himself to learn another art, and without reversing the picture; he has merely to paint in this black ink just as he would paint ordinarily, and he can see the effects that he produces. The artist does his work, in fact, in the same way as it should appear when printed. The specimens that have been exhibited bear out Prof. HERKOMER's claim that the new process is capable of indicating every subtle variation of tone. The granulation of the inked surface has the peculiarity that the coarser particles of the powder go where the ink is thicker, while the finest particles only are received where there is little ink—that is, for grey and light tones.

ANNOTATIONS.

EVENING MEETING IN LONDON.—At the next evening meeting of the Pharmaceutical Society, which it should be specially noted is fixed for Tuesday evening, February 11, instead of the time-honoured Wednesday, the following papers are announced to be read:—(1) "The Detection of Aconitine," by Professor Wyndham R. Dunstan, M.A., F.R.S., Sec. Chemical Society, and Francis H. Carr, Salters' Research Fellow in the Research Laboratory of the Pharmaceutical Society; (2) "Essential Oils of Black and White Peppermint," by John C. Umney. The chair will be taken by the President of the Society at 8 o'clock precisely. Before the reading of the papers the formal transfer of the Burroughs' Memorial Fund will be made to the President, it having been decided that the Memorial shall take the form of a scholarship. Subscribers to the Fund are invited to be present.

DEATH OF AN OLD-TIME DRUGGIST.—The *Liverpool Post* publishes an interesting paragraph in connection with the death of Mr. Edmund Jackson, of Castle Park, Lancaster, who died on Monday last, in his ninetieth year, having been born on April 16, 1806. He was formerly in business as a chemist in Lancaster, but was never registered under the Pharmacy Act. He is said to have been the first tradesman to introduce plate glass into his windows (? at Lancaster). It appears that young Jackson attended the same school at Lancaster as the late Professor Owen, Professor Whewell having just left at the time he entered. He has lived under four sovereigns—George III., George IV., William IV., and Victoria—and was present at Westminster Abbey on the occasion of the coronation of the Queen. He was the oldest freeman of the borough of Lancaster, and has only one surviving son, the Rev. Edmund Jackson, Rector of Gilmorton, Leicestershire.

THE MANUFACTURE OF POISONOUS SHEEP-DIP.—The *West Ham Herald* refers to the conditions under which the manufacture of a new kind of sheep-dip is alleged to be carried on in certain East London factories. The sheep-dip is composed of caustic soda, sulphur, and arsenic, and the *Herald* states that in spite of every precaution—the use of overalls, silk handkerchiefs for the face, proper ventilation and washing arrangements—the deadly powder penetrates to the skin, works into the finger-nails, and clogs the men's eyes. It seems to be impossible for work on such materials when used wholesale to be conducted without certain injury to the workers, and a doctor has given it as his opinion that no one can survive more than four or five years' constant work at the trade. The *Daily Chronicle* asks if this is not a case which the Home Secretary should ask the Departmental Committee now inquiring into dangerous trades to look into at once?

ENLARGEMENT OF THE "ANALYST."—It is satisfactory to note that the Society of Public Analysts finds itself able to further extend the usefulness of the *Analyst* by increasing the number of pages. Commencing with fourteen pages of matter in each number, it now contains twenty-eight. Arrangements have been made to collect more systematically than hitherto everything in chemical literature that the modern scientific analyst should know.

EDINBURGH CHEMISTS' BALL.—Scottish readers are reminded that this Ball will be held on Wednesday, February 5, in the Masonic Hall, Edinburgh. The arrangements are under the auspices of the Trade Association. Mr. Peter Boa, 119, George Street, Chairman of the Association, is convener of the Ball committee, and tickets can be had from him and other members of committee.

THE NEW PHOTOGRAPHY.—Further practical applications of photography by the new "x" rays are reported from Paris, several negatives representing human limbs having been exhibited to the Academy of Sciences on Monday last by Professor Lannelongues. One photograph of a diseased thigh-bone confirmed the theory that the destruction of the bone spreads from the interior to the surface. The second specimen threw some light upon the diseased bones in a child's hand, and the third showed the effects of tubercular decay of the wrist. At a meeting of the Royal Photographic Society on Tuesday, Mr. J. W. Gifford, of Chard, exhibited some further specimens, one especially noticeable being a representation of a human foot, showing that the cause of deformity was the enlargement of the metatarsal, pushing the other toes on one side. This gives clearly the diagnosis of the malady. Another photograph, of a lady's hand, shows clearly the slender bones and all the joints, and a gold ring on the middle finger is brought out prominently in very dark colour. Some faint traces of the flesh enwrapping the bones sufficiently indicate the outer forms of the fingers, but there appear no visible traces of the nails. The absence of finger nails is also marked in the photograph taken of the hand of Mr. C. Bayley, the Assistant-Secretary of the Society, in which some whitish patches at the ends of the fingers may at first sight be mistaken for those appendages; but they are really due to the moisture of the hand when pressed down upon the sensitive photographic plate. Besides these remarkable examples of photographing through the flesh, there were numerous photographic representations of metal discs and other objects, from which some information may be ultimately derived as to the nature and action of the remarkable force by which these mysterious photographic changes are effected. In some instances there appeared to be evidence of sparking. One other remarkable photograph was that of the Crookes' radiant-matter tube itself, displaying the concentration of its luminosity and other details. This was taken with a pin-hole camera. In taking the lady's hand the sensitive plate was put in a cardboard box and the hand on the sensitive plate. A lid of cardboard was then put over the box and covered with an inverted porcelain dish, the whole arrangement being finally put inside a thick black bag, and the Crookes' radiant-matter tube placed three or four inches above the bag. A report of an interesting lecture on the "Röntgen" rays, delivered before the Liverpool Physical Society, by Prof. Oliver Lodge, is unavoidably held over until next week.

AMERICAN COMMITTEE ON SCIENTIFIC RESEARCH.—A committee has been appointed by Prof. Alfred Dohme, chairman of the Scientific Section of the American Pharmaceutical Association to direct investigations in the pharmacognosy, chemistry, biology, histology, etc., of drugs. It consists of Prof. A. B. Prescott, of Ann Arbor, president; Prof. Edward Kremers, University of Wisconsin; Prof. L. E. Sayre, University of Kansas; Prof. John U. Lloyd, president of the Cincinnati College of Pharmacy; Prof. Samuel P. Sadtler, Philadelphia College of Pharmacy; and Dr. Charles Rice, chairman of the National Committee on the Revision of the United States Pharmacopœia.

"PEDIATRICS."—The diseases of children are to have an illustrated semi-monthly publication devoted to them, which will appear simultaneously in New York and London. The first number of *Pediatrics*, edited by Dr. Geo. A. Carpenter, assisted by a large editorial staff, contains an article on infant feeding, by Dr. A. Jacobi, practical notes, abstracts, and several other special articles. The paper is published by Messrs. John Bale and Sons, Great Titchfield Street, London, W., and the subscription price is eight shillings per annum.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.—A special meeting of this Society was held on Thursday, January 23, when Professor G. F. Fitzgerald, F.R.S., delivered a memorial lecture on the life and work of the late Professor von Helmholtz. The lecture dealt mainly with very abstruse questions of the physical constitution of matter, viewed in relation to theories enunciated by Helmholtz, and the lecturer proceeded to show some of the difficulties inherent in Lord Kelvin's suggestion, based on Helmholtz's theories, that atoms are vortices in a perfect fluid, and went on to consider some of the applications of thermodynamics to chemical theory as worked out by Helmholtz. Passing to the discussion of some of the problems of capillarity, solution, and electrolysis, he concluded by saying that Helmholtz, by his physiological, chemical, and physical researches, had brought us measurably nearer to an ultimate dynamical explanation of the universe. In proposing a vote of thanks Sir Joseph Lister, President of the Royal Society, said he recollected with pride that Helmholtz was a medical practitioner. He would have done enough to claim the gratitude of physicians and surgeons if he had done nothing else than explain the accommodative power of the eye to varying distances and invent the ophthalmoscope. Dr. Frankland seconded the resolution, and among the subsequent speakers were Lord Rayleigh, Sir Henry Roscoe, Professor Armstrong, and Professor Poynting. In adjourning the meeting the President, Mr. A. G. Vernon Harcourt, mentioned that Helmholtz was half an Englishman, seeing that his mother was a Miss Penn, connected with the family of the founder of Pennsylvania.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.—On Wednesday, January 22, at Exchange Rooms, Birmingham, Mr. T. C. Clarke gave a description of his "Personal Experiences of the Minor." The meeting, which was arranged more especially for the junior members, was well attended.

In his opening remarks the speaker reminded those present that in detailing his experiences it was his intention to give prominence to those points in connection with which he had encountered difficulty rather than otherwise, and by showing some stumbling-blocks in a candidate's path, set up a few danger signals which he hoped might at least serve as a safeguard to those candidates present against becoming a prey to these particular pitfalls. The speaker then proceeded to detail his difficulties in preparing for undergoing examination. In conclusion, he urged all those who had still to pass to start study at once, to start seriously and work earnestly; above all, he desired them to pay no heed whatever to those disparaging remarks directed either at the examiners or the examination which, he was sorry to say, one heard only too frequently. He assured them that they would find almost invariably that alleged severity or want of courtesy emanated from those who were least worthy of success. When they had covered the course set out in the curriculum by steady, honest work he advised them to go up to the examination with confidence, and in few instances would that confidence be misplaced; to go up with the knowledge that they had done their work well; and should any latent feeling of uncertainty come over their minds, to think of the words:—

"He either fears his fate too much
Or his desert is small
Who fears to put it to the touch
And win or lose it all."

At the termination of his remarks, which proved instructive to most, and certainly of interest to all, Mr. Clarke was accorded a hearty vote of thanks.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.—A meeting was held on Thursday, January 23, Mr. E. J. Eastes, Vice-President, in the chair.

A paper entitled "Flowers and Their Visitors," by Mr. A. Lander, was read in the absence of the author by the Honorary Secretary, Mr. Ernest Goulding.

The paper dealt with the structure and habits of a number of flowers, and after describing the arrangements to secure pollination among flowers not dependent on insects, proceeded to describe those which employ insects to carry their pollen and the methods they use. The attractions which flowers offer to visiting insects were enumerated. Among these colour and odour play a prominent part, together with the supply of honey.

It was shown that a certain species of yucca, if introduced into a new country, is not reproduced unless the particular moth which carries its pollen is imported together with it. The arums imprison insects for the time, lasting from the maturity of the stigma to that of the anthers supplying them with food meanwhile. Only certain insects, which are favourable to the plant, are skilled in effecting entrance to such flowers as the snapdragon and toadflax. Some Composites harbour and supply with food a number of ants, who in return defend the plants from the insects whose attacks would destroy it. One of the orchids of Australia is provided with a sensitive lip, which, when stimulated by the weight of an insect, tilts the insect inside, and closing upon it compels it to effect its egress by an opening where it becomes loaded with the pollinia.

The paper was illustrated by diagrams kindly lent by Professor Reynolds Green.

A discussion followed in which the Chairman, Messrs. T. A. Henry, and R. Payne, took part. A vote of thanks to the author was proposed by the Chairman, and carried with acclamation.

The amendments to the rules of the Association proposed at the previous meeting were discussed and voted upon *seriatim*, and were in each case carried *nem. con.*, the Chairman, Miss Gair, Messrs. Brown, Goulding, Henry, Jowett, Lean, and Umney, taking part in the discussion.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.—On Thursday the 23rd inst. the first general meeting of 1896 took place in the University College under the presidency of Mr. T. S. Wokes, who was supported by a good attendance of members.

As usual, the miscellaneous communications were productive of much that was interesting, as well as valuable, some of the specimens shown being entirely new to the majority of the members present.

Mr. Mitchell read a letter he had received from the Tasmanian Eucalyptus Oil Company, drawing attention to a specimen of unguentum eucalypti made by them from the fresh leaves of the eucalyptus growing in Tasmania. The ointment was of good consistence, excellent odour, and of very attractive appearance, being of a light green tint, about that of well-made unguentum sabinæ. The proportion of essential oil in it, judging by the action of the ointment when rubbed into the skin, was such as to cause no irritation, whilst being sufficient to act as an effectual and pleasant antiseptic. Such an ointment, however, was thought by Mr. Mitchell and the members generally to be unsuitable for use in English pharmacy, or for including in the ranks of the B.P. ointments, from the fact that fresh eucalyptus leaves were not obtainable here except in very small amount.

A series of specimens were then shown and described by Mr. P. H. Marsden, pharmacist to the Liverpool Royal Infirmary, many of them being obtained by him during a period he spent in a French pharmacie. Among them were true "Crab's Eyes"—*Cancerorum oculi*—or Yeux d'Écrevisses, concretions of carbonate of lime shaped somewhat like a small mushroom, found among the membranes in the stomach of the fresh-water crayfish, *Astacus fluviatilis*, Crustacea, order Decapoda, just before the period of moulting or ecdysis sets in. They consist of a membranous skeleton and pure calcium carbonate, this latter is gradually used up by the crayfish in the formation of its new shell. Crab's Eyes were in great repute in the past as an antacid, and entered into the composition of many of the peculiar compounds of the ancient pharmacopœias which are even now sometimes prescribed on the Continent. Nowadays creta preparata in small nodules is sold as Crab's Eyes, but as this entirely dissolves in excess of dilute hydrochloric acid, leaving no membrane or skeleton as the genuine would do, the fraud is easy of detection. A tube of dried "Cloportes," or wood lice, was then passed round. These insects, the *Oniscus asellus*, class Crustacea, order Isopoda, contain a small quantity of nitrate of potassium, and were given for asthma and as a diuretic in the shape of a soup or bouillon, or their expressed juice was administered in half-ounce doses. A tincture of the living insect is official in the American 'Homœopathic Pharmacopœia.' Mr. Marsden likewise exhibited some Æthiopian pepper, the dried carpels of *Unona æthiopia*, natural order Anonaceæ, also called *Uvaria æth.*, *Xylophia æth.*, *Habzelia æth.*, or *Xylophia aromatica*, used by the natives of Central Africa as a condiment, and known in France as "poivre de singe." A fine set of the beans of *Mucuna urens*, sometimes met with among Calabar beans, some roasted acorns of various species of *Quercus*, used instead of coffee by the peasants of Southern France, and two varieties of eucalyptus flowers from Nice completed the series.

Dr. J. R. Logan, M.B., then proceeded with a lecture illustrated by means of numerous experiments on "Albumin and its Allies." The lecturer remarked that the importance of albumin and its occurrence in the animal world was only equalled by that of cellulose in the vegetable kingdom, the great distinction between the two lying in the fact that whereas cellulose as a tissue is practically dead, albumin, on the contrary, plays a very active part in the animal tissues generally. The representative albumin upon which most of the experiments were performed, was egg albumin, of which the composition was discussed, and the action of various reagents towards it explained. Plant albumin was not so definite as that of animals, that is, it varied with different plants. Other closely allied bodies might be mentioned, such as proteids or albuminoids, which, in the case of those termed "albumins," always contained sulphur with phosphorus, and were invariable constituents of the very active parts of animal tissue, such as the nuclei of cells. Blood contains two albumins, fibrinogen and fibrinoplastic substance, which react when the blood is drawn from the body and clot, leaving the clear serum, which gives the same reactions as egg albumin, and which is used in the arts for the same purposes as white of egg. The red colouring matter of the blood is hæmoglobin, which owes its colour to the presence of iron.

The value of foods is mainly judged by the amount of albuminoids they contain, though their absolute nutritive worth must be regarded as dependent on the quantity of readily available or extractable albumins, which varies considerably in animal and vegetable foods. The action of the gastric juice, which may be approximately represented by an acidulated solution of pepsin, is to produce from the albumins submitted to it bodies termed peptones, which are isomeric with albumins but are not coagulated by heat and belong to the class of substances termed crystalloids, from their power of passing through membranes by osmosis. Albumin, on the contrary, is a colloid body, so that before it can be used by the animal economy for reconstructive purposes it must be rendered soluble by means of digestion, which may be done not only by pepsin, but by pancreatine, by vegetable diastase, by such ferments as papaine, and by the action of bacteria. The products of its digestion are ultimately peptones, but many intermediate bodies are formed termed albumoses, the first being uncoagulable and not giving the biuret reaction, the second giving the biuret reaction as peptones do, but otherwise similar to a globulin, being precipitated by a saturated solution of sulphate of magnesium. Many of these albumoses are of an extremely poisonous nature when injected into the circulatory system, most serpent poisons belonging to this class, as does also abrin, a toxic albumose from the jequirity seeds. The biuret reaction referred to is given by peptones to which a small amount of cupric sulphate and excess of an alkaline hydrate have been added in the cold, and is the development of a pink colour. Another test for proteids shown by the lecturer was the xanthoproteic, a yellow-brown colour produced by boiling the substance with nitric acid and adding excess of ammonia. A peculiarity of the digestion of egg albumin by means of pepsin and a dilute acid in test tube experiments was that a point was reached at which peptone ceased to be formed, the pepsin seeming to be inhibited in its work by the quantity of peptone formed. There is an analogy in this to the accumulation of alcohol in alcoholic fermentation when it reaches the proportion of 20 per cent. by weight, preventing the further action of the yeast. The peptones, as soon as they are formed in the stomach, pass by osmosis into the cells forming the walls of that organ, in some of which the peptone becomes regenerated, and appears again as an albumin.

The action of pepsin on gelatin, or the cartilaginous portions of animal food, is to give peptones also, but these differ from those of albumins, in being useless for the building up of new tissues. The effect of cooking foods was touched upon by the lecturer, who held the view that, broadly speaking, cooking made most foods less easily digested, but that it served one good purpose—that of killing the spores or bacteria, by which such diseases as tuberculosis are propagated. In milk we have a typical albumin, the casein, which was an alkaline albumin not precipitated by boiling, but readily coagulated by the addition of acids or of the rennet ferment. Milk may not be exactly improved by boiling, except so far as sterilisation is concerned.

After recapitulating the classification and reactions of the albumins he had touched upon, the lecturer brought his remarks to a close.

A good discussion ensued, and a vote of thanks was passed to Dr. Logan for his kindness in lecturing before the Society, special

attention being drawn to the successful manner in which the experiments illustrating the lecture were performed.

MIDLAND PHARMACEUTICAL ASSOCIATION.—A meeting of the above was held at Mason College on January 21, when a paper was read by Mr. F. Smith, entitled "The Sun and His Attendant Family." There were present Messrs. Gibbs (President), Prosser, Allcock, Poole, Jarvis, Mackenzie, Reedman, and others. The lecturer gave a brief review of the Ptolemaic system, and an epitome of the Copernician system, upon which all modern systems are founded, the rules of the solar system and source of light and heat were touched upon, also the theory of solar contraction, physical constitution of the sun, photospheres, chromospheres, prominences, corona, and sun spots. The size and distance of the moon, influence of moon upon the tides and eclipses of the moon, the planets and their satellites, possibilities of Mars being inhabited, asteroids, comets, were also described, as also was the description of the motion of the solar system in space. The lecture was illustrated by limelight views, and proved of much interest to those present. A short discussion took place at the conclusion of Mr. Smith's paper, and the customary votes of thanks were then passed.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.—At the meeting held on Friday, January 24, at 9.15 p.m., Mr. J. Mackintosh Cameron in the chair, the minutes of last meeting were read and approved, and in the absence of the author, Mr. Hill read a paper by Mr. Alexander Sutherland, entitled "The Irreducible Minimum": A Study. In this it was pointed out that when a man starts on the business of life, he must be properly equipped before that business can in any way be a success. The tendency of the present day is to reduce that equipment more and more, but if reduction be carried below a certain point, the equipment proves inefficient and the result is disastrous. This particular point may be called "The Irreducible Minimum."

The goal towards which most students of pharmacy are wending their ways is the Minor examination. Many seem to look on the Preliminary examination as an excuse for extorting a fee permitting them to enter the pharmaceutical race. This idea is erroneous. The Preliminary examination is a test of a small portion of the student's equipment, and no one until he has passed it is "a fit and proper person" to go much further into the pharmaceutical contest.

The minimum of preliminary education in English should include an elementary knowledge of etymology, at least as far as the meaning of the principal terms used in pharmacy. In arithmetic there should be a thorough knowledge of weights and measures in common use, as well as of the metric system. There are few who enter pharmacy who do not seem to be muddled over the difference between a troy and an avoirdupois ounce. This should have been inculcated at school. When one shows a tendency to "mix up" our present weights it is unlikely he would be much better even with such a model system as the metric. Ignorance, joined to want of practice, or, what is much worse, careless practice, will make even the simple seem complicated and ridiculous.

The requirements in Latin should be extended so as to include a book of Celsus. Cæsar is excellent, but even a slight acquaintance with a man who actually used Latin to tell us of the drugs of his day would have a wider influence. In history the student should be able to sit down and give a short and intelligent sketch of "the rise and progress" of the calling he proposes to adopt. A knowledge of geography, with a view to habitats, should be required, and more stress laid on that. Everybody connects opium and tea with China and India, but more than that is required. A Chinese student in the same manner when asked the source of whisky might answer "Europe."

Possibly these things may seem to be beyond the scope of the Preliminary examination, but why not divide the Minor into two and increase the scope of the examination, taking matters of more general knowledge and reading first, and then after an interval the practical test? It might possibly be a better plan to arrange the examinations something as follows:—

1. *General Knowledge Examination*.—Subjects: Latin and English—as at present in the First examination; arithmetic; and elementary mathematics.

2. *Preliminary Examination* (at least two years after First examination).—Subjects: Latin—translation from some work bear-

ing on drugs; etymology—a knowledge of the meaning and derivation of some of the principal names and terms used in pharmacy; history—an outline of the history of medicine and pharmacy; elementary pharmacy.

3. *Minor Examination* (three years after second examination).—Subjects as at present, but examination to be divided into two parts. An interval of at least six months to elapse between the two portions. A high percentage (say 95 per cent.) having been obtained in any single subject, the candidate be held to have passed in that subject. Were this the rule the standard might be raised with advantage all round, I believe.

4. The Major examination must remain the goal for the would-be pharmaceutical chemist. To many of us the practising and reading for the Major is the one green spot of our lives. We may never muster up courage nor think ourselves fit to go up and astonish the examiners with the variety (or scarcity) of our knowledge, yet the goal remains ahead, and we exercise ourselves on the race-course hoping to get past some day. It might be thought that the “irreducible minimum” had become a “maximum,” but, if anything, the foregoing was rather low in standard.

What was termed an “invidious distinction,” occurring in Section 20 of the Pharmacy Act, 1868, was here referred to. It was suggested that the words “being in business on his own account” ought to be repealed. There is no such stipulation made after one has passed the Major, and there should not be any after the Minor has been passed, as it is not the opening of a shop, but the passing of an examination that gives a man his legal status in the first place.

After becoming legally qualified it is necessary to remember that the public does not restrict itself to the Pharmaceutical Society's examination schedules, therefore, young pharmacists should not be afraid of knowing too much. They will always find somebody in the Pharmaceutical Society who know at least as much as they do, and plenty of the general public who fancy they know more.

Thorough observation and then classification of observed facts form the bases of all knowledge of material things, and must underlie the work required in every curriculum and by every examination schedule. The trouble many suffer from is this, that having been unaccustomed to the thinking and observing processes in the beginning, they have swallowed “patent pharmaceutical foods” until now, and, suffering from partial atrophy they think there is only one food suitable for all because it agrees with them. Its name is “A Minimum of Study.”

Having cultivated the observing faculty and begun to classify, students should learn to think logically and to infer, and to state their inferences and facts in plain and orderly language, carefully distinguishing between the facts and the inferences. A language or two would help to widen one's horizon, and by ascertaining the meaning, original and acquired, of the name of everything used, one could obtain an amount of information which would stand in good stead. With human interests getting enlarged, the next step would be to seek to know more of the countries around, and from the constitution of *materia medica* specimen to the country which yielded that specimen, there was a course of study and of pleasure which would drive out of head all ideas of a “minimum” of education.

In conclusion, it was urged: First, that the minimum of education allowable must be that sufficient to meet the business of our daily life, and not merely what may prove sufficient to pass the Minor examination as at present constituted; secondly, that the Major examination in most respects more nearly approximates to the actual requirements; thirdly, that additional knowledge to that scheduled is required, and may possibly be best introduced by re-arrangement of the present examinations if the Minor is to remain as the qualifying standard; fourthly, that there are many things which it is to one's interest to know, which do not come strictly within an examination schedule, and not the least of these are accurate thinking and reasoning. In conclusion, students should not strive too much after an “irreducible minimum,” and not in their quest for knowledge forget the other necessary graces of life. Then, some time in the future it might be said of each one—

“I would the great world grew like thee,
Who grewest not alone in power
And knowledge, but by year and hour
In reverence and in charity.”

The reading of the paper was followed by a discussion, which was taken part in by Messrs. Cameron, Dey, Hay, Hill, McBain,

Macpherson, Sinclair, and Thwaites; and on the motion of the chairman, it was unanimously agreed to send a letter to Mr. Sutherland at Burra Firth, Unst, Shetland, thanking him for his interesting paper, and expressing a hope that he would soon be restored to his usual health.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.—A meeting of this Association was held on Thursday evening last in the Rooms, West Regent Street, Glasgow, Mr. W. L. Currie, President, in the chair.

Mr. Currie, who is also Local Secretary of the Pharmaceutical Society, read a paper on—

UNQUALIFIED ASSISTANTS IN BRANCH SHOPS.

The immediate reason, he said, which had impelled him to bring this subject more directly before their notice was the reference made by the President of the Pharmaceutical Society (Mr. Carteighe) at the Council meeting, held on January 8. No one who had carefully read what was said, and studied it, could have any two opinions as to the meaning and value attached thereto. In his opinion, the President felt called upon to make some official statement after the recent prosecutions and the remarks which they called forth in the public press, and no better method than that could have been adopted. If they were to raise themselves above suspicion in that matter of unqualified assistants in branch shops they must boldly face the question and give their dignified but united support to the Pharmaceutical Council. He was not so sure of the method to be adopted in persuading any erring brother in trade, and there were some, to fulfil the legal and common-sense requirement, because the matter was a difficult one although it should not actually be so. But the interference in the conducting of another man's business might be construed with a wrong meaning. It might be a neighbourly act to discuss the question, but every man conducts his own affairs in his own way, and any movement in that direction might be resented. It might be the duty of the local secretary, if such breaches of the laws were within his actual knowledge, to communicate with the offender, pointing out the fault and suggesting it to be reminded to prevent publicity. If one could set aside the friendly capacity, and for the time being assume the official, with the assurance that no ill-feeling would be engendered as an after consequence, good and well. But when a strained feeling was likely to result, then other means would require to be adopted. He didn't mean by this that the local secretary should shirk his duty, but he would require to be careful not to give offence. What he thought should be done was, that the Pharmaceutical Society through its officials should send to every drug shop in the country a printed copy of the President's remarks on this very important subject, and if after such plain speaking there should still be those who ignored the demand to comply with the law, then there need be no hesitation, either by neighbour or local secretary, in reporting the offender to the proper authorities. That question of branch shops and their management was no new one, but was one of wide importance in view of the present day requirements. Even yet there were those who went the length of saying that the qualified chemist was entitled to have as many branch shops as he liked provided he put competent men in charge. There was a vast difference between competency and qualification, and while the private individual thought he was the best judge as to the capacity of the manager of a branch, the law did not recognise anything but qualification. The assistant might be a thoroughly reliable dispenser, a dependable man in every way, but he should give evidence of his competency by qualifying. Why was it that in the case of a widow carrying on a business she had to engage the services of a qualified man? Simply because he believed the Legislature intended that every shop should be in charge of a qualified person, and what was the difference between the branch shop and the widow's shop? None! Moreover, at the earliest opportunity the operation of the “widows' clause” should be cancelled. It had been a powerful argument against them during recent years. They, in Glasgow, had a very great evil to contend with in the case of the drug shops owned by doctors and by unqualified owners, covered in some way by doctors, where business was carried on in most cases without regard to Pharmacy Acts or any other Act; and recent prosecutions, which showed a deplorable state of affairs, instead of stopping the growth of such premises, seemed to have the opposite purpose, for they were on

the increase. And what he would say in that connection was that pharmacists should take a strong stand in that matter. They should make it their duty to conduct their business on strictly legal as well as moral lines, and also see that others did so. If doctors' premises were to be kept open for the purpose of retailing drugs of all kinds to the public, as was done at present, then he thought they should come under the category of branch shops and be in charge of qualified men, instead of, as was done at present, boys and girls. The doctor could not attend to two businesses at one time, and if he was exercising his profession outside he could not be supervising inside. Chemists should exercise a wise discretion in the sale of poisonous commodities (whether in small or large quantities) to persons they had no knowledge of, and, in conducting such sales, hedge them round with every legal difficulty. He did not say that the sale of poisons by qualified men only would prevent people from taking their own lives if they very much wished to do so, but when such an emergency arose, and inquiry resulted in the procedure being shown to be according to law, then they had done their duty. They must never forget that the public safety had strong claims on them, and they should see that every possible means was used to preserve and protect their prerogative. No more powerful evidence could be produced of the desire of the Pharmaceutical Council to improve the position of pharmacy than that on which he had been speaking, and the best reward the Society could have would be to receive the support of every qualified man throughout the country.

In the discussion which ensued,

Mr. Laing said he thoroughly approved of President Carteighe's proposals. He looked, as the ultimate result, for the advent of a new Bill to make it impossible for any drug shop to have a manager or anyone who was not a qualified chemist.

Mr. Robertson remarked that it was but fair that chemists with unqualified shops should be prosecuted as well as doctors.

Mr. Dunlop thought that Mr. Carteighe's proposal would involve rather much on the local secretary, and pointed out that it was a very delicate matter for a local secretary to inform on a neighbour.

Mr. Watson spoke as to the delicacy of such work being put upon the local secretary, and he stated that this move on the part of the Society would do much to raise the status of pharmacy.

Mr. Yates suggested that, although it might be a more expensive way, the Society should engage inspectors for England and Scotland, who would find out the condition of shops throughout the country, and that would take the burden off the shoulders of the local secretary. Offenders against the Pharmacy Act should be treated in the same way as offenders against the Food and Drugs Act, or any other nuisance.

Mr. Taylor said that in the past the Society had not carried out the provisions of the Act as the trade had been led to expect. They had not been sufficiently grasping in the past.

Mr. Bruce said that the great trouble in Glasgow had been doctors' shops, and there was the further objection in connection with them that doctors wrote out their prescriptions in cipher which it was impossible to decipher generally.

Mr. Mackenzie suggested the passing of a Bill in which all B.P. drugs, either alone or in preparations, could be dispensed only by qualified chemists.

Mr. Russell said the plan he proposed two or three years ago should be adopted in a Bill, that a census should be taken by the Society of all drug shops in the country, either by the local secretaries or by inspectors specially appointed. The census would show the condition of each shop as far as the qualification of the persons engaged in that shop was concerned.

Mr. Laing moved, "That that Association thoroughly approves of the views of the President of the Pharmaceutical Society in regard to unqualified managers in branch shops and concurs in his remarks; and we think that copies thereof should be sent from the Registrar of the Society to all druggists and drug shops throughout the country."

Mr. Russell moved, as an amendment, that the matter should be remitted to the Standing Orders Committee with powers, in order that the view suggested by him of taking a census of drug shops should be embodied in the motion.

On a division, 9 voted for the motion and 7 for the amendment.

Mr. J. A. Russell, secretary of the Association, then read the following paper on—

PROPRIETARY MEDICINES IN THE MEDICAL SERVICE.

The suggestion of proprietary medicines in connection with our

medical service stirs up feelings of great bitterness in the minds of dispensing chemists as each one recalls his own associations therewith. To enquire into the causes of this bitterness and to define the elements of its constitution would form a study at once complex, interesting, instructive, and, in some respects to our prouder selves, humiliating. It does not follow, however, that a display of such a study at this particular stage would prove profitable, and it is to be borne in mind that the aim of this Association is towards the practical rather than towards the merely theoretical, no matter how brilliant that might be.

Setting aside, therefore, for the time being the aggravating circumstances of the multiplicity of preparations similar to each other, but by different makers, which we are required to handle, the accumulation of bad stock upon our shelves consequent upon the growth and decline of successive fads, and the question of "cutting prices," or, to be more accurate, cut profits to the retailers of proprietaries, all painful facts with which we are only too familiar, I ask you to look beyond into the position of medical men in regard to proprietaries.

Consideration of the prescribing of medical men is quite within our sphere as chemists; indeed, it is a duty required of us if we are to accomplish our share in the work of applied medicine. It is unfortunately the case that on this borderland between us so many jealousies have developed and so much acrimony exists between the rank and file of the two bodies that the one does not receive more than the fraction of the true service it might receive from the other, and the fullest opportunity is furnished to the enterprising advertiser of nostrums.

These conditions attracted my attention with special force in connection with parish work. Reduced from a matter affecting the whole country to one within the confines of a parish and the administration of a Parish Council, this question, so far as the aspect now under consideration is concerned, becomes easily analysed. Yet do I make bold to say, the principles which have guided and controlled action in the one case are equally applicable to the other. In the Glasgow City Parish this question applies to medicine dispensed in five chemists' establishments, and supplied to a population of between five and six thousand poor persons (very sickly, about 40 per cent. being on the sick list), and it applies to services rendered by twelve medical men. The principles apply equally, irrespective of the area or numbers involved. It was found in this instance that proprietaries, including an emulsion of cod-liver oil, a combination of chloral and potassium bromide, one of santal oil and cubebs, a petroleum emulsion, and a wine of cod-liver oil with peptonate of iron, were being prescribed. The absurdity of such a procedure is apparent when we know that in none of these instances was the prescriber cognisant of all the ingredients in the preparation which he prescribed, though probably those specified as contained in them, and on the action of which he, no doubt relied for results, were the important ones. Still he was working in the dark, he was at the mercy of advertising manufacturers, having no check upon them, and for all he knew he might be administering something having an action differing very materially from that which he believed himself to be prescribing. In contra-distinction to this are the circumstances that qualified chemists were at his service who were quite capable and prepared to compound the drugs prescribed in the form desired with this advantage, that he would know exactly all he was giving to patients, both active drugs and combining adjuncts. In addition to this the important question of economy comes in. In regard to the emulsion of cod-liver oil, around which preparation the discussion chiefly waged, it was shown the compound desired could be furnished at about one-fourth the cost of the proprietary. You will notice I do not oppose myself to proprietaries because they are proprietaries, but because of the conditions connected with their production and administration. The conditions I have attempted briefly to delineate are attached more or less and with but little exception to all of them. Any of them to which these conditions are not attached necessarily do require to be regarded in accordance with their peculiarities. It was pushed forward as a justification and reason for their use that they were prescribed in other parishes without objection, in the public hospitals also, and by men undeniably eminent in their profession. Of course that was met then by pointing out that although objectionable practices might be followed in other institutions and by persons in high places, they remained none the less objectionable, and were to be regarded accordingly. The fact of such an argument being put forward, however, reveals something in connection with our public hospitals deserving of the gravest consideration by those in the

medical profession who strive for the suppression of abuses and the realisation of its highest ideals.

Public hospitals are schools for medical teaching, and their physicians occupy the van of medical progress. If through thoughtlessness they fall into bad habits it is to be expected these bad habits will be propagated and spread throughout the country in the persons of their pupils and followers. I say through thoughtlessness on their part, because upon inquiry I have learned on good authority that in some hospitals at least these teachers—whom it is a very delicate matter to correct—very frequently are requested and do alter prescriptions for proprietaries to their equivalents compounded by the hospital dispensers. This does not appear to be generally known, and another example of the same thoughtlessness is that they speak of preparations by proprietary titles instead of by the drugs of which they are composed, so that proprietaries get the credit of therapeutic qualities which should be attributed to the drugs composing them. The evil influence of such a practice must be very far reaching. It would be altogether unjust to say anything against pharmacists or others for endeavouring to meet the increasing requirements of physicians, or who are endeavouring to improve upon the modes of administering medicine, but there are different ways of doing things, and all are not good.

It is much to be feared that physicians are permitting themselves to be led a little blindly by enterprising individuals into experimenting with novelties without having mastered what has been made known regarding substances no longer novelties. This phase of the question is one falling to be dealt with by the medical profession, and we need do no more than refer to it. Another side falls to our consideration. It was said by a medical man—somewhat rudely, I think—"But chemists cannot make these preparations properly." That contention was at once completely rebutted by the chemist present volunteering personally to give satisfaction in the matter. Now, there is this difficulty to be met. Medical men are not prepared to work out for themselves good formulæ to take the place of proprietaries; if the combination be left to chemists they have no standard to go by. The consequence is good results may be obtained here, bad results there, and when we consider the competition which exists, and efforts made to undersell each other, this is less surprising.

We would not desire that medical men should be confined to the B.P. in their prescribing, but I would suggest that official formulæ for popular preparations be compiled and published. The General Medical Council is the authority for the Pharmacopœia, let the Pharmaceutical Council through the facilities within its power attend to the other. This would be a standing work for it to accomplish, and the fruits of this work would render future compilations of the Pharmacopœia much more easy.

The discussion on Mr. Russell's paper was adjourned till a future meeting.

LIVERPOOL CHEMISTS' ASSOCIATION.—The annual general meeting of this Society was held on January 23 at the Royal Institution, Colquitt Street, Mr. M. Conroy presiding.

Mr. Wardleworth exhibited a specimen of Ceylon coca, very similar to the usual Huanuco variety, but better grown and dried.

The annual report was then read by the Secretary, Mr. A. S. Buck, showing a membership of 127. A proposal to admit as associates of the Association, at a nominal subscription of 1s., such apprentices or students as were not on the Register of Chemists and Druggists was agreed to, and it was intimated that for their benefit the library and museum would be overhauled and brought well up to date by the purchase of new works of reference and fresh specimens.

The Treasurer's report was passed as very satisfactory, a balance of £16 9s. 3d. being the result of the year's working. Of the recent edition of the price-lists 978 copies had been sold, only 22 remaining on hand. After the usual votes of thanks had been passed, the scrutineers, Messrs. Cowley and Dutton, proceeded with the collection of the voting papers issued for the election of the new council, with the result that after the counting, Dr. Symes, Messrs. T. F. Abraham, J. Hocken, A. H. Samuel, F.C.S., and Wellings were re-elected, together with two new members, Messrs. C. J. S. Thompson and H. Wyatt, jun., to fill the seven vacancies.

The President on this occasion departed from the time-honoured precedent of a presidential inaugural address, and instead Mr. Edward Davies delivered an interesting address upon the "Illuminating Power of Hydrocarbons." He showed experimentally how calcium carbide, when placed in water, yields

acetylene. This gas, when ignited, gives a flame of greater illuminating power than ordinary gas, and has a peculiar odour, not unlike that associated with gunpowder. Added to ordinary gas in the proportion of 10 per cent., it gives almost equal illuminating results without the pungent odour. It was thus shown how acetylene could be utilised for enriching ordinary gas, and also how useful it might become for magic lantern and other purposes. After dealing with the various theories as to the cause of the luminosity in gas, Mr. Davies finally gave an interesting exposition of the lighting power of the various components of gas separately ignited.

He was warmly thanked at the close of the lecture and a brisk discussion ensued.

INSTITUTE OF CHEMISTRY.—At the examination for admission to the membership of this institute, held from January 7 to 10, the following candidates were successful:—G. H. Appleyard, Yorkshire College, Leeds; J. H. Coste, Finsbury Technical College; G. George, Merchant Venturers' Technical College, Bristol; F. Hudson-Cox, School of the Pharmaceutical Society, and University College, London; P. C. H. Hunt, Mason College, Birmingham; and E. J. Parry, B.Sc. (London), Guy's Hospital. Of the candidates for the intermediate examination the following satisfied the examiners:—P. G. Jackson, University College, Nottingham; E. J. Read, B.A. (Cantab); and H. S. Shrewsbury, University College, Nottingham. The examiners were Professor W. R. Dunstan, and Mr. Otto Hehner. The members of the institute now number over 900, and there are over 200 registered students.

LEGAL REPORTS.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT.

THE PRESENCE OF COPPER IN PRESERVED PEAS.

At Southwark Police Court on Wednesday afternoon the case of A. A. Grist, Sanitary Inspector of St. Saviour's District Board of Works, against H. C. Summers, trading as George Mence Smith, at High Street, Borough and also many other places, for selling preserved peas mixed or coloured with an ingredient rendering them injurious to health, viz., 8/10ths of a grain of copper per pound of peas, whereby the defendant became liable to a penalty of £50, again came on for hearing.

The case has already been reported in our columns (see *ante* pp. 59, 78.)

Mr. Frank Dodd, barrister, again appeared to prosecute, and Mr. Bonsey, barrister, defended.

Dr. B. H. Paul, Fellow of the Institute of Chemistry, etc., stated he was aware of the result of the analysis, and had specially considered it with regard to this case. It was a common statement that the copper was put into the peas to give them a green colour, but that was quite incorrect. Dr. Paul then put forward two liquids—showing that the green colour of preserved peas is not given by the copper-salt used in the process of preserving—one, containing about $3\frac{1}{2}$ grains sulphate of copper, was colourless, and the other containing the natural colouring ingredient of the peas, was dark green. In contact with the peas the copper salt used in the process of preservation decomposed, the copper becoming insoluble. The quantity of copper in a pound of peas would not make them injurious to health. The witness had never heard of a case of injurious effects from the use of preserved peas. Copper was only an acute poison in large quantities. It was very doubtful whether chronic copper poisoning existed. The greater part of copper, even if taken in a soluble form, passed away from the system. The witness had made personal experiments, and would not hesitate to take himself peas containing three times as much copper as those in this case, although it would be unwise to put that amount in the peas, as it might cause them to have a metallic taste. Dr. Paul further emphatically stated that the copper was not employed to give the peas a green colour, but simply to "fix" their original green colour.

The witness, in cross-examination, was taken through a number of authorities, whom it was admitted were eminent and well-known men; but he emphatically stated that their opinions as to the alleged injurious effect of preserved peas were decidedly wrong, and remarked that when once an error got into a book it was passed on into others and was very difficult to get rid of it.

Mr. Bonsey then addressed the magistrate for the defence.

After a few remarks on the difference between the experience and qualification of the medical gentlemen called for the prosecution and

for the defence, he remarked that in order to prove an offence the article of food must be shown to have been rendered injurious. It was not enough to assume that a certain ingredient might be injurious in itself when administered in considerable quantity, and then to infer that its use, in small proportion, in the process of preserving peas would render them injurious: that was begging the question, for the compound formed might be harmless, as was maintained in this case. He contended that the prosecution had been unsuccessful in the endeavour to show that the peas were rendered injurious. They might perhaps be indigestible, but even if that were proved, the Legislature could not protect the public against indigestion. No doubt copper was poisonous in large doses, but the quantity here in evidence was so infinitesimal as to make the prosecution appear a very trivial affair. The onus of proof that the peas were injurious to health rested upon the prosecution, but he submitted there was an absolute failure of such proof. The prosecution had fallen into the error of supposing and representing that because copper salts in large doses might be poisonous, therefore—under all circumstances of chemical combination and in however minute proportion—the presence of copper must be regarded as rendering any article of food injurious to health. The fact that twenty million cans of preserved peas are annually consumed, and that during thirty-six years no case of injury has occurred, was enough to show the harmless character of these goods. The matter had been exhaustively investigated by the Board of Health in France, and the result arrived at was that no injury resulted from the small amount of copper in preserved peas, etc. The prosecution had suggested that peas are preserved with copper only to be exported to this country, and that they are not allowed to be sold in France. However, the fact was that no restriction existed upon the sale of coppered peas in France any more than in this country; and in proof of that he produced a certified copy of a decree of the Minister of the Interior, addressed to the various Prefects throughout France. He submitted that the prosecution was ill-judged and vexatious, and on behalf of the defendant he asked for substantial costs.

Mr. Fenwick said it was an important matter, and he would adjourn the case for a week in order that he might consider his decision.

THE SEIDLITZ POWDERS CASE.

In connection with the prosecution of Mr. E. F. Strickland, chemist and druggist, of Ealing, for selling seidlitz powders not prepared according to the formula of the British Pharmacopœia, and reported at length in our last issue, Mr. F. Walker, solicitor for the defendant, applied to the Brentford Justices on Saturday last to state a case for the consideration of the High Court of Justice. The grounds on which he based his application were (1) whether the summons issued against the said E. F. Strickland disclosed any offence: (2) whether the public analyst duly complied with Section 16 of the Sale of Food and Drugs Act; (3) whether the person requiring the article to be analysed duly complied with Sections 13 and 16 of the said Act; (4) whether the evidence adduced at the trial of the said case proved any offence under the said Act; and (5) whether there was any sufficient legal evidence to show that the article purchased by the complainant was delivered to the public analyst?

Mr. Sharp (one of the justices) said there was little or nothing in the points. The great point had been missed. It was whether chemists should be confined within the B.P. and never be allowed to sell compounds not made according to its formulæ.

Mr. Walker submitted that he raised that very point. The grave question was whether a man in selling, as Mr. Strickland did, a similar thing as one prescribed in the B.P., but in larger proportions, was committing an offence.

The Chairman said that the justices considered the points frivolous, but at the same time they would be willing to give all the help possible.

Subsequently Mr. Walker renewed his application in the following terms:—I ask the Bench to grant my application, on the ground that a chemist does not commit any offence under the Sale of Food and Drugs Act if, on being asked for a box of seidlitz powders, he supplies powders of the same ingredients and in similar proportions to the effervescent tartarated soda powders of the British Pharmacopœia, but containing a larger quantity of such powder than the quantity there specified.

The Bench granted a case.

Mr. Walker asked that he might include the grave point whether Section 16 was complied with, but the Bench replied in the negative,

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulae for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

SODIUM IODIDE IN PILLS.

According to R. van Gool (*Journ. de Pharm. d'Anvers*), sodium iodide can be easily and quickly made into pills by adopting the following formula:—Sodium iodide (anhydrous), 4 Gm.; powdered sugar, 40 Mgm.; distilled water, 1 Gm.; starch powder, 60 Mgm. Triturate the iodide and sugar together, add the water, then the starch, and incorporate thoroughly. The pasty mass is covered with starch powder, and left awhile, then rolled whilst still soft. They should be dried by rolling them in a slightly warmed capsule, and finally sugar-coated.

RESINATE OF COPPER.

By dissolving copper sulphate, 50 parts, in water, 1000 parts, heating the solution to 100° C., and then adding ordinary resin, 100 parts, *résinate de cuivre*, a new veterinary remedy, is formed (*Ann. de Met. Vet.*). The resulting product is greenish, and described as insoluble in essential oils or alcohol. To prepare it for use, dissolve green or black soap (? soft soap), 100 parts, in amylic alcohol, 100 parts, and to the warm solution add the resinate, 60 parts.

PREPARATION OF BONE MARROW.

Barr's method of preparing this (*vide B. M. J.*, 1895, i., 358) is to make fresh bone marrow, 3 oz., into a paste with port wine, 1 oz.; glycerin, 1 oz.; and gelatin, 5 dr. Soak the gelatin in sufficient water to soften it, then melt with the glycerin. Mix the marrow and wine separately in a mortar, and finally add the mixed gelatin and glycerin.

ANTI-ASTHMATIC CIGARETTES.

Dried leaves of belladonna, 50 parts; hyoscyamus, 20 parts; stramonium, 30 parts; tobacco, 40 parts; jaborandi, 10 parts; sage, 20 parts; and water drop wort (*Phellanium aquaticum*), 12 parts. Cut fine, sift to remove dust, moisten with 40 parts of cherry-laurel water well distributed, and then make into cigarettes of the usual size. One should be used before and after each attack, the smoke being deeply inhaled.

MEDICATED PASTILLES FOR HOARSENESS.

Mix cocaine hydrochlorate, 5 Mgm.; morphine hydrochlorate, 5 Mgm.; tincture of aconite, 2 drops; marshmallow flowers in powder, 150 Mgm.; and powdered sugar, enough to make one pastille. From 6 to 8 should be used daily.

SOPHISTICATION OF CODEINE WITH SUGAR.

Elievant reports (*Répert.* [3], vii., 491) having met with a sample of codeine which was adulterated with sugar candy; the crystals of saccharose and codeine being closely alike in appearance, the fraud would be likely to pass unless chemical tests were applied.

A PREPARATION OF MILK FOR DIABETIC PATIENTS.

Following the suggestion of Dr. Sydney Ringer, Martindale prepares a solution of caseinogen thus: Thirty ounces of milk are mixed with an equal volume of water, and the caseinogen thrown down by the addition of about 90 C.c. of 10 per cent. acetic acid. The curd is allowed to settle, the clear liquid syphoned or decanted off, and the precipitate washed on a calico filter. The caseinogen is then rubbed up in a mortar with calcium carbonate, and water added, when the organic compound is again dissolved, and the calcium carbonate allowed to settle down, the milky fluid being decanted off. In this way what is essentially milk without lactose is obtained; if desired, it may be sweetened by the addition of about 2 per cent. of glycerin (*B. M. J.*, 2, 95, 1412).

APPLICATION FOR CHAPPED HANDS AND CRACKED LIPS.

Compound tincture of bee-zoin, 1; absolute alcohol, 15; rose water, 15; glycerin, 60 parts. To be rubbed on the chapped surfaces at night after bathing the parts with warm soap and water (*Rev. de Thérap. Med. Chirurg.*, lxii., 740).

NOTICES TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

LETTERS.

SEIDLITZ POWDERS.

A.P.S. says "I believe it is a very common practice with chemists to stock three strengths of seidlitz—one practically identical with the official soda tart. efferv.; a small seidlitz, containing a smaller quantity of both 'blue' and 'white'; and a strong seidlitz, popularly asked for as a 'double-strong seidlitz powder,' consisting of the ordinary powder with the addition of about a quarter of an ounce of Rochelle salt. It is to be hoped that the case referred to in your editorial of 25th inst. will determine whether or not such practice is legitimate."

SPT. AMMON. AROM. AS A MASSING AGENT.

MR. W. LYON explains that he was not aware Mr. Dunlop had, a year ago, made a communication on aromatic spirit of ammonia as a massing agent. He says, "Had I known of his paper I would not have brought the subject forward. I do not think his other remarks call for comment, but I may say it seems to me the Revision Committee would be taking a poor view of their duty if, in considering the pill formulæ, they merely took into consideration the massing of the ingredients, and overlooked the possibility of the pill being frequently prescribed along with some chemical which was incompatible with the official massing agent."

ANSWERS.

"ASPIRANT."—You cannot do better than procure the latest edition of Thorpe's 'Inorganic Chemistry' (Collins, 2 vols., 5s. 6d. each).

"BALSAM."—It is probably the so-called "French or German mustard" you refer to. That is prepared by mixing mustard flour with salt, olive oil, and vinegar in which various flavouring materials have been macerated, such as garlic, tarragon, thyme, parsley, etc.

"NUX VOMICA."—We are unable to give advice in the matter. Your case seems peculiarly one for a medical practitioner.

"CARBON."—We do not know where you could get the loan of specimens of anthracite and other varieties of coal, but you might apply to Mr. T. D. Russell, 78, Newgate Street, London, E.C., Mr. Samuel Henson, 97, Regent Street, W., or Messrs. J. R. Gregory and Co., 1, Kelso Place, Stanford Road, Kensington, W., who are the leading dealers in collections of minerals, etc.

G. NIND.—We are endeavouring to obtain the information you ask for.

G. W. BLYTHE.—The process by which you state you can easily and directly prepare pure anhydrous hydrocyanic acid, though interesting, is unlikely to be of any practical use, and any such process must of necessity be extremely dangerous to work.

"J. C."—You must protect the article before offering it for sale. Apply to the Comptroller of Patents, Patent Office, Southampton Buildings, Chancery Lane, London, W.C., for information how to proceed. Perhaps your best plan would be to secure the services of a good patent agent, or you might apply to the manager of *Invention* Patent Department, Mitre Court, Fleet Street, London, E.C. Having properly protected the article, you should then send specimens and particulars to the wholesale firms likely to be interested.

QUERIES.

"KAPPA" asks (1) "would any correspondents kindly say whether they have tried the depilatory liquid, the formula for which was quoted in the Journal of August 24, 1895 (p. 174) from a French source. It contains iodine, oil of turpentine, collodion, etc. I made some strictly according to formula, and experimented on my arm. The result was not satisfactory, though it certainly removed a hair here and there. I should be glad to know if anyone else has had the same experience? (2) What is the best agent for removing the stain caused by picric acid? In using a solution, as recently recommended for burns, it is almost impossible for the dresser to avoid his hands being stained. Even after well washing the hands, the flavour of the picric acid is imparted to bread, etc., for hours afterwards."

MR. D. WALKER asks if any correspondent can favour him with information as to the composition of the black liquid used for the sights of guns.

OBITUARY.

YOUNG.—On January 5, W. F. Young, Chemist and Druggist, Kilmarnock. (Aged 29.)

WALKER.—On January 20, Benjamin Walker, Chemist and Druggist, Tetbury. (Aged 45.)

HUNTER.—On January 22, Thomas Hunter, Chemist and Druggist, North Shields. (Aged 71.)

BANKS.—On January 23, at his residence, Enfield, John Banks, manager of the surgeons' instrument department of the firm of Messrs. S. Maw, Son, and Thompson, druggists' sundriesmen, of Aldersgate Street. Mr. Banks was in his sixtieth year, and had been with the firm forty-four years, commencing his career in the service as a boy in 1852. He had conducted with signal ability and success the business of the department over which he presided, and was greatly respected by a large circle of business and other friends.

HEADLEY.—On January 25, Morris Headley, Pharmaceutical Chemist, Filey. (Aged 89.)

PUBLICATIONS RECEIVED.

MACHINERY AND APPARATUS FOR MANUFACTURING CHEMISTS. BY JAMES C. SHEARS, ASSOC. M. INST. C. E. Pp. 93. Price 3s. 6d. (London: E. Marlborough and Co., 51, Old Bailey, E.C., 1896.) From the Publishers.

A SECOND NOTE ON THE DISCOVERY OF THE SNAKE BITE CURE. BY DINSHAH ARDESHIR TALEYARKHAN. From the Author.

HISTORY OF THE CHOLERA CONTROVERSY. BY SIR GEORGE JOHNSON, M.D. Lond., F.R.C.P., F.R.S. Pp. 78. Price 3s. (London: J. and A. Churchill, 11, New Burlington Street, W. 1896.) From the Publishers.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Ames, Ansterberry, Ashford, Barker, Bates, Bindloss, Bird, Blythe, Boa, Brearley, Brown, Clark, Cribb, Davies, Daybell, Dryden, Dyer, Forrett, Griffin, Gunn, Harris, Heron, Hill, Idris, Jarvis, Johnston, Last, Line, Linstead, Lyon, Mander, Morgan, Mumbray, Muratowsny, Oliver, Phillips, Pike, Pryse, Reynolds, Robinson, Scamler, Shattock, Sinclair, Smalley, Stephenson, Thompson, Tocher, Vogl, Walker, Wart, Wells, Whitaker, Williams, Wilson, Wyatt, Zimmerman.

**SCROPHULARIA NODOSA, L.,
ITS SPHÆROCRYSTALS AND SOME ALLIED BODIES.**

BY DR. AUGUST E. VOGL,

Professor of Pharmacology, etc., to the University of Vienna; Honorary Member of the Pharmaceutical Society.

In all the green parts of the knotty figwort, *Scrophularia nodosa*, L., unusually beautiful sphærograins, or sphærocrystals of an organic compound occur, which are specially interesting on account of their being present in the living plant itself, and not produced by drying or by the action of certain reagents. At present I am not able to give any information as to their nature, but in many respects they resemble the sphærocrystals found in buchu leaves, in the leaves of *Conium maculatum*, and other umbelliferous plants, and considered to be hesperidin. They are most easily seen in the stem-leaves, the structure of which may be briefly detailed.

The leaves of the figwort are shortly petiolate, somewhat oblique, ovate or elongated-ovate, acute, contracted at the base, and unequally crenate-dentate; in structure they are

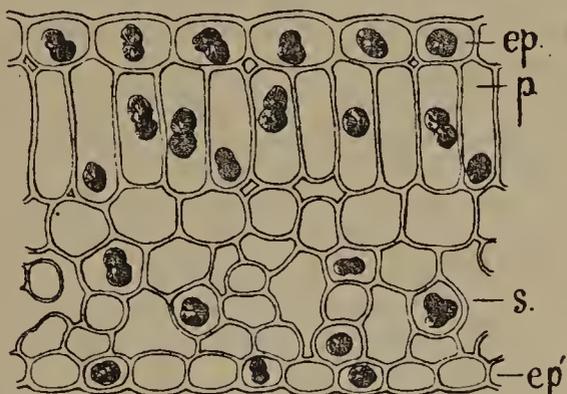

Fig. 1.—*Scrophularia nodosa*, L. Portion of transverse section of leaf; *ep*, epidermis of upper surface; *ep'*, epidermis of under surface; *p*, palisade tissue; *s*, spongy parenchyma. In most of the cells a single or double sphærograin.

dorsi-ventral (Fig. 1). The upper epidermis (Fig. 2) is composed of tabular cells with sinuate walls, those of the lower epidermis, on which alone stomata occur, being very wavy. Here and there on the veins are very small capitate hairs, with a short, one-celled, thin-walled pedicel, and a two, three, or four-celled head, which in section is almost reniform. The palisade tissue occupies about one-half of the mesophyll, and consists of a single row of somewhat slender

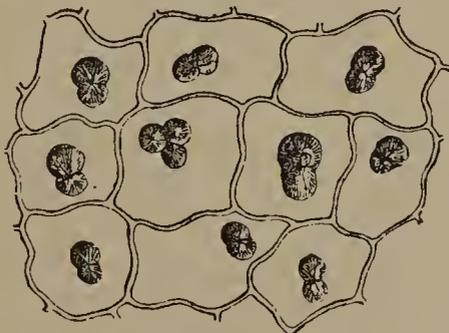

Fig. 2.—*Scrophularia nodosa*, L. Epidermis of upper surface.

cells, which are connected, by a row of absorbing cells, with a spongy parenchyma about three cells wide. The chloroplasts are relatively large, disc-shaped, or pointed-elliptic, and contain abundance of starch.

In transverse and in surface sections of the fresh leaves, either without any preparation at all or after the action of water, alcohol, glycerin, or chloral hydrate, comparatively

large spherical or double spherical masses (resembling a compound starch-grain) the brightness and yellow colour of which renders them at once conspicuous, can be observed in some or many of the cells of the epidermis and mesophyll. A high power shows a radiate and occasionally concentric formation, the former being characterised by fine radial striae and sometimes fissures. Usually the sphærograins occur singly in the cells, but in the cortical tissue of the stem numerous small ones are to be found crowded into a single

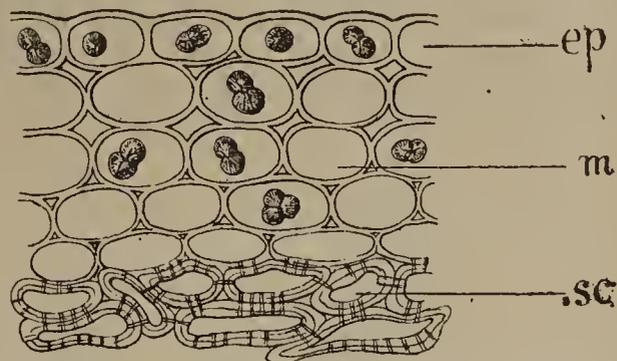

Fig. 3.—*Scrophularia nodosa*, L. Transverse section of carpellary wall; *ep*, epidermis; *m*, central tissue; *sc*, sclerenchymatous tissue.

cell. They lie in colourless, or, in the peduncle, in red cell-sap, and are accompanied by a few microsomes, by one or two oil-globules, and in the green parts of the plant also by chloroplasts. As far as could be determined, these sphærograins are insoluble in water, glycerin, chloral hydrate, alcohol, acetic, and hydrochloric acids even when warmed; caustic potash and ammonia dissolve them. Ferric chloride shows the presence of iron-greening tannin in all cells containing chlorophyll and in isolated groups of epidermal cells, but does not affect the sphærograins, or at most changes their colour to a brownish green.

The sphærograins are present in variable number, not only in the leaves of the figwort, in which they occur in the green

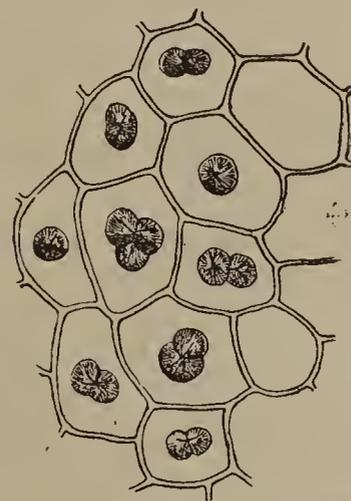

Fig. 4.—*Scrophularia nodosa*, L. Epidermis of carpellary wall—surface view.

cells of the mesophyll, and are more numerous in the epidermis of the upper than of the under surface, but also in the epidermis and cortical parenchyma of the stem, and in the tissue of the calyx and of the carpellary wall (Figs. 3 and 4). The last named is the easiest object in which their presence in the living plant can be demonstrated, for the chlorophyll-cells, suspended in their own cell sap, show the sphærograins.

As far as I am aware this is the first observation of the kind that has been made. Zimmermann in his excellent

work, 'Die Morphologie und Physiologie der Pflanzenzelle,'* draws particular attention to the fact that such sphaerocrystals never occur in the living plant, but make their appearance only after the action of certain reagents.

The commonest, and to a certain extent, typical form of the sphaerograins of the figwort is the double sphere already alluded to. Large and small simple spherical grains also occur as well as disc-shaped. Sometimes the small grains grow together in masses resembling tubers, glands, or bunches of grapes. Sometimes the larger ones seem hollow in the centre. In the comparatively large, axially elongated cells of the chlorophyll tissue of the stem there sometimes occur great numbers of sphaerograins, usually small in size and of

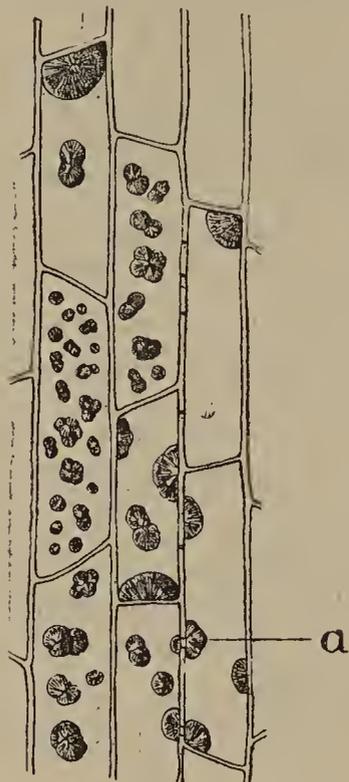

Fig. 5.—*Scrophularia nodosa*, L. Sub-epidermal tissue of stem.

typical shape, or in spherical grains, or warty, tuberous, glandular, or grape-like aggregations, and frequently, like other well-known sphaerograins, attached to the cell wall. In the latter case the cell wall is thickly covered on both sides with such grains, which appear then to be connected one with another through the pores in the wall.

Glycerin seems to promote the separation of sphaerocrystals. If the cortical tissue of the stem be treated with that reagent, small, usually radiately aggregated crystals will make their appearance, sometimes in whole rows of cells; these are probably substantially identical with the sphaerograins.

As far as my investigations during the vacation this and last year in South Tyrol extend, the sphaerograins described are of regular occurrence in *Scrophularia nodosa*. I have examined plants from very varied localities for sphaerograins, and have never failed to detect them, although sometimes but few were to be found. They often occurred, however, in considerable number, and in some specimens, gathered in a vineyard after flowering, every epidermal and mesophyll cell contained a sphaerograin. The influence that the period of vegetation has upon the sphaerograins has yet to be decided; I have been able to ascertain that the leaves of non-flowering shoots also contain them sometimes in large

numbers. They could not be detected in the root or tubercles, the parenchymatous cells of which are filled with somewhat large-grained starch, nor in the wood or pith.

In conclusion, I should like to draw attention to the extremely elegant capitate hairs on the flowering stem and its branches; they are accompanied by the small capitate hairs already alluded to, and consist of a pedicel composed of two cells of unequal size bearing a compressed hemispherical, or almost disc-shaped, or, if seen from the side, lens-shaped head. The lower of the two pedicel cells is comparatively very large, inelegant, and abruptly conical; the upper, short and disc-shaped. The head consists of numerous (40 to 50) club-shaped cells filled with violet sap and enclosed within a cuticle, thus recalling to a certain extent the glands of kamala (from *Mallotus philippinensis*). Warmed with solution of caustic potash the cuticle bursts or is dissolved, and the mass of cells is set free. As these trichomes perish the head collapses, the edge bends over and downwards, and the hair then resembles a delicate fungus.

Allied to the sphaerocrystals of buchu and, perhaps, identical with them, are the sphaerites, which occur in large numbers in the epidermal cells of a species of jaborandi (*Pilocarpus trachylophus*, Holmes, Ceará jaborandi).* The latter possibly correspond to the roundish balls that may be observed in the epidermal cells of the official jaborandi leaves (*Pilocarpus jaborandi*, Holmes); they are brown, and dissolve with production of a lemon-yellow colour in caustic potash.† Different in their nature are the sphaerocrystals that I found in the hairs on the anthers of *Verbascum* (Flores Verbasci)*; they are present in the drug, that is, in the dried flowers, and separate from the fresh plant on the addition of glycerin.

Very similar sphaerocrystals occur in the beard-like hairs on the lateral petals of the pansy, *Viola tricolor*, L.; these hairs are club-shaped, one-celled, thin-walled, and filled with colourless, yellow, or (in the garden variety) blue cell sap. They separate easily and invariably when a preparation of the fresh plant is placed in glycerin. In the course of two or three hours, or frequently sooner, yellowish-brown sphaerocrystals make their appearance. Possibly the similar yellow bodies in the well-known scales on the leaves of *Elæagnus angustifolia*, L., belong to this class of sphaerocrystals.

The sphaerocrystals that I had an opportunity of observing in the vacation of 1894 in the leaves of the purple loose strife, *Lythrum salicaria*, L., more nearly resemble hesperidin. As these leaves are interesting from another point of view also, I propose describing them a little more fully.

The leaves of the purple loosestrife are elongated lanceolate in shape, bluntly pointed, cordate at the base and dark green in colour, the under surface being paler. The structure is dorsi-ventral, the palisade tissue being composed of a single row of cells occupying about one-half of the mesophyll, its cells are slender and large, as are also those of the spongy parenchyma, of which there are about three rows. The epidermis of the upper surface is composed of sinuate polygonal cells, that of the under surface of wavy cells, on the side walls of which there are knot-like thickenings. Stomata occur on both sides, and there are also hairs which consist of one or two thick-walled cells, and are pointed, erect, or some-

* *Pharm. Journ.*, xxiv., 1065.

† Compare A. Vogl, 'Pharmakognosie,' p. 93.

‡ Vogl, 'Pharmacognosie.'

what oblique and finely striated. Numerous rosette-crystals of calcium oxalate, sometimes of considerable size, are present in the mesophyll. The chloroplasts are relatively large and contain abundance of starch. In the epidermis of both surfaces there are irregularly distributed groups of two, three, or more cells containing a homogeneous, strongly refractive mass, and conspicuous by reason of their projecting into the mesophyll beyond the other cells.

If a portion of the epidermis is separated and placed in glycerin, the contents of these cells contract, with indication of stratification, and folds are formed in the cell walls. Alcohol acts more quickly. Doubtless the cell contents consist principally of mucilage (and sugar). Caustic potash colours it almost gamboge-yellow, whereas the contents of the other epidermal cells assume a yellowish-red colour, whilst those of the collenchymatous cells in the veins and of the chlorophyll cells turn deep orange-yellow. If transverse sections are soaked in alcohol and then treated with caustic potash, the chlorophyll cells are coloured brownish-yellow, all the cell walls, including those of the hairs, pale yellow, whilst the contents of the guard cells turn orange-red. Iron blueing tannin is abundantly present in all the parenchymatous elements of the mesophyll, with the exception of the crystal cells, in the collenchyma of the veins, in isolated as well as groups of epidermal cells, and in many hairs, particularly in the terminal cell of pluri-cellular ones. It is, however, present in greatest quantity in the palisade, and spongy parenchyma. In the cells of these tissues iron salts produce a deep indigo-blue coloration; even the cell walls are tinged, at least transiently, blue. Chlorzinc-iodine colours all cell walls, except those of lignified elements of the vascular bundles, blue.

If sections of fresh leaves be examined in water, glycerin, alcohol, or chloral hydrate, small prismatic or acicular, colourless, or sometimes yellow sphaerocrystals or groups and

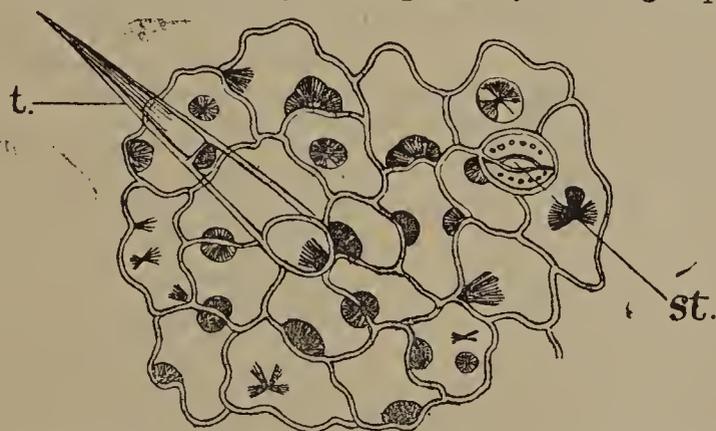

Fig. 6.—*Lythrum salicaria*, L. Epidermis of upper surface of leaf after the action of alcohol; sphaerocrystals in almost all cells, as well as in hairs (*t*); *st*, stoma.

tufts of crystals will make their appearance in the epidermal cells and in the hairs; in the latter they are often situated on the cell wall or the septum, or radiate in long needles from the apex. This separation of crystals takes place most abundantly after treatment with alcohol, but maceration in glycerin for several hours also results in the production of beautiful sphaerocrystals and tufts of needles. Dilute caustic potash dissolves them. They are not present in the living plant, but, as is the case with buchu, conium and jaborandi leaves, separate only in consequence of the evaporation of their solvent, or after treatment with dehydrating reagents (alcohol, glycerin). Whether these crystals consist of hesperidin remains to be determined.

I have recently observed bodies resembling the sphaerograins of *Scrophularia nodosa*, in the dried leaves of *Vicia faba*, and in the fresh leaves (collected in September) of *Calamintha acinos*; in the latter they occur in the epidermis, and, together with chloroplasts, minute wedge-shaped crystals of calcium oxalate and globules of oil in the cells of the mesophyll.

Mucilage cells resembling those in the epidermis of *Lythrum salicaria* are found, as is well known, in plants belonging to many other orders, as, for instance, in the epidermis of the upper surface of the leaves of *Reseda odorata* and other species, of *Viola silvestris*, *Viola hirta*, and doubtless other species of *Rhamnus frangula*, *Lavatera trimestris*, *Hibiscus trionum*, etc., etc.

Mucilage cells also occur in the epidermis of the leaves of various species of *Cytisus*, whilst in the leaves of *Onobrychis sativa* mucilage is found in enlarged cells of the palisade tissue, in *Chrysanthemum leucanthemum* in the large tongue-shaped terminal cell of pluri-cellular hairs. It is interesting here to note that in other Compositæ, e.g., *Matricaria chamomilla* (peduncle), *Leontodon hastilis* (leaves and stem), similar hairs occur in which the terminal cell secretes no mucilage.

MEDICATED GRANULES.

BY M. MANSIEB.

A short time since this novel form of exhibiting medicines was introduced to the notice of therapists, and seemed to please both doctors and patients, not because the use of the granules was more convenient than that of preparations of the old "armamentarium," but because they represented a pharmaceutical novelty. The granules are obtained by saturating specially broken sugar with medicated solutions, and allowing the solvent to evaporate. As far as is possible, the liquid used to make the solution should have as its base, alcohol, ether, or chloroform, so as not to dissolve the sugar. Then to reduce this to the granular form it must be gently triturated in a marble mortar so as to avoid the formation of powder, and afterwards sifted through a metallic sieve of five meshes to the centimetre. The sugar from this first sifting is now freed from adherent sugar dust by means of a sieve, either of hair or covered with gauze such as is used for surgical dressings with about twelve meshes to the centimetre.

As a typical example of such granular medicaments, I will now give the method of producing "granulated kola" (*kola granulée*), which is at present very much in vogue on the Continent: Take of hydro-alcoholic extract of kola, 7.50 grammes, granulated sugar, 150 grammes. Dissolve the extract in half its weight of alcohol at 60° by means of a water bath; pour the solution on the granulated sugar placed in a marble mortar, mix well by means of a stirring rod, place on a thin sheet of paper, and dry between 20° and 30° C. f. taking care to separate from time to time the adhering masses of granules. When dry, preserve in wide-mouthed bottles. Each teaspoonful of these granules weighs 4 grammes, and contains 0.20 gramme of extract. Not only medicinal extracts but almost any medicine can be made to lend itself to this way of preparation. The glycerophosphates of the alkali metals being very soluble in water, but only very slightly so in alcohol, may be dissolved in their weight of water, and then an equal quantity of alcohol at 60° added before pouring over the sugar. As for the glycerophosphate of lime, now so much prescribed, this is rather insoluble in water (1-15); a way out of this difficulty is, however, found in dissolving the salt (previously mixed with twice its weight of alcohol at 60°) with the aid of lactic acid. When this is done a solution is certainly formed but it is not of glycerophosphate of lime, but consists of lactate of lime and free phosphoglyceric acid. — *Répertoire*.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

MEETING OF THE COUNCIL.

WEDNESDAY, FEBRUARY 5, 1896.

Present:

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. JOHN HARRISON, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bottle, Corder, Cross, Gostling, Grose, Hampson, Hills, Johnston, Martin, Martindale, Newsholme, Savory, Schacht, Warren, and Young.

The minutes of the previous meeting were read and confirmed.

THE LOT FOR THE NEXT COUNCIL.

The lot having been taken in the usual way to determine the seven members of Council who shall retire in May next, the following names were drawn:—Carteighe; Corder; Harrison; Hills; Martindale; Newsholme; Savory.

The following who remained in by lot last year now retire by rotation:—Messrs. Cross, Gostling, Johnston, Martin, Schacht, Storrar, and Warren.

The following seven remain in office another year:—Messrs. Allen, Atkins, Bottle, Grose, Hampson, Southall, and Young.

DIPLOMAS.

The undermentioned being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Armitage, Nathaniel Newborn.	Dyson, Thomas Hatfield.
Arrowsmith, George Micklem.	Lamb, William Henry.
Arundel, Edmund.	Lucas, Harry.
Boorne, Herbert Edward.	Taylor, Charles Ludlow.
Cocker, Lewis Alexander.	Udale, George William.
	Walker, John Robert.

ELECTION OF MEMBERS.

The following having passed the Major Examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Pharmaceutical Chemists

Armitage, Nathaniel Newborn, Leeds.	Highfield, Henry, Sheffield.
Arrowsmith, G. Micklem, Whitstable.	Lamb, William Henry, Whitby.
Arundel, Edmund, Manchester.	Lilly, Arthur, Chelsea.
Blissett, Francis Howman, London.	Taylor, Charles Ludlow, Brinkworth.
Boorne, Herbert Edward, Bristol.	Udale, George William, London.
Cocker, Lewis Alexander, Ripponden	Walker John Robert, Cockermouth.
	Young, James Clements, Manchester.

The following who were in business before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Chemists and Druggists.

offhouse, James, Fleetwood.	Roberts, Robert B., Llanfairfechan.
-----------------------------	-------------------------------------

ELECTION OF ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor Examination.

Anning, James John, Leeds.	Mitchell, Robert Harry, Liverpool.
Colley, Herbert William, Grimsby.	Rees, Rice William, London.
Davies, John, Herne Hill.	Sanders, Francis Theodore, Sutton.
Day, John Robert, Liverpool.	Slinn, Albert Edward, Nuneaton.
Jackson, Frederic, Bawtry.	Stone, G. P. R., Burnham Market.
Leins, Heinrich, London.	Vinden, Frederick William, Exeter.
Lowther, Herbert Reginald, Mumbles.	Vogt, George, Kendal.
	Williams, John, Bala.

Modified Examination.

Felix, David Lewis, Mold.

ELECTION OF ASSOCIATES.

The following having passed their respective examinations and tendered or paid as "Students" their subscriptions for the current year, were elected "Associates" of the Society:—

Minor Examination.

Adams, John, Uxbridge.	Hopkins, William Edward, Llandoverly.
Alder, Sydney Frank, Cheltenham.	Howell, Ellen May, London.
Alexander, Ernest Glover, Sheffield.	Johnstone, John, Selkirk.
Barlow, Samuel, Truro.	Kellam, Edward Henry, Stamford.
Barnes, Victor Geo. Harry, Tillington.	Knight, William Arthur, Leicester.
Beachell, John, York.	Latham, Hugh, Kirkcaldy.
Blyton, John Henry, Manchester.	Lewis, Richard Rice, Barmouth.
Bonnar, William, Glasgow.	Littlefield, Robert Dexter, Ventnor.
Caldwell, John, Kirkinvillech.	Littler, John, jun., Frodsham.
Currie, Archibald, Leith.	Melville, John, Edinburgh.
Daybell, Samuel Maltby, Ilkeston.	Michie, Alexander, Hawick.
Dewdney, A. Victor, Newton Abbot.	Morrell, John G., Stockton-on-Tees.
Duncan, James George, Turriff.	Nicholson, John Gordon, Carnoustie.
Fowler, Frank, Little Lever.	Scott, George Baty, Belford Station.
Francis, John, Merthyr Tydvil.	Smith, Ernest Edward, Bristol.
Hammond, Wm. H., West Burton.	Sykes, Richard Alfred, Manchester.
Harris, Abraham, Sheffield.	Tindale, Joseph Edward, Whitby.
Hendry, Simon, Belfast.	Turner, Walter Frederick, Norwich.
Hickman, Fredk. Stanley, London.	Walker, William Henry, Willenhall.
Holman, Henry, Silverton.	Westley, George Ernest, Walsall.

Wilson, Harold, Bridlington.

Modified Examination.

Burn, Thomas, Hartlepool.

ELECTION OF STUDENTS.

The following having passed the First Examination and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Andrews, Silas Fred., Chatham.	Moore, Herbert Richard, Bath.
Buttress, Henry James, Portsmouth.	Nursaw, Edward, York.
Chambers, Charles Ward, Goole.	Nuttall, Maurice William, Alfreton.
Clegg, Aldhelm, Manchester.	Phippen, Harry Garnet, Newbridge.
Cleworth, John, Leigh.	Pratt, Edward Adams, Bridgnorth.
Coverdale, Arthur E., Kennington.	Prescott, John, Butterwick.
Davies, Emlyn Holt, Aberystwith.	Purdie, Percy Wilfred, London.
Dean, John, Ashbourne.	Purves, William James, Hartlepool.
Dixon, William, Kendal.	Robinson, John L., Bournemouth.
Hickes, Charles Edward, Pocklington.	Robson, Harold, Huddersfield.
Jewson, John Robert, Wisbech.	Smith, Alfred, Derby.
Johnson, George Sheriff, Istock.	Spear, Frederick Augustus, Plymouth.
Johnson, Wm. Danily, London.	Stewart, William N., Glasgow.
Jones, John, Llanfagan.	Summers, George Edward, Derby.
Kemish, Luther, Downham Market.	Truscott, Gilbert Edgar, Southampton.
Kennard, Lilian Sarah, Lambourn.	Venn, Samuel Ernest M., Devonport.
Kingdon, Arthur J., South Molton.	Walters, John, Llanboidy.
Knight, Thomas, Reading.	Wherly, Charles, Stockton-on-Tees.
Leech, Peter, Ulverston.	White, David, Upper Weston.
Linnett, Louis John, Sevenoaks.	Whitehead, Thomas, Northallerton.
Mattock, William Henry, London.	Williamson, John Stanley, Liverpool.
Medley, William T., Newport (I.W.).	Woods, Benjamin A., King's Lynn.
	Wright, Arthur Childs, Bury-St.-Edmunds.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who have severally made the required declarations, and paid the restoration fee, were restored to the Register of Chemists and Druggists:—

Clode, Charles, 64, Corbyn Street, Hornsey Rise, N.
Marsden, John, 65, Shaw Road, Oldham.
Prowse, Frederick, Swain Street, Watchet.

Several persons were restored to their former status in the Society upon payment of the current year's subscription, and a nominal restoration fee of one shilling.

Mr. CORDER asked if a member who had not paid his subscription for many years was eligible to be restored to membership on payment of one year's subscription or had he to pay the arrears.

The PRESIDENT said he was only required to pay a small fee and the current year's subscription. Formerly he had to pay the arrears, but the bye-law was altered some years ago.

REGISTRAR'S REPORT.

The Registrar's report on the numerical strength of the Society was laid on the table. It is printed at pp. 106 7.

The PRESIDENT moved that the report be entered on the minutes and published in the *Pharmaceutical Journal*.

Mr. BOTTLE said he should like to express his regret at finding that their brother chemists did not rally around the Society as they might and, he thought, ought, to do. He said this as an old member of the Society, who felt that chemists had here a nucleus around which all could rally, and why so many of them were blind to their own interests he could not understand. He noticed with gratification that what he might call the younger element—the associates, were increasing, and he trusted the day was not far distant when the Council would be able to see its way to elect a goodly number of them as members of the Society.

Mr. ALLEN said the real question was whether or not the larger proportion of the younger men who passed the examination at the present time were joining the Society. It was only to be expected that a considerable number of the pharmaceutical chemist members would drop off from time to time, as many of them were amongst the older men. Enquiries had been made several times within recent years, and it appeared that of those passing the Major examination by far the larger proportion joined the Society, or were attached to it even before passing.

Mr. HILLS remarked that the present report showed that during the year there had been 68 successful Major men, and 57 had joined the Society.

The PRESIDENT thought it was very gratifying to find that the associates in business were so loyal to the Society, and that a number of chemists and druggists in business who had not previously joined were now coming to them.

The resolution was then adopted.

FINANCE COMMITTEE.

The SECRETARY read the report of this Committee, which recommended the payment of certain accounts.

The PRESIDENT (as Chairman of the Committee) moved the adoption of the report and recommendations. With regard to the General Fund Account, the receipts included subscriptions, examination fees, ground rents, and advertisements. The payments were of the usual character, excepting the half-yearly solicitors' bill, which amounted to upwards of £400. With regard to the Benevolent Fund, the Treasurer had been obliged to draw all the money in hand; but money was coming in, and he hoped would come in still more. They could do with as much as their friends would give them, and the Committee would be happy to vote it away to deserving cases. Two donations of ten guineas each had been received from old friends—Mr. John Thistleton Davenport, a former President, and Mr. Burden—in addition to those gentlemen's regular subscriptions, for which the Council was very grateful.

The resolution was adopted.

BENEVOLENT FUND COMMITTEE.

The report of the Committee included the recommendation of the following grants:—

£10 to a former member (67), who has been unsuccessful in business, and is without present means of support. (Oxford.)

£10 to a registered chemist and druggist (63), who has been unable to work for some time past, on account of bronchitis. He failed in business in 1890. (Hornsey.)

£10 to a registered chemist and druggist, whose stock and fixtures were sold up for rent in 1894. Has since been unable to find regular employment. He has a wife and three children to support. (New Cross.)

£10 to the widow of a former member and subscriber. Has had three previous grants of £10 each. She suffers from rheumatism, and can only do a little needlework occasionally. (Brixton.)

The SECRETARY had reported that one of the applicants for assistance had died since the receipt of the application. Two cases had been declined, and one had been deferred pending receipt of certain particulars.

The SECRETARY had also reported the death on January 15 of Mrs. Julia Johnson, of Hammersmith, aged 83, who had been an annuitant on the Benevolent Fund since 1885.

The VICE-PRESIDENT (as Chairman of the Committee), in moving the adoption of the report, reviewed the seven cases which came before the Committee. Of these one applicant had since been

removed by death, and as to the remaining six, grants were made in four cases, three of them to men. The effect of this, they hoped, would be far more than the temporary help afforded, as assisting them to earn their own livelihood in the future was the best form of assistance, it seemed to him, that they could make to those overtaken by distress; it helped to place them on their feet, and put them in a position to help themselves. A grant was also made to a lady who had been relieved on two previous occasions, her circumstances remaining much the same as they were on the occasion of her first application. Two other cases received very careful and long consideration, and as the result the Committee unanimously came to the conclusion that the applications did not come within the sphere of operations of this Fund.

The report was then adopted.

LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

Library.

The report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
December ...	Day	392	29	3	16
	Evening.....	127	11	2	8
Year 1895 ...	Day.....	4148	32	0	14
	Evening.....	1465	16	1	7
Circulation of Books.					
	Total.	Town.	Country.	Carriage paid.	
December	175	101	74	19s. 0½d.	
Year 1895.....	2176	1119	1057	£13 6s. 1½d.	

Donations to the Library had been announced (*Pharm. Journ.*, Jan. 18, p. 47), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended the purchase of the under-mentioned works:—

For the Library in London:—

Allen, Chemistry of Urine. A second copy.

For the Library in Edinburgh:—

Kelly's Directory of Chemists and Druggists.

Museum.

The Curator's report had been received, and included the following particulars:—

Donations to the Museum had been received (*Pharm. Journ.*, Jan. 18, p. 48), and the Committee recommended that the usual letter of thanks be sent to the respective donors.

	Attendance.	Total.	Highest.	Lowest.	Average.
December ...	Day.....	463	37	3	20
	Evening.....	36	9	2	2

Specimens had been distributed to Professor Tschirch, and to Professor G. Planchon.

The Exeter Association of Chemists and Druggists had also been supplied with specimens for their materia medica cabinet.

The report of this Committee included a recommendation that a grant of £20 be made to the Liverpool Pharmaceutical Students' Association for the purchase of a cabinet and specimens of materia medica, the cabinet to be placed in the Liverpool University College and to bear an inscription stating that it was the property of the Pharmaceutical Society of Great Britain.

There was also a recommendation passed at a special meeting of the Committee with regard to the Burroughs' Memorial Scholarship.

The PRESIDENT moved the adoption of the first portion of the report, as the latter portion would form the subject of a separate resolution. In addition to the usual routine business, the Committee had further considered the application from Liverpool for a cabinet and specimens of materia medica, for the purpose of promoting pharmaceutical education in Liverpool, especially in connection with the University College, Liverpool. As the Council was aware, the authorities of that College proposed to adapt their scheme of education, so as to fit in with the wants of students of pharmacy, and the College was equipped with the necessary apparatus for the teaching of chemistry and botany, but materia medica was not provided for. After careful consideration, the Committee thought it would be well that the cabinet should be placed in that College, but remain the property of the Society. There was sometimes a difficulty in connection with local Associations, and, at all events, this cabinet being held in trust by the authorities of the College for special purposes would be as available for pharmaceutical students as it could be in any other way. The

REGISTRAR'S REPORT.

Committee felt that some question might be raised as to the propriety of handing over to another educating body a cabinet of this kind, but after full consideration it was felt that it was the duty of a corporate body like that to assist in every way to promote education in its widest sense. It must be to the distinct advantage of the rising generation of chemists and druggists that they should be taught elementary chemistry, botany, and other branches of pharmaceutical education in classes or lecture rooms and laboratories side by side with other students, and the fact that such a system of education could not be self-supporting, induced the Committee to make this recommendation with regard to the special subject of *materia medica*. In a certain sense it was furnishing the teacher or lecturer the necessary material with which he could, in conjunction with his colleagues, give a complete course of pharmaceutical education.

Mr. BOTTLE asked if any information was furnished as to the fees to be charged.

The PRESIDENT said the fees were not yet fixed, but it was understood they were to be moderate.

Mr. BOTTLE said he put the question because a very handsome public building had recently been erected at Dover for promoting technical education, and he regretted to hear that the scale of fees was rather prohibitive. In all cases where the Society assisted such institutions in any way it should take care that the fees were not too high.

Mr. SCHACHT expressed his gratification that this experiment was being made in Liverpool. Once or twice before he had expressed the idea that assistance should go rather in the direction of subjects not usually taught in such schools. Chemistry and botany were generally very well and systematically taught, and there was no difficulty in an ordinary student reaping all the advantages offered, and sometimes even *materia medica* was taught in medical schools affiliated to these colleges; but there still remained the one subject of pharmacy. Many thought, as he did, that this subject could be best learned in a well-appointed master's establishment, but that opportunity did not always occur, and many young men completed their pupilage without gaining that instruction in practical pharmacy which they ought to have. If the grants made by the Society could take that direction, he thought they would go where they were most needed. He found by experience that there was not sufficient demand for that class of teaching to justify the Council of a University College in appointing a teacher. General science teaching drew pupils from a much larger area, and even in the case of *materia medica* there were a considerable number of medical students to appeal to, but for pharmacy proper there was but a very narrow field. In that direction he thought, therefore, the Society might assist local organisations so that in the end they might have a complete curriculum, not only for their own pupils, but for those members of the medical profession who wished really to qualify themselves in all branches of the art of medicine. The Liverpool College was on a much larger scale than any other provincial institution, and fortunately, owing to private munificence, each chair was endowed to the amount of £10,000, so that the authorities were in a position to be generous to the students, but other places were not so fortunate. He was very glad to see so good an example set in Liverpool, and hoped it would be followed, as it would tend to great general good as well as to the special advantage of pharmacy.

Mr. MARTIN had great pleasure in expressing his approval of the scheme, and congratulated the Society upon being connected with such a plan to be carried out in an important centre. He thought there was a tendency sometimes to underrate the difficulties of teaching practical pharmacy and the various manipulations which it should be the aim of every practical pharmacist who was thorough in his work to teach his students during their apprenticeship; that this proposal was well calculated to meet some of the difficulties encountered. With regard to fees he did not think there should be any discouragement of students in that direction. At Newcastle they supplied a course of thirty lectures for a guinea, and for these somebody had actually suggested the sum of 5s. only should be charged, a preposterous sum as it seemed to him. So far from complaining of the moderate fees which had to be paid he felt they should encourage their being raised rather than lowered. If students were so poor that they really could not afford to pay the modest fees now universally charged, he thought they should take to some other calling than pharmacy.

The PRESIDENT pointed out that the scheme was based on precisely the ideas that had been given expression to, and expressed

his opinion that it would be a valuable means of supplementing the training students in practical pharmacy and in some other points of training of general interest and concern to them all as chemists.

Mr. CORDER said he was sorry to hear that pharmacy was to be introduced as a subject at Liverpool, believing as he did that the chemist's shop was, if not the only, certainly the chief and foremost place in which to learn practical pharmacy, and that masters had no business to take premiums for apprentices without teaching something more than mere shopkeeping, and including practical pharmacy in their curriculum.

Mr. ATKINS was afraid his friend had rather an ideal than a practical state of things in view, and he only wished that practical end more closely approached the ideal than his own experience led him to believe was the case. His own views rather tended towards the idea indicated by Mr. Schacht that a more complete course of education for our students was wanted, especially as regarded practical pharmacy and *materia medica*. It was all very well to talk about what the master ought to do. The whole conditions of apprenticeship had altered, and were being altered. Frequently the master no longer resided on the business premises, but lived away, and any who had carefully watched the Society's examinations would know how largely students came from the country untrained and unfitted for the work which they aspired to do. He was exceedingly glad to find an effort was being made to remedy this state of things, and by means of institutions at Liverpool and other centres to give their students opportunities of perfecting themselves in their profession.

Mr. HAMPSON pointed to the examples of France, Germany, and other countries in this matter as calling for increased facilities for practical training being encouraged, and especially to the attention which was being paid to cookery in England, as the public recognition of a need for more practical and thorough training in all matters bearing on the health and happiness of the people.

Mr. CROSS, whilst sympathising with Mr. Corder's views, pointed to another side of the advantage of teaching pharmacy, in the comparative ignorance of the present race of medical men with the practical side of that subject, which too often was left to them to pick up after they had entered on practice. He believed many medical practitioners would be among the first to deplore the present methods of their training, and that very much good might result from medical students and their own students being brought to work side by side in an institution of the kind they were considering. He thought the Society was to be congratulated on the opportunity afforded it of aiding and recognising schools of this description, and he was still more gratified to think that pharmacy would be taught there.

Mr. MARTINDALE, as having been a teacher of pharmacy both to medical and pharmaceutical students, whilst agreeing with the advantages of shop teaching in practical pharmacy, pointed out that there were certain things not there obtainable, but which would be covered by the lectures and teachings at an institution like that they were considering.

Mr. HILLS, considering pharmacy was an applied science, and that the application of the science ought to be taught during apprenticeship, yet was glad to hear of the pharmacy classes, believing as he did that their influence must be for good, and that they need not interfere with, but should be regarded as valuable aids to, the teaching of their apprentices in pharmacy.

Mr. GROSE said his experience of late years had been that whenever he took a junior assistant he had to teach him many things that he might reasonably have expected would be learnt during his pupilage, and he spoke of a case, which he supposed was not exceptional—where everything sold in a so-called chemist's shop, down to the ointments, was bought in London—as showing the altered condition of things to which reference had already been made.

Mr. ALLEN supported the view to which expression had been given of the great advantage of having pharmacy taught in an institution where medical and pharmaceutical students sat side by side. Such teaching, however elementary might be the subjects, must result in advantage to both classes of student. A great fault of the present day was an imperfect knowledge of pharmacy and *materia medica* generally, resulting from the prevailing methods of training both as doctors and chemists. He could not help thinking both of these classes would be materially benefited if it should be found possible to teach them successfully side by side.

Mr. MARTINDALE said a pharmacist must know a great deal more about pharmacy than a medical man.

Mr. ALLEN said it had been found possible in other countries.

The PRESIDENT said the discussion was no doubt valuable, but as practical men they had to deal with students as they found them. The evils referred to had been known for years, but until a curriculum was enforced he feared all that could be done was to endeavour to aid the student in any department in which he was weak. Unquestionably, many of them were partly responsible for the fact that pupils were not well trained. Some would not take pupils, and he was not sure that there ought not to be a statutory enactment compelling them to take a certain number of pupils. The difficulties in connection with the learning of the business in many parts of the country were very great, and no doubt it often happened that parents when they apprenticed their sons did not really know what was before them, and what they would have to learn in order to qualify themselves to carry on the business. Often it was only towards the end of his term that the pupil discovered what he had to learn before he could pass his examination. On the whole he thought they might congratulate themselves on the fact that there was now a higher standard of education throughout the country; perhaps they had not gone ahead so much at the upper end of the scale, but the average assistant was certainly a much better man than he was thirty years ago. Seeing the difficulties assistants had to face, they must not expect too much from them. It was a serious thing to take an assistant of full age who was not registered, and the tendency was, as it was in medicine, for a young man to get his qualification as quickly as he could, though he still had a good deal to learn with regard to practical work. The old plan suggested by the founders of the Society was that when a youth was 21 he should pass an assistant's examination, and then after a few years' more practice in pharmacy go in for the pharmaceutical chemist's examination. No doubt that plan was an excellent one, but practically it had been upset by the Pharmacy Act of 1868, and they must now deal with things as they were. Sympathising as he did with what Mr. Corder had said, he must say that their paramount duty as a public body was to do their best for students as they found them.

The resolution having been carried,

The PRESIDENT said the Committee had held a special meeting on the previous day to consider the question of the Burroughs' Memorial Scholarship, when a letter was read from the Secretary of the Memorial Fund Committee—saying the opinion of that Committee was that the Scholarship should be an annual one for secondary education, open to pharmaceutical chemists who desired to advance their knowledge of chemistry and pharmacy. The Committee adopted that suggestion, and recommended that regulations should be drawn up in due course. That suggestion was made after the Memorial Fund Committee had had an interview with Messrs. Allen and Martindale, the feeling being that more good would be done in that way than if a scholarship were founded for primary education. The Library Committee thoroughly endorsed that suggestion, and he now moved that the recommendation of the special meeting of the Library, Museum, School, and House Committee, held on February 4, with reference to the Burroughs' Memorial Scholarship, be adopted, and that the Committee be requested to draw up the regulations under which the Scholarship may be competed for and held. The income would not be immediately available, probably not until July in next year. It was proposed to formally hand over the Fund at the evening meeting on Tuesday next, when the Council would be glad to see any subscribers to the Fund present.

Mr. ATKINS asked if the Fund was closed.

The PRESIDENT said no. They were anxious to raise £1000, but only £850 had as yet been received.

The resolution was carried.

DIVISIONAL SECRETARY.

The PRESIDENT moved that Mr. J. T. De Peare, of 14, Highbury Park, be appointed Divisional Secretary for the parliamentary division of East Islington in place of the late Mr. Howard Hall, who died a few weeks ago after a long illness. Mr. De Peare had taken a considerable interest in the Society.

The resolution was carried.

RESEARCH COMMITTEE.

The following interim report was read by the President:—

“The Committee has met once a month during the past half year, and has received periodical reports from the directors.

“The Committee has to report that the educational and research work of the Research Laboratory has made satisfactory progress.

“The investigation of the aconite alkaloids has been continued. With the approval of the Committee, a grant having been made for the purpose to the Director by the Royal Society, several important results have been obtained.

“These and the results of other experimental inquiries as to the constituents of podophyllum and of Indian opium, which have been prosecuted during this period, will be published in due course.

“Papers on the determination of aconitine, by the Director and Mr. Tickle; and on detection of aconitine, by the Director and Mr. Carr, will be read at the Evening Meeting on February 11.

“Pure specimens of new substances and of specially purified drugs have been supplied to five different investigators for the purposes of physiological and therapeutical inquiries.

“In October last the Committee nominated Mr. Francis H. Carr for re-election to the Salters' Company's Research Fellowship in chemistry, and the nomination has been approved by the Court of the Salters' Company.

“Mr. T. A. Henry, formerly Redwood scholar, is continuing his work in the Research Laboratory with the aid of a grant from the Manchester Scholarship Fund.

“Including Mr. Jowett, the Demonstrator, and Mr. Harold Brown, the Redwood Scholar, there are six workers in the Research Laboratory at the present time, of whom five are pharmaceutical chemists.”

The PRESIDENT moved that the interim report of the Research Committee be received—there was nothing in it to adopt. The Committee believed that these six gentlemen were doing valuable work. Of course, there were new comers every year who for the first few months were simply being educated, but he had repeatedly expressed the view that the educational portion of the work of the Research Laboratory was of great value, quite apart from the question of the results of the investigations which were conducted. He held that from the Director down to the last comer, each and all were doing useful work, and were pervaded by the true spirit of research.

Mr. SCHACHT had much pleasure in seconding the resolution, and was glad of the opportunity of saying that he believed the work being done was thoroughly genuine, and worthy the sympathy of the Council and all interested in scientific investigation. Of course the task of investigating in the regions of the unknown must always be carried on with more enthusiasm on the part of the worker than results for a long time might seem to justify. It was not every day that argon or helium was discovered; it was only by patient work for many years that anything turned up worth the consideration of the world. He believed that in the Research Laboratory they were working on the right lines. The Director was most enthusiastic, and he was glad to hear that the young men around him were showing corresponding enthusiasm, and were working energetically, steadily, and hopefully. Before the end of the year they would all probably be able to judge by the published papers that certain results might be expected. Some had come already, and more were coming. Whether the subjects treated were of the greatest importance to pharmacy might be an open question, but that they were of very great importance he thought was undoubted, and he was satisfied that the lines of work were such as reflected credit on the Society in the eyes of the whole scientific world.

The resolution was adopted.

CERTIFICATE IN LIEU OF EXAMINATION.

It was resolved that the Board of Examiners be empowered to accept in lieu of the First examination a certificate granted by the University of Turin, to D. O. Dompé, of Milan.

REPORT OF EXAMINATIONS.

January, 1896.

	Candidates.		
	Examined.	Passed.	Failed.
England and Wales:—			
Major	24	10	14
Minor	187	57	130
Scotland:—			
Major	4	1	3
Minor	165	65	100
First Examination	383	189	194

Thirty-three certificates by approved examining bodies were received in lieu of the Society's First examination.

CORRESPONDENCE.

The PRESIDENT read a letter from Mr. J. Anderson Russell, Secretary of the Glasgow and West of Scotland Pharmaceutical Association, forwarding a resolution that had been passed, thoroughly approving of the views of the President of the Pharmaceutical Society in respect to unqualified managers of branch shops, and whilst concurring in his remarks, expressing a hope that a reprint of them might be made and sent by the Registrar of the Society to all druggists and druggists' shops throughout the country.

GENERAL PURPOSES COMMITTEE.

The Council then went into committee to receive and consider the report of this Committee, which included the usual letter from the Solicitors, dealing with cases which had been placed in their hands. Upon resuming, the report and recommendations were adopted, and a special resolution was passed authorising the Registrar to take proceedings against the persons reported upon, in accordance with the provisions of the Pharmacy Act.

FIRST EXAMINATION RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Wednesday, February 5.

Certificates by approved examining bodies were received from the undermentioned in lieu of the Society's examination:—

Baker, Charles B., Nuneaton.
Eggleton, Eric H., Streatham.
Johnson, William Danily, London.
Kent, Charles Wesley, Louth.

Pearson, George Ernest, Wakefield.
Rotheray, Harry, Rawdon.
Sarjeant, Herbert William, Holloway.
Shaw, Henry Woolhouse, London.

The report of the College of Preceptors on the examination held on January 14 was received.

383 candidates had presented themselves for examination, of whom 194 had failed.

The following 189 passed, and the Registrar was authorised to place their names upon the Register of Apprentices and Students:—

Alexander, Robert, Fraserburgh.
Allan, David, Houldsworth, Govan.
Arnott, William John, Topcliffe.
Audsley, Benjamin, Horbury.
Barclay, J. Williamson, Dunfermline.
Barron, Jn. Lancelot, West Hartlepool.
Baxter, James Robert, Whitby.
Beech, E. Jos. Worthington, Balsall H.
Bell, Frederick Alexander, Llangollen.
Bellingham, Edg. Silvalus, Blackburn.
Beveridge, John Paton, Edinburgh.
Bisset, William, Aberdeen.
Bonner, Charles Ernest, Totnes.
Bottomley, Py. Kingdom, Gt. Horton.
Bowen, John, Carmarthen.
Braham, Alice D., Birmingham.
Brand, Arthur, Wallsend.
Bremner, Robert Storrar, Dundee.
Broughton, Robert Price, Wilmslow.
Brown, Thomas Frederick, Gravesend.
Browne, Henry Charles, Eastbourne.
Bullock, Charles Henry, Cirencester.
Bullock, Edmund Rayner, Gloucester.
Burt, William, Wishaw.
Cairncross, Hugh L., Edinburgh.
Campbell, Arthur George, Thirsk.
Chalmers, Edward, Willesden.
Chapman, Edward John, Hull.
Chinchen, Charles Joseph, East Cowes.
Christie, Andrew Ewing, Crieff.
Cleobury, George, Birmingham.
Correy, Alexander, Edinburgh.
Dalton, Tom Sydney, Wilmslow.
Dealve, Louis Norman, Tavistock.
Delaney, Joseph, Fulham.
Derrick, Thomas, Lanark.
Dick, James, A. R., Forfar.
Douthwaite, Percival Few, Newport.
Downing, Thomas, Macclesfield.
Duffield, George Alfred, Leeds.
Duncan, James, Newcastle-on-Tyne.
Dunn, James, Newton-Stewart.
Dyson, Harry, Waterloo.
Endicott, William Bassett, London.
England, Herbert, Scarborough.

Evans, Frederick Watkins, Cardigan.
Evans, Harvey Atkins, Birmingham.
Evans, Jessie Maria, Lampeter.
Fardell, Edgar Cooper, Leicester.
Faulds, Horace Wilson, Fenton.
Ferry, Thomas Robson, Wallsend.
Firth, John Naylor, Mansfield.
Fisher, Percy, Bradford.
Flamank, Arthur, Stafford.
Ford, John, Edinburgh.
Ford, Maggie Grace, Kirriemuir.
Fowke, Valentine Hamand, Stafford.
Fox, Albert T., Strathpeffer-Spa.
Furness, Tom Edgar, Chesterfield.
Garvie, William Charles Hogg, Leith.
Gateley, Stephen W., King's Norton.
Georde, John, Aberdeen.
Goodyear, Cyril J., Wakefield.
Gray, Albert Edward, Landport.
Green, Charles H., West Hartlepool.
Hackett, John, Shepherd's Bush.
Hackforth, John E. Swithin, Leyland.
Haddock, John, West Bromwich.
Hague, Samuel William, Lincoln.
Hall, Stanley Mayne, Newcastle-on-T.
Hallgarth, Arthur, Thorne.
Halloway, Ernest, Maryport.
Hamilton, George A., Gatehouse.
Harbinson, John, Glasgow.
Harris, John, Neath.
Haswell, Robert, Cambois.
Hawley, John P., Winchcombe.
Heaton, Thomas, Accrington.
Henderson, James Gall, Aberdeen.
Henderson, Robert Allan, Fraserburgh.
Hockin, Arthur William, Dartmouth.
Hodges, Edward Henry, Southsea.
Houlson, George, Abergavenny.
Hunter, John, Maybole.
Hunter, Thomas, Cumnock.
Irving, Eldred, Liverpool.
Isaac, William, Kidwelly.
James, Arthur, Narberth.
James, Ernest Henry, Guisboro'.
Jefferies, Fred., Colwyn Bay.

Jeffery, John Augustus P., Gateshead.
Jeffrey, John Edwin, London.
Jenkin, Baldwin Henry, Camborne.
Jones, John, Llandyssil.
Kay, James William, Caistor.
Kember, George Norman, Pittenweem.
Kendall, Joseph Pattinson, Maryport.
Knight, Frank Robert P., Dartford.
Kossick, Joseph, Newcastle-on-Tyne.
Lamont, Harry, Fortrose.
Lawrence, John Henry, Nottingham.
Legge, Henry George B., Norwich.
Lightbourne, James, Glasgow.
Lockwood, Arthur, Worksop.
Lusher, George James, Norwich.
McGinlay, Joseph C., Greenock.
McHattie, James Reith, Edinburgh.
Mack, George, Edinburgh.
Magan, Frances, Hampstead.
Mansley, Thomas Henry, Chorley.
May, E. D. Gasson, Hollingbourne.
Metcalf, John Mason, Hexham.
Milner, S. Hannah, Poulton-le-Fylde.
Mitchell, Alfred, Liverpool.
Morris, David, Llanelly.
Morris, Henry, St. Clears.
Morris, John Lewis, Whitland.
Morton, J. Lamont, Ramsbottom.
Mungall, Allan, Bathgate.
Negus, Irvin Thomas, Northampton.
Oxendale, T. T. Ranson, Edinburgh.
Pailing, Amos Heron, Paddington.
Palmer, Collis Unwin, East Molesley.
Palmer, Peter E. A., Altrincham.
Parker, Walter John, Grantham.
Paterson, G. Frederick, Southampton.
Paterson, William Dougald, Dumoon.
Paterson, G. R., Corbridge-on-Tyne.

Wood, Isaac, Aspatria.
Wood, Septimus Reginald, Edinburgh.

Wyllie, Alexander D., Kinghorn.

The questions set at this examination were published in the *Pharmaceutical Journal* for January 18, p. 49.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre, and the result.

	Candidates.				Candidates.		
	Exam-ined.	Passed.	Failed.		Exam-ined.	Passed.	Failed.
Aberdeen	18	12	6	Lancaster	6	5	1
Birmingham	23	11	12	Leeds	22	8	14
Brighton	6	1	5	Lincoln	5	2	3
Bristol	11	3	8	Liverpool	14	7	7
Cambridge	3	0	3	London	32	12	20
Canterbury	2	0	2	Manchester	30	9	21
Cardiff	5	2	3	Newcastle-on-T....	24	12	12
Carlisle	8	3	5	Northampton	5	4	1

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

FIFTY-FIFTH YEAR OF PUBLICATION.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, FEBRUARY 8, 1896.

THE COUNCIL MEETING.

At the opening of the meeting last Wednesday the PRESIDENT mentioned that apologies for non-attendance had been received from Mr. SOUTHALL and Mr. STORRAR, the latter being prevented by a cold.

On taking the lot for the seven Members of Council who are to retire next May, the names drawn were Messrs. CARTEIGHE, CORDER, HARRISON, HILLS, MARTINDALE, NEWSHOLME, and SAVORY. Those who retire by rotation are Messrs. CROSS, GOSTLING, JOHNSTON, MARTIN, SCHACHT, STORRAR, and WARREN.

The additions to the Society comprised fifteen members, fifty-eight associates, and forty-five students.

The annual report of the Registrar, showing the numerical strength of the Society, statistics of the examinations in 1895, and the state of the Registers of pharmaceutical chemists, and chemists and druggists, was presented, and will be found at pp. 106-7. It shows that 475 persons have been registered during the past year and that, after allowing for erasures, there has been an increase of 204 in the number of registered chemists and druggists, and of 38 in the number of pharmaceutical chemists.

The number of members of the Society is 2193, that of Associates, 2613. Mr. BOTTLE expressed regret, as an old member of the Society, that the number connected with the Society does not increase as he thought it ought to do, since chemists have in the Society a nucleus round which they could rally to promote their interests. The fact that so many of the younger members of the body are becoming Associates he regarded with satisfaction, and hoped the day was not far distant when the Council would be able to elect them as members. Mr. ALLEN suggested that the more important question was as to the proportion of examined men that joined the Society, and in reference to this, Mr. HILLS pointed out that last year most of the successful Major men had apparently joined the Society.

The report of the Finance Committee showed nothing unusual in regard to receipts or payments, excepting the solicitors' bill, amounting to more than four hundred pounds and showing that the administration of the Pharmacy Act is by no means so profitable as it is sometimes supposed to be. The available resources of the Benevolent Fund have been

exhausted, but the PRESIDENT anticipated more money would come in to enable the Committee to assist deserving cases. Mr. JOHN THISTLETON DAVENPORT and Mr. BURDEN have each sent a donation of ten guineas.

On the recommendation of the Benevolent Fund Committee, four grants of ten pounds each were ordered to be paid. The death of Mrs. JOHNSON, who had been an annuitant since 1885, was announced, and the Vice-President, as Chairman of the Committee, pointed out the beneficial influence of temporary help in enabling those overtaken by misfortune to help themselves.

The report of the Library, etc., Committee, in addition to the usual records relating to the Library and Museum, contained a recommendation that a grant should be made to the Liverpool Pharmaceutical Students' Association for the purchase of a materia medica cabinet, to be placed in the University College. The object in view is to promote pharmaceutical education in connection with the local University College, and also to take advantage of the disposition of its authorities to adapt their scheme of education to the wants of pharmaceutical students. The Committee was also influenced by consideration of the benefit resulting from the association of such students with others being taught chemistry, botany, etc., with different objects. Mr. BOTTLE suggested that in making such grants there should be some stipulation that the fees should not be too high. Mr. SCHACHT expressed gratification that this experiment is to be made in Liverpool, because the College is so liberally endowed that it can be generous to students. He suggested that the Council might also give assistance in a similar direction for the teaching of pharmacy, for though it is best to be learnt by practice under a master in a well-appointed establishment, that opportunity does not always offer. Mr. MARTIN concurred in the opinion that some of the difficulties of teaching pharmacy might be overcome in the way suggested, and while fees should not be too high it is desirable that they should not be unreasonably reduced. Mr. CORDER on the contrary expressed regret that pharmacy was to be made a subject of class teaching at Liverpool, as he believed that the chemist's shop is the chief, if not the only, place to acquire a knowledge of the art of pharmacy, and that it is a master's duty to teach his apprentices that as well as the business of shopkeeping.

Mr. ATKINS was of opinion that Mr. CORDER took a too ideal view of the matter. His own observation showed that the majority of masters do not teach their apprentices, as appears from the fact that so many candidates for examination are untrained and unfitted for the employment they aspire to. The discussion was continued by Messrs. HAMPSON, CROSS, MARTINDALE, HILLS, GROSE, ALLEN, and the PRESIDENT, all of whom agreed that the association of pharmaceutical with medical students would be attended with much mutual advantage, and that class teaching need not interfere with the practical teaching of apprentices.

Another recommendation in the report of the Library Committee related to the application of the Burroughs' Memorial Scholarship for the purposes of secondary education of pharmaceutical chemists; this was adopted by the Council, and the Committee was requested to draw up regulations, under which the Scholarship is to be competed for and held.

Mr. J. T. DE PEARE was appointed Divisional Secretary for East Islington, in place of the late Mr. HOWARD HALL.

The interim report of the Research Committee was read and received on the motion of the PRESIDENT, who expressed the belief of the Committee that the workers engaged in the Research Laboratory are doing valuable work, and his own opinion that each and all, including the Director, are pervaded by the true spirit of research. Mr. SCHACHT, in seconding the motion, expressed a similar belief, and predicted that future results would enable a judgment to be formed that the work reflected credit on the Society.

A letter from Mr. ANDERSON RUSSELL was read containing a resolution passed by the Glasgow and West of Scotland Pharmaceutical Association approving of the views expressed by the PRESIDENT at the last Council meeting on the subject of unqualified managers of branch shops.

The report of the General Purposes Committee gave the usual account of progress made with cases placed in the Solicitors' hands, and on the recommendation of the Committee a resolution was passed authorising the Registrar to take proceedings against persons reported to have infringed the Pharmacy Act.

THE UNQUALIFIED DENTIST CASE AT DUNDEE.

THE *British Medical Journal* observes that Dundee would appear to be almost a paradise for the unqualified dentist, judging from the result of the recent prosecution under the Dentists' Act (see *ante*, p. 72). After quoting the fantastic summing-up of Mr. Sheriff CAMPBELL, and his remarks to the effect that he convicted unwillingly and should therefore impose a nominal penalty, though the offence was clearly proved, our contemporary remarks that it is difficult to comment upon such a travesty of justice. "It is often impossible to set the law in motion without finding sooner or later that penalties are withheld or inflicted in homœopathic doses by the presiding magistrate. In the Dundee case the magistrate went out of his way, and by no means added to the dignity of his position, by treating all qualified men as simply monopolists." The necessity is also pointed out of the law recognising that the Dentists' and Medical Acts—and, it may be added, the Pharmacy Acts—were especially framed to distinguish between "the qualified and the unqualified, the properly educated and the ignorant"; not for the purpose of promoting monopolies, but for the safety of the public from uneducated and untrained pretenders to skill and knowledge that they do not possess.

THE DANGER OF WEED-DESTROYERS AND VERMIN-KILLERS.

A REMARKABLE instance of the danger accompanying the storage of poisonous weed-destroyers in private houses is afforded by a case at Tockington, reported on page 117 of this week's Journal. The arsenical solution was kept in the same cupboard apparently as materials used for cooking purposes, and when some "grape wine" was required to make "tipsy cake," the contents of the weed-destroyer jar were inadvertently used. Some of the supposed wine was drunk at the same time, and as a result the person drinking it died in a few hours' time. Fortunately, the cake was destroyed as soon as it was apparent from the taste of the liquid that something was amiss; otherwise more fatal cases might have had to be recorded. The facts reported seem to indicate that the jar of weed-destroyer was not plainly marked, if at all, so as to indicate the nature of its contents, but whether this were so or not it is a distinctly reprehensible

practice to store such dangerous preparations anywhere in a private house, and especially in cupboards where articles in everyday use in the household are also kept. The *Lancet* records another case, at Silvertown, in which a little girl died suddenly with all the signs of irritant poisoning, after eating a piece of cake. Several other children who shared the cake became ill with similar symptoms. The poisonous cake had been sold for destroying vermin and was found by the children in what was supposed to be a safe place, where it had been placed as a bait for mice. As the *Lancet* remarks, the custom of poisoning household vermin is not the best means of destroying them, on account of possible subsequent putrescence in hidden places, and poisons ought most certainly not to be used for the purpose, except in such a form that their presence is clearly indicated to children, as well as to others into whose hands they may fall. It may be noted here that the Ballikinrain Ant-Destroyer, which recently figured in a Pharmacy Act case, at Glasgow, is a solution of white arsenic and sugar, resembling honey in appearance. The danger of such a preparation is manifest, yet it is reported that Mr. ALEX. CROSS, M.P., intends to endeavour to persuade Parliament that its sale by seedsmen and others should be allowed, that is to say, without restriction of any kind. In view of the two cases noticed above, the mischief of such retrograde legislation should be apparent to everyone.

INTERNATIONAL PHARMACEUTICAL EXHIBITION AT PRAGUE.

FURTHER information has been received as to the arrangements made by the Executive Committee for the celebration of the twenty-fifth anniversary of the Pharmaceutical Society of Prague (see *ante*, p. 33). Dr. EMANUEL KUSÝ, Dr. IGNAZ PELC, A. VON WALDHEIM, Dr. A. HELLMANN, Dr. A. BĚLOHOUBEK, F. SCHNÖBLING, and J. DITTRICH have been appointed honorary presidents, and the exhibition, which is to take place between August 15 and September 15 next, will be arranged under the following sections:—

- I. Scientific apparatus, etc., used in Pharmacy.
- II. Literature of Pharmacy and the Allied Sciences.
- III. Machines and apparatus for production of pharmaceutical preparations.
- IV. Arrangement and fittings of pharmacies.
- V. Materials, drugs, and pharmaceutical preparations employed for pharmaceutical purposes.
- VI. Documents, books, statistics, apparatus, vessels, and appliances illustrative of the history of pharmacy.
- VII. Pharmaceutical corporations and societies.
- VIII. Hygiene and the care of the sick.

The State departments and officials as well as the local professional corporations, and the medical faculties of the two universities have promised their support, and numerous applications from intending exhibitors have already been received. The general meetings of the Austrian Apotheker Verein and of the Pharmaceutical Society will take place at the time of the exhibition, and many of their members are expected to be present on the occasion. Altogether it is thought that there is a prospect of the exhibition surpassing anything of the kind that has hitherto been attempted. Attention is especially directed to Section VII., and pharmaceutical organisations are invited to assist in making it complete by supplying descriptive information as to their nature, history, etc.

ANNOTATIONS.

EVENING MEETING IN LONDON.—Tuesday next, February 11, is the date of the next evening meeting of the Pharmaceutical Society, at 17, Bloomsbury Square. The President is expected to take the chair at eight o'clock precisely, and the first business will be the formal transfer of the Burroughs' Memorial Fund, subscribers to which are invited to be present. The following papers will then be read:—(1) "Estimation of Aconitine," by Professor Dunstan and Mr. T. Tickle; (2) "The Detection of Aconitine," by Professor Dunstan and Mr. F. H. Carr; (3) "Essential Oils of Black and White Peppermint," by Mr. J. C. Umney.

"THE DISCOVERY OF OXYGEN."—A short series of articles appeared in the last volume of the third series of the *Pharmaceutical Journal*, dealing with the life and work of Scheele, Priestley, Cavendish, and Lavoisier, special reference being made to their connection with the discovery of oxygen and its immediate results, including the overthrow of the phlogiston theory. At the conclusion of the series it was thought desirable to reprint the articles as a slight memorial of the chemists whose work had been briefly summarised, the more especially as the one hundred and fiftieth anniversary of the birth of Scheele, and the centenary of the death of Lavoisier had quite recently been celebrated in various ways. After careful revision of the matter this has been done, and it is now proposed to offer copies of the reprint for sale at a nominal price of one shilling each, post free. It forms an attractive octavo book of sixty pages, and is illustrated with portraits of Scheele, Priestley, Cavendish, and Lavoisier, together with sketches of the apparatus employed in their experiments. It will be ready for distribution shortly, and applications for copies should then be sent to the publishers, Messrs. Street Bros., 5, Serle Street, Lincoln's Inn, London, W.C.

DEATH UNDER PENTAL.—A fatal case, in which pental was used to produce anæsthesia in a case of dental operation, is reported from the Chorlton-on-Medlock Dental Hospital. The patient was examined previous to operation by the anæsthetist of the hospital, and appeared to be in a fit condition. At the fifth extraction the respiration ceased, and all attempts to restore the patient were successful. At present the opinion of experts seems to be divided as to the safety or danger of pental, and the *Lancet* suggests that further investigation of this fatal case would seem to be desirable.

POISONING BY ANTIPYRIN.—A correspondent of the *British Medical Journal* calls attention to the danger attending the amateur administration of antipyrin, and describes a case in which a dose of 10 grains produced very alarming effects. The writer remarks that since antipyrin is undoubtedly a dangerous drug, the careless and casual way in which the recommendation to "take an antipyrin powder" is often made by irresponsible persons cannot be too strongly condemned. He expresses a decided opinion that antipyrin ought to be scheduled as a poison, and dispensed only on a written order from a qualified medical practitioner being produced.

ROYAL INSTITUTION.—A General Monthly Meeting of the members of the Royal Institution was held on the 3rd inst., Sir James Crichton-Browne presiding, and the following were elected members:—Mrs. Montagu, Mr. Robert R. Tatlock, F.C.S., and Mr. Ernest Westlake. We are asked to announce that Professor H. Marshall Ward, F.R.S., Professor of Botany in the University of Cambridge, will begin a course of three lectures on "Some Aspects of Modern Botany" at the Royal Institution on Thursday next, February 13.

PROFESSIONAL UNIONISM.—As bearing upon this subject, which was specially referred to in last week's Journal (p. 91), the following emphatic resolution passed at a crowded meeting of medical men, recently held at Nottingham, is of interest:—"That in the opinion of this meeting it is unprofessional and undignified for any medical man to accept the post of medical officer of any institution, promoted by and for the pecuniary benefit of men outside the profession." The example of this meeting may be commended to local pharmaceutical associations, which should pass and do their utmost to enforce similarly salutary resolutions, bearing especially on the aid afforded by legally qualified pharmacists to carry on drug stores for the pecuniary benefit of non-pharmacists. In places where no local association exists, there should be no difficulty in calling meetings of the chemists and druggists in the district to take similar action.

NEW VOLATILE OILS.—A new volatile oil for use in perfumery, soaps, etc., is described under the name of "frejar oil" in Haensel's quarterly report on essential oils and fruit essences. It is made from a fragrant wood, and in the crude state is somewhat thick, having a specific gravity of 0.9293. On rectification, it loses 20 per cent. of resinous matter, and is then colourless, and has a specific gravity of 0.9065 at 15° C. "Nagkesar oil" is a volatile oil distilled from the flowers of *Mesua salicina*, Planch., and Triana (*Mesua ferrea*, Linn.) has been introduced to the notice of perfumers by Mr. Haensel, who has prepared it from imported dried flowers. So little is obtainable from the dried flowers, that its present price is prohibitive. The perfume is spoken of as very fragrant, somewhat allied to that of the violet, but not exactly comparable with that of any known oil. It might therefore possibly be worth the while of planters in the East Indies to produce the oil on the spot from fresh flowers.

KELLY'S 'LONDON MEDICAL DIRECTORY' FOR 1896.—The eighth edition of this useful reference book has just been published by Messrs. Kelly and Co. It contains twenty-three pages more than the volume for 1895, the increase being mainly due to the greater fulness with which the contributions to medical literature, by individual members of the medical profession, are recorded. A number of new societies, institutions, and publications are also treated of in this volume, whilst the information regarding many older ones has been amplified. The price of the book remains as formerly (6s. 6d.), and the office of publication is 182, High Holborn, London, W.C.

THE USE OF INDIGENOUS DRUGS IN INDIA.—The Indigenous Drugs Committee is reported to have held its first meeting in Calcutta on January 3, when all the members were present, and Dr. King, as President, occupied the chair. The proceedings were of a preliminary character only, Dr. Watt being elected Secretary, and other business of a formal nature transacted.

THE CHEMISTS' CLUB.—The Committee of this Club intimates that the premises at 10 and 11, Stonecutter Street and 2, Farringdon Avenue, will be open for inspection to all chemists and chemists' assistants on Thursday, February 6. A smoking concert will take place in the evening at 8 p.m., to which all chemists and assistants are cordially invited. Tickets can be had on application to the honorary secretary, Mr. H. T. Butler, at the above address. The Committee hopes that a large number of visitors will take this opportunity of seeing for themselves the arrangements made for the comfort and convenience of members.

JUNIOR PHARMACY BALL.—On Wednesday next, February 12, the fifteenth Junior Pharmacy Ball will be held at the Portman Rooms, Baker Street, W. Mr. Mortlake Mann's Orchestral Band will be in attendance, and the first dance will commence at 9 p.m. precisely. Inclusive tickets (7s. 6d. each) may be obtained of the honorary secretary, Mr. H. Arliss Robinson, 29, Chapel Street, Belgrave Square, S.W., and application should be made for them without delay.

NEW WORK ON PHARMACOLOGY.—The New Sydenham Society is publishing a translation of the second edition of the 'Lectures on Pharmacology for Practitioners and Students,' by Dr. A. Binz, Director of the Pharmacological Institute in the University of Bonn. This is a most important work, and the translation by Mr. A. C. Latham, M.A., M.B., represents practically a new edition, a considerable amount of fresh matter having been added by Professor Binz, who has also revised the whole of the proof-sheets. The work will be published by subscription, and Volume I. is about to be issued immediately to the subscribers for 1895. This volume deals with anæsthetics: ether, etc.; chloroform, etc.; morphine and allied drugs; some more recent hypnotics; the bromides, coniine, curare; aconitine and allied drugs; the nitrites; iodine and its preparations; artificial sleep; atropine, caffeine, and digitalis; secale cornutum; Calabar bean; pilocarpine; nicotine; strychnine; the ammonium salts; alcohol; the ethereal or essential oils. For the convenience of intending subscribers, it may be stated that the annual subscription—one guinea—should be remitted to the New Sydenham Society's agent, Mr. Lewis, 136, Gower Street, London.

A NEW INDUSTRY AT DRONFIELD.—A new industry in this town has been commenced by Mr. H. Walker, who has laid out works for the manufacture of fuller's earth. The works cover an area of an acre and a half, and are situated at Cliffe Sidings, on the Midland Railway Company's system. The works have been fitted up with the most modern type of machinery, the whole plant being automatic throughout, and the material being handled once only by the men up to its finishing point. Mr. Walker is reported to have brought his fuller's earth under the notice of Her Majesty's Government for use in the manufacture of dynamite, nitroglycerin, and other explosives, the idea being that the earth should take the place of the German infusorial earth, kieselguhr. He is also suggesting its use for the filtration of all kinds of liquids, including drinking water.

THE HOPES OF PUBLIC ANALYSTS DEFERRED.—In the annual report of Dr. Sedgwick Saunders, the public analyst for the City of London, recently submitted to the Commission of Sewers, it is remarked that the hope entertained by public analysts throughout the kingdom that by this time the Legislature would have effected improvements in the working of the Acts relating to the adulteration of food and drugs, had not been realised. Some attempt has been made in that direction by a Select Committee of the House of Commons, which is described as having taken voluminous but not exhaustive evidence upon the subject. Dr. Saunders proceeds to say that it would be useless to reiterate the objections to the present anomalous arrangements under which the chemical authorities at Somerset House are enabled to over-ride the decisions of the most eminent analysts upon data they have never formulated, or to dwell further upon the extraordinary and discordant decisions given by magistrates throughout the country. Such decisions are alleged to be nearly always in favour of the dishonest trader, and more in accordance with the idiosyncrasy of the individual functionary than the requirements of science and common sense.

PROCEEDINGS OF SOCIETIES.

ROYAL SOCIETY OF EDINBURGH.—At a meeting of the Royal Society of Edinburgh, held on January 20, Professor Crum Brown, M.D., described an experiment illustrating the modern theory of salt solutions. He said there is a well-known instance in the case of chloride of zinc, which is not precipitated on the addition of sulphuretted hydrogen from a solution acidified with hydrochloric acid, the reason being that the zinc sulphide, if formed, would be immediately decomposed by the hydrochloric acid, which has a stronger affinity for the base. If, however, potassium acetate be added to the solution, there is an immediate precipitation of zinc sulphide. This is usually explained by saying that the potassium acetate is decomposed by the free hydrochloric acid, with formation of potassium chloride and free acetic acid, which, being a weaker acid, does not prevent precipitation of the zinc sulphide. This is the old explanation, and it is perhaps correct, so far as it goes, for the above instance. There is another case, however, in which such an explanation does not apply where we have the same acid throughout. The lecturer had a solution of ferrous acetate, to which he added a considerable excess of acetic acid. He now added sulphuretted hydrogen, but there was no precipitation of ferrous sulphide. On adding neutral or faintly acid potassium acetate, an immediate precipitation of black ferrous sulphide was observed. It is quite obvious that there must be some other explanation in this case. It is here that the modern theory of salt solutions is of service. The non-precipitation of ferrous sulphide in a solution of ferrous acetate containing much free acetic acid, is due to the great concentration of hydrogen ions, the effective acidity of the solution being due to this high concentration. The addition of potassium acetate has the effect of reducing the concentration by ionisation of the hydrogen, thus weakening the effective acidity of the solution. Under these conditions we have immediate precipitation of ferrous sulphide, although titrametrically the solution contains the same quantity of free acetic acid as it did previous to the addition of the potassium acetate. This reduction of effective acidity by ionisation of the hydrogen may be easily shown by adding an alkaline acetate to a quantity of acetic acid. Such a solution only turns blue or red litmus paper purple, and thus behaves very like a neutral solution, although on titration it will be found to contain as much free acid as it indicated previous to the addition of the alkaline acetate.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.—Under the auspices of this Society, a lecture, entitled "From Mont Blanc to the Matterhorn," was delivered in the Montgomery Hall, Sheffield, by Mr. W. Lamond Howie, F.C.S., on Wednesday evening, January 29. Sir Henry Stephenson presided, and the lecture was illustrated with 120 magnificent views, photographed by the lecturer, and thrown on a 16-ft. screen by powerful limelight lanterns. At the outset, the lecturer said a more well-worn theme, or a district more thoroughly exploited than that from Mont Blanc to the Matterhorn, could scarcely have been selected for a lecture. The earliest, as well as the greatest, climbers have said that no matter how often they are visited, or however long the traveller may remain, the overpowering grandeur of these marvellous mountains must continue to fascinate. Magnificent views were shown of the peaks and tributary glaciers of the Mer de Glace, near Chamonix, obtained on a visit to the "Jardin," a grassy oasis under the peak of the Aiguille Verte, surrounded on all sides by the weird desolation of limitless rock and glacier. Several views of Chamonix followed, leading up to an ascent of the Brevent, which commands Mont Blanc, much like looking across a street from an upper window, only the street is more than three miles wide, and the pavement about 5000 feet below. The monarch of mountains in sunshine and storm was illustrated by impressive photographs and graphic description. Then followed a series of interesting glacier views, depicting faithfully the various aspects of one of these great ice rivers from the collecting fields of everlasting snow to the extremity, where the ice frozen some half a century before on the mountain top is finally melted in the hot sun. The views of the crevasses and transparent icy walls of the glacier grotto being most realistic. The three days' journey round Mont Blanc to Courmayeur was of the most varied and charming description. At burning noon resting in the shady piazza of a mountain inn within touching distance almost of the great snow peaks and glaciers, then zig-zagging the steep, pine-clad slopes, or traversing

the alpine pastures, the long grass almost invisible beneath a waving wealth of blossom, crossing snow slopes, through rocky gorges, by brawling glacier streams, whose murmur lulls to sleep in the quaint out-of-the-world rest houses, where the nights are passed; not the least of the pleasures being the ever-varying, magnificent cloud scenery, great white masses, crisp and shining, against the deep, ultra-marine of the alpine sky. Mountain mules, the Italian customs guard, the glaciers and tremendous peaks of the Allée Blanche and Val Veni followed, culminating with the famous Giant's Tooth, which overlooks Courmayeur, contrasted with the summits of Mont Blanc according to Mr. Whymper and a nervous lady; the latter being provocative of great laughter and applause.

The antiquities of Aosta were next dealt with, dating from the time of Augustus Cæsar. At one point impressive evidences of three great eras in the world's history in juxta-position were pointed out. The "pagan," represented by the old wonderfully preserved city wall, of date 43 B.C.; the "Christian," by a shrine to some saint built between two of the archways; and the "scientific," by the electric street lamps. From this old pagan world a rapid journey was made to Milan, and the sunlit marbles of the famous cathedral, shown in a series of slides of marvellous fidelity and beauty, which repeatedly evoked warm marks of appreciation. Views of Lakes Como and Maggiore, the quaint architecture and tropical vegetation of the district, and the mountains surrounding the lakes bring us by the Rhone Valley and Zermatt to the foot of the Matterhorn, which formed the conclusion and *pièce de résistance* of the lecture.

The wonderful views obtained from the hut on the north-east ridge of the Matterhorn from the Gabelhorn and Gorner Grat were singularly interesting and impressive. Piquancy was given by climbing incidents and examples of the humours of alpine guides and artists. The last slides, representing the great peak in several striking aspects—in sunshine, then cloud-enveloped, and, in conclusion, clear in the moonlight, cold, majestic, terrible in its stately magnificence, soaring to the very heavens as it keeps its nightly silent watch with the pole-star over a sleeping world—neither curtain nor the allurements of softest pillow can blot it out. Sleeping or waking, the Matterhorn remains to all who have felt the influence of its matchless yet fearful beauty a never-fading and glorious memory.

BRISTOL PHARMACEUTICAL ASSOCIATION.—The annual meeting of this Association was held at University College, on January 29, Mr. Allen, the President, in the chair. The Hon. Sec. read the following report of the Council:—"The membership of our Association shows a slight increase of numbers as compared with last year. The library and the materia medica cabinet are still housed in the buildings of University College. The Council regrets that the library is not made more use of by the students of the neighbourhood. This, it is thought, must be due to the fact that they are not aware of its existence or of the facilities afforded by the Association for lending the volumes. In accordance with the wish of the Council, the Hon. Sec. took steps in the autumn to ascertain how many students were likely to attend a pharmacy and materia medica class if it should be resumed, and finding there was a probability of getting ten or twelve members, the class was begun again in October with eleven students, who have attended the weekly meetings with very fair regularity. As most of the students were fresh members, the Council thinks this number justifies the class being resumed. The class, by permission of the Executive, meets in one of the class-rooms of University College." The Treasurer also read his report, showing a balance in hand of £10 17s. 9d. The President moved the adoption of both reports, which was unanimously agreed to. A conference followed, discussion being invited on the recent development of company pharmacy in the neighbourhood. Mr. Schacht explained the position of the Council of the Pharmaceutical Society in the matter, and ultimately the discussion was adjourned to February 26, in order to obtain a still larger attendance of members of the trade in the district.

LIVERPOOL PHYSICAL SOCIETY.—A meeting of this Society was held in the Physics Theatre, University College, on Monday, January 27, 1896, for the purpose of listening to a lecture on "Professor Röntgen's Discovery," by Dr. Lodge, Professor of Physics at University College. There was an extraordinarily large attendance, all the seats, gangways, and even behind the lecture table being filled with persons who were interested in the subject, among them being a very large proportion of ladies. Many persons were unable to get into the room, and filled the passages outside. The Chairman called upon Professor Lodge amid prolonged cheering.

The lecturer said that the greater part of what Professor Röntgen had now found out was already known in 1894, but as he was lecturing to an audience who desired to know something of the subject, he would first of all speak about the electric conductivity of metals, liquids, and gases. With regard to metals, nothing very definite is known, with liquids it is a procession of molecules, each molecule communicating its charge to its neighbour farther on, the charge traversing the whole distance. Gases are not conductors ordinarily but are generally broken down, undergoing electrolysis.

The history of the vacuum tube divides itself into three principal epochs. The tube of 1850, which was exhausted to about 1/100th of an atmosphere, on the passage of the electric discharge glowed throughout its entire length, but the light showed no definite structure. The appearance of the discharge in the 1860 tube was very different owing to the improved means of producing high vacua. The electricity on being passed in at both ends travelled towards the centre, the + at about half the velocity, the - much slower, and met at Faraday's dark space when the glow resolved itself into striæ, and a second dark space was seen round the cathode. This phenomenon was first discovered by Crookes, and shown to the British Association in 1879. With higher vacua the cathode dark space fills the whole tube, driving the positive column before it, leaving a black space. With these high vacua, when the electric current is turned into the tube, the glass phosphoresces, German glass giving a green, and English a blue; it seeming as if the whole space were full of electrically-charged particles, which start from the cathode and impinge against the inside of the glass.

These different conditions were then practically illustrated:—

(1) A strong electric current was passed through a moderately rarefied vacuum-tube, when there was a blueish glow, which was without structure.

(2) A current was passed through a tube containing some barium sulphide; the glow was blue as before, but on stopping the barium sulphide, gave a green phosphorescence.

(3) The current was now passed into a higher vacuum, when the division into striæ took place, but no dark space around the cathode was visible.

(4) The current was now passed into a vacuum tube with two anodes and one cathode, when the cathodic dark space was immediately seen, then being full of cathode or invisible rays.

(5) The electric current was now passed into a tube of German glass, in which the cathode was cylindrical, when the glass had a green phosphorescent glow.

To show that glass was not the only substance transparent to the rays, the lecturer had five minerals, including Iceland spar, held in a glass claw. The cathode in this case was at the top of the vertical tube, and when the rays were passed through the minerals they were rendered luminous, their luminescence being greater than that of the glass.

Professor Lodge next took a hollow glass ball, fixed the cathode at one side in a plate, and then moved the anode about. In this case the vacuum was not very great, and consequently there was a glow at each place to which he fixed the anode. He then took another ball in which the vacuum was 1/1,000,000th of an atmosphere. In this case also he had the cathode fixed, and moved the anode to three different places. The cathode rays went straight across the ball making the glass green and hot; the fixing of the anode made no difference, and the phosphorescence could be moved by a magnet. The rays were afterwards allowed to impinge upon a phosphorescent screen, but in their passage they formed a red bar of light which could be deflected in any way by means of a magnet. The lecturer incidentally remarked that the speed of the particles could be calculated by this deflection.

He then went on to speak about the energy of these cathode rays, their heating and mechanical effects. To illustrate their heating power a piece of platinum foil was placed in a high vacuum tube, and exposed to the path of the rays, the foil became quite hot, but cooled again if the rays were deflected by means of the magnet. Their mechanical power was not so great as their heating power, but still sufficient to turn a small windmill. This was thrown on to the screen by the lantern. The rays met with an obstacle in the glass, were deflected, and then the windmill revolved at a great speed.

All these experiments were performed with Crookes' vacuum tubes, which had been kindly lent by Mr. L. Higgins.

The next stage described was the discovery of Hertz in 1890, who found that these cathode rays can pass through metals, aluminium being almost transparent, but platinum and other dense metals were opaque to the rays. Philip Lennard, assistant to Hertz, in 1894 passed the cathodic rays into the outside atmosphere by means of a tube with a disc-shaped cathode at one end, and the other closed by an aluminium plate or window of sufficient strength to withstand the high external atmospheric pressure, the tube being highly exhausted. By interposition of opaque substances between this aluminium window and photographic plates shadow-thrown photographs were obtained.

A photographic plate, the right hand half of which was covered with aluminium foil, and the lower part with a plate of quartz, was exposed to the rays, with the result that the uncovered part was totally affected, that covered by aluminium alone not so much, that by aluminium and quartz scarcely, and the part covered with quartz alone only slightly more so. Incidentally Professor Lodge said that Professor Lennard had been asked to come to last year's meeting of the British Association and lecture upon his discovery, but being a shy, retiring man, had declined. However, he had as good as promised to come this year, and they hoped to persuade Professor Röntgen to come too.

The lecturer went on to say that, scientifically, Professor Röntgen had not done much more, but practically he had made great improvements, as he had been able to cause the rays to come through the glass in far greater quantity, and with better penetrating power. Professor Lodge was inclined to think that they were the same as those obtained by Lennard, but on this point there was difference of opinion. The rays pass easily through vacua, but not so easily through material substances.

The practical application of the discovery was accidental: Professor Röntgen had some fluorescent paper of barium platinum cyanide near; this in the rays gave a greenish hue, and when the hand was in the way gave the outline of the bones in the hand. After using the paper, Professor Röntgen then tried photographic plates. He found that the rays passed through a heavy German treatise of 1000 pages, and that rays usually pass through substances in proportion to their densities, some being more turbid than others to the light, just as milk is turbid to ordinary light.

In speaking about the alleged difference between the Lennard and Röntgen rays, whether the latter consisted of electrically charged particles, or whether they are part of the ether and analogous to light, Dr. Lodge said that, as was shown, Lennard's rays are deflected by a magnet, and those of Röntgen are apparently not; the reason, Röntgen says, being that Lennard's rays are moving slower than his. But if, as Röntgen asserted, and Lord Kelvin is inclined to believe, they are ether waves, then this will be the greatest physical discovery of the age, for they would have as many laws as light.

Professor Lodge then proceeded to describe the various slides which were thrown upon the screen by Mr. Robinson. The first one was of some coins which had been placed in a light-tight box made of wood a quarter of an inch thick, and had an hour's exposure. The coins came out as black round masses, though no inscription was at all visible. The next one was a horse-shoe magnet, the definition being extremely good. Then came one of three sizes of wire gauze; over a corner of each an hour-glass-shaped piece of aluminium was placed. The outline of the aluminium was scarcely visible at all, while the mesh of the gauze was very clear. With intensification the aluminium became slightly more visible. The next was one of a horse-shoe magnet with the rays of light, but owing to the close proximity of the poles of the magnet it was difficult to see whether the rays were deflected or not. Subsequently was shown a photo of a series of superimposed rectangular sheets of tin-foil, each smaller than the one before. The outside rectangle was almost transparent, but as the centre was approached the picture became darker and darker.

The following slides showed some wire wound on a wooden bobbin. The bobbin was quite invisible on the screen, and only the wire was seen. Dr. Lodge mentioned that this would be useful to electricians as they would be enabled to see defects in coils without the tedious labour of unwinding. Then came one of a compass needle which had an aluminium case and lid. When taking the photograph the lid was left on, but on the screen all to be seen were the compass needle, the degrees and the lettering. Dr. Lodge said the fact that the lettering and degrees appeared was probably due to their having been printed with metallic ink. The next was what

Professor Röntgen calls "the profile of a door." On the door was placed a piece of platinum foil, this was rendered dark in the picture, but all around was a blaze of light.

A photo of Professor Röntgen's hand showed the bones and his ring very distinctly, while the flesh was almost invisible, the bones being not so turbid to the light as the metal. Prof. Lodge remarked that if it were possible to photograph so thick a thing as a man's skull, and if a bullet were inside the skull, it could then be seen. The lecturer said that no doubt the greater part of his audience would have seen in the press that applications of the discovery had been made to surgery, but it was also applicable to engineering, since flaws and joints in metal could be seen. This was shown by a slide illustrating a piece of zinc which had been mended by a skilled mechanic, in which the joints were quite distinct. The next one was one of a razor in its case. The case and horn handle were quite invisible in the photograph, only the metallic parts being seen. The next one was Mr. Campbell Swinton's hand. This was not so good as that of Professor Röntgen's, but it showed the bones of the fingers very distinctly; the palm was almost black, being thicker; and the flesh, was visible all over the hand.

For these last two slides he was indebted to Mr. Campbell Swinton, who had used a Tesla arrangement. A current of six or seven e.h.p. from an alternating dynamo was sent round the primary of an induction coil, the secondary of which was attached to two Leyden jars in a teak box, which were connected to the primary of a second coil, and then to a Leyden jar in oil. The secondary terminal was carried to the tube, of which the anode and cathode were of tin-foil. On passing the current, the noise was almost deafening, and on holding a piece of sheet aluminium over the tube, it was bent, owing to the flaws present.

In conclusion the lecturer touched upon the three hypotheses of the nature of this light:—

(1) That the rays were particles of highly charged electrical matter.

(2) That they were ultra-ultra violet rays, high up in the pitch and about the size of atoms. Professors Fitzgerald, J. J. Thomson, and Schuster, the last of whom had lent photographs to Dr. Lodge received from Professor Röntgen, were all of this opinion. Possibly by this means atoms could be photographed, and then the way in which the atoms are arranged in molecules would then be seen to the great joy of all chemists.

(3) That they were longitudinal waves more like sound than light.

Of these three hypotheses Dr. Lodge said that he personally inclined to the first.

PLYMOUTH, DEVONPORT, STONEHOUSE, AND DISTRICT CHEMISTS ASSOCIATION.—The members of the junior section of this Association held a very successful meeting at the Foresters' Hall, Union Street, Plymouth, on Thursday evening (January 30). There was a very good number of members present, amongst whom were Messrs. O. A. Reade, Blackmoor, Vibert, Barber, Downing, Reynolds, Trencer, Waldon, H. O. Westcott, Jas. Cocks, E. A. Hodge, T. Darke, Harris, and the hon. secretary (Mr. G. Fairweather). Mr. E. A. Hodge was voted to the chair, and after some introductory remarks on the importance of the subject, called on Mr. Jas. Cocks (the hon. secretary of the Association) to read his paper on—

"Dispensing Notes, Pill-coating, etc."

Mr. Cocks remarked that there were three methods of coating pills applicable at the dispensing counter: 1st, varnishing; 2nd, pearl coating; and 3rd, gelatin coating. He expressed his opinion that varnishing was not a good way of coating pills, as the varnish was not very soluble in the stomach, although it had the advantage of the other coatings in taking very much less time to do than the other methods. Mr. Cocks uses a varnish consisting of gum sandarach 5 drachms; tinct. tolu, 2 drachms; ether meth. to 2 ounces.

Next, coming to pearl coating, Mr. Cocks said he had been trying for years to obtain a good moistening solution, and thought he had obtained the result at last. His solution consisted of equal parts tinct. tolu, mucilage of acacia, and syrup. He coated some pills with this solution and dropped them into the French chalk, and after a little while turned them out quite as good as factory-made pills, with the advantage of knowing what was inside the coating.

Mr. Cocks then turned to gelatin coating, and said it was undoubtedly the best coating, as the coating was perfectly soluble in a very short time at the temperature of the body and being also transparent, the colour of the pill could be seen and might often prevent mistakes.

The essayist then showed a machine of his own invention for coating from three to six dozen pills. It consisted of a water bath heated by a Bunsen burner and a couple of large corks pierced with needles which could be rotated quickly by means of a large cog-wheel and two smaller ones, the pills were stuck on the needles and dipped into the gelatin solution, and then lifted up and the surplus gelatin allowed to drop off. Then the corks were quickly rotated, and in a few minutes the coating had set. Mr. Cocks coated some pills and passed them around to the members, and all agreed that they were very well done.

Mr. Cocks used the following formula for his gelatin coating:—

French gelatin	ʒiiss.
Boric acid.....	ʒij.
Mucilage of acacia.....	ʒij.
Water to	ʒviij.

The lecturer also mentioned keratin coating and concentric coated pills, but said they were very rarely ordered.

Mr. Cocks then showed some gelatin capsules which he had made. He said he could not very well give any hints as to making them; it was practice that was required.

Mr. Blackmoor proposed a vote of thanks to Mr. Cocks for his interesting and highly instructive paper.

Mr. O. A. Reade, in seconding, remarked that at the Naval Hospital they did not trouble to coat their pills. If the patients did not like them they could not go to the stores next door, but he did see a prescription once which ordered the pills to be coated with collodion. The way they did it was to string the pills on a piece of cotton and dip them into the collodion, and then whirl them about until dry. They then cut off the cotton close to the pills, and the patient got a piece of cotton as well as a pill.

The Chairman, Mr. H. O. Westcott, and Mr. Fairweather also took part in a discussion, and the resolution was carried unanimously, Mr. Cocks replying in suitable terms.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.—A meeting of this Association was held on January 29, at the Exchange Rooms, Birmingham. Mr. T. C. Clarke (President), occupied the chair, and in opening the proceedings said that at previous meetings it had been suggested that some suitable way should be found by which the members could be brought together during the summer months, in the interest of the Association. He asked the members to make what they considered practicable suggestions. A brief discussion followed and suggestions were made that a photographic club should be formed for the summer months, and that country trips should be made for the purpose of collecting botanic specimens. These, it was contended, might serve as the ground work for papers to be read at the meeting in the winter.

Mr. A. L. Taylor then read a paper on "Chemistry, Past and Present." In the course of the paper, he said that he thought the science of chemistry stood at the head of all the sciences in its universal importance and application. Manufactures, arts, and last, but by no means least, medicine were indebted in a greater or less degree to chemistry. He took it that the first chapter of the history of chemistry extended from the fourth to the seventeenth century, ending in 1627 with their illustrious fellow-countryman, Robert Boyle. The chemistry of those 1400 years was really based on the teaching of Aristotle. He thought they might pride themselves on the fact that Boyle completely overthrew the doctrines of Aristotle and of Geber, and inaugurated a new era of chemistry. Boyle was one of the first chemists to advocate the study of chemistry for its own sake. The lecturer dealt briefly with the work of the more recent chemical discoverers, and concluded by stating that he was pleased to have had the opportunity of addressing the members of the Association, even though it had been in the inadequate manner in which he had treated the vast subject he had placed before them. On the motion of the Chairman a hearty vote of thanks was accorded Mr. Taylor for his paper.

ENGLISH NEWS.

SUICIDE OF A SCHOOL TEACHER.—Major Taylor held an inquest at the Great Northern Hotel, Stanningley, on January 31, on the body of Tom Gordon (28), assistant master at the Richardshaw Lane Board School, Pudsey, who had committed suicide by poisoning himself with prussic acid. Deceased's widow said he was usually of a cheerful disposition, but on the previous Thursday night he appeared somewhat despondent. He said he had not been very well lately. He was troubled about his class, and said he had intended having a right good report this time, but the class had not done so well. He was also troubled because he had not passed an examination.—Joseph Thomas Brewer, landlord of the Crown Hotel, Stanningley, said deceased had spoken of this trouble to him. He had threatened to poison himself, and produced a bottle containing poison on Wednesday night, which witness destroyed, but Gordon only laughed and said he could get more. Witness tried to dissuade him, and afterwards he was quite cheerful.—Arthur J. Powell, chemist, spoke to supplying deceased with prussic acid on Wednesday. He said he wanted it to destroy a dog. He was supplied with another quantity the following day, Gordon then stating that he had knocked the first lot of acid over.—A verdict of "Suicide whilst temporarily insane" was returned.

THE CARELESS STORAGE OF POISONOUS WEED-DESTROYER.—On January 31, Dr. E. M. Grace held an inquiry touching the cause of death of Mrs. Susannah Hester Williams, wife of Mr. Alphonso Williams, of The Elms, Tockington.—Florence Edith Lanfear stated that she was a servant of Mrs. Williams. About four o'clock on Wednesday afternoon Mrs. Williams told her she wanted to make some tippy cake, and went to a cupboard to get some grape wine for the purpose. Deceased told witness to get the jar out, and asked her to hold a jug while she poured it out. She asked her mistress if she was sure it was the right jar, and she said it was. The cupboard contained other jars, and was always kept locked, no one having access except Mr. and Mrs. Williams.—Elizabeth Amelia Witts deposed that on Wednesday afternoon the deceased said she would like to make a cake. She went with the servant to get some wine from a cupboard, which Mrs. Williams poured upon some sponge cakes for the purpose. Some time afterwards the deceased, who had gone to lie down, complained of feeling sick and unwell, and said she was afraid she had used some very disagreeable stuff for the cake, and that she had drunk some of it to taste it, and it would be better to throw the cake away and use some wine from a large jar. She continued to feel ill, and about half-past seven witness went to Dr. Irwin's, at Olveston, and told him what had happened. The doctor advised that the deceased should take some brandy and water, and if she did not get better to send again. This they did about nine o'clock, but Mrs. Williams continued to get worse, and died about three o'clock on Thursday morning. The coroner read a letter from Dr. Irwin, which stated that upon arriving to see the deceased he found her in a state of semi-consciousness and also pulseless. A telegram was received yesterday from the makers of the liquid contained in the jar, in answer to an inquiry as to the nature of the contents, and they stated it to be arsenic. A verdict was returned to the effect "That the deceased met with her death by misadventure through accidentally drinking a weed-destroyer containing arsenic."

WELSH NEWS.

FIRE AT A CHEMIST'S SHOP.—The shop of Mr. Thomas Richards, chemist, Station Street, Treorky, was last week completely gutted by fire. About half-past three o'clock a boy named Ellis, apprentice, was awakened by the smell of smoke. The other inmates of the house being roused, it was discovered that the shop was on fire. A minute later the shop windows were blown to atoms with a loud report, and the flames spreading rapidly, gained a complete mastery of the premises in less than half an hour. Strenuous efforts were made by Inspector Gill and half a dozen police constables to extinguish the blaze with a portable hose, and they were successful in so far as the prevention of the flames spreading to the adjoining premises. Some five minutes after the premises were destroyed, the Ystrad Fire Brigade drove up under the command of Dr. James. Although too late to render assistance, the brigade was highly complimented on having turned out with such promptness, Ystrad being six miles distant and the roads heavy. The damage done is estimated at £1000.

IRISH NEWS.

PHARMACEUTICAL PROSECUTION IN BELFAST.—In the Summons Court of the Belfast Police Courts on Friday, January 31, before Messrs. Garrett Nagle, R.M., Thomas M'Clelland, J.P., and Dr. M'Gee, J.P., the Pharmaceutical Society summoned Mathew Ballantine and James C. Carson, trading as J. Lizars, optician, 73, Victoria Street, Belfast, for keeping an open shop for selling and retailing poisons, they not being registered druggists in compliance with the Pharmacy Act. A second summons was issued against the same defendants for selling a scheduled poison, namely, sublimate of mercury.

Mr. S. Channon Millin (instructed by Mr. W. B. Galway) appeared for the complainants, and Mr. E. J. Shaw defended.

Mr. Millin said that the facts of the case were very simple, but the case was one of very great importance to his clients, who were prosecuting in the public interests. The Pharmacy Act was passed to protect the public against the sale of poisons by persons unqualified. Various devices had been adopted to render the object of the Act nugatory; but the means employed in the present case displayed an ingenuity that seemed to be in accordance with the boast once made by a distinguished Irish lawyer, "that he could drive a coach and four through any Act of Parliament." The question which the Court, or, if needs be, a higher tribunal, would have to determine was whether an unregistered person could, under any circumstances whatever, keep an open shop for the sale of poisons. The defendants evidently thought that by employing a registered druggist as their assistant they could evade the penalty imposed by the Statute. He (counsel) urged upon their Worships the necessity of assisting the Pharmaceutical Society in every legitimate way to put down the sale of poisons by unqualified persons.

Andrew Downey gave evidence to having bought from the defendants, on October 7 last, a packet of sublimate of mercury, which he sent for analysis.

Samuel Templeton, A.R.C.S., deposed to the analysis of the packet, which contained a scheduled poison.

Mr. Shaw contended that, inasmuch as the sale of poison was under the personal management of a registered druggist, the defendants were not liable.

The Court held that the defendants were liable to the penalty under Section 30, and imposed a fine of £5 and 20s. costs for each offence.

PROFESSOR TICHBORNE gave a lecture last week at Dalkey on "Atmospheric Air and Recent Discoveries Thereon," illustrated with numerous experiments; in the course of which, through the incautious handling by an assistant of a vessel containing CO₂, the learned professor unfortunately got his right hand somewhat severely "burned."

FOREIGN NEWS.

ACADEMY PRIZE FOR A PHARMACIEN.—The Académie des Sciences has awarded the Prix Jecker to M. Tanret, a pharmacien, with a sum of 6000 francs from the fund attached to the prize, and the title of Lauréat de l'Institut. M. Tanret carries on business in the Rue d'Alger, Paris. Several of his preparations, notably standardised solution of ergotinin, are current articles in French pharmacies. He has for some time past been designated for honours by the Academy as a recompense for his analytical researches. The isolation by him of the active principles of many drugs, such as ergotinin, pelletierine, hesperidin, etc., has earned for him the reputation of being one of the most distinguished analytical chemists in France. The committee complimented M. Tanret on the accuracy of his work and the lucidity of his reports.

NEW ADULTERANT OF SAFFRON.—M. Cesare Chicote, of St. Sebastian, Spain, publishes in the *Journal de Pharmacie* a description of a new adulterant of saffron, to add to the numerous sophistications of that drug. At first sight the specimen appeared genuine, although of inferior quality owing to the presence of a rather larger proportion than usual of the yellow filaments. On pressing a portion between folds of white blotting-paper, numerous reddish-blue lines were distinguished, differing entirely from the stain produced by true saffron. An examination with a lens showed three different structures, the stigmata of saffron, the yellow filaments of the same (often present more or less), and numerous filaments of a bluish-red colour. These last on treatment with cold distilled water gave up their colour and became white. The author was unable to determine the botanical origin of these filaments, but believes them

to be derived from a flower of the Caryophyllaceæ order, resembling the carnation, which grows abundantly in Spain. The colouring matter extracted by water was on analysis found to consist of acid fuchsine, and a certain quantity of glucose (used as a fixing agent for the dye) was also detected. This form of adulteration was considered very ingenious, as on a cursory examination the dyed filaments would escape detection.

ILLEGAL USE OF TITLES.—A pharmacist who had lately acquired a business in the north of France continued making use of the titles of "Pharmacien de Ière Classe" and "ex-Interne des Hôpitaux" belonging to his predecessor. This seems to have caused great annoyance to a rival member of the profession, who invoked the aid of the legal authorities in order to restrain the new comer from assuming qualifications to which he was not entitled, alleging that it was unfair competition, and had prejudiced him in his business, for which he claimed damages. The tribunal considered that no detriment had been proved, but ordered the offending pharmacist to restrict himself to the use of his personal qualifications.

A LITIGIOUS PHARMACIST.—A Paris pharmacien, M. MacAuliffe, has made considerable use of the law courts lately in disputes with his next-door neighbour, Mme. Pouteau, a china dealer. He sued this lady for alleged assault, which was answered by a counter-charge and damages claimed. The tribunal, with evenly-balanced justice, fined both parties 25 francs. Shortly after he was summoned by the lady for striking one of her employés. The pharmacien conducted his defence with much spirit, but the adverse witnesses were numerous. It was elicited, however, that the doctor had given a certificate of injuries inflicted on the lady's statement only, without making any examination, and the defendant protested that he could not have committed the assault, as he was away in the country on the date alleged. Nevertheless, he was found guilty by the Court. M. MacAuliffe appealed, but the judgment was confirmed. Not to be beaten, however, he prosecuted all the witnesses for perjury! The testimony was so conflicting on this case being tried that it was dismissed. One would think this would have finished the affair, but the pharmacien was still unsatisfied, and has carried the matter to a higher Court. A French paper, commenting on this, aptly remarks that it does not know who to commend most—the clients who have waged such persevering legal warfare, or their lawyers who have managed to give their learned assistance without discouraging them.

CURE OF SNAKE-BITES.—Further evidence of the action of anti-venom serum against poisonous snake-bites, the efficacy of which was the subject of a communication to the Académie des Sciences last November, and was mentioned in these columns at the time, is now to hand, and has been placed before that Society. The serum, procured in large quantities from immunised horses by Dr. Calmette, Director of the Institut Pasteur at Lille, has been dispatched for experimental purposes to those countries infested with deadly snakes, such as India, Australia, and the French Colonies. It is estimated that the remedy, when freshly obtained, has an immunising power of 20,000 to 1; for example, 10 centigrammes will render innocuous a deadly dose of cobra venom in an animal weighing 2 kilogrammes. Dr. Hankin, of the Bacteriological Laboratory at Agra, found that his consignment of serum had deteriorated by its voyage during the hot weather, and that it represented about a fifth of the above strength. At Saigon, in Cochin China, Dr. Lepinay, of the Colonial Bacteriological Institute, on studying the action of the serum on animals, found that they resisted the virus when previously immunised. He also relates the case of a native who had been bitten by a "Naja," forming part of a collection of reptiles destined for the Pasteur Institute. A deep wound had been inflicted on the hand, which at once became very painful and much swollen. The sufferer was conveyed to the hospital about an hour afterwards, when an injection was at once given of 12 centigrammes of serum. The next day all dangerous symptoms had disappeared, a certain rigidity of the muscles was the only remaining sign of his mishap. On the other hand, a native who had been unable to receive timely assistance died two hours after a bite from one of the recently-captured reptiles destined for the same collection. Dr. Calmette considers that the anti-venom serum is a certain cure when administered shortly after the bite, and in any case it has no ill-effects on the constitution.

LEGAL REPORTS.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT.

PRESENCE OF COPPER IN PRESERVED PEAS.

At Southwark, on Wednesday, Mr. Fenwick delivered his decision in the case of Mr. A. A. Grist, the sanitary inspector of the St. Saviour's District Board of Works, Southwark, against H. C. Summers, trading as George Mence Smith, at High Street, Borough. The case has already been reported (see *ante*, pp. 59, 78, and 98). Mr. Fenwick said that the case was an important one, but, so far as he was concerned, extremely difficult to decide owing to the conflicting evidence which was given by scientific witnesses, whose ability and eminence were beyond dispute. The defendant was charged under Section 3 of the Sale of Food and Drugs Act with selling an article of food which was mixed or stained with an ingredient that rendered it injurious to health: it was said that the peas having been treated with copper—in such a manner that a bottle or a pound of peas contained eight-tenths of a grain of copper, equivalent to 3·16 grains of sulphate of copper—the defendant in selling those peas had brought himself within the operation of the Act. It was useless for him to go into the technicalities of the evidence. He had brought to bear upon the case his best consideration and attention, having gone carefully through the whole of the evidence on both sides, and considered the authorities put forward by the various witnesses. The conclusion he had come to was that—having regard to the whole of the evidence and to the quantity of copper in the peas—the prosecution had succeeded in establishing a case against the defendant. He should therefore impose a penalty of 40s. and 12s. 6d. costs. Notice of appeal was given by the defendant's solicitor.

NEW REMEDIES.

[The notes given under this heading embody recent suggestions in therapeutics. They cover both new drugs and preparations, and old ones under new aspects. The word "parts" is used to represent parts by weight, both for solids and liquids.]

PHENOL IN SCROTAL PRURITUS.—Brocq recommends the use of phenol dressings, by means of compresses moistened in the following solution:—Phenol, 20 parts; glycerin, 75 parts; alcohol, 25 parts; distilled water, 300 parts; to be diluted with 3 parts of water before use. Internally, he recommends antipyrin, and also phenol, which is given in the following pill:—Phenol, 5 centigrammes; extract of valerian, 10 centigrammes; powdered valerian, 20 centigrammes. From one to four such pills to be taken with food daily (*Rev. de Thérap. Méd.-Chirurg.*, lxii., 766).

ENTEROL A NEW INTESTINAL DISINFECTANT.—According to Foss, there exists naturally in the intestines a mixture of isomeric cresols in definite proportions, to which he applies the name "enterol." He claims to have prepared this body in the form of a whitish transparent liquid, crystallising at ordinary temperatures, but the crystals liquefy when they have absorbed about 5 per cent. of moisture. Enterol has a powerful penetrating odour, and when diluted to 1 in 1000 with water is absolutely harmless in doses of 1 to 5 grammes. It acts as a powerful intestinal disinfectant, and has proved very efficacious in various forms of enteritis. Foss is at present investigating carbonate of enterol, which is odourless and non-irritant (*Rev. de Thérap. Méd.-Chirurg.*, lxii., 767, after *Deutsche Med. Woch.*).

CALOMEL IN TUBERCULOSIS.—Edelheit (in *La Semaine Méd.*) recommends the use of calomel, combined with balsamic and anti-septic substances, such as balsam of tolu, benzoic acid, and creosote. It may be given in all stages of pulmonary tuberculosis or of broncho-pneumonia, except when hæmoptysis is present. He prescribes it in pills thus: Calomel and benzoic acid, of each 30 centigrammes; beechwood creosote, 2 grammes; balsam of tolu, 8 grammes; extract and powder of *Acorus calamus*, sufficient to mass. Mix and divide into sixty pills; six to be taken daily for ten days. For broncho-pneumonia he prescribes calomel, 30 centigrammes; benzoic acid, 25 centigrammes; sugar, 2 grammes. Mix and divide into ten powders; one or two of these to be taken daily (*Rev. de Thérap. Méd.-Chirurg.*, lxii., 759).

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulæ for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

OINTMENT FOR CHAPPED HANDS.

Menthol, 1 part; salol, 2 parts; olive oil, 2 parts; wool fat, 60 parts. To be applied to the hands twice a day—night and morning (*Bullet. Comm.*, xxiii., 514).

TALCUM DUSTING POWDER.

Finely powdered boric acid, 25; corn starch, 50; powdered talcum, 444; oil of rose geranium, 1 part. Mix and put up in cylindrical sieve-top boxes (*Mod. Méd.*, iv., 259).

BEETLE POWDER.

Wheat flour, 2; powdered borax, 1; unslaked lime, 1; powdered sugar, 4 parts. Mix thoroughly and keep dry. Place on papers about infested localities. (*Pharm. Era*, xiv., 685).

WINTER WASH FOR FRUIT TREES.

Crude potash, 1 lb.; caustic soda, 1 lb.; warm water, 10 gallons; (*Garden*, xlvi., 1256), to be applied warm to every portion of the tree in the form of a spray. All moss and lichen should be removed, as these conceal the eggs of the winter moth, of which there appear to be great numbers this winter.

LEMONADE FOR DIABETIC PATIENTS.

The following, says the *Medical Times*, affords a pleasant beverage for diabetic patients who suffer from thirst, and to whom sugar is forbidden. Citric acid, 5 parts; glycerin, 20 to 30 parts; water, 1000 parts.

DISPENSING DIFFICULTLY.

"MAJOR" has asked for an opinion as to the most correct way of dispensing the following:—

R Hydrarg. biniodid.	gr. ½.
Liq. arsenici chlorid.	ʒss.
Syrup. simpl.	ʒiv.
Glycerin	ʒii.
Aq. chlorof.	ʒij.
Aq. ad.	ʒvj.

Biniodide of mercury is partially soluble in glycerin in the cold, but the biniodide should be well rubbed with hot glycerin, which will easily effect solution. Protect this solution with the syrup, and add the remaining ingredients. The addition of tragacanth (1 grain to the ounce) does not seem to be required. Put a "Shake the Bottle" label on.

CREAMY EMULSION OF COD-LIVER OIL.

Cod-liver oil, 500 parts; finely sifted sugar, 190 parts; powdered gum acacia, 5 parts; powdered gum tragacanth, 5 parts; infusion of coffee, 200 parts; rum or kirsch, 100 parts (*Méd. Mod.*). Mix the sugar and the gums in a mortar, and in the bottle which is to contain the emulsion shake together the oil and the cold infusion of coffee. Pour sufficient of this liquid into the mortar to make a paste, emulsify thoroughly, add the rum to the liquid remaining in the bottle, and gradually mix with the emulsion in the mortar.

RESORCIN FOR CHILBLAINS.

Boeck (*L'Union Pharm.*) recommends the following application for unbroken chilblains. Resorcin, ichthyol, and tannin, of each 2 parts; water, 10 parts; mix. The liquid, after thoroughly shaking up the bottle, should be painted on the affected parts every evening. When applied to the skin it forms a varnish-like layer in a few minutes. Where the staining of the skin produced by the above is objected to, the following formula may be substituted, but it is not so efficacious as the above:—Resorcin, 8 parts; gum acacia, 5 parts; water, 15 parts; powdered talc, 2 parts. A coating of this liniment to be applied every evening after well shaking the bottle.

PREVENTIVE LOTION AGAINST INSECT BITES.

Acetic ether, 5 parts; eucalyptol, 10 parts; eau de Cologne, 10 parts; tincture of *Pyrethrum roseum*, 50 parts (*Journ. des mal. cutan.*). One part diluted with 3 or 6 parts of water to be used as a lotion.

NOTICES TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

LETTERS.

COMPOUND COLOCYNTH PILLS AND PHARMACOPEIA REVISION.

MR. THOMAS DUNLOP, of Glasgow, writes as follows:—"The object of my previous letter was not, as Mr. Lyon seems to have inferred, to direct his attention to what I had done a year ago. In his reply he says he does not think the 'other remarks,' which were the point of my letter, 'call for comment,' whilst at the same time he expresses his opinion *re* the 'duty' of the Revision Committee. I made a statement of fact in reply to his abstract statement. Now he modifies that—again without saying anything definite—and speaks only of 'the possibility of the pill being frequently prescribed along with some chemical which was incompatible with the official massing agent.' Under such a visionary contingency the Revision Committee would be quite justified, without in any way taking a 'poor view' of its duty, in making official an excipient which Mr. Lyon himself testifies is 'far superior to any agent I have tried.' The duties of the Revision Committee are onerous enough without laying on its shoulders the additional onus of taking into consideration—when compiling the galenical preparations—possible incompatible combinations. It is the 'duty' of the pharmacist to cope with these when they arise."

ACETUM VINI *v.* ACETUM LIGNI.

MR. R. G. MUMBRAY, of Twickenham, says:—"The very practical letter of Mr. Proctor places this vexed question in a new light, and his humorous treatment of it reduces it to the *argumentum ad absurdum*. Our mutual friend, Mr. Corder, does not, however, appear to see the humour of it. The question of adulteration generally is farcical, for there is scarcely an article of domestic utility but can be bought in various degrees of dilution. Margarine with butter in the proportion of 75 per cent. of the former is largely consumed by the discriminating British public. Coffee with chicory, thus designated, passes muster, although some varieties called 'French' possess scarcely a flavour of the Arabian berry; as for a glass of genuine home-brewed malt and hops, it is a matter of history. Bread with potatoes is never interfered with, provided it does not contain alum. A grower informed me he had ten tons of the tuber that were not fit for sale. He got rid of them to the bakers!—honest man. Why should he lose such a pile of money with an open market? But what do doctors say of the prevalence of indigestion and other complaints resulting from injurious food or deficient nutrition? But I submit that all this 'scientific nonsense' about vinegar, etc., is absolutely inane, unless there are some persons, not mentioned, who derive advantage by keeping up the agitation. Let us consider the subject divested of its 'wickedness.' First, we have the old brown vinegar, say the strongest, No. 24—the law allowed the addition of 1/1000th part of sulphuric acid to keep it. Still, even this did not prevent its becoming 'mothery,' so the makers adopted some other plan, with a satisfactory result. But acetic, wood acid or pure pyroligneous acid is pronounced an adulteration, though not injurious to health. It is the Excise that objects. Now, why cannot our enlightened legislators open a way of escape for the trader, who desires a living profit, and to keep honest by permitting a definite quantity of acetic acid to be used, not *ad libitum*, as in the butter, coffee, or beer trades, with their vile substitutes? Many years ago I was in the habit of using that very useful article, acid. acet. fort., manufactured by Beaufoy and Co., the largest vinegar makers of the day (note this); I was in the habit of supplying French vinegar imported by Messrs. Kent and Co., Upton-on-Severn, in 25 gal. casks, but it generated eels, and I found the most effectual cure for these organisms was acid. acet. pur. I dealt with another house for brown vinegar, and in order to improve it, adopted the infamous practice so touchingly alluded to by Mr. Proctor, and

in order to satisfy my conscience (not too flexible I trust) submitted two samples for the decision of an experienced club steward—he decided in favour of the sophisticated article as being more brisk and better flavoured. I made another experiment, having a quantity of grapes that did not ripen—I made them into wine—this wine went off rather sour—so I, still persevering in my evil courses, mingled it with the substitute, and bottled it off as genuine "white wine vinegar," the faintest touch of sacch. ust. completed the deception. This vinegar was praised by my customers—particularly by the French refugees, who were numerous at the time—as of the very best quality, *bien agréable* for salads."

THE USE OF TITLES BY LIMITED COMPANIES.

MR. J. LEACH, of Macclesfield, says "I should be glad to hear opinions as to the legality of limited liability companies having over their premises 'Cash Chemist.' The employment of a qualified assistant can scarcely give them that right, and though we cannot prevent them dispensing and selling poisons, surely we ought to have the power of protecting our title. If something could be done in the matter, I think for once chemists would be united."

QUERIES.

A CORRESPONDENT asks if any reader knows a preparation called "Dryden Ointment," a preparation which is largely used in Holland as a general salve. It is sold in short sticks of a dark brown colour.
"GLUTEN" requires a recipe for making gluten biscuits.

ANSWERS.

G. W. BLYTHE.—Morphine will not dissolve in rectified spirit to anything like the extent you mention. Refer to the latest edition of Squire's 'Companion to the British Pharmacopœia,' which will give you complete and reliable information upon all the points you refer to.

GEO. NIND.—The special peculiarity of "Hovis Bread" seems to be that the flour from which it is prepared is mixed with the ground germ or embryo of the wheat grain. In making the bread, kneading or moulding must be avoided, and it must be baked rather longer than ordinary bread.

ROBT. L. MORRIS.—(1) You will find Muter's 'Short Manual of Analytical Chemistry' a very satisfactory book. (2) Write to the Secretary, 17, Bloomsbury Square, W.C., for a copy of the pamphlet 'Advice to Students,' and read the article on 'Herbaria' in the 'Encyclopædia Britannica,' which should be available at any public library. Hayward's 'Botanist's Pocket Book' is the handiest flora for students' purposes.

T. PRITCHARD.—Your notice is unsuitable.

W. R. FIELDING.—You can obtain stains in powder to mix with spirit varnishes so as to imitate the colours of various woods, from Williams and Co., of Hounslow. The other matter you inquire about is receiving attention.

OBITUARY.

BAXTER.—On January 5, William Baxter, Chemist and Druggist—Liverpool. (Aged 63.)

RAE.—On January 14, John Rae, Chemist and Druggist, Newmarket, (Aged 53)

BROWN.—On January 23, William Brown, Chemist and Druggist, Norwich. (Aged 57.)

JEWELL.—On January 28, John Jewell, Chemist and Druggist, late Liverpool. (Aged 58.)

BROOKS.—On January 30, Owen Brooks, Chemist and Druggist, Llandudno. (Aged 50.)

SAXBY.—On February 2, Henry Saxby, Pharmaceutical Chemist, Lewes. Mr. Saxby was a member of the Pharmaceutical Society and formerly local secretary for Lewes.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Allen, Allenby, Barnes, Bayley, Bentley, Brackenbury, Bray, Davies, Davis, Dryden, Dunlop, Eastman, Elborne, Elliott, Fielding, Fitton, Foster, Gaul, Garrod, Gower, Griffen, Hampson, Hill, Holt, Howie, Kern, Langley, Lawrence, Leach, Leefe, Morris, Mumbray, Northray, Orchard, Peck, Powell, Prichard, Purvis, Reynolds, Rimmington, Smith, Squire, Stokoe, Thompson, Walker, Winter.

CONTRIBUTIONS TO OUR KNOWLEDGE OF THE ACONITE ALKALOIDS.—PART XIII.

THE ESTIMATION OF ACONITINE.

BY PROFESSOR WYNDHAM R. DUNSTAN, M.A., F.R.S.,

Director,

AND

THOMAS TICKLE,

late Redwood Scholar in the Research Laboratory of the Pharmaceutical Society.

[From the Research Laboratory of the Pharmaceutical Society.]

As has been stated in previous papers, for some time we have been engaged in working out in detail a process for the estimation of aconitine, depending on the fact that this alkaloid furnishes on hydrolysis 18·5 per cent. of benzoic acid and 9·25 per cent. of acetic acid, or, if the hydrolysis is partial, as is the case when an aconitine salt is heated with water, only acetic acid is separated, a result which also ensues if the aconitine is heated in the dry state at its melting point. As has been shown in previous papers (*Journ. Chem. Soc.*, 1894 and 1895), there is no difficulty in obtaining accurate results with pure aconitine by analytical processes based on these facts, nor is there any difficulty in estimating the quantity of aconitine in presence of benzaconine or of aconine. We have made determinations with mixtures of these known alkaloids by four different methods. Three of these are direct methods in which the acetic acid is directly estimated either by the dry heating of a known weight of the alkaloid in a small flask at about 190° C. in a current of air, the acetic acid distilling over being titrated in the usual manner, or by converting the alkaloids into a neutral solution of the sulphates, which is heated in a closed tube at 125° for three hours, after which the acidity of the solution is estimated, and the acetic acid thus found reckoned as aconitine. Or the total alkaloid may be completely hydrolysed in alkaline solution, the liquid acidified with dilute sulphuric acid, the benzoic acid extracted with benzene, and the acetic acid then distilled off and titrated. In these cases the acetic acid having been directly determined, the amount found is calculated into aconitine, and if, in addition, the benzoic acid is determined by shaking out with benzene from an acidified solution after complete hydrolysis, the amount of benzaconine may be calculated from the quantity of benzoic acid found over and above that derived from the aconitine present. A fourth and indirect method of getting at the quantity of aconitine present in a mixture containing also benzaconine and aconine consists in hydrolysing with a known volume of standard alcoholic solution of alkali. The amount of alkali remaining is calculated, and from the loss the total acidity is reckoned. If the weight of benzoic acid is found by extraction from the acidified solution, and this deducted from the total acidity the remainder may be calculated as acetic acid. Wherever benzoic acid has to be extracted from a solution containing acetic acid, we find benzene preferable to ether, since the latter solvent also extracts notable quantities of acetic acid.

Numerous experiments with aconitine and with mixtures containing aconitine have been made with these various methods with the view of finding a sufficiently accurate process of estimating the acetic acid. The indirect method in which only the benzoic acid is directly determined, and the acetic acid calculated by difference has not afforded satisfactory results, chiefly owing

to the fact that all the errors of the determination are thrown upon the acetic acid. The principal error arises from the circumstance that in the presence of free alkaloid, none of the usual indicators will sharply define the point at which the alkali has been exactly neutralised. We have, therefore, employed a process in which the acetic acid is directly determined with as high a degree of accuracy as possible. Unless great accuracy is secured it is obvious that no process founded on the principle of estimating the acetic acid can be of any value for pharmaceutical purposes. It has to be remembered that aconitine furnishes less than 10 per cent. of this acid; that in the first calculation of this amount of acetic acid into aconitine any error will be multiplied by more than ten, and, further, having regard to the fact that in dealing with aconite root or galenical preparations made from it the quantity of aconitine actually operated on would probably not much exceed ·1-2 gramme, and, therefore, would furnish less than ·01-02 gramme of acetic acid, it is obvious that no coarse method would be of the slightest use for the practical purpose of defining the dose of this drug. It will be unnecessary for us to give a detailed account of the very large number of experiments which have been carried out in testing the adequacy of various methods, but we may proceed at once to describe the process which has given us the most accurate and concordant results.

It depends on the fact demonstrated by us some years ago, that when aconitine sulphate is heated in a closed tube with water at 125° C. for three hours it undergoes partial hydrolysis with production of one molecular proportion of acetic acid and the separation of a very little benzoic acid. Direct titration of the liquid with standard alkali gives only approximately accurate results with small quantities of aconitine, even when allowance is made for the small amount of benzoic acid liberated. Distillation of the liquid and titration of the acetic acid in the distillate is attended with the difficulty of distilling off the whole of the acetic acid without decomposition of alkaloid, etc., taking place in the concentrated solution. The most satisfactory plan is to make the liquid taken from the tube alkaline with pure soda, and to remove the alkaloid by shaking twice with chloroform, then acidifying with pure sulphuric acid, removing the small quantity of benzoic acid by shaking once with benzene, then distilling the acid liquid until the whole of the acetic acid has come over, and titrating the distillate with standard $\frac{N}{25}$ soda, or better, baryta water. The most suitable indicator for the purpose is phenol phthalein. The accuracy of the method may be illustrated by the results of determinations with pure aconitine. Aconitine taken, ·2228 gram.; $\frac{N}{25}$ baryta required 8·65 C.c.; aconitine found, ·2238 gram., a result which is about ·5 per cent. too high. In another experiment, aconitine taken, ·3054 gram.; aconitine found, ·3061, which is about ·2 per cent. too high. It is doubtful whether much greater accuracy than this can be obtained with such small quantities of alkaloid. The process answers well for the estimation not only of small quantities of aconitine alone, but of aconitine mixed with the other known constituents of the total alkaloid of the plant, benzaconine and aconine.

Being thus in possession of a suitable method of directly determining the acetic acid, we proceeded to apply it to the determination of the quantity of aconitine present in the total alkaloid extracted from the root of *Aconitum napellus*, and in that extracted from the tincture and extract of

aconite. Before the method of estimation based on the determination of the acetic acid can be accepted as valid, it must be shown to be applicable to the total alkaloid of the plant, from which we have so far isolated and defined only the three alkaloids, aconitine, benzaconine, and aconine. Other apparently amorphous alkaloids are present, which it has not so far been possible to separate and characterise, since their salts resist all attempts to crystallise them. To settle the validity of the method for the determination of aconitine in the natural total alkaloid is not easy, since there is no method known of completely separating the aconitine from the mixture, whilst no process is known, except that now under examination, by means of which the amount of aconitine in the mixture may be determined. The proceeding we have followed is to convert the total alkaloid soluble in ether into hydrobromide by solution in dilute aqueous hydrobromic acid. The exactly neutral solution is evaporated, and the aconitine crystallised and removed as hydrobromide. By repeated evaporation and prolonged standing a condition is reached in which nearly all the aconitine and much of the benzaconine have been removed as crystalline hydrobromides. The alkaloid is then regenerated, and the process of crystallising as hydrobromide repeated. Finally, an amorphous resinous mixture is obtained, from which no more aconitine can be crystallised as hydrobromide. A little aconitine, however, still remains, since a solution of the alkaloid produces tingling of the tongue, and by comparison in this respect with solutions of pure aconitine we have been able to form a very rough idea of the percentage of aconitine remaining.

The process for the determination of the acetic acid described above, as well as the various methods previously noticed have been applied to numerous specimens of alkaloid freed from nearly all the aconitine in this manner, and to mixtures of this alkaloid to which a known quantity of aconitine had been added. The result has been invariably the same. The quantity of acetic acid obtained has been largely in excess of the amount derived from the aconitine present, even after a very liberal allowance has been made for the aconitine not removed as hydrobromide. A few results may be alluded to here out of the large number we have obtained. Amorphous "aconitine free" alkaloid taken .5688 gramme; aconitine calculated from acetic acid found .1949 gramme. This quantity corresponds with 34.2 per cent. of aconitine in the mixture, whereas the quantity actually present could not have much exceeded 5 per cent. and was probably far less, since we have found no difficulty in crystallising aconitine as hydrobromide from prepared mixtures containing 5 per cent. of this alkaloid with amorphous bases.

In other similar cases where different specimens of the amorphous alkaloid were employed, percentages of aconitine were indicated much in excess of those actually present. In mixtures in which the quantity of aconitine was not believed to much exceed amounts ranging from 1 to 10 per cent., the amounts calculated from the acetic acid found were in the vicinity of 10, 20, and 30 and 40 per cent. That the acid estimated was, in fact, acetic acid was proved by completely converting that present in the distillate into the silver salt by adding silver oxide, and then estimating the silver in the salt. The result corresponded with that calculated for silver acetate.

We have spent a considerable amount of time in

trying to definitely ascertain the cause of these high results, but so far without complete success. Whatever plan is followed for the determination of the acetic acid, the amount found is much higher than the expected quantity, and the highest results are obtained when any process involving complete hydrolysis by alkali is used. Putting aside as highly improbable and unsupported by facts the possibility that the considerable percentages of aconitine calculated from the acetic acid obtained could be present, the most probable explanation is that there occurs in the plant, and therefore in the total alkaloid, some substance which, like aconitine, furnishes acetic acid on hydrolysis. Attempts to separate this hitherto unknown constituent have not met with any success, since no crystalline base could be separated from the mixture nor any crystalline salt prepared from it. Whatever the explanation of the fact may be, it is clear that at present the determination of the acetic acid furnished by the total alkaloids of *Aconitum napellus* cannot be taken as a basis for the calculation of the quantity of aconitine. Until a satisfactory process for the estimation of aconitine in the total alkaloid has been found, no progress can be made in standardising galenical preparations made from the plant.

CONTRIBUTIONS TO OUR KNOWLEDGE OF THE ACONITE ALKALOIDS.—PART XIV.

THE DETECTION OF ACONITINE.

BY PROFESSOR WYNDHAM R. DUNSTAN, M.A., F.R.S.,

Director,

AND

FRANCIS H. CARR,

Salter's Company's Research Fellow in the Research Laboratory of the Pharmaceutical Society.

[From the Research Laboratory of the Pharmaceutical Society.]

At the present time there is no chemical test for aconitine which is sufficiently specific to be used in qualitative analysis for the detection of small quantities, and on this account in toxicology the physiological action is generally relied on as a proof of the presence of this alkaloid. During the course of some experiments we have been conducting in studying the oxidation products of aconitine, we have noticed a reaction which does not seem to have been observed before, which is sufficiently distinctive and delicate to be of service in detecting aconitine, and may prove of value in toxicology. It depends on the production of a purple crystalline, sparingly soluble permanganate of the alkaloid, which is precipitated when a solution of an aconitine salt is mixed with a very slight excess of a solution of potassium permanganate.

The purple precipitate is fairly stable, especially in presence of a small quantity of acetic acid; in fact a slightly acidified solution of aconitine acetate furnishes a precipitate which darkens only very slowly. In very dilute solutions the micro crystalline precipitate appears after vigorous stirring. Under the microscope the precipitate is seen to consist of pyramidal needles, generally arranged in tufts or rosettes. When the precipitate is heated with the liquid it rapidly darkens, with production of an oxide of manganese. The precipitate dissolves in concentrated sulphuric acid without coloration, and on heating the solution benzoic acid sublimes. When the dried and almost black precipitate is gently heated, acetic acid distils from it. The reaction is extremely delicate; a solution containing 1 part of aconitine

in 4000 (.025 per cent.), gives a distinct precipitate after standing and stirring, whilst a solution containing 1 part of alkaloid in 2000 (.05 per cent.) gives an immediate precipitate. One drop (.05 C.c.) of a solution of this strength gives a distinct purple crystalline precipitate when a drop of permanganate solution (decinormal) is added, which means that .000025 gramme of aconitine has been detected without difficulty.

Whilst the presence of a slight excess of acetic acid conserves the precipitate, anything like a large excess of this acid must be avoided, since the salt is somewhat soluble in it. The precipitation of the aconitine is never quite complete, even in neutral solutions, owing to the slight solubility of the permanganate. The reaction cannot, therefore, be applied gravimetrically for the estimation of aconitine.

The crystalline salt has been collected and analysed. Its composition is represented by the formula $C_{33}H_{45}NO_{12}$, $HMnO_4$, since it furnished 10.89 per cent. of manganese trioxide (Mn_2O_3), the amount required by this formula being 10.31 per cent. When the salt is kept in solution or collected and dried it gradually decomposes, oxide of manganese separating and the aconitine undergoing oxidation to a crystalline nearly neutral substance, which still appears to contain both the benzoic and acetic groups of aconitine. This substance is now under investigation.

The behaviour of the principal alkaloids towards potassium permanganate has been studied by Beckurts, who states that aconitine salts give no precipitate but a brown coloration. We can only suppose that the aconitine used must have been highly impure.

We have re-examined the reaction of the more important alkaloids with potassium permanganate, and have found that the only alkaloids which give a purple precipitate are cocaine, hydrastine and papaverine, but the permanganates of these alkaloids are easy to distinguish from the aconitine salt. Veratrine, it may be noted, decolorises permanganate, forming a brown precipitate. Solutions of cocaine salts are not distinctly precipitated in solutions containing much less than 1 per cent. of the alkaloid. Like aconitine the cocaine salt is crystalline but is very readily dissolved by water. The same is true of hydrastine, and in this case the precipitate is pinker than the aconitine salt and is not crystalline. Papaverine is only precipitated in solutions of about the same strength, and here again the precipitate is distinctly pink and is amorphous. Moreover, aconitine permanganate is not changed by the addition of a drop of bromine water to the mixture, whilst the cocaine salt turns a deep orange and that of hydrastine a bright yellow. These three alkaloids are, however, so readily distinguished from aconitine by other reactions that there is scarcely any possibility of their being confounded with it.

Of the other aconite alkaloids, pseudoaconitine behaves most like aconitine, but this crystalline permanganate is not precipitated readily in solutions containing much less than .5 per cent., and the precipitate is more stable than the aconitine salt. On heating it with the liquid it dissolves, and on cooling separates out in acicular crystals, whilst in the case of aconitine the purple precipitate rapidly darkens when warmed. Aconine salts are not precipitated by potassium permanganate, but they rapidly effect decolorisation of permanganate. In strong solutions, salts of benzaconine furnish a permanganate resembling the aconitine salt, but a 1 per cent. solution of benzaconine (acetate) is not precipi-

tated, so that there is no difficulty in distinguishing this alkaloid from aconitine, nor does the presence of this alkaloid materially affect the recognition of the aconitine in dilute solutions. In isolating aconitine from mixtures (*e.g.*, in toxicology) as a preliminary to applying this test, the slightly acidified extract should be well shaken with ether to remove extraneous substances soluble in ether, the liquid should then be made alkaline with a slight excess of ammonia (never with soda or potash), and the aconitine extracted with ether. The permanganate test should then be applied to a 1 per cent. solution of the ethereal residue made acid with acetic acid, or the ethereal solution may be shaken with dilute acetic acid. As a confirmatory test for aconitine the fact that the base gives off acetic acid when heated to $190^{\circ}C$. may occasionally be of service since the operation can be conducted in a capillary tube.

ESSENTIAL OILS OF BLACK AND WHITE PEPPERMINT.

BY JOHN C. UMNEY.

Peppermint has been cultivated in the district of Mitcham, Surrey, for about 150 years, and during the last thirty years or more, to some considerable extent at Market Deeping, in Lincolnshire; the herb is also grown at Hitchin, Hertfordshire, and in some parts of Cambridgeshire.

The two varieties of the plant (*Mentha piperita*) grown in and about Mitcham are known as black and white peppermint respectively, the black mint occupying the greater part of the acreage under cultivation. The preference given by growers to the black is based chiefly upon the fact that the plant is more hardy than the white variety, and the yield of essential oil is considerably greater.

I learn from Mr. W. Holland, of Market Deeping, and also from Mr. Ransom, of Hitchin, that the cultivation of the white peppermint has been discontinued in their respective districts, owing to the limited demand for the oil derived from this variety. There is, however, a constant demand for certain purposes for oil of white peppermint, notwithstanding its value is considerably higher than that of the black mint oil.

I am aware that some essential oil dealers hold strongly to the opinion that the difference between the oils is more imaginary than real, and also that there is with some a prejudice in favour of oil of white mint based upon "rule of thumb" knowledge rather than upon accurate laboratory observation.

Careful comparison, however, shows an unmistakable difference in the odour of the two oils and in the waters distilled from them by the process of the British Pharmacopœia, and it was in order to determine whether any chemical or physical characters could be found that would correspond to the difference in odour and taste that this investigation was conducted.

The two plants of black and white peppermint are botanically identical, but the difference between the appearance and habit of the two is sufficiently marked to make their characterisation quite distinctive. The black peppermint herb has purple stems, dark green leaves, not deeply serrated, and rarely flowers in this country, except in unusual summers, such as that of 1893. The white peppermint possesses more lanceolate, brighter green leaves than the black variety, the margin being much more

deeply serrated and the stems being green. Its flowers are greyish and easily seen at a distance, the flowering occurring in those seasons when hardly any is observable on the black variety.

It has already been stated that the yield of essential oil from the black is considerably greater than from the white variety, for whilst the former yields in good seasons as much as 8 lbs. per ton of fresh herb, the latter rarely yields more than 6 lbs., and usually not more than 3 or 4 lbs. per ton. The distinction in the odour of the two oils consists in the well-known pungency of that of the black, being agreeably toned down in that of the white variety by a pleasant smell not easily described.

For the purposes of these experiments I have been supplied with oils of last year's (1895) distillation from unmixed black and white plants respectively by Messrs. J. and G. Miller, of Mitcham.

The two oils differed considerably in colour, the black being pale yellowish-green, whilst the white was dark yellow. The two oils were exposed to a temperature of -4° C. and stirred, but although the black oil became pasty, through separation of menthol, the white oil remained quite fluid.

The specific gravities at 15° C. of the oils were—

Black	·9036
White.....	·9058

or somewhat lower than the average I have obtained from many samples of ordinary English oil (black mint), which is ·906.

The optical rotations showed considerable differences, being in a tube of 100 Mm.—

Black	$-25^{\circ}\cdot5$
White.....	-33°

This rotation is explained by the difference in proportion of the optically active constituents of the oil, which will be subsequently described.

Colour Reactions.—Notwithstanding I have avoided the majority of these tests as a means of identification of essential oils, on account of the frequent uncertainty as to which constituents produce the reactions, the adoption of them in the case of peppermint oil by the U.S. and other pharmacopœias, is the reason of reference to them.

The glacial acetic acid test, which consists in mixing 1 part of oil with 3 parts of glacial acetic acid and allowing to stand some hours, shows marked difference—giving an intense greenish-blue with copper fluorescence in the case of the white oil, and only a very pale blue in the black oil; the modified test of the U.S.P., in which nitric acid is employed in addition to acetic acid, at once yielding equally distinctive reactions.

The other reaction of the United States Pharmacopœia consisting in warming a solution of 1 C.c. of the oil in 5 C.c. of alcohol with $\frac{1}{2}$ gramme of sugar, and 1 C.c. of hydrochloric acid, shows equally striking differences.

The finest American oil gives practically the same colour reactions as the white oil, and, as the proportion of esters in the white oil is very similar to that found in the best oils from that country, it seemed possible that the reactions might be dependent upon these bodies, and experiments with the white oil from which the esters have been completely removed strengthen this view. It is noteworthy also that Japanese oil, which contains a low proportion of esters

of menthol, gives no dark blue colour or copper fluorescence by any of the tests referred to.

Fractionation.—Under identical conditions fractionation affords a useful means of making a preliminary comparison of peppermint oils, and in the present instance considerable divergence was found, especially in the proportions boiling below 200° C.

The percentages obtained were as under:—

	White oil.	Black oil.
Below 200° C.....	24 per cent.	5 per cent.
200-205	15 "	27 "
205-210	15 "	31 "
210-215	15 "	22 "
215-220	13 "	7 "
Above 220	18 "	8 "

The fractions boiling below 200° C. in both cases were distinctly acid to litmus, due to the acids produced by the decomposition of the esters present in the oils.

It will be evident when the ester determination of the oils is considered that the difference in the proportions of this fraction is due in great part to the variation in the amount of these bodies present in the two oils.

The percentages obtained by the fractionation of the black oil agree closely with those obtained in the examination of many samples of various distillers, both in Mitcham and the other districts of England referred to.

The fractions from both oils boiling below 200° C. contained phellandrene as indicated by the nitrite test.

The methods suggested by Power and Kleber (*Pharm. Rundschau*, xii., 1894, 157) in their examination of American peppermint oil have been adopted for the estimation of the principal constituents of the oil, viz., menthol, esters of menthol, and menthone.

Menthol Determination.—Although there may be doubt whether in the case of English peppermint oils the total percentage of menthol is by any means the most important factor in the aroma value of the oil, yet the determination of the menthol and esters of menthol is the best starting point for the chemical examination of the oils of both black and white varieties.

By saponification with alcoholic potash the black oil indicated 3·7 per cent. of menthol in the form of esters, whilst the white yielded under similar treatment 13·6 per cent. of menthol in similar combination. The percentage of esters in the black oil is slightly lower than usually obtained, viz., from 4 to 6 per cent.

The total percentage of menthol as such and as esters was determined by the acetylation process, and found to be in the black oil 63·1 per cent. and in the white oil 65·5 per cent. :—

	Menthol as Esters.	Total Menthol.	Free Menthol.
Black ...	3·7 per cent.	63·1 per cent.	59·4 per cent.
White...	13·6 "	65·5 "	51·9 "

I have already suggested (*Ph. J.* [3], xxv., p. 1040) the presence of a different menthol, possibly a liquid one, in English peppermint oil to that contained in Japanese in order to account for the fact that oils of these varieties, although indicating practically the same menthol percentage by the acetylation process, show considerable difference in freezing properties.

This difference is marked in the case of the black and white varieties, for whilst the portion of the black boiling from $210-215^{\circ}$ C. becomes solid immediately on placing in a freezing mixture, the similar fraction of the

white oil did not even perceptibly thicken at -4° C. It is worth recording, however, that the white oil, from which the esters have been removed by saponification with alcoholic potash, readily solidifies at a temperature of 0° C. Either, therefore, the treatment to which the oil has been subjected causes isomeric change in the menthol, or the esters considerably retard its crystallisation.

Menthone determination.—The ready reduction of menthone to menthol forms an easy means for the estimation of this constituent, which has been long known to be present in most peppermint oils. For this purpose a portion of the black oil was saponified with alcoholic potash and the alcohol removed by washing. This oil was divided in two portions, in one of which the menthol was estimated by the acetylation process, and the other dissolved in twice its volume of absolute alcohol and treated at a boiling temperature with metallic sodium. The oil was separated by addition of water, and after thoroughly drying the menthol now present was also estimated by the acetylation process.

The amount present before treatment with metallic sodium was 63 per cent., whilst after reduction of the menthone to menthol, it was found to be 74.5 per cent., or 11.5 per cent. of menthol, equal to 11.3 per cent. of menthone.

The white oil similarly treated indicated 9.4 per cent. of menthol resulting from reduction of menthone equal to 9.2 per cent. of that substance.

Examination of Esters.—In order to determine whether the greater percentage of esters in the white oil was the sole cause of the modification in its odour as compared to the black oil, or whether it was due to different esters of menthol, 100 grammes of the white oil was saponified with excess of alcoholic potash and the alcohol evaporated at a low temperature.

The saponified oil was then washed three times with water to remove the potassium salts of the acids present in the form of esters in the oil. This was concentrated, acidified with nitric acid and shaken with ether. The ether left on evaporation a strong smelling yellow oily liquid which was strongly acid; .328 gramme of the silver salt of this acid yielded .169 gramme of silver as chloride, viz., 51.5 per cent., the calculated yield for valerianic acid being 51.6 per cent.

The boiling point of the acid liberated from the silver salt was found to be 173° - 174° C., and it is evidently isovalerianic acid.

The only other acid that could be detected was acetic acid in the acidified liquid after it had been shaken with ether.

Precisely similar experiments were conducted in the black oil, the acids obtained were in this case both acetic and isovalerianic. It would appear, therefore, that if the odour of the oil is influenced by the esters present, as seems almost certain, the quantity of them rather than a variation in their composition must be held accountable for it.

An attempt was made to determine the proportion of the two esters present in the oils, using a modification of Luck's method for the separation of the lower fatty acids. The acids, resulting from the decomposition of the esters, were removed by distillation, neutralised with baryta water, evaporated to dryness and fractionally extracted with absolute alcohol. The difference in the solubilities of the acetate and isovalerianate of barium in that liquid was not sufficient to render quantitative separation practicable. The

small proportion of esters in the black oil was also a great obstacle to this process.

The principal physical and chemical characters by which the white oil of peppermint may be distinguished from the black may be summarised thus:—

1. In having greater optical activity.
2. In not depositing menthol at a low temperature, possibly owing to the fact that a portion of menthol present exists in a modified liquid form.
3. In containing a greater proportion of esters of menthol (acetic and isovalerianic).
4. In giving intense blue coloration with copper fluorescence, with glacial acetic acid, and the other reactions of the United States Pharmacopœia.

It seems certain, moreover, that the variation in the aroma of the two oils is dependent upon one, if not more, well-defined differences pointed out in the constitutions of the respective oils.

My thanks are due to one of my assistants, Mr. R. S. Swinton, for help in carrying out the experiments necessary for this communication.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

DONATIONS.

At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 12th inst., the Librarian presented the following report of donations:—

To the Library (London).

- Royal Society of London:**
Catalogue of Scientific Papers, 1874-83, Vol. 11, Pet-Zyb.
- Miss A. Babington, Tunbridge Wells:**
Prantl, Lehrbuch der Botanik, 8. Auflage, 1891.
- Professor Bradbury, University of Cambridge:**
The Bradshaw Lecture on Some New Vaso-Dilators, 1895.
- Dr. L. Planchon, École supérieure de Pharmacie, Montpellier:**
Observations sur la résistance vitale de l'Argas reflexus, 1895.
- To the Library (Edinburgh).*
- Mr. W. C. Baker, 13, Dundas Street, Edinburgh:**
Cole, Studies in Microscopical Science, 1883-84. Two vols., with plates.
- Mr. A. J. R. Swanson, 9, N.W. Circus Place, Edinburgh:**
Pharmaceutical Journal, August 18, 1894, to April 20, 1895, and July 6 to December 28, 1895.

The following report of donations was presented by the Curator:—

To the Museum.

- Il Marchése Thos. Hanbury, F.L.S., Ventimiglia:**
Specimen of the resins of *Pinus halepensis*, *P. maritima*, and *Cupressus sempervirens*.
- Messrs. Horner and Sons, London:**
A log of Indian sandalwood and a specimen of the oil distilled from the wood; a specimen of oil of juniper berries and of the berries from which the oil was distilled.
- Dr. Wilks, M.D., F.R.C.S., London:**
A specimen of guarana and of guarana seeds, and a model in guarana of the pirarucu fish, the palate of which is used for grating the guarana by the native Indians of Rio Grande do Sul, also a dried palate and three letters relating to the specimens.
- Mr. E. L. N. St. Cyr, Hayti:**
A lilaceous root employed by the natives in amenorrhœa.
- Mr. T. Wardleworth, Liverpool:**
Specimens of Angelica root, and of the rhizome of *Acorus spurius*, from Japan; also a leaf of the Carnauba palm (*Corypha cerifera*).

Messrs. Geo. Curling and Co., London :

Five specimens of medicinal products from Peru.

Messrs. Wright, Layman, and Umney :

Specimens of the oils of "black" and "white" peppermint.

Mr. W. Elborne :

Specimen of cocus wood from Cuba (*Aporosa*, sp.).

To the Herbarium.

Mr. J. Ch. Sawyer, F.L.S., Brighton :

Specimen of the flowering and non-flowering varieties of the patchouli plant from Java.

Professor H. H. Rusby :

Specimen of *Pilocarpus selloanus*.

EVENING MEETING IN LONDON.

On Tuesday, the 11th inst., an evening meeting of the Pharmaceutical Society was held in the large Examination Hall at No. 16, Bloomsbury Square, the chair being taken by the President, Mr. Michael Carteighe, at 8 o'clock.

THE BURROUGHS MEMORIAL.

The PRESIDENT said it had been arranged that the first business of the evening should be the official handing over to the Pharmaceutical Society of the Fund which had been raised to commemorate the memory of the late Silas Mainfield Burroughs. He appeared in the double capacity of Chairman of the Committee which had collected the Fund and President of the Society which was about to receive it in trust, and in the latter capacity he need not say how gratified he was to receive the substantial amount which had been raised. The Honorary Secretary of the Committee and himself had received numerous telegrams from friends of Mr. Burroughs regretting that they were unable to be present, amongst them one from Mr. H. M. Stanley, M.P., whose public duties that evening rendered it impossible for him to attend.

Mr. HELBING (Hon. Sec. to the Committee) was then called upon by the President. He said it was but natural that the late Mr. Burroughs' friends should try to retain his memory fresh amongst them, and endeavour in some way to perpetuate his name. That the friends of Mr. Burroughs were numerous was well known, for everyone who came in close contact with the man was bound to like him. Ever ready to help where help was required, he took friendly interest in the affairs of others, and had always their welfare at heart. The appeal to his friends had not been in vain, and they had been able to carry out the scheme which was first considered a year ago. A substantial fund had been raised, the interest of which would be sufficient to enable every year a pharmaceutical chemist who had talent but not a superfluity of means to continue to advance his studies during another year as a Burroughs scholar. The Fund which the Committee had the pleasure that evening to hand over in trust to the Council of the Pharmaceutical Society had been freely and liberally subscribed to. From all parts of this country, from the Continent, the United States, and even Africa, friends had replied to the appeal, and the list of subscribers was quite an international one. It comprised not only the individual pharmacist, the wholesale druggist, and the chemical manufacturer, but a great number of personal friends of Mr. Burroughs who had no connection whatsoever with pharmaceutical business. Men of science and of literature, politicians and Members of Parliament, medical men and others, had combined together to do honour to their deceased friend. The great majority had expressed their opinions in favour of a Scholarship as the best and most suitable form of memorial, and in asking the Council of the Pharmaceutical Society to become trustee of the Scholarship Fund and to assist the Burroughs scholar by allowing him to make use of the Society's laboratories, the Committee desired to express its assurance that it felt perfectly confident the Burroughs Scholarship Fund would be the means of doing good and of keeping alive the memory of their deceased friend.

Mr. JOHN MOSS (Hon. Treasurer) said the Honorary Secretary had already covered much of the ground which he should have liked to touch upon. This occasion was, no doubt, a formal one, but it was none the less important. In the

thought that beneficent intention was approaching consummation there was a good deal of gratification, but that feeling was overwhelmed and subdued, if not hidden, by the surging recollections of what happened a year ago. It only remained for them now to remember Mr. Burroughs, and to keep his memory green. He was a man who had endeared himself to troops of friends by his frank, genial, loyal, lovable disposition, and it was felt by all that he was a man whose memory the world would not willingly let die. No sooner was a memorial suggested than the idea was caught up with ardour, and the President of the Pharmaceutical Society having expressed his approval, and offered to act as Chairman of the Committee, the success of the movement was assured. It was the man himself they wished to honour. He was of exceptionally attractive character, who seemed to have a genius for discerning capability and worth in those with whom he came in contact, especially the young, with whom he was always a favourite, and whose difficulties he always seemed to understand and appreciate, and to whom he was always ready to accord sympathy, encouragement, and often material help. It was these considerations which led the Committee to feel that the memorial should take the form of a Scholarship for the encouragement of exceptional merit or endeavour; and to further the study of the subjects in which their friend had been educated; and were connected with the calling which he had followed. The question was submitted to the subscribers, who cordially agreed to that suggestion, and they asked the Pharmaceutical Society to take charge of the administration of the Fund, in order that the Scholarship might be held in that institution for the study of the higher branches of pharmacy. It was in the belief that the Burroughs Scholarship would prove of inestimable advantage to future generations of pharmacists, and through them to pharmacy itself, that he had been instructed to ask the President of the Society to take charge of the Fund, which amounted to £850.

The PRESIDENT, on the part of the Council, thanked the donors for the confidence they had placed in it, and in the educational work done by the Society, with which he thought they might all be satisfied, and of which he was proud. Whatever difference of opinion there might be with regard to certain forms of education they were all agreed that since everyone who desired to be a pharmacist was compelled to pass a preliminary and a qualifying examination, it was wise to give opportunities to those who had obtained this qualification to pursue a further year's study, either there or elsewhere, because there was a provision in the draft deed of trust which would under certain circumstances permit the Scholarship to be held elsewhere, if necessary. In practice no doubt for some years the Burroughs scholar would pursue his work there, and whatever work was carried out by him would be work which would not only redound to his credit individually, but would perpetuate the memory of Mr. Burroughs in the most fitting form, and in the way which probably he himself would have chosen. In the name of the Council he accepted the Fund, and in due course he should ask the members of the Committee to affix their names to the deed of trust. He had just received a telegram from Mr. Wellcome expressing his deep regret that at the last moment he found it impossible to be present, and how gratified he was at the success of the Fund. Not the least gratifying feature of the meeting was that Mrs. Burroughs was able to be amongst them. In conclusion he desired on behalf of the whole of the subscribers to tender thanks to the Honorary Secretary and Treasurer, to whose zeal and energy the whole success of the Fund was due.

THE ACONITINE RESEARCH.

Two papers on "The Estimation of Aconitine" by Professor Dunstan and Mr. Tickle, and on "The Detection of Aconitine," by Professor Dunstan and Mr. Carr, were next read. They are printed at pp. 121-2. At the conclusion of the second paper, Professor Dunstan, with the aid of Mr. Carr, performed some of the experiments described.

Mr. JOHN C. UMNEY asked if there was any connection between the two alkaloids as the result of the benzoyl group in the cocaine and in the aconitine, and was there a benzoyl group in hydrastine?

Mr. GERRARD said any man who discovered and published a distinctive test for aconitine would do a great service to toxicology, and he should like to know if Professor Dunstan felt positively assured that this, if taken alone, was such a test. He also asked if he had made comparative experiments with other alkaloids, such as that obtained from the root of *Veratrum viride*, because he thought experiments of that kind could scarcely be considered

complete unless alkaloids of that class were considered which possessed characteristics so closely allied to those displayed by the alkaloids of aconite. It was interesting to know that the permanganate of aconitine was of a different colour, and possessed different physical characteristics to those of some of the other alkaloids, especially solubility in water, but he could not yet feel quite satisfied that one could distinguish definitely between the alkaloids of aconite and those of other bases by the test described.

Mr. MARTINDALE regretted that there had not yet been discovered any means of distinguishing aconitine by a rough and ready method from any other alkaloid, and estimating from the acetic or benzoic acid the amount of true aconite present. However, it was more convenient to get something you could see and weigh, and that seemed to have been accomplished. He did not quite gather whether, when the permanganate was formed in the way described, it could be separated and carefully weighed.

Professor DUNSTAN said no; it was merely a qualitative reaction, not a quantitative test.

Mr. MARTINDALE said the same thing occurred with regard to cocaine; he had tried several experiments, and found that even in solution it decomposed and passed off rapidly.

Professor ATTFIELD remarked that this paper was not only interesting from a toxicological point of view, but still more from a pharmaceutical. He could but sympathise with the authors in their failure to discover a method for quantitatively estimating aconitine in its various preparations, but he was not disposed to be quite so despondent as Professor Dunstan himself, because he hoped that the skill which some years ago enabled him to obtain strychnine separately from the alkaloids of nux vomica, would in time enable him to devise a process for separating and estimating aconitine from the other alkaloids in aconite. He entirely agreed with the remark as to the comparative uselessness of estimating the total alkaloids; for certain purposes no doubt it might be useful, but until they could separate the aconitine, processes for the assay of aconite would be comparatively useless. He congratulated the authors on their courage in attacking this subject, because aconite was shown to be the most difficult of all alkaloid-containing drugs, for in nearly every other case the total alkaloids at least could be separated, and even that had not yet been done with aconite. In his capacity as Editor of the *Pharmacopœia*, he could not help noticing that while there was hope at least of obtaining good assay processes for the respective alkaloidal drugs, there seemed to be no hope whatever of doing so with aconite; but he really felt now that even that was within measurable distance. This was a fitting opportunity to draw the attention of those working in this direction to the important fact that while they could fairly well estimate the total alkaloids in many instances, they were quite unable in the majority of cases to isolate the special characteristic alkaloid, and that there were many objections to the official recognition of processes for the total alkaloids excepting in just a tentative way. The effort should be to isolate the chief active principle, as Professor Dunstan had done in the case of strychnine.

Mr. JOWETT thought the discovery of this test for the detection of the alkaloid should draw attention to the value of true research work. Both the test for the detection of aconitine and also the attempt, unsuccessful so far, to estimate the quantity by estimating the acetic acid, sprang from work proceeding on the line of true research, not work initiated with those special objects, but simply the search for truth. Whether working on aconitine or any other alkaloid, if they proceeded in the same spirit, simply seeking to discover the truth, they were certain in the end not only to find a means for detecting the alkaloid, but also a method for estimating it.

Professor DUNSTAN, in reply, said nothing could be said definitely at present as to the influence of the benzoyl group. Every group present in the alkaloid must have some effect in determining its properties, and to that extent no doubt the benzoyl group had something to do with the formation of the precipitate, but whether it had more than a slight subsidiary effect it was impossible to say at present, as they knew next to nothing about the central nucleus of the alkaloid. Mr. Gerrard's question almost implied proving a universal negative, and it was practically impossible to try every alkaloid, but as stated in the paper they had tried the most important; veratrine behaved in an entirely different manner, cocaine, papaverine, and hydrastine were the only important alkaloids which were precipitated by permanganate under the same conditions, and in those three cases they showed how a distinction might be arrived at. Mr. Martindale referred to the

quantitative application of the method. The difficulty was not so much that the permanganate of aconitine suffered decomposition on drying, as that it was not completely precipitated. A number of experiments were made in the hope of finding some particular condition in which the whole of the aconitine would be precipitated as permanganate when there was a slight excess of acetic acid, but a slight amount still remained undissolved. With regard to Professor Attfield's remarks, he ought to make it clear that it was quite easy to determine the total alkaloids, but it was absolutely useless, as he had indicated; much more so than in the case of nux vomica to determine the percentage of strychnine and brucine together. Brucine had in some respects a similar action to strychnine, but in the case of aconite, as far as he could make out, nothing but the aconitine was of the slightest value, and therefore the determination of the total alkaloids would be entirely misleading. Still, it could be done, if desired; it was merely a question of extraction with chloroform. Mr. Jowett's remark was important. They were not likely to reach the practical conclusions desired if they aimed directly at them. It was very unlikely, if they had set out to search for a method of detecting aconitine, and taken a year in trying the reactions of various salts, that they would have noticed this reaction. They would probably have referred to previous work, and have been prejudiced by the fact that permanganate of potash did not seem to be a likely agent to succeed. As a matter of fact, when this reaction was noticed, they were engaged on a totally different line of inquiry, studying the oxidation products of the alkaloid, and in the course of that work this interesting matter cropped up. They did not claim that this test could absolutely be relied on alone, and personally he should not consider it right to hang a man on the evidence of any one test. A number of different reactions must be taken into account, the production of acetic acid and the behaviour of the alkaloid in other ways. No one test could be relied on as absolutely conclusive.

The PRESIDENT, in proposing a vote of thanks to the authors of these papers, said he quite concurred in the remarks which had been made as to the true spirit of research. Pharmacy was founded upon certain sciences, and true research in pharmacy, if it were to produce results which would stand the test of time, must be conducted on purely scientific lines, and that could only be done by prolonged study, attacking things systematically. That process was slow and costly, and if the Pharmaceutical Society could not afford to do it, it must give it up; but it could not be done in any other way. The word "research" was often used in such a loose way that it was necessary to make a protest. When a man obtained a certain reaction by accident, you could not call that research. An average laboratory boy could obtain any number of reactions, and probably, if he were kept long enough at it, and the results were noted, and he were supervised from time to time, he might achieve something in the end. But in dealing with such subjects as the alkaloids in aconite root they must be attacked entirely from the chemical side first, and then in due time the knowledge obtained would be turned to practical account. Research in pharmacy pure and simple was hardly practicable; it must be in the domain of the sciences on which pharmacy was based.

PEPPERMINT OILS.

Mr. JOHN UMNEY then read a paper on "The Essential Oils of Black and White Peppermint." It is printed at p. 123, and gave rise to the following discussion:—

Mr. MILLARD said he had suggested at a recent meeting of the Chemists' Assistants Association, bearing in mind that attar of roses varied very greatly according to the different altitudes at which the plant was grown, that possibly these two varieties so well known at Mitcham should vary also. What they required to know most of all, however, was how to distinguish foreign from English oil of peppermint, as this oil was very largely adulterated with foreign oil. He hoped Mr. Umney would enable them to clear away this ignorance.

Mr. MARTINDALE said he was surprised to find that there was so much more black peppermint cultivated than white, and should like to know what was the case in America.

Mr. McEWAN said when he was in Chicago he had a conversation with Mr. Todd, of Calmazon, who told him that some years ago he had a large number of white peppermint seedlings sent him from this country, and at that time—viz., in 1893—he had several hundred growing in Michigan. He had been mainly interested in the subject from the scientific side, having heard a

great deal of the superiority of the Mitcham variety of peppermint he wished to satisfy himself on that point, and he told him that the oil was undoubtedly superior. He should like to know if Mr. Umney had discovered that any of this white peppermint was grown in America, because it would be interesting to know if the transplantation to that country caused any difference in the chemical constitution.

Mr. HOLMES said that from a botanical point of view there were several interesting points in this paper. With regard to black peppermint not flowering, he might say that that grown in his garden flowered every year. It often happened that plants cultivated to a large extent, which were cut down before they flowered, after a time ceased to flower. That was the case with the rhubarb cultivated at Banbury, where, he was told, that it was the rarest thing to see a plant in bloom. Perhaps the peppermint being generally cut before it was thoroughly in flower would produce the habit of ceasing to flower regularly. With regard to the green peppermint, as had been pointed out, there was no botanical difference, and no distinctive characteristics by which it could be classed as a separate species, and yet different chemical results were obtained from the two varieties, certain substances being formed in a much larger degree in one than in the other. The same thing occurred with *Mentha arvensis*; when grown in this country it had a disagreeable odour, and in America the plants had to be removed entirely from the fields in which peppermint grew on that account; the same species in Ceylon had the odour of common garden mint, and in Japan oil of peppermint was distilled from the same species. He had no knowledge as to which plant was cultivated in America, but he had a specimen of black peppermint which he had received from Dr. Rusby, so that that variety must be grown there. Mr. Umney had made it quite clear that the oil of green peppermint was superior to the black, and that being so it would appear that it is to be preferred for medicinal use.

Mr. JOHN MOSS said it had been known to him for twenty years or more that oil of black peppermint was produced in much larger quantity than white, one reason no doubt being that the proportion of oil yielded by white plants was much smaller, and it was of course more costly. It was more esteemed on account of its more delicate flavour, and he held was only used in high-class confectionery. It was a very important observation that the difference in odour was due to the different proportion of menthol in the two oils, in combination as esters. From that point probably further work would proceed, and chemists would be endeavouring to promote the combination of menthol into ester compounds so as to produce the more highly esteemed kind of oil from that now obtained from the black peppermint.

Mr. J. C. UMNEY, in reply, said he was not aware of any difference in the case of peppermint arising from the altitude at which it was grown. In the case of oil of lavender there was a most marked difference, the proportion of esters in oil distilled from plants grown at an altitude of 4000 feet being from 39 to 41 per cent., at 2000 feet, 31 or 32 per cent., and at 1000 feet, 15 or 16 per cent. His attention had been called to the point mentioned by Mr. Martindale by the results now described. The majority of American peppermint, at any rate the best, contained 12 to 14 per cent. of esters of menthol, which was practically the same as the white oil contained. He had written to some of the principal distillers in the States to ask whether they produced their oil from black or white peppermint. The best American gave the same reaction with glacial acetic acid as the white, but whether it was derived from the white peppermint or the black which had been altered by cultivation in a different climate he did not know. He had been trying some experiments with the object of promoting the formation of esters in black peppermint oil, and if he succeeded he would submit the results to Mr. Moss.

The PRESIDENT, in proposing a vote of thanks to Mr. Umney, said some pharmacists appreciated the merits of white peppermint oil quite as much as high-class confectioners. If Mr. Umney lived long enough he would probably be able to produce the white oil artificially in the laboratory.

FERRIPYRIN IN DENTAL OPERATIONS.—Frohmann, of Berlin, states that ferripyridin is an excellent hæmostatic in the treatment of alveolar hæmorrhage. It also possesses analgesic as well as hæmostatic properties, and is said to materially assist in allaying the pain which sometimes follows the extraction of teeth (*Journ. Brit. Dent. Assoc.*, xvi., 719).

BRITISH AND FOREIGN SYRUPS.*

BY JOSEPH INCE,

Lecturer in Pharmacy to the Pharmaceutical Society of Great Britain.

DEFINITIONS: A syrup is a preparation of sugar and water; simple, as in syrupus; medicated, of which syrupus papaveris is an example; or chemical, as instanced in syrupus ferri phosphatis.

Dr. Paris: Pharmacologia. [Syrups] are solutions of sugar in water, watery infusions, or in vegetable juices.

Remington: Syrups are concentrated solutions of sugar in water or aqueous liquids; simple, medicated, or flavoured.

Paris Codex: Les sirops sont des médicaments liquides ayant une consistance visqueuse, qu'ils doivent à une forte proportion de sucre.

Dorvault: Les sirops sont des liquides de consistance visqueuse, formés par une solution concentrée de sucre dans de l'eau, du vin, du vinaigre, soit purs, soit chargés de principes médicamenteux.

A few have little claim to official recognition, being flavouring adjuncts to various medicinal compounds, or colouring agents, as syrupus croci.

This last has enjoyed a fitful existence in official pharmacy, its presence being as fugacious as its colour.

It is no longer British; as an official preparation, the French macerate the saffron in Malaga wine or in vin de grenache (15 per cent. alcohol); the Germans do the same, using 18 ozs. of sugar to 11 ozs. of filtered liquid.

The British official syrups [1885] are seventeen in number, and one was added in 1890.

Official British Syrups.

1885. [1890.]

Syrupus. Sp. gr. 1.330.

Derivatives.

Syrupus Aurantii. Sp. gr. 1.282. Tinct. Aurant., 1. Syrup. 7.
Syrupus Chloral, in aquâ solutus. Sp. gr. 1.320. Strength, 10 grains in 1 fluid drachm.

Syrupus Zingiberis. Tinct. Zingib. fort., ʒvi. Syrup. ʒxix.

Not Classified.

Syrupus Aurantii Floris. Sp. gr. 1.330.

Orange-flower water, added last.

Syrupus Scillæ. Sp. gr. 1.345. [Acetum Scillæ.]

Syrupus Tolutanus. Sp. gr. 1.330. Stirring essential. Heat applied at 212° F. (100° C.)

Syrupus Limonis. Sp. gr. 1.340. Cortex, Succus.

Syrupus Mori. Sp. gr. 1.330. Succus.

Syrupus Rosæ Gallicæ. Sp. gr. 1.335. Rosarum petala.

Syrupus Tolutanus. Balsamum Tolutanum.

Syrups containing Rectified Spirit.

Syrupus Mori. Preservative.

Syrupus Papaveris. Sp. gr. 1.330; to aid filtration.
Spirit recovered by distillation.

Syrupus Rhei. Sp. gr. 1.310. Fructus Coriandri.
Percolation [Sp. v. Rect., 1; Aq. Dest., 3].

Syrupus Rhœados. Sp. gr. 1.330. Preservative.

Syrupus Sennæ. Sp. gr. 1.310. Oleum Coriandri. To aid filtration; also preservative. Spirit not recovered.

Syrups in which Infusions are used.

Syrupi Hemidesmi, Papaveris, Rhœados (stirring essential), Rosæ Gallicæ, Sennæ (digested at 120° F. [48° C.]).

Chemical.

Syrupus Ferri Subchloridi. Sp. gr. 1.340. [1890.]

„ Ferri Iodidi. Sp. gr. 1.385, 1.400 (Umney).

„ Ferri Phosphatis. Sp. gr. 1.305.

* Read before the Chemists' Assistants' Association, February 6, 1896.

The Paris Codex of 1839 contained 112; that of 1866 115; while that of 1884 contains 104.

Other foreign pharmacopœias limit this class of remedies. In the Pharmacopœa Germanica, Editio Altera, 1882, and in the Translation by C. L. Lochman, 1884, there are only 20 syrups, being a diminution from 1872, when the number was 29.

The subject was first brought before the notice of the Pharmaceutical Society by Mr. John Savory, during the Presidency of William Allen.

His paper was a running commentary on methods of preparation officially adopted here and abroad, somewhat to the disparagement of the former, with suggestions for amended processes. Many of these recommendations have been superseded, but attention may be directed to his note on Syrupus Tolutanus, to which reference will be made hereafter. The type of this class of preparations is—

Syrupus Simplex.

The B.P. formula is—

Refined sugar 5 pounds.
Distilled water 2 pints.

Dissolve the sugar with the aid of heat, and subsequently make up the weight of the product to seven pounds and a half. Sp. gr., 1.330.

A syrup, which is a preparation of sugar and water, having the above specific gravity, that sp. gr. depending on the relative proportions of sugar and water, does not retain the sugar permanently in solution.

Where this fact is disregarded, the sugar deposits in a crystalline condition. In the so-called chemical syrups the salt or salts do not of themselves precipitate, but are mechanically carried down, and thus precipitated by the sugar in excess, which deposits in a more or less crystalline form due to the acid which the formula may contain.

Mr. Ekin (August 7, 1874) confirms this: "I have found that the acid solution of the precipitated phosphates will keep for years without the sugar." Mr. Umney (same date): "I can quite corroborate what Mr. Ekin has said, for I have for years made a solution of phosphate of iron, which I have found to keep very well."

So also Professor Redwood, in the original discussion [1842], observed "that it was quite as important to avoid adding too much sugar as the reverse, for that when crystallisation commenced, it did not cease at the point of saturation, and hence a hot syrup, in which a greater quantity of sugar is dissolved than it is capable of holding in solution when cold, becomes ultimately much weaker than it would have been if less sugar had been added at first."

Contrast for a moment syrupus simplex with the construction of the two syrups, syrupus rhei and syrupus sennæ, both from the nature of their ingredients prone to deposition of sugar. One is a percolate; both contain coriander, which with advantage might be oleum coriandri in both instances, and both keep well.

Final stage—Syrupus Rhei. B.P. 1885.

Evaporated liquid..... $\bar{z}xv$.
Sugar 24 ounces [only].
Sp. gr. about 1.310.

Final stage—Syrupus Sennæ. B.P. 1885.

Evaporated liquid..... $\bar{z}xvj$.
Sugar 24 ounces [only].
Sp. gr. about 1.310.

It will be convenient here to turn to the tabulated diagram of Professor Oldberg showing the relation of solutions of sugar and water to bulk, and specific gravity. This has been copied by others, doubling the figures:—

Sugar.	Water.	Bulk.	Sp. gr.
Ounces.	Fl. ozs.	Fl. ozs.	Result.
16	12	22½	1.273
16	10	20½	1.298
*16	8	18½	1.330
14	8	17½	1.311
12	8	16	1.290
10	8	14½	1.264
8	8	13¼	1.231

The third on the list, marked by an asterisk [*], represents syrupus of the British Pharmacopœia.

Let us see what is the Continental practice with regard to a preparation which is typical of the rest.

The Paris Codex of 1839 (my first introduction to pharmacy) ordered syrupus to be made with sugar and water in the proportion of two to one, but to be dissolved cold, and after twelve hours' contact to be filtered through animal charcoal. The sp. gr. was 1.320.

Next came the Codex of 1866, which was issued under the personal direction of many distinguished professors and members connected with the Faculty of Medicine and the School of Pharmacy. The preface was written by Jean Baptiste Dumas.

There were two forms of simple syrup, namely:—

Sirop de Sucre Incolore.
Syrupus Sacchari.

White sugar 1000
Water 525

a cold preparation, subsequently filtered; it is to the relative proportion of sugar and water to which I wish to draw attention.

The other was prepared by heat, and clarified by the use of albuminised water.

The albuminised formula has disappeared, and in the Codex of 1884, édition corrigée, we get the following:—

Sirop de Sucre.
Sirop Simple.

Sacchari Albi 1700 grammes.
Aquæ Destillatæ 1000 grammes.

Break the sugar in small pieces; add to the water; raise to the boiling point; strain or filter.

Syrup, when boiling, marks 1.26.
Sirop de Sucre à froid.

Sacchari Albi 1800 grammes.
Aquæ Destillatæ 1000 grammes.
Dissolve cold, filter marks 1.32.

German pharmacy carries out the same idea. The Pharmacopœa Germanica, 1846, gives this formula:—

Syrupus Simplex.

Sacchari optimi 36 ozs.

Dissolve in—
Aquæ Destillatæ..... 20 ozs. (weight).

Ut fiat syrupus. Sit coloris expers.

The sugar is described as sit albissimum et siccum. Pharmacopœa Germanica, 1882-1884.

Syrupus Simplex.

Sugar 60
Water..... 40 (weight),

to produce finally 100 parts of syrup; filter when cold. The formula in the Pharmacopœa Austriaca, 1889, is—

Sacchari contusi 400
Aquæ destillatæ..... 250

Syrupus cilicio coletur antequam sit refrigeratus. Cilicium is a woollen strainer, the syrup to be strained while hot.

In the U.S.P. (1893) there are thirty-two official syrups. Remington: "Four are made by solution with heat, fourteen by simple addition of medicating liquid to syrup, thirteen by agitation of the sugar with the medicating liquid without heat, and one by maceration or digestion."

Syrupus U.S.

Sugar in coarse powder..... 850 grammes.
Distilled water, sufficient to make 1000 C.c.

Dissolve the sugar with the aid of heat in 450 C.c. of distilled water, raise to the boiling point; strain and pass enough distilled water through strainer to make the product, when cold, measure 1000 C.c. An alternative method is by percolation. Sp. gr. 1.317. W. A. H. Naylor, in a concluding paper on Constructive Criticism, which ended the series so admirably inaugurated in the *Chemist and Druggist* by P. W. Squire, said: "As a general remark, it may be observed that the specific gravities of the syrups of the Pharmacopœia are unnecessarily high. The density might be reduced without any corresponding disadvantage to 1.320. These illustrations will show that the specific gravity of 1.330 has not been universally adopted.

In order to prevent deposition, certain special and selected sugars have been recommended.

It is desirable in the general interests of pharmacy, that the formula for syrupus should be so constructed as that white sugar, as commonly met with in honourable commercial manufacture, should meet the requirements of the pharmacist.

German pharmacy it has been seen, insists that the sugar should be very white and dry.

Remington, that it should be pure and not artificially blued by ultramarine; that it should answer pharmacopœial tests, and, moreover, that in accordance with the U.S.P. it should be dry, because the permanency of syrups largely depends on their containing the correct proportion of sugar and water.

Dr. Paris, in the *Pharmacologia*, states that sugar, perfectly free from the extractive matter with which it exists in combination in nature, and which constitutes that compound to which the name of Sweet Principle has been given, will not, however diluted, undergo any kind of fermentation, for it is to the presence of this peculiar extractive matter, the natural leaven of fruits, that enables it to undergo that process.

The syrup of iodide of iron has a literature of its own. It was introduced as a therapeutical agent to British practitioners by Dr. Anthony Todd Thomson.

Finding that the solid salt was an unsatisfactory preparation, he made a solution containing 3 grains to a drachm, and by the suggestion of Mr. Peter Squire, inserted a coil of clean iron wire, as a means of preservation. Subsequently he made a strong solution by boiling iron and iodine in water; this was filtered, evaporated to two-thirds, and converted into a thick syrup by the addition of sugar, dissolved by a gentle heat. The syrup as prepared in December, 1840, was exhibited in a perfectly limpid state on July 7, 1841.

Mr. Henry Scholefield, at a later date, commented on Thomson's method, suggesting a much larger quantity of iron than is actually necessary, and that the mixture should not, in the first instance, be raised to the boiling point. His formula gave a syrup containing 3 grains of anhydrous iodide to the fluid drachm, and from that day to this the syrup has engaged the attention of practical pharmacists.

Mr. Richard Phillips, jun., maintained that the change in the syrup was the formation of hydriodic acid resulting from the decomposition of the water, iodide of iron being hydrated and containing one atom of iodide and five atoms of water; the oxygen of

the water combined with the iron to form protoxide, which latter, gaining oxygen from the air, became peroxide.

He remarked also, that if a solution of a per- or proto-chloride of iron be mixed with syrup, no precipitation takes place on the addition of ammonia, a fact of considerable service in dispensing.

In process of time, by exposure to the air, the hydriodic acid becomes decomposed, yielding iodine, and the iron protoxide is peroxidised, the latter still being held in solution by the syrup.

Mr. Walter Hemingway made a solution of iodide of iron (grs. xxx. to fl. ʒj.) by agitation in a mortar without heat; this was mixed with simple syrup, 15 fluid ounces of which had been reduced 2 ounces avoirdupois by gentle ebullition. Each fluid drachm contained 4 grains of crystallised iodide, the equivalent of rather more than 3 grains of the dry.

Messrs. T. and H. Smith made a solution of iodide in a flask with cold water and agitation. When the action was finished, the solution was boiled until the brown colour disappeared. This was filtered into a graduated bottle containing sugar broken into small pieces; boiling water was added till the liquid reached the level of the mark previously arranged.

Solution was effected in a hot water bath, the required level of the syrup was adjusted, and finally the syrup was bottled in small phials.

The original Edinburgh strength was five grains in one fluid drachm, and this was altered in accordance with Thomson's recommendation to 3 grains in 1 fluid drachm. This method commends itself for effective simplicity. We turn now to the impossible formula of the British Pharmacopœia of 1885. A concentrated syrup is first to be made by dissolving 28 ounces of refined sugar in 10 ounces of the water with the aid of a little heat, the result being a crystallised saccharin paste. The remaining 3 ounces of water are used to form the iodide solution, heating slightly with occasional agitation. Add now 2 fluid ounces of the syrup and boil gently for ten minutes. The problem is to find these 2 fluid ounces; which leads to a second, how to filter the result obtained from ten minutes' additional boiling. "Then filter the liquid while still hot into the remainder of the warm syrup, and mix."

The official strength is 4.3 of iodide of iron in 1 fluid drachm. Total: a congealed, dark-coloured mass which should be sent out in a wide-mouthed stoppered bottle. To my great satisfaction, I find since this was written, that Mr. Charles Umney comes to the same conclusion. He states that the specific gravity is 1.400, and not 1.385. After a few days the sides of the bottle are studded with crystals as large as those of sulphate of sodium. The upper part of the liquid is tinged with free iodine. Mr. Umney would amend the formula by making the product weigh, when cold, 2 lb. 11 $\frac{3}{4}$ ozs.; the present writer would suggest the better amendment of cancelling the arrangement.

The formula of the U.S.P. contains by weight about 10 per cent. of iodide of iron. Iron wire, 25 grammes in a flask of the capacity of 500 C.c.; distilled water, 150 C.c. added, and afterwards iodine, 83 grammes.

Now mark what comes next: "Shake the mixture occasionally, and when the solution has acquired a greenish colour, and has lost the odour of iodine, heat it to boiling." Filter rapidly, the point of the funnel dipping below the surface of 600 grammes of syrup contained in a tared vessel. Wash the flask and filter with a mixture of 25 C.c. each of syrup and distilled water heated to near 100°C., withdraw the funnel and make up with syrup till the product weighs 1000 grammes. Sp. Gr. about 1.353 at 15°C. (59°F.) as compared with 1.385 B.P.

(To be continued.)

PUBLIC COMPANIES AND THE IRISH PHARMACY ACT.

A DECISION was given in the Queen's Bench Division, Dublin, on Monday last, which has the effect of placing corporations in Ireland on the same footing as in Great Britain with regard to restrictions imposed by pharmaceutical legislation. In the original case, the firm of ALEXANDER BOYD and Company, Limited, of Lisburn, was charged with infringing the provisions of the Pharmacy Act (Ireland) by compounding medical prescriptions, the members of the firm not being legally qualified to do so. For the defence it was contended that a limited company is not a "person" within the meaning of the Act, and it was, moreover, shown that the medical department of the firm's business is conducted by a pharmaceutical chemist duly qualified and registered under the Pharmacy Act (Ireland). The Justices dismissed the summons, but stated a case for a higher court, and the appeal was heard by Justices O'BRIEN, JOHNSON, and HOLMES.

Counsel for the Pharmaceutical Society of Ireland contended that the word "person," in the section under which the prosecution was brought, includes limited companies like that proceeded against, because it contains a prohibition addressed to everyone, while the Interpretation Act of 1889 provides that on the construction of every enactment relating to an offence punishable on indictment or by summary conviction, the expression "person" shall include a body corporate, unless the contrary appears to be indicated. On the other side, the decision of the House of Lords in the case of the Pharmaceutical Society of Great Britain *v.* The London and Provincial Supply Company was relied upon, and it was argued that the whole tenor of the Irish Act indicates that it is applicable to individuals only. Further, it was contended that if the appeal were successful, great diversity would be introduced between the law in Ireland and that in Great Britain, whilst a large number of established businesses would be interfered with.

In giving judgment, Mr. Justice O'BRIEN said that all the members of the Court agreed in upholding the decision of the magistrates. They held that Section 30 of the Pharmacy Act (Ireland), 1875, combines Sections 1 and 15 of the English Act

of 1868, and that whatever the views of the Legislature may have been, the words of both enactments admit of no ambiguity. Both must be regarded as relating to the same subject matter and receive the same interpretation. If the Interpretation Act had been intended to apply in such a case as that before the Court, the object was capable of being attained, and should have been attained, by the use of language different from that actually employed. The law says that no person shall be entitled to compound medicines unless he is a qualified and registered pharmaceutical chemist, implying that the person to whom the penal provision applies is an individual capable of qualifying himself under the Act. A corporation, however, could not be meant by that description, and no person reading the Act could arrive at any other conclusion than that a corporation never was intended to be referred to. Consequently, penalties could not be recovered from a corporation under the Act as it stood.

MEDICINE AND PHARMACY IN KASHMIR.

AN important work on Kashmir has recently been published, in which the author, Mr. W. R. LAWRENCE, I.C.S., C.I.E., Settlement Commissioner, Kashmir and Jammu State, gives much interesting information regarding native drugs, etc. The *Cannabis indica* (Bhang) grows in great profusion along the banks of the Jhelum and the Vishau, and it has been the custom to reserve the land on the river banks for the growth of this plant, for a distance of fifteen yards on either side. The right to collect the products of the hemp plant formerly yielded as much as Rs. 25,000, but for the last five years the revenue has averaged Rs. 6,200 only. The Kashmiris usually speak of the drug manufactured from the hemp plant as "charras," but "ganja" is procurable in Srinagar, the annual production of the latter being 70 maunds, whilst some 400 maunds of hemp fibre is collected every year in that district, and 600 maunds in the country below Srinagar. The leaves of the hemp plant are not used locally for smoking or drinking purposes, but a preparation called "majun" is eaten to some extent. A very common plant in Kashmir, "tetwan," is a species of *Artemisia*. The leaves of this yield a preparation known as "ibsantin," a name probably derived through the Arabic from the Greek *absintha*. The fresh plant of *Narhex asafetida* is used for cooking purposes in Astor, but the asafetida of commerce does not appear to be manufactured there.

Medicinal properties are said to be attributed to every plant by the hakims of Kashmir, the native physicians. The more common medicinal herbs are *Aconitum heterophyllum* (Patis or Nar-Mada), *Hyoscyamus niger* (Bagar bhang), *Macrotomia benthami* (Gao zaban), *Viola serpens* (Banafsha), *Artemisia*, sp. (Tetwan), *Peganum harmala* (Isband), *Euphorbia thomsoniana* (Hirbi), *Pichorhiza kurrooa* (Chob-i-kor), *Berberis lycium* (Kaodach), *Senecio jacquemontiana* (Khalar), *Salvia*, sp. (Sholra). *Podophyllum emodi*, *Colchicum luteum*, and *Atropa belladonna* are common, but not used medicinally. A long list is also given of other indigenous medicines, the botanical sources of most of which have not yet been identified. In addition to *Hyoscyamus niger*, the following poisonous plants were noted:—*Impatiens roylei* (Trul), *Aconitum napellus* (Mohundguji), *Datura stramonium* (Datur), *Atropa lutescens*, and *Rhus acuminata* (Arkhor).

The seeds of *Datura stramonium* are largely exported. The root of *Saussurea lappa* (Chob-i-kot) has a scent like orris, with a slight blend of violets, and possesses a commercial value, its sale being a State monopoly, whilst the leaves of *Macrotomia benthami*, and the leaves and seeds of *Hyoscyamus niger* are also marketable commodities. Violets are collected, and the seeds of the quince (Bihdana) are exported in large quantities to the Punjab. The flowers of *Salix caprea* (Bed mushk) yield an essential oil used in perfumery, and the roses of Kashmir were formerly used for the production of attar, the roses and willows having yielded a revenue of one lakh of rupees in the Mughal times. The value of the drugs exported from Kashmir during 1891-92 was Rs. 4,07,969, but in 1892-93, Rs. 1,60,625 only. Medicine and midwifery give occupation to 738 workers and dependants in Srinagar, which is the twenty-second in order of magnitude among the towns of India, occupying an area of 3795 acres, and containing a population of 139,410 persons. The chemists and druggists number 557. Most occupations seem to have been directly taxed at one time, and during 1871-72 the amount collected from leech sellers and dealers in medicine was 913 Chilki rupees, each equal to ten annas. However, these direct taxes on shops and artificers have now disappeared.

SECONDARY PHARMACEUTICAL EDUCATION.

THE BURROUGHS' Memorial Scholarship constitutes a not unimportant addition to the facilities afforded to British pharmaceutical students, who wish to extend their scientific training beyond what is strictly necessary for the due performance of their professional duties as pharmacists. For many years the JACOB BELL Memorial Scholarships were the only pharmaceutical scholarships that existed in this country, and the funds available in connection therewith have always been devoted exclusively to primary technical education. The REDWOOD Scholarship was founded on similar lines, but has since been diverted to the purposes of secondary education, and the Manchester Pharmaceutical Association Scholarship funds have been similarly employed, for, although intended for elementary students, no candidate has as yet been successful in gaining the Scholarship. The Burroughs' Memorial Scholarship is likewise intended to encourage the extension of secondary education, and will, on account of its pecuniary value, be the most important in that connection. It is gratifying to observe that so many friends of pharmacy, whilst anxious to perpetuate the memory of deceased masters and friends, should find the best outlet for their sympathy with the work of the past in making fitting provision for elevating the position of the craft in the future.

PHARMACEUTICAL SOCIETY OF IRELAND.

THE new edition of the Calendar of the Pharmaceutical Society of Ireland has just been published in the usual form, and gives the customary particulars regarding membership, etc. The number of pharmaceutical chemists on the register at the end of last year was 501, members 175, chemists and druggists 306, registered druggists 379, associate druggists 78, and assistants to pharmaceutical chemists 12. Full information is also given respecting the Irish legal restrictions affecting pharmacy, pharmaceutical examinations, poison regulations, etc. The Calendar is published and sold by the Registrar, at 67, Mount Street, Dublin.

ANNOTATIONS.

THE JOURNAL OF THE AUSTRIAN APOTHEKER VEREIN.—Herr A. J. Sicha, the Editor of the journal, issued by the Austrian Pharmaceutical Society, under the designation of the *Zeitschrift*, reminds us that it is the oldest pharmaceutical journal published in the German language, having been commenced in 1846 by Professor Martin S. Ehrmann as a private undertaking in conjunction with Apotheker W. J. Sedlaczek, and continued by Josef Ehrmann and Franz Klueger up to 1882, when it became the official organ of the Austrian Society, and has been edited since 1886 by Herr Sicha. During the past fifty years the main object has been to advance the scientific position of pharmacy as an art, and to promote the material interests of those engaged in its exercise. In both respects the journal is very generally considered to have rendered much good service.

PHARMACY AND LAW.—The series of lawsuits mentioned last week (see p. 118) between M. MacAuliffe, pharmacist, of Paris, and his neighbour, Mme. Pouteau, have terminated in the Court of Appeal by the reversal of the judgments given in the Inferior Courts, and by the condemnation of Mme. Pouteau and her three witnesses (who were prosecuted for perjury at the instance of the pharmacist) to three years' imprisonment, and a fine of fifty francs in each case.

MALINGERING IN CHILDREN.—The *Lancet* recently pointed out how the children of Nasington—a village in Northamptonshire—go to work in order to avoid the toils of school. On account of the number of children who were kept from school because of a rash on their bodies, Dr. C. N. Elliott, the medical officer of health of that district, was asked to examine them with a view to finding out the nature of the strange disease. His report showed that the whole affair was a case of malingering. The children, about twenty-five in number, were suffering from no real disease, but in order to stay away from school they had rubbed their hands and arms with the juice of the plant called "Patty Spurge." The result of this was that a vesicular eruption appeared which, in most of the cases, resembled a herpetic eruption, but in some there were blisters as large as half-a-crown.

ECONOMIC BOTANY.—The November number of the *Kew Bulletin*, which has only been issued during the past month, contains interesting particulars regarding a number of economic products. Ai or Ngai camphor, which was described in the *Pharmaceutical Journal* many years ago ([3], iv., 710), is the subject of a communication from Dr. A. Henry, who gives an account of the process adopted for preparing the camphor. Information is also given respecting sumach, whilst it is stated on Sir Frederick Abel's authority that any increase in demand for camphor, involving a rise in price is not due to its application as a constituent of smokeless powder.

'INDEX KEWENSIS.'—It will probably surprise many botanists to learn, on the authority of the *Kew Bulletin*, that the 'Index Kewensis' is in no sense intended to be a standard of nomenclature, or to represent the views of Kew in the matter. It is stated to be nothing more than an index of published plant names, with references to the works in which they were first promulgated and the countries of which the plants are natives. No attempt has been made to ascertain the validity of the names cited. The whole expense of preparing the work has been defrayed by the family of the late Charles Darwin, but the Clarendon Press, Oxford, has borne that of printing and publication.

THE FORMULA OF HYDROGEN PEROXIDE.—Referring to the recent note in "The Month" (*ante*, p. 81) concerning Brühl's conclusion with regard to the constitution of hydrogen peroxide, Mr. C. T. Kingzett points out that his earlier investigations led him to the same conclusion—that hydrogen peroxide must be looked upon as containing tetratomic oxygen. In a paper communicated to the British Association in 1882 (*vide Chemical News*, xlvii., 120) he expounded the view that oxygen may behave either as a triad or tetrad, and he also suggested for hydrogen peroxide the formula now advocated by Brühl.

THE NEW REGISTER AND BOGUS REFERENCES.—A correspondent complains of the trouble caused by the use of bogus references by assistants requiring situations, and suggests that others who have suffered by the presentation of such would do well to consult the Register of Chemists and Druggists, so as to ascertain whether the person referred to is actually registered. Further, in case of doubt, the local secretary of the Pharmaceutical Society, in the place where the person referred to lives, should be written to. The list of local secretaries appears in the Society's Calendar, and most if not all of those whose names are given would gladly make the necessary inquiries. In one case instanced by our correspondent the individual whose name was given for reference proved to be an assistant, whilst in another the manager of a drug store gave a reference from his private address. There is little doubt that registered chemists would save themselves much trouble in this and other ways by more frequently referring to the Register and Calendar, new editions of which have just been published.

PRESENTATION AT THE SCHOOL OF PHARMACY.—An interesting event took place at the Pharmaceutical Society's House in London, on February 5, when a presentation was made to Mr. H. T. Durant on the occasion of his departure to take up the position of laboratory manager to Messrs. Loewenstein and Co., of Johannesburg. Mr. Durant has recently worked in the Research Laboratory, and also acted as lecture assistant to Professor Dunstan, his work being much appreciated by all with whom he came in contact during the performance of his duties. The students in the chemistry class gave evidence of their appreciation by presenting him with Mendelejeff's 'Principles of Chemistry,' and Frankland's 'Micro-Organisms in Water.' Professor Dunstan supplemented this with Bence Jones' 'Life of Faraday,' and the students in the Research Laboratory added a copy of Rose's 'Metallurgy of Gold.' Mr. Durant has left for his new position accompanied by the good wishes of many friends.

CURARE AS A PROPHYLACTIC TO STRYCHNINE.—M. Laborde has made some interesting experiments before the members of the Académie de Médecine, by which he demonstrated the utility of curare as a preventive of strychnine poisoning, as well as a cure. He administered a fatal dose of strychnine to two frogs, one of which had been previously injected with a solution of curare. On the one thus treated the strychnine had no effect, whilst the other succumbed. As an example of the inverse action, a similar dose of strychnine was given to another frog, and on the appearance of the tetanic symptoms an injection of curare was made, when the convulsions rapidly disappeared. M. Laborde stated that similar effects were produced on dogs and guinea-pigs, and that it was probable the same therapeutic action would be realised in the human subject. The curare extract used was prepared directly from the plant and diluted to a definite strength for accuracy of observation.

THE NEW PHOTOGRAPHIC DISCOVERY.—The January issue of the *Photographic Journal*, the official organ of the Royal Photographic Society, contains a *résumé* of the various papers which have been published dealing with Professor Röntgen's discovery, together with special articles on the subject by Mr. J. W. Gifford. It is illustrated with reproductions of the results obtained by that experimenter, as well as one by Messrs. Swinton and Stanton, of the living hand, showing the bones very clearly, nine of the new photographs in all being reproduced. The *Photographic Journal*, edited by Captain W. de W. Abney, C.B., D.C.L., is published by Harrison and Sons, Pall Mall, London, at 1s.

SHADOW PHOTOGRAPHY.—In repeating his lecture on Professor Röntgen's discovery (see *ante*, p. 115) on Monday, February 3, before the Liverpool Physical Society, Dr. Lodge referred to the erroneous impression that the effects produced were due to light, since light had to be totally excluded and prevented from having any action on the plate at all. He exhibited some fresh photographs of hands, living frogs, and a sole. These displayed the osteological structure very clearly. In concluding, Dr. Lodge stated that the opinion that these-called "x" rays were streams of electrically charged particles was now disproved, as it was found that negatively charged bodies are diselectrified by the rays. If the rays were of ultra-violet light, it was probable judging from their effects that their vibrations were as much more rapid than white light as that was more rapid than sound. However, he was inclined to think that they were longitudinal ether waves, and if that were proved to be the case there would be a new department of physics as large as any existing one.

RECENT PHOTOGRAPHY.—At a meeting just held of the Société de Médecine et Chirurgie de Bordeaux, Dr. Armaignac showed a very clear photographic proof which he had obtained by simply exposing to the light of a petroleum lamp furnished with a parabolic reflector, a negative in contact with a sensitised gelatin bromide plate, enclosed in an iron box. After three hours' exposure, the plate was developed in the usual manner, and gave a very distinct positive image of the negative. In his experiments with the light of a petroleum lamp, Dr. Armaignac observed (like M. Lebon) that two or three sheets of black paper entirely arrested the photogenic rays, whilst a sheet of iron permitted their easy transmission.

'SCIENCE PROGRESS' for February contains several matters of interest from a medical point of view. Dr. G. A. Buckmaster treats of the diagnostic and therapeutic use of mallein which, he considers, must consist of soluble bodies derived from the specific micro-organism of glanders, just as tuberculin consists of soluble bodies from the tubercle bacillus. Its use for therapeutic purposes appears useless, but it possesses considerable value as a means of diagnosis in glanders. A brief, but interesting, article on the suprarenal capsules is contributed by Professor W. D. Halliburton, and Dr. E. Starling deals with Pawlow's researches on the physiology of secretion. "Emancipation from Scientific Materialism," by Professor W. Ostwald, is, of course, philosophical in its nature, and correspondingly attractive. It concludes with the statement that science may never recognise bounds to her progress, and amidst the struggles for some new possession her eyes must not become blinded to the fact that beyond the territory she is striving to conquer still wider plains extend, which later must also be subdued.

PROCEEDINGS OF SOCIETIES.

CHEMICAL SOCIETY.—At the ordinary meeting held on February 6, Mr. A. G. Vernon Harcourt, President, took the chair, and the first paper read was by Professor Tilden, F.R.S., and R. E. Barnett, on "The Molecular Weight and Formula of Phosphoric Anhydride and of Metaphosphoric Acid."

Professor Tilden read the paper, and stated that most of the oxides of phosphorus had already been pretty well examined, the only one remaining was P_2O_5 , and he explained the difficulties to be encountered in the matter of manipulation. P_2O_5 sublimes without melting, and so we know nothing of its melting or boiling points. The authors doubt that the formula is P_2O_5 and not P_4O_{10} , hence the investigation. The formula P_2O_5 was based on Victor Meyer's P_2S_5 formula, but P_4S_6 has been shown not to be P_2S_3 , and $P_4O_6S_4$ has been shown not to be $P_2O_3S_2$. They think that P_2S_5 is probably dissociated, the formula likely being $P_4S_6S_4$ at the high temperature necessary for taking the vapour density. Metaphosphoric acid undergoes partial dissociation on being volatilised and is likely to be $H_2P_2O_6$ and not HPO_3 . The molecule of phosphorus seems to be an extremely stable structure.

In opening the discussion on this paper, the President mentioned that Professor Morley, of Ohio, was present, and invited him to make a few remarks. The Professor somewhat reluctantly acceded to the request, and the few words he spoke did not immediately concern the subject under consideration.

Professor Thorpe stated that he and a collaborator had had the volatility of phosphoric anhydride brought under their notice in trying to get phosphorous oxide. They found that the anhydride was easily volatilised, that glass was much attacked and corroded, and finally gave way. They had studied the action of sulphur on phosphorous oxide, hoping to get $P_2O_3S_3$, but without success. Phosphorous oxide and sulphur may be heated much together without any action taking place.

The President remarked that the vapour density of a body in the gaseous state at a high temperature did not indicate the molecular weight of the same body in the liquid or solid state at a lower temperature.

Professor Tilden, in the course of his reply, said that the vapour density is no criterion of molecular weight.

The next paper was on "Lead Tetracetate and the Plumbic Salts," by Dr. A. Hutchinson and W. Pollard. This was an attempt to prepare a series of tetra-salts of lead. Red lead treated with glacial acetic acid dissolves and forms a colourless solution. With dilute acid it is not all dissolved; a portion always remains undissolved. Jacquelin's salt is said to have the formula $PbO_2 \cdot 3(C_4H_4O_3)$, but the authors found it really had the composition $Pb(C_2H_3O_2)_4$. Little was known about the tetrachloride, and it was determined to see if it could be obtained by double decomposition. The salt was dissolved in glacial acetic acid, to which was added strong H_2SO_4 , and dry HCl driven through. They succeeded in this, and also in preparing a double salt by pouring a solution of the tetracetate into a solution of ammonium chloride, the compound thus formed having the formula $2NH_4PbCl_4$.

The tetracetate is crystalline. Its molecular weight, with solvent of glacial acetic acid and by freezing point method is 407.412; by boiling point method, 355.376. Real M.W., 443. Specific gravity of the salt—liquid, a saturated solution in glacial acetic acid—found to be 2.228.

The third paper was by Mr. A. H. Allen on "An Improved Method of Determining Urea by the Hypobromite Process."

It had been found that by the ordinary process not more than 92 per cent. of the total nitrogen could be obtained. This was thought to be due to the reversion of urea to cyanate of ammonium. Mr. Allen sought to anticipate or nullify this by adding potassium cyanate (as it had been found to retard such reversion) and reversing the order of procedure generally. In a suitable apparatus, devised by Mr. Allen for the purpose, the urea was placed in a lower bulb along with the alkaline solution and the potassium cyanate, and the bromine, which was placed in an upper separator bulb, run into it. By this means the nitrogen could be determined to a nicety—from 99.5 to 100 per cent. of the total.

A discussion arose between Mr. Allen and Mr. Fenton as to the respective merits of the hypobromite and the hypochlorite methods. The latter method, however, required from fifteen to forty minutes for its performance, whereas Mr. Allen, by his own improved method, could get a result in four or five minutes.

Professor Thorpe, in the discussion which followed, asked if the nitrogen evolved had been examined, as, at Lord Rayleigh's request, for an easy method of obtaining chemically pure nitrogen, he suggested decomposing urea by hypobromite solution. But the nitrogen obtained smelt like a dead rat, and could not be easily purified.

The last paper read was by Dr. Wilson Hake, "On the Absorption of Moisture by Deliquescent Salts." This note was briefly but severely criticised by several of those present.

The following papers were taken as read:—"An Examination of the Products Obtained by the Dry Distillation of Bran with Lime," by W. F. Laycock, Ph.D.; "Luteolin," by A. G. Perkin; "On γ -Phenoxyderivatives of Malonic Acid and Acetic Acid and Various Compounds Used in the Synthesis of These Acids," by W. H. Bentley, B.Sc., E. Haworth, B.Sc., and W. H. Perkin, jun., F.R.S.; "Note on the Preparation of Glycol," by E. Haworth, B.Sc., and W. H. Perkin, jun., F.R.S.

CHEMISTS' ASSISTANTS' ASSOCIATION.—At the meeting of this Association, held on Thursday, February 6, a paper on "British and Foreign Syrups" was read by Mr. Joseph Ince (see page 128).

In the discussion which followed, Mr. Hill remarked upon the samples of syrup of lemon shown, saying they were very elegant preparations. Mr. Elliott said that in order to procure samples of syrup of lemon he had sent to five different establishments, and three out of the five said they did not keep the B.P. article. He produced two samples prepared according to the official process, which were by no means elegant preparations. He suggested that the crystallisation was due to the conversion of sugar into grape sugar by fermentation set up by albuminous matter. With regard to syrup of squills, the B.P. gave sp. gr. 1.345. Prepared according to the official process it does not answer to that requirement, and, moreover, does not keep. It did not state in the B.P. what liquid was to be used in bringing it up to the required sp. gr. He presumed it was with acet. scillæ. He would suggest for the next B.P. that it should be made up to a definite weight. Mr. Jones thought this paper would be of incalculable service to the Committee of the B.P. in its work of revision. Commenting on the dark colour which developed in syr. ferri iodid., Mr. Brown, of the Bloomsbury Square School of Pharmacy, had shown that this was not due to free iodine, but some compound, the formula of which he gave, and which was published at the time. He did not see why in the case of syrup of lemon, citric acid should not be substituted for the fresh lemon juice; with this and soluble essences of lemon a nice preparation could be made. He agreed generally with the remarks which had been made by Mr. Ince. Mr. Strother asked Mr. Ince if he did not think the peculiarity of the names of French syrups were attributable to the desire to conceal from the patient the real nature of the medicine. Mr. Morley Taylor, referring to Mr. Ince's remarks on syr. croci, said he had not noticed so much that this preparation lost its colour, but he had found that gelatinisation took place. He had not experienced any difficulty in making small quantities of syr. ferri iodid. He remarked upon the rarity with which syr. ferri subchlor. was used. Mr. Guyer said the only time he had occasion to make it was at the examination. This was not even a stock article in some wholesale houses. Mr. Melhuish wished to know if Mr. Ince advocated the deletion of syr. chloral. from the B.P. altogether, or merely a reduction in strength.

Mr. Ince in replying to the various remarks commented on the two samples of syrup of lemon produced by Mr. Elliot. They were unsatisfactory, but he blamed the formula and not the pharmacist. Syr. scillæ should be made up with acet. scillæ he thought. The chief precaution in preparing syr. ferri iodid. was to avoid heat in the first part of the process. He could not explain the gelatinisation referred to by Mr. Morley Taylor; he thought it was attributable in a great measure to atmospheric conditions. Syrup. ferri subchlor. was a Scotch remedy rarely used in England. The deposit in syr. ferri phosph. was due to the precipitate being imperfectly washed. He would not advocate the deletion of syr. chloral. but a reduction of the strength—1.20, as in the Codex.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS ASSOCIATION.—At the monthly Committee meeting, held on the 4th inst., the delegates who had been appointed (Messrs. Geo. Breeze, F. Maitland, and Jas. Cocks) gave the result of their interview with

Messrs. Kearley and Morton, the Members of Parliament for Devonport. This was in every way satisfactory. Mr. Kearley seemed specially interested in the limited companies' question, which, he said, would in all probability be considered during the session. He hoped to take an active part in the matter, and would bear in mind the chemists' grievance, that unqualified persons were able at the present time to evade the Pharmacy Act by forming a limited company. The anomaly of the recent Poor Law regulations was also explained, and the difficulty the Pharmaceutical Council at present has in getting poisons, such as carbolic acid, etc., scheduled.

A unanimous vote of thanks was passed to Messrs. Evans, Gadd, and Co., of Exeter, for their valuable gift of 'Carpenter on the Microscope.' This was followed by the election of the following six new members: Messrs. Saver, S. H. Estlick, F. C. Osborne, W. P. Harris, A. T. Buckley, and G. H. Howells (Royal Naval Hospital). The Secretary also announced that Mr. O. A. Reade, of the Naval Hospital, author of 'Botany of the Bermudas,' had kindly consented to take the younger members for weekly botanical rambles during the summer months, on Wednesday afternoons.

The Secretaries of the late Ball Committee, Messrs. Maitland and Westcott, announced that they had a large balance in hand, the greater proportion of which they proposed to use for the benefit of the Association.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.—The members of the above Society were favoured on Wednesday evening with a lecture by Dr. H. C. Sorby, F.R.S., in which he gave the results of long and patient labours in mounting animals for use in lantern slides. The meeting was at the rooms of the Society in Surrey Street. Mr. J. F. Eardley, the President, occupied the chair, and there was a good attendance.

Dr. Sorby explained at the outset that he did not propose to deal with the life history of the animals that would come under notice, except to a very slight extent, but would mainly confine his remarks to certain questions more or less relating to chemistry and chemical methods. In microscopical studies the staining of portions of animals played a very important part, but Dr. Sorby said he had devoted his attention to staining entire animals, not for microscopical purposes so much as for use in lantern slides. For this purpose very different treatment was necessary, and it by no means followed that what was good staining for one purpose was suitable for another. His object was to bring out more distinctly important structural peculiarities on a comparatively large scale, which would be visible when shown on a screen as in an ordinary lantern slide.

The lecturer exhibited some of his early preparations of marine animals in order to show what wonderful improvement in preparing such specimens had been made in the course of the last few years. Specimens were exhibited showing the results obtained by using a great variety of staining materials; but, unfortunately, some of the newer results could not be shown, because the preparations were not sufficiently hard to stand the heat of the lantern. Dr. Sorby's latest researches had been with a view of obtaining the animals in a permanently mounted condition with the colouring which they possessed when alive. The natural colour in many cases was rapidly lost, and it was requisite to stain with some material which will give the true colour in a permanent condition. It was also necessary in some cases to stain different portions of the animal with different materials in order to imitate the true natural colour. Latterly Dr. Sorby said he had been trying a variety of experiments in order to ascertain the result of staining animals when alive in sea water, and a number of these were exhibited. It seemed probable that in some cases the animals absorbed the staining material in a different way when alive from what they did when dead. It was also found that after being kept for some time in alcohol, certain stains had no effect on the animal, and were not mordanted by any of the tissues, which readily coloured if tried shortly after being taken out of their natural sea water. Dr. Sorby stated that he is now employed on what might be regarded as the very reverse of the staining process, namely, removing certain natural pigments more or less diffused over the entire animal, and leaving other pigments not in any way faded where related to the structure of the specimen. None of these again could be shown, on account of the preparations not being yet in a fit condition for use. So far, Dr. Sorby said the main object he had in view had been attained—the exhibiting of lantern slides of the real animals, thus showing far more than it would be possible to do with a mere drawing. Altogether, about fifty specimens were thrown on the screen, and the perfection with which they had been coloured and mounted excited much surprise.

ROYAL PHOTOGRAPHIC SOCIETY.—The accommodation afforded by the lecture room at 12, Hanover Square proved quite inadequate for the large gathering which assembled on the 11th inst. to hear Mr. A. A. Campbell Swinton lecture on "The New Shadow Photography." The first portion of the proceedings was of the usual routine description associated with an annual meeting, but was rendered interesting to an outsider by the presentation of the Progress Medal, which had been awarded to Mr. Dalmayer of lens fame. Captain Abney, who occupied the chair in the absence of the President, complimented the recipient in a few well-chosen remarks, and then announced the result of the election of officers for the session, which showed that he had been selected for the presidential chair. Mr. Swinton next proceeded with his lecture. At the outset he demonstrated, with the aid of a Ruhmkorff coil capable of giving a 10-inch spark, how the size of the spark is directly dependent upon the electrical resistance of the surroundings, and for this purpose he rendered nearly vacuum an ordinary tube by means of a pump, the flame becoming gradually brighter and larger as the electrical resistance decreased. The nature of the spark was also demonstrated by means of tubes which had previously been made vacuum by means of a mercurial pump, and it may here be noted that the ordinary Geissler tubes will not answer the purpose, as a much higher vacuum is needed than they will stand. Proceeding, a distinction was made between the Geissler and Crookes' vacuum tubes, the luminescence of the former being attributed to the different kinds of glass used in making the tubes, whilst the vacuum power is low. On the other hand, that of the Crookes' tube is high, and the luminescence is due to the cathodic rays. In referring to the various hypotheses which have been advanced to account for the nature of Röntgen's rays, Mr. Swinton remarked that the belief that they were something of the nature of longitudinal waves as opposed to the transverse waves of light, was one which had gained many adherents amongst German scientists, although the late Professor von Helmholtz was opposed to it. A large number of striking experiments were then carried out in illustration of the properties of the cathodic rays. Thus, platinum in the shape of a cross enclosed in a Crookes' tube was connected to the terminals of the battery, and, at first, stands out in bold relief, and apparently black. After a short time, however, the glass gets fatigued, and if the platinum be dislodged from its position a white cross will be seen in the same place as that where the dark shadow of the platinum first appeared. The facility with which the rays could be deflected was also illustrated, and it was remarked that these considerations were strong arguments in favour of the rays being electrified particles of matter. It should be noted that after passing through glass they are entirely unaffected by the magnet, are incapable of refraction, and only slightly capable of reflection. The tubes used for the purpose of the experiments were of German manufacture, Mr. Swinton remarking *en passant* that he understood the reason why English glass-blowers could not overcome the difficulties of the work was that they used lead glass whilst their Teutonic competitors only used the soda and potash varieties.

Several articles were now handed from the audience to be photographed, and, whilst the plates were being developed, an attempt was made to photograph a hand which the owner said had been injured. Unfortunately, however, the latter was not a success, and could not be shown on the screen subsequently, but the other plates came out very well, amongst the objects shown being eye-glasses in case, the contents of a purse, pencils, magnifying-glasses, and a sovereign purse. It may be mentioned that in photographing these objects it was considered advisable to limit each exposure to fifteen seconds, allowing the same time to elapse before another exposure, so as to minimise the risk of fracture of the tube. Altogether, the miscellaneous articles were exposed for three minutes, and the hand for eight minutes. A large number of photographs were shown on the screen illustrating the application of this new phase of photography, a razor in its case, hands, feet, contents of a pocket, a frog, sections of resin, sulphur, sal ammoniac, as well as an aluminium cigar-case, in which the contents were shown, and in connection therewith Mr. Swinton remarked that the successful application of the discovery to medicine and surgery would be considerably discounted, unless means were taken which would enable the object to be photographed in a minute or two—five at the outside. He concluded by expressing his thanks to his assistants for the help received in the necessary work.

PHARMACEUTICAL SOCIETY OF IRELAND.—On Wednesday, the 5th inst., the monthly meeting of the Council of this Society was held at 67, Lower Mount Street, Dublin, at three o'clock p.m. The President, Mr. W. F. Wells, presided, and referred to the results of prosecutions in Belfast of a Scotch firm, against whom two penalties of £5 each, with £1 costs, were recovered for an unlawful sale; and at Rathfriland, where two penalties were recovered against a defendant for unlawfully keeping open shop for the sale of poisons. The defendant in the latter case appealed to Newry Sessions, and the County Court judge there adjourned his decision, saying he "would do his best to upset" the Society, whose solicitor had declined to be satisfied with one penalty only. It was unnecessary to refer to the late decision in the Queen's Bench. Another important case would come on in that division on the following Monday.

Mr. Alexander Bryan, of Agnes Street, Belfast, who was fined £10 on November 26 last for breaches of the Pharmacy Act, wrote asking the Council for a mitigation of the penalty. It appeared that Mr. Bryan, who at the time was not a registered druggist, unlawfully compounded two prescriptions. He stated that he had since qualified as a registered druggist, and promised to obey the law in future. His application was refused. A letter from Mr. R. J. Edwards, of Corn Market, Belfast, enclosed a memorial from nine assistants and apprentices in the employment of Messrs. Grattan and Co., Limited, of that city, praying that their cases might be taken into consideration with a view to being admitted to the examination for the licence. Five of them had passed the Preliminary examination, and held certificates in the educational courses; a sixth who had passed the "Preliminary" was attending the lectures and classes; and the remaining three were preparing for the "Preliminary." Their apprenticeships had commenced at different dates since May, 1887.

The memorial was discussed in committee. On the one hand it was urged that the case of Mr. Cleeland, whom it was proposed to admit to the Licence examination in consequence of the recommendation of the judge of the Queen's Bench and as an act of special grace, was quite an exceptional one; whilst on the other it was contended that it would be unjust not to treat with consideration cases so much resembling his, although not so strong. Eventually, on the motion of Professor Tichborne, seconded by Mr. Beggs, the memorial of Mr. Cleeland and also that of the nine apprentices and assistants was submitted to the legal adviser of the Society with a view to get advised as to the legal power of the Council to grant the prayers of those memorials. Donations were acknowledged from the Pharmaceutical Society of Great Britain, of a copy of their Calendar for 1896, and from the Colonial Pharmacy Board of the Cape of Good Hope of a copy of their 'Medical and Pharmacy Register' to January 30, 1895, and thanks were voted to the donors. Some other business having been disposed of, the Council adjourned.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.—The usual fortnightly meeting of this Society was held at University College, under the presidency of Mr. T. S. Wokes, on February 6. The fruit of *Bixa orellana*, N.O. Bixaceæ, from which annatto is prepared, the capsules of *Ricinus communis* grown in Italy, and the kernels of the drupaceous fruit of the oil palm, *Elæis guineensis*, were shown by Mr. G. V. C. Last. From the last-named palm nut oil, a white fat largely used in soap making, is extracted, quite a different substance to yellow palm oil, which is from the fleshy part of the drupes. The residue of the palm kernels after the extraction of the fat, is used for cattle feeding. Mr. Frank Walker drew the attention of the meeting to the advisability of dispensers marking on the prescriptions passing through their hands any additions required, such as mucilage, to turn out a satisfactory preparation, and instanced a recipe containing a large quantity of carbonate of bismuth, which had been previously made up evidently with mucilage, but as to the amount used the first dispenser gave not the slightest indication for the guidance of those into whose hands the prescription subsequently might come. The President and members expressed a wish that something like uniformity might be arrived at in these cases by emphasizing the advice of Mr. Walker as to the procedure to be observed.

An illegible prescription was passed round by Mr. H. Peirson. It seemed to be—

Trit. mur. hyd.	gr. xii.
Sacch. alb.	3i.
M. divide in pulv. iv.	

Mr. Peirson had tried the Irish moss mucilage for making cod-

liver oil emulsion as advised by Mr. Walker, and had found it answer very well, but would like some information as to its keeping qualities.

Mr. Walker replied that it would keep indefinitely if a few drops of chloroform were added to it. An exposition of the many and devious ways of quacks and of the art of quackery was then given by Mr. H. B. Morgan, with musical illustrations, in which he was assisted by his brother. The subject, with its comic aspects, was very cleverly treated by Mr. Morgan, whose lecture was certainly one of the most novel the students have had the pleasure of hearing for some time.

A paper on "Aquatic Plants" was next given by Mr. W. A. Cockshott, in which the first principles governing the life history of aquatic plants were broadly touched upon, and the peculiar characters of such plants sketched. The Cryptogams were disregarded as being too numerous, and outside the scope of an ordinary field botanist's range of observation, Phanerogams only being mentioned. These were explained to be partly aquatic and partly aerial, those entirely submerged being designated by the term "hydrophytes." The two principal factors in the plant's life history were the inherent tendency of the plant's growth, and the effect of its environment or all the external conditions affecting it. The water is not simply a passive medium without influence on the plants growing in it, but is a solution containing all the bodies readily available for their sustenance, which are taken up by osmosis by the stem and leaves. The epidermis is specially constructed with this object, and is simply a thin layer of shallow cells, distinguished from that of the aerial plants by the term epithelium, and differing from the epidermis of such plants by being free from hairs and stomata. The roots of aquatic plants are not very highly organised, as the nourishment of the plant being directly absorbed from the water there is not much work for the roots to do—the term rhizoid is generally used to designate them. The structure of these plants was then explained and contrasted with that of the usual aerial plants, and their external form and the influence of the environment on determining this were then gone into, the lecturer illustrating his remarks by means of many herbarium specimens lent by Mr. Last, and others of his own collection.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES ASSOCIATION.—The fifth meeting of the eighteenth session was held in the Pharmaceutical Society's Hall, 36, York Place, Edinburgh, on Friday, the 7th inst., at 9.15 p.m., Mr. J. Mackintosh Cameron in the chair.

The minutes of last meeting having been read and approved, Mr. George Coull gave a lecture and practical demonstration on "Flame Tests," in which he fully explained the beautiful methods of dry-way analysis devised by Bunsen, and described in a paper published in the *Zeitschrift für Analytische Chemie*, 1866. These methods, he said, had never received the attention they deserved in this country, and they were generally overlooked by the pharmaceutical student. In German text-books there was usually a special section devoted to them, but in such a book as Attfield's, the borax bead was only once mentioned, namely, under manganese. Teachers, too, seemed to give too little attention to them. All the tests could be applied by means of a Bunsen flame, which he described, particular attention being paid to the oxidising and reducing parts of the flame. The film test, the match test, the borax bead tests, etc., were all practically shown and explained.

The lecture was followed by a discussion, taken part in by Messrs. Cameron, Cowie, Duncan, Hill, and Macpherson, and a hearty vote of thanks was awarded to Mr. Coull.

IRISH NEWS.

VACCINE PREPARATION.—Resulting from the late enormous increase in vaccination in Dublin, owing to the outbreak of small-pox (now, happily, almost entirely stamped out), Dr. Knox Denham and some friends have established a depôt at Sandymount, county Dublin, for the production of calf lymph.

MR. J. T. CHAMBERLAIN, L.P.S.I., has returned to his old quarters at Furlong's Medical Hall, Upper Merrion Street, Dublin, *vice* Mr. Daniel O'Sullivan, L.P.S.I., who has gone to Messrs. Anderson and Adams (Mr. J. E. Brunner, M.A., M.P.S.I., proprietor), 68, Grafton Street, Dublin.

ENGLISH NEWS.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.—A musical and social evening was held at the Exchange Rooms on Wednesday, February 5, Mr. H. S. Lawton (Vice-President) in the chair. An excellent programme, which included the following items, was gone through:—Mr. Clarke, violin; Mr. Williams, 'cello; Mr. Rogers, banjo; Mr. Martin, recitation, "Jameson's Ride." Songs were rendered by Messrs. Casson, Clarke, Cornish, France, Lacey, and Small. Mr. Wheeler presided at the piano, and the whole arrangements were in the hands of Mr. P. C. Arblaster.

THE FOOD AND DRUGS ACT IN SHEFFIELD.—In his quarterly report to the Sheffield City Council, Mr. A. H. Allen, the Public Analyst, stated that during the last three months ten samples of vinegar had been received, of which three had the characters of malt vinegar and two others were of fair quality. Four other examples contained added acetic acid of the strength of vinegar to the extent respectively of 50, 50, 67, and 90 per cent.; the last sample in addition containing 0.06 per cent. of free sulphuric acid. The tenth sample contained only a small proportion of malt vinegar. Of seventeen samples of spirit eleven were within the legal limit of strength, the other samples being diluted with water. Of six samples of paregoric, five were of fair quality, but one was deficient in alcohol, containing only two-thirds of the proportion directed to be used in the preparation of the paregoric or paregoric elixir of the British Pharmacopœia. Of the six samples of laudanum, four were of fair quality, one of inferior quality; and one deficient in alcohol, containing only about two-thirds of the proportion directed by the British Pharmacopœia to be used.

SCIENCE TEACHING AT LEICESTER.—Elementary practical physics and chemistry are subjects that are being encouraged by the Technical Education Committee of the Leicestershire County Council, and up to the present the results have been very gratifying. The Committee in its report of the work of the past session states that in the above subjects there have been 151 students, and aid has been granted, to make the teaching more efficient, in six of the chemistry classes, whilst new laboratories have been fitted up at Loughborough and Hinckley Grammar Schools. Another satisfactory feature in connection with the grammar schools in the county is that twenty-three of the teachers in them have attended a course of instruction in elementary practical physics and chemistry. Another proof of the Committee's good intentions is a grant, not to exceed £300, for the special fittings and apparatus required in the physical and chemical laboratories at the new Thomas Rawlings' School at Quorn. Technical education is making very satisfactory progress in the county, and the Committee is to be congratulated on the sound and practical common-sense way in which it is dealing with the subject.

DEATH OF A RETFORD CHEMIST.—A veteran Retford chemist, in the person of Mr. Frederick Appleby, of 1, Market Square, died on Friday morning last at the mature age of 81 years. He was one of the oldest tradesmen in Retford, where he set up in business when he was 21 years of age. Deceased was a native of Egmanton. He had been a widower for twenty years, and leaves one son, Dr. Appleby, of Newark. Mr. Appleby took but little interest in public affairs, the only matters in which he greatly concerned himself being the formation of the Old Retford Burial Board and the laying out of the cemetery in 1854. As a collector of old coins, china, and curios, however, he was widely known.

PILLS IN A BISCUIT BOX.—An amusing case was heard at the Sheffield Police Court on Friday last, a little girl named Florence Vitty, fourteen years of age, being charged with having stolen a quantity of pills. The girl went into the shop of Mrs. Matilda Eyre, of 655, Attercliffe Common, and took a tin box, which presented the appearance of a small biscuit box. It really contained, however, three dozen small boxes of "wind and water" pills. Shortly after the theft the box was returned. The girl, when arrested, said she had been disappointed, as she thought the tin contained biscuits. A fine of 15s. was inflicted.

THE DANGERS OF BENZOLINE STORAGE.—On February 5 two alarming explosions took place at the establishment of Mr. J. P. Hewitt, chemist, Division Street, Sheffield. An assistant had gone into the cellar with a light to obtain some turpentine. An explosion occurred, which threw him to the ground, and played sad havoc in

the shop, blowing out a window and badly damaging the stock. Fortunately a large quantity of silver sand was stored close by, and by the liberal use of this the fire was extinguished. The injured assistant was conveyed to the hospital. About four in the afternoon an employé of the Gas Company visited the shop and descended into the cellars to examine the pipes and meter. He foolishly struck a match, and immediately there was a second explosion, another window being blown out, the door dashed from its hinges, and the gas-man very badly scorched and injured. The amount of damage caused by the two explosions has been estimated at between £500 and £600, but is covered by insurance.

FIRE AT A HARROW CHEMIST'S.—Late on Saturday night last a disastrous fire broke out at Harrow on the premises of Messrs. Tuck and Co., chemists and druggists. About 11 o'clock a Mrs. Stroud, who lives on the premises, slipped on the stairs and upset a paraffin lamp she was carrying in her hand. Her clothes immediately became ignited, and before the flames could be extinguished she was badly burnt about the body. Owing to the combustible nature of the contents of the shop and the amount of drugs stored near the spot where the lamp upset, the whole place was soon alight, and on the arrival of the firemen flames were bursting out through all the windows, and fears were entertained that the walls would collapse. The shop was completely gutted, nothing remaining but the bare walls.

AN OVERDOSE OF LAUDANUM.—A fatal case of laudanum drinking was reported to the Ashton police on February 7, the victim being Louisa Fiddler, single woman, of Charles Street. The woman had suffered severely from bronchitis and dropsy, and for some time had been an inmate of the workhouse hospital. On the previous Thursday night she said she would have some laudanum to ease the pain, and sent a boy for a pennyworth, which she drank right off. She fell asleep at once, and, despite every effort to restore animation, never recovered consciousness.

POISONING BY CARBOLIC ACID.—An inquest was held at Manchester, on February 7, concerning the death of Edward Hallam, the two-year-old child of Matthew Hallam, hotel porter, living at 224, Hyde Road, Ardwick.—The evidence was to the effect that the child was left playing in one of the bedrooms where there was a beer bottle containing carbolic acid on the mantelpiece. During the mother's temporary absence the child got hold of this bottle, and drank some of the acid. His mouth and throat were badly burnt, and though medical assistance was promptly procured, and the child ultimately taken to the Royal Infirmary, the lad died at that institution some time afterwards.—The Coroner said there were far too many cases of poisoning by carbolic acid dealt with in that court. He could not help feeling how stupid and how careless it was that people should keep corrosive poisons in bottles which it was usual to use for drinking purposes. It too frequently happened that a beer bottle or a ginger-beer bottle was used for this purpose, and everybody knew how easily children learnt habits, and how they would naturally think they could drink from a bottle they had seen others using. He would like to see it an offence for keeping a poison in a bottle other than a proper poison bottle. They had had no fewer than thirty cases of carbolic acid poisoning in that court during the past twelve months, chiefly of children.—A verdict of "Accidental death" was returned.

A NOTTS CHEMIST ROBBED.—The establishment of Mr. Fill, chemist, of Gringley-on-the-Hill, Notts, was broken into and robbed in the latter end of last week. Entrance was gained by the removal of a square of glass from the window, and the till was ransacked.

CO-OPERATIVE DRUG STORE AT PLYMOUTH.—According to the annual report of the Plymouth Mutual Co-operative Society, Limited, it is proposed to build a drug store in connection with the Society's clothing and provision stores in Frankfort Street, Plymouth.

FIRE AT A BOSTON PHARMACY.—On Saturday last, between 10 and 11 o'clock in the morning, a fire was discovered in a back room on the premises of Messrs. Grimble and Kent, chemists, of High Street, but was happily extinguished before any serious damage was done. The room in which the fire originated is situated behind the shop, which is heated by means of a stove, the chimney of which runs into the flue of the ante-room, and it is supposed that a quantity of soot ignited by sparks from the stove fell into the fireplace

of the back room and set fire to a quantity of straw, the flames spreading to some empty casks. Some sulphur also caught fire, but beyond damage done by smoke and water nothing serious resulted. The flames were extinguished without the assistance of the brigade.

EARLY CLOSING MOVEMENT AT EXMOUTH.—Mainly through the instrumentality of Mr. Toone, an early closing movement, which has been started at Exmouth, has resulted in the chemists of that town mutually agreeing that on and after Monday, February 10, they will close their establishments at 8 o'clock every evening, Saturdays excepted, instead of at nine as hitherto.

BUSINESS EXTENSION AT PLYMOUTH.—In consequence of an extension of business, Messrs. S. B. Turney and Sons, chemists of Union Street, Plymouth, have made a very effective enlargement of their premises. The front shop, in addition to being extended several feet, has been newly fitted up, and all the latest improvements in modern pharmacy have been introduced.

SCOTTISH NEWS.

EDINBURGH CHEMISTS' BALL.—The thirteenth annual ball took place in the Freemasons' Hall, George Street, on Wednesday, 5th inst. About eighty couples were present, and the company included Mr. J. Laidlaw Ewing, Chairman of the North British Branch Executive and Board of Examiners; Mr. P. Boa, President; and Mr. C. F. Henry, Hon. Secretary of the District Chemists' Trade Association; and Messrs. Coats, Smith, Thompson, MacLaren, etc. The duties of M.C. were efficiently performed by Messrs. J. T. Coats and R. Butchart, and a very pleasant time was spent to the music of Messrs. Dunn and Davidson's band. At the supper, purveyed by Mr. Sawers, the chair was taken by Mr. Boa, and the toast "Success to the Chemists' Ball" was proposed by Mr. J. Laidlaw Ewing. In acknowledging the toast Mr. Boa said this was the first year of the Ball under the management of the Trade Association, and it gave every indication of success. The company separated about 3 a.m.

GLASGOW AND WEST OF SCOTLAND PHARMACEUTICAL ASSOCIATION.—At the last meeting of this Association—Mr. W. L. Currie, presiding—the Chairman said that the Law Committee had had under consideration the matter of the comments recently made by Scottish judges in connection with pharmacy prosecutions, and they were getting up a protest on the subject. He had in his possession a protest that had been written out by Mr. Laing, and it would be submitted in due course by the Law Committee for discussion, to be afterwards forwarded to the Privy Council.

A long discussion then took place on Mr. Russell's paper, read at the previous meeting, on proprietary preparations (see *ante*, p. 97). The Chairman said Mr. Russell had received many congratulations and letters from chemists and medical men throughout the country, showing the great interest his paper had aroused. One letter in particular, from Mr. Kerr, of Dundee, was read. It stated that the practice dealt with by Mr. Russell of doctors prescribing proprietary preparations was a scandal. Messrs. Laing, Robb, McKellar, Bruce, Mackay, Blair, Watson, and Dunlop took part in the discussion. It was suggested that the fault lay very much with the professors of *materia medica* at the schools, in recommending certain preparations to the students. A representation should be made to them to mend their ways. Mr. Russell did not agree with that, and suggested that a representative should be sent to the Council of the Pharmaceutical Society, with a view to the question being brought before the General Medical Council. Mr. Laing moved that a memorial on the lines suggested by Mr. Russell be submitted to the Council of the Pharmaceutical Society, and that was agreed to.

Mr. George Robertson, Partick, then read the following paper:—

Extract. Ipecac. Acet.

The official mode of preparing ipecac. wine, I think, leads to a much better product than that of the preceding Pharmacopœia, both in regard to therapeutic and keeping qualities. The process is tedious and troublesome on the small scale, and if it were necessary in dealing with larger quantities to increase the details in an equal ratio, it would not be very inviting. The note given in Squire's 'Companion' regarding the acetous extract is fairly exhaustive, and I can only verify it, on several occasions having used 4 ounces of root and the full quantity of water to percolate four pints. The extract obtained was very nearly a constant quantity, somewhat over 90 grains to the ounce of a nearly

dry extract, for, in deference to general opinion, I stopped short of the absolute dryness which the B.P. demands; yet I am not ready to admit that the extract would suffer by carrying the evaporation to that point. Latterly I have used eight ounces at a time, percolating with half the quantity of water. On the last occasion, the percolate was taken and evaporated pint by pint, with this result:—The first pint yielded 640 grains solid extract; the second, 180 grains; the third, 75 grains; and the fourth, 23 grains; total from 8 ounces of root, 2 ozs., 43 grains, which is the best yield I have ever had. I took two grains of an extract (equivalent to .44 of a fluid ounce of wine), allowing it to dissolve or disintegrate in the mouth, time, sixty seconds, and it took effect after nearly an hour. Three grains of the last made extract (equivalent to .52 of a fluid ounce of wine) had very similar effects as to time, and slightly more powerful action; but in both instances the effect was sudden and then over, so that a comfortable meal taken almost immediately after, gave great satisfaction owing to its staying powers.

Mr. Laing then submitted a short paper on—

"Cypher Prescriptions."

He would, he said, like to have the opinion as to how far a chemist may venture, both legally and conscientiously, in the compounding of a prescription when the ingredients are not written in the way they ought to be. It would appear that up-to-date prescribing seems to depend very largely on the plausibility or gullibility of the setting forth. Along with that chemists have to contend with the prescriber who also owns the article prescribed, or at all events can only trust his dispensing to certain individuals, usually on his own supposed premises, for what reason they well knew. True they had still a large number of medical men who can rely on their own knowledge for the proper compiling of a prescription, and on the experience of the chemist for the compounding of it; but they seemed to be getting fewer and fewer, giving place to the proprietary prescriber and cypher writers. With regard to the prescriptions written in cypher, these and such like are quite beyond considering, except, perhaps, to request in a humble manner a supply from the intellectual person, who alone is able to compound such preparations to the satisfaction of the careful physician, nothing being mentioned as to his pecuniary gain thereby. In regard to others, they observed preparations prescribed that there were no recognised formulæ for. In other cases it was often due pretty much either to ignorance or forgetfulness. In most cases such prescriptions were written for the benefit of the writer, and as that was a growing evil, some districts being considerably affected already, he thought a discussion on the matter could not be out of place; certainly one would fancy that the patient is the person who should have the most say as to where the medicine ought to be got, and if he or she has done a sensible thing by employing the proper medical man, and no doubt each medical man thinks he is the right man in the right place, then they ought to be allowed also to use their own discretion as to the proper chemist to employ. That was still the opinion of some medical men. Whether a communication to the medical societies would be of any service might be worth while considering.

In the discussion that ensued Mr. Russell said that in one particular instance he had been the means of obtaining the opinion of the Glasgow Faculty of Physicians and Surgeons on the question of cypher prescriptions, and it was decidedly opposed to the practice. The same view was held by the Faculty in London.

MR. ROBERT DAVIDSON is about to open a new pharmacy at 8, Bridge Street, Hawick.

COLONIAL NEWS.

SOUTH AFRICAN CHEMISTS.—The first monthly meeting of the Cape Town Chemists' Assistants' Association was quite recently held, Mr. F. H. Carman (President), reading a capable paper on "The Cape Examinations." He gave a list of the questions put to a candidate at a recent examination, and considered them quite equal to the English questions of four years ago. Concluding, he thought the public might have full confidence in the men who succeeded in satisfying their examiners. The secretary was instructed to draw up a petition to the Colonial Pharmacy Board asking whether it could not still hold its own preliminary examination, which, as assuring a solid foundation of general education upon which to build professional knowledge, was most necessary. For 1896 the following officers have been elected: President, Mr. F. H. Carman; Treasurer, Mr. Mücke; Secretary, Mr. Sainsbury.

NEW REMEDIES.

[The notes given under this heading embody recent suggestions in therapeutics. They cover both new drugs and preparations, and old ones under new aspects. The word "parts" is used to represent parts by weight, both for solids and liquids.]

EXTRACT OF CONIUM IN ANAL FISSURE.—Aaler recommends the following ointment to be applied locally after each action of the bowel in cases of anal fissure:—Extract of conium, 5; castor oil, 15; lanoline, 30 parts (*Dub. Journ. Med. Sci.* [3], No. cclxxxviii., 311, after *Thérap. Monats.*).

ICE IN ASPHYXIA.—In cases of asphyxia, in chloroform, opium, and other narcotic poisoning, Beer and Forges advocate the application of small pieces of ice to the mucous membrane of the nose and lips. The effect of these applications is to stimulate the respiratory nerve centre and to aid respiration (*Mod. Med.*, iv., 246).

CALCIUM BISULPHITE IN PITYRIASIS.—Leistikow prescribes the following ointment in pityriasis versicolore, the affected parts being rubbed with solution of bisulphite of calcium, 60 parts; lanolin, 20 parts; vaselin, 20 parts. A thorough lathering of the parts once a week should be practised, using quinine soap (*Rev. de Thérap. Med.-Chirurg.*, lxii., after *Bull. Med.*).

AMYGDOPHENINE IN ACUTE RHEUMATIC ARTHRITIS.—A derivative of paramidophenol, in which amygdalic acid is substituted for an hydrogen atom in the amide group, and ethyl carbonate for another atom of hydrogen in the hydroxyl molecule, has been introduced under the name of amygdophenine. In eleven cases of acute febrile rheumatism in which it has been given, it exercised a beneficial action in ten; in seven of these in from four to six days all the symptoms were relieved, the temperature lowered and cure resulted. In four other cases two cures were more slowly effected. In eleven cases of rheumatism without fever five rapid cures were effected, and only one remained intractable. The antithermic action of the drug was demonstrated in two tubercular cases, in which a dose of 1 gramme resulted in a fall of 2° in temperature in three hours. It also has marked anti-neuralgic properties, even in instances of grave affections of the nervous system, such as tabes and multiple scleroses. The dose given is 1 gramme, in the form of powder or tablets, administered several times a day up to a daily dose of 6 grammes. In the course of a trial for six months in the hospital at Frankfort-on-Maine, Stave has only met with two cases in which the drug occasioned vertigo (*Rev. de Thérap. Med.-Chirurg.*, lxii., 722).

ETHYL CHLORIDE IN HYSTERICAL APHONIA.—Kebbell has found the local application of ethyl chloride to the nape of the neck, in such a manner that a small spot, about the size of a shilling, is frozen, most efficient in the treatment of this troublesome affection (*Lancet*, I., 96, 161).

CHRYSAROBIN IN ALOPECIA AREATA.—For the past four years Leistikow has successfully treated alopecia almost entirely with chrysarobin. He uses it in the form of sticks composed of chrysarobin, 30 parts; resin, 5 parts; yellow wax, 35 parts; olive oil, 30 parts. This is rubbed like cosmetic over the scalp, care being taken to avoid touching the hair. The head is then covered with a skull-cap, and the next morning the chrysarobin is removed with olive oil. After some days irritation of the scalp comes on, manifested generally by a characteristic redness, very seldom by bullæ and pustules. When this occurs the frictions with chrysarobin are replaced by zinc ointment, which is also in due course removed with olive oil. As soon as the irritation has subsided the chrysarobin pencils are again used. The result is satisfactory in proportion to the regularity and perseverance with which the treatment is carried out. Some cases are cured in four weeks, but more often the treatment has to be continued for several months (*B. M. J. Epit.*, 2, 95, 103, after *Monats. f. prakt. Derm.*).

CAFFEINE AS AN ANTIDOTE TO OPIUM.—A case of opium poisoning through an overdose of Dover's powder is recorded by Dr. Sharp, in which the administration of 6 grains of caffeine was followed by a prompt improvement in the character of the respiration, resulting in recovery (*Therapeut. Gaz.* [3], xi., 732).

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulae for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

MIST. BISMUTHI C̄ PEPSINA.

The following formula gives very satisfactory results, and should serve your purpose:—

Bismuth Citrate	1600 grains.
Distilled Water	} q.s.
Liq. Ammon. Fort.	

Dissolve, keeping the volume as small as possible, then add—

Chloroform	1 fl. .
Tinct. Nucis Vom. (conc. 1-7)	5½ fl. dr.
Acid. Hydrocyan. Scheele	5½ fl. dr.
Morphin Hydrochlor	13½ grains.
Liquid Cochineal	400 minims.
Rectified Spirit	7 fl. ozs.
Glycerin	4½ fl. ozs.
Soluble Scale Pepsin	320 grains.
Distilled Water	q.s. to make 1 pint.

It is doubtful whether the pepsin is of the slightest use in an alkaline preparation like the foregoing, as it is difficult to prove that it has any effect upon coagulated egg albumin. [*Reply to W. R. F.*]

GLYCERIN. PEPSIN. ACID.

There is no recognised formula for this preparation. The following is from the 'Era Formulary':—

Pepsin	128 grains.
Glycerin	4 ounces.
Dilute hydrochloric acid	75 minims.
Alcohol	3 ounces.
Water, to make	1 pint.

Soluble scale pepsin should be employed. The proportions of pepsin and acid might be increased with advantage, and the quantity of alcohol should be reduced. Indeed, it is a distinct advantage to avoid the use of alcohol altogether, if possible. [*Reply to Student.*]

EMULSION FOR REMOVING TICKS FROM CATTLE.

Dissolve 8 ounces of yellow soap in 2 quarts of hot water. When the soap is dissolved, add 1 pint of kerosene, and agitate. In from three to five minutes the liquid becomes creamy; it may then be stored for use. For application 1 part of this emulsion is diluted with 3 parts of water and applied over the animal by means of a spray pump.

PREPARATION OF CALCIUM GLYCEROPHOSPHATE.

Lambotte recommends the following method of preparing this salt (*Répert.*, li., 152). A mixture of 250 grammes of powdered glacial phosphoric acid is mixed with 500 grammes of glycerin and boiled over the naked flame; the acid rapidly dissolves, and the liquid gives off vapours and darkens. In about half-an-hour the reaction is complete. The mass is then cooled, water is added, and then freshly-slaked lime, until only a faintly acid reaction is obtained. This requires about 127 grammes of calcium hydrate. The liquid is strained through flannel, and the collected paste suspended in water and filtered. Strong alcohol is added to the mixed filtrates until the calcium salt is completely precipitated. The alcoholic solution is filtered off from this, and the precipitate is washed with alcohol, by suspension, to remove all the adherent glycerin. It is then dried. So prepared the salt is a white, neutral, light powder, 6.25 parts of which are soluble in 100 parts of water.

TRAUMATOL.

Under this name an iodocresol has been introduced as an anti-septic germicide. It is a reddish-violet powder, free from odour, insoluble in water and in alcohol, but readily dissolved in chloroform and carbon bisulphide. It is neither irritant nor toxic (*Répertoire*, vii., 14).

NOTICES TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

LETTERS.

CLASS FEES FOR CHEMISTS' APPRENTICES.

MR. J. F. BROWN, of Dover, writes to say that he is trying to obtain from the Technical Instruction Committee of the Dover Town Council an abatement of the fees charged to chemists' apprentices, who are studying in the science classes of the School of Art. He continues, "Would any of your readers help me by sending me through the post particulars of the fees charged elsewhere for teaching science under the grant made to the County Councils."

FERMENTATION.

MR. A. W. HUDSON, of Cranbrook, writes as follows:—"Mr. John Welsh, in his paper on 'Fermentation' (*Ph. J.*, February 1), states that 'it is said the presence of fousel oils in alcohol produced by yeast is due to the fungus spores of *Mucor mucedo* and *Penicillium glaucum*.' I am under the impression that fousel oil is due to an organism entirely distinct from either of the above, which was isolated in 1892, and referred to in 'The Month' at the time."

THE DETECTION OF NITRATES AS IMPURITIES IN NITRITES.

MR. J. OLIVER, of Chard, writes as follows:—"As particular attention is now paid to the detection of impurities in chemical compounds in the Minor examination, perhaps the following test for nitrates as impurities in nitrites—especially that of sodium nitrite, B.P. addendum—will be serviceable to students. The present Pharmacopœia mentions many tests for the detection of impurities in the official preparations, but neglects to give one for sodii nitris. Test: Take ten grains of sodium nitrite and dissolve it in one fluid ounce of ammonium chloride solution, evaporate to dryness. Take some of the residue, dissolve in water and apply the ordinary nitrate test with FeSO_4 and H_2SO_4 . If the sample of sodium nitrite employed was free from nitrate, the black ring at the union of the liquids will not be obtained, but if the minutest trace of nitrate was present it will be immediately detected. The reaction is as follows: $\text{NaNO}_2 + \text{NH}_4\text{Cl} = \text{NaCl} + 2\text{H}_2\text{O} + \text{N}_2$. From the above equation it will be seen that the whole of the nitrogen is eliminated, whilst if any nitrate is present, the whole of the nitrogen of the nitrate is retained as ammonium nitrate. $\text{NaNO}_3 + \text{NH}_4\text{Cl} = \text{NaCl} + \text{NH}_4\text{NO}_3$. For experimental purposes the student should make two solutions of a mixture of sodium nitrite and ammonium chloride, and to one of them add a grain or two of sodium nitrate, apply the same tests to each solution, and compare the results. I suggest that this or some other suitable test be added in the new Pharmacopœia, for the B.P. sodium nitrite seems to be falling

in the favour of many medical men, and it is very important that this particular salt should be absolutely pure when employed in the treatment of disease."

THE ANTI-CUTTING AGITATION.

"LIVE AND LET LIVE" is the signature appended to the following communication:—"To prevent, as far as possible, the insane cutting of proprietary articles, we have decided to materially increase our prices to the trade for those manufactured by ourselves, as we see no necessity for giving to the public the profit that would otherwise fall to the share of the retailer. Those who adopt the cutting principle do not do so in the public interest, but to draw customers to their so-called stores for their own selfish ends, and, in so doing, are indifferent as to how many they force into the Bankruptcy Court, or, who sinks so long as they swim. We think, too, that the trade generally would do well not to support those houses, who, not content with their wholesale trade, open shops in different neighbourhoods on the cutting principle. It was bad enough when they did so on fair lines, it is infinitely worse now. There is no doubt purchasers would pay full prices were it not for the action of the stores in making leading articles of those goods the retail prices of which are advertised."

ANSWERS.

T. H. POWELL.—Hausmann's powder-measuring apparatus may be obtained from the inventor, Fr. Hausmann, Hechtapotheke, Goliathgasse 4, St. Gallen, Switzerland.

"DENES."—We are not aware that any authentic formula has been published. Your best plan would be to resort to analysis.

"SPERO."—See foregoing reply to T. H. Powell.

QUERIES.

MCDADE'S ANTISYPHILITIC MIXTURE.—Information respecting the composition of this mixture is asked for.

PERMANENT GREEN COLOUR FOR SHOW CARBOY.—"Myrtle" requires a formula for a permanent light myrtle green liquid for a show carboy. There must be no suspicion of blue in the colour required, which is most nearly approached by an acidified and fairly strong solution of nickel sulphate. The exact shade required is that observed on holding a pint bottle of Grossmith and Son's Wood Violet Perfume to the light.

CALCIUM CARBIDE.—A correspondent wishes to know where this product can be obtained on a commercial scale.

HOMŒOPATHIC PRESCRIPTION.—A correspondent asks if any reader can explain how to dispense the following homœopathic prescription:—

R Sulph.	2/30	1-11
"	2/200	2-12
	Mitte tales pulv., xii.	

Sig.—A powder night and morning in a wineglass of water.

OBITUARY.

WILLIAMS.—On January 26, Franklin Williams, Chemist and Druggist, Chester. (Aged 75.)

MAIR.—On January 31, Alexander Mair, Chemist and Druggist, Leith. (Aged 43.)

REDMAN.—On February 2, Frederick Redman, Chemist and Druggist, Lincoln. (Aged 77.)

STRINGER.—On February 3, E. C. Stringer, Chemist and Druggist, Peckham. (Aged 76.)

SHARP.—On February 5, John James Sharp, Pharmaceutical Chemist, late Seychelles. (Aged 51.)

APPLEBY.—On February 6, Frederick Appleby, Chemist and Druggist, East Retford. (Aged 81.)

INGRAM.—On February 7, John Ingram, Chemist and Druggist, Sinnahard, N.B. (Aged 70.)

FOOTIT.—On February 9, Charles Miller Footit, Chemist and Druggist, Glan-y-Ffordd, late Great Marlow. (Aged 49.)

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Atkinson, Bastow, Blackburn, Bindloss, Bird, Brittain, Brown, Callis, Coleman, Cripps, Cracknell, Davis, Davies, Durant, Donnan, Drayton, Eastman, Griffin, Gunn, Hill, Hudson, Holloway, Keech, Henry, Lurcock, Nicholson, Norman, Notting, Reece, Ridlington, Roe, Rose, Schneider, Tovey, Turner, Umney, Watt, Williams, Williamson, White, Whyte, Young.

**ON THE PRECIPITATION OF TOXALBUMINS
BY NUCLEIN.***

BY M. TICHOMIROFF.

Since it has been shown that bacteria produce their effects by the agency of the poisonous materials they construct, the importance of inquiries into the chemical characters of the toxalbumins and alkaloidal poisons produced by various pathogenic organisms has become generally recognised. The latest contribution to the literature of the subject is contained in a paper by the author.

Ricin was the first substance experimented on. A 5 per cent. aqueous solution of pure ricin was precipitated with a 1 per cent. solution of nuclein. The precipitate, after being washed in alcohol and ether and desiccated, was dissolved in a solution of sodium carbonate, and it was found that the precipitate was equally poisonous with the pure ricin, about .005 Mgr. of each on an average being found to cause the death of a white mouse a few days after the poison had been injected under the skin. In examining the poison of tetanus, it was found necessary to separate the bacilli from the culture medium by filtration through a Chamberland filter, because otherwise living bacilli were carried down with the precipitate. To a ten-day old bouillon culture of tetanus bacilli 5 per cent. of phenol was added, passed through the porcelain filter, acidified with acetic acid, and precipitated with nuclein. After washing and drying, the precipitate was found to be fatal to mice in doses corresponding to .04 Mgr., whether dissolved in sodium carbonate solution or simply suspended in water. Death ensued in from eighteen to twenty hours with all the symptoms of tetanus. The dried precipitate gave the biuret and Millon's reactions, and was found to have retained its poisonous property unimpaired at the end of a month. The toxalbumin of diphtheria behaved in a similar manner. The dried precipitate, after being kept for three months in stoppered bottles in the dark, proved fatal to guinea-pigs when given in doses of from 0.2 to 0.04 Mgr. Death occurred in from two to four days. A less active poison was obtained from the flesh of fish in a state of putrefaction.

Negative results were obtained from cultures of the *Streptococcus pyogenes*; for, though the original culture was highly poisonous, the precipitate obtained was quite harmless. Similarly negative results were obtained with cultures of the *Staphylococcus aureus* and the typhoid bacillus, and the cholera spirillum. As the writer observes, these observations point to the possibility of differentiating poisons according to their behaviour towards nuclein. It is well known that nuclein will precipitate albumins and pro-peptone from acid solutions, but it would be too hasty to conclude that all the poisons which are thrown down by nuclein are of an albuminous nature; for it has been observed that in the formation of such precipitates the really precipitable substance is apt to be associated with other substances which, when similarly dealt with in pure solutions, are not precipitable. This phenomenon has been observed in most varied substances, colloids and crystalloids, both organic and inorganic, and in different cases is due to different causes. In

this connection, the author recalls the observation made by Brieger to the effect that after sufficient purification the poisons of both tetanus and diphtheria can be shown to be free from albumin. The method described by the author calls for far less minute manipulation than is required for the precipitation of toxic substances by saturation with ammonium sulphate.

TABASHEER.

BY WALTER H. INCE, PH.D., F.C.S., F.I.C.

Tabasheer, or Tabûsheer, is a white, smooth, porcelain-like substance rarely found deposited in the knots of the bamboo, where it forms a thin saucer-like layer. Owing to the fact that this deposit occurs so seldom, several valuable medicinal properties have been ascribed to it. The Indian (E. Indian) population use it in Trinidad as a specific against fever, malaria, and ague. I have been told by a creole Indian, *i.e.*, one who has been born in the West Indies, that the name is derived from the French "tabatière." This is, however, much to be doubted, seeing that neither the form nor colour, nor occurrence of the substance remotely suggests anything connected with tobacco snuff, or its uses.

A Java variety is said by Tonningen (*Jahresb.*, 1860, 531) to have the following composition:—

SiO ₂	86.39
Fe ₂ O ₃42
CaO24
K ₂ O	4.81
Organic matter51
Water.....	7.63
	100.00

I find, however, after examining several samples, that its composition varies very considerably. They all contain large quantities of silica, with indefinite quantities of iron, potassium, and calcium. From this it would seem that the substance is not a definite silicate, but silica contaminated with accidental admixtures of other silicates.

	Tonningen's Analysis.	I.	II.	III.
SiO ₂	86.39	91.69	89.77	90.45
Fe ₂ O ₃42	trace	.665	trace
CaO.....	.24	2.057	3.81	.725
K ₂ O	4.81	4.332	3.35	1.524
Organic matter	.51	.52	.0	3.122
Water	7.63	1.613	3.051	4.13
	100.00	100.112	100.656	99.961

No. I. and III. are Trinidad samples, No. II. is an imported East Indian sample. For the first I am indebted to Mr. J. H. Hart, F.L.S. (Superintendent of the Royal Botanic Gardens), and for the second and third to Ali Rhamseraam Boccas, high priest, Tunapoona.

Government Laboratory,
Port of Spain, Trinidad.

* Abstract of a paper in the *Zeitschrift für Physiologische Chemie*, July, 1895.

BRITISH AND FOREIGN SYRUPS.*

BY JOSEPH INCE,

Lecturer in Pharmacy to the Pharmaceutical Society of Great Britain.

(Concluded from page 130.)

The Pharmacopœa Germanica, 1872, differs so little from that of 1882 (Editio Altera, Berlin), that the latter only need be quoted:—

Pulv. ferri.....	20
Aquæ	300
Iodine	41
Sacchar.....	650

The solution made as usual, and filtered upon the sugar, raised to the boiling point, and evaporated to 1000. One hundred parts of this syrup, called syrupus ferri iodati, contain 5 parts iodide of iron. The recommendation of the preceding pharmacopœa to preserve the syrup by means of a coil of iron wire, and to keep it in *loco aprico*, exposed to light, was not retained.

The French sirop d'iodure de fer differs from all other formulæ. It was not included in the Codex of 1839. In the Codex of 1866 it was as follows:—

Iodine.....	4.25
Iron filings.....	2.00
Distilled water	10.00
Syrup of gum	785.00
Syrup of orange-flower	200.00

[The iodine in 1884 was diminished to 4.10.]

Put the iodine in a small flask with the distilled water, add the iron filings in small portions, shaking each time. Let the action take place for some instants, then heat gently until the liquid has assumed the green colour proper to the proto-salts of iron. Filter the solution into the syrups and wash the filter with water sufficient to make 1000 grammes. Twenty grammes contain 0.10 (centigramme) of iodide of iron.

English practice would not favour the introduction of the two syrups named, but attention is once more directed to the precaution of applying no heat to the solution until the first action is over. The syrup keeps well.

The Austrian formula (1889), Vienna, is:—

Ferri pulverati	4
Aquæ destillatæ	87
Iodi	10
Sacch. pulv.	141

Mix by agitation only and filter on to the sugar.

[5 per cent. ferrous iodide.]

A simple arrangement of the B.P. formula has proved satisfactory:—

Iron.....	10
Iodine.....	20
Sugar	245 (<i>vice</i> 280)
Water	130 fluid

Digest the iodine and iron with 30 of water; shake and apply heat, when, and not before, the first action is over and the solution is nearly cold.

Filter the green ferrous iodide solution into the hot syrup made by—

Sugar	245
Water	100

the tube of the funnel dipping just below the surface of the syrup.

A tasteless syrup of iodide of iron has been proposed under the names of syrupus ferri citro-iodidi. A green solution is made with iron, water, and part of the iodine, heat to boiling, filter, and wash the filter with hot distilled water. To the hot filtrate add citrate

of potassium, and afterwards the remainder of the iodine. Agitate till green and pour on the sugar; when cold add distilled water, so that each fluid drachm may contain an amount of iron corresponding to about 3.6 grains of ferric iodide. The iron is in the ferric condition.

Few aromatic syrups occur in British pharmacy:—

Syrupus aurantii is only a mixture, a poor substitute for the original formula made with fresh infusion. The aroma of syrupus aurantii floris is conserved by adding the orange-flower water last. Syrupus zingiberis is wisely made with the strong tincture, as the old method was unsatisfactory.

Syrupus toltanus, as made formerly, required great skill in manipulation. The balsam was boiled in distilled water, and while in full ebullition was poured over the sugar, ready to hand, and instantly converted into syrup. The cinnamic acid was retained, and the art consisted in such rapidity of treatment as that the result might be a clear viscid syrup, rich in aromatic flavour.

The B.P. directions are to boil the balsam for half an hour, with occasional stirring, filter cold, and in the solution dissolve the sugar by the aid of steam or water bath. The occasional stirring is essential to the process.

The U.S.P. has a cumbersome method in which the balsam is dissolved in alcohol, and added to a mixture of calcium phosphate and part of the sugar, the alcohol is evaporated, the residue treated with water, and filtered bright. The filtrate is heated to about 60° C. (140° F.), and in it the remaining sugar is dissolved by agitation. With the usual precautions the syrup is brought up to the required amount.

Sirop de Baume de Tolu. Codex, 1884 [édit. corrigée].

Baume de tolu sec	50 grammes.
Eau distillée	1000 "
Sucre très blanc	<i>q.s.</i>

Digest balsam of tolu with half water, two hours with agitation; decant and repeat the process, mix the two digestions, cool, and filter.

Aromatic liquid	100
Sugar	180

Make into a syrup over the water bath and filter. Observe the relative proportions of sugar and water, a reduction even on the Codex of 1866.

Aromatic liquid.....	100
Sugar	190

The general method for the preparation of syrupus limonis adopted in the B.P., and formerly in the U.S.P., is based upon the necessity of coagulating the albumin of the succus by heat. So prone to deterioration is this syrup, that there appears to be a general desire to have it replaced officially by a perfectly stable form of syrupus acidi citrici, and this has already been done. The application of heat to the succus is an injury, as it alters the aromatic character and tends to subsequent coloration, but until some other means are found to effect coagulation, it is unavoidable, for the syrup will not keep while the albumin is present. One must object to the final B.P. directions to dissolve the sugar in the filtered liquid with the aid of heat, as it is an error in galenic pharmacy, and carefully avoided by those supplying effervescent syrup beverages. Two pounds and a quarter of refined sugar, added to 1 pint of strained lemon juice, is regarded by some as a printer's error.

The formula of the U.S.P., 1880 (not official in their latest pharmacopœia), is—

Lemon juice strained	40
Sugar in coarse powder	60
Water, <i>q.s.</i> to make	100
Fresh lemon peel	2 parts.

* Read before the Chemists' Assistants' Association, February 6, 1896.

Dissolve the sugar in the filtered liquid by agitation, without heat, and strain. The succus has previously been heated to the boiling point.

A fragrant syrupus limonis may be extemporaneously prepared, when not desired to be kept in stock, by taking advantage of the remarkable influence of sugar in conserving aromatic principles.

Pour the strained lemon juice directly upon the sugar, adding the peel, and allowing the whole to make a cold solution. Citric acid should be added, 1 per cent.

As the peculiar taste noticeable in syrupus limonis, which in wine would be termed *corke'd*, is due to the action of heat on the succus, it would clearly be an advantage to be able to coagulate the albumin by other means. Rectified spirit was naturally suggested—the coagulation was complete, and a bright succus was obtained, but the aroma had been effectually dissipated. The alcohol method was of no service. A more definite experiment was subsequently made: Lemon juice (strained) was treated with 20 per cent. of spirit. vini rect., and filtered; the result was unsatisfactory, little or no lemon flavour was perceptible; indeed, there was a somewhat unpleasant odour.

Mr. William Elliott therefore conducted a series of experiments to see whether the direct action of sugar in the extraction and diffusion of aromatic volatile principles could not be utilised in this preparation. The following formula is suggested, by means of which fragrance is preserved, and a syrup made of definite acid strength:—

Syrupus Limonis [Ince's method].

Lemon-peel (outer peel cut thin)	2
Sugar (coarse powder)	36
Distilled water	22
Citric acid	3

Intimately mix the sugar and lemon-peel; let stand five days, shaking occasionally. Add then water, 19 fluid ounces, and warm by means of a water bath until dissolved. Dissolve the citric acid in the remainder of the water, cold, and mix with the cold, strained syrup. It contains about 5 per cent. of citric acid. Weight, 61 parts.

The power possessed by sugar of developing and retaining volatile principles when brought into direct contact, may be illustrated in many ways, and is somewhat analogous to *enfleurage* with regard to fats. Vanilla steeped in pure white sugar diffuses its aroma throughout the whole mass; it seems to permeate every grain, and to be an actual combination.

The odorous principle so transferred is not a mixture but an impregnation.

Any artificial aromatic water, as aqua menthæ piperitæ, or aqua carui, may be prepared by adding the essential oil to cut sugar (not powder), crushing down the sugar and adding cold distilled water. The oil globules do not separate, nor does the water need filtration.

Germany makes any required aromatic lozenge by the use of rotulæ sacchari; these are fused discs of sugar over which the volatile oil is sprayed, no dampness is apparent, and the aroma is persistent.

On this method depend the oléosaccharures of France, and the elæosacchara of Germany.

Thus aniseed, citron, bergamot, cédrat, and orange are combined with and preserved in sugar. So it was that Mr. John Savory devised his method for the preparation of syrupus toltanus.

Triturate the balsam with half the quantity of sugar, previous to simmering for some time in the prescribed quantity of water; filter when cold and make into a syrup in the usual manner with the remaining sugar.

Anodyne syrups are a small group, far more esteemed in Continental practice than amongst ourselves.

The general public, however, is apt to place implicit confidence in non-official formulæ of this nature, and to credit the virtues assigned to them in tractates and advertisement.

The syrupus papaveris of the B.P., 1885, is admirable in all respects. An infusion is made of poppy capsules freed from seeds, and in coarse powder, with subsequent percolation to exhaustion. Carefully reduce to a definite quantity over the water bath, and when cold, add rectified spirit. The alcohol renders filtration possible by coagulating albumin; let stand and filter.

The spirit having been distilled off, the remaining liquor is evaporated and made into a syrup with sugar.

Refined sugar	4 pounds.
Anodyne liquor	2 pints.

The sugar in this case does not precipitate, being held in suspension by the tenacious character of the liquid. Observe that no rectified spirit is present in the finished product, an inestimable advantage, seeing that this is essentially a children's remedy.

I look back with regret on the manner in which syrup of poppies has been traditionally made in times gone by. Let me give an exact copy of a formula which was in use for upwards of a century:—

Papaver. album., 50 lbs. (avoird.),

boil twice, strain, and boil down to 6 gallons (common measure); dilute with pump water, bag, and boil to 45 lbs., add sugar, 75 lbs., and simmer to 112 lbs. When cold add spirit. vini rectific., 2 quarts (C.M.). To make 115 lbs. when done.

It is the firm belief of many that I am the *laudator temporis acti*, but in this instance I confess that the new is better than the old.

On the other hand, here is syrupus chloral, with its unfortunate strength of 10 grains of hydrate in 1 fluid drachm. The maximum official dose is 2 fluid drachms, that is equivalent to 20 grains. It will be urged that chloral hydrate has a maximum dose of 30 grains, a discrepancy which has not escaped notice.

We know the stereotyped notion of the harmlessness of a syrup. We know also, unhappily, how this syrup has crept into domestic use. The result has been disastrous, not the less because a teaspoonful, by which the syrup is too often measured, is a vague method of administration. We have in foreign pharmacy all manner of anodyne syrups:—Sirop d'aconit, de belladone, de chlorhydrate de morphine, de codéine, diacode, de jusquiame, de lactucarium opiacé, de laurier-cerise, de morphine, d'opium, de pavot blanc, and de sulfate de morphine, and, when we come to the Codex of 1884, sirop de chloral hydrate as thus prepared:—

Chloral hydrate	50
Aqua destillata	45
Syrupus	900
Spirit. menthæ pip.	5
	1000

The strength is 1 in 20, as compared with 1 in 6, B.P.

I think it advisable to say a few words respecting French opiate syrups, as I am told that some slight misapprehension exists.

Syrupus de ipecacuanhâ compositus bears no relation whatever to our pulvis ipecacuanhæ compositus, which our *confrères* will persist in calling poudre de Dower. It is an essentially Codex preparation, not adapted to our use. Dover's powder is distinguished as poudre d'ipécacuanha opiacée, which differs both in strength and constitution from the English form.

There are three opium syrups, made from extractum opii, not from pulvis opii.

Sirop Diacode.

[New Synonym Sirop d'Opium faible.]
To replace Syrupus Papaveris.]

Ext. opii	0.50 (50 centigrammes).
Aq. dest.	4.50 (4 grammes, 50 centigrammes).
Syrup.	995 grammes.
	1000 grammes.

Dissolve the extract in the distilled water, filter the solution and mix with syrup. Twenty grammes of this syrup contain 1 centigramme of extract of opium.

2.

Sirop d'Opium.

[Synonym. Sirop Thébaïque.]

Ext. opii	2 grammes.
Aq. dest.	8 "
Syrup	990 "
	1000 "

Twenty grammes of this syrup contain 4 centigrammes of extract of opium

3.

Sirop de Karabé

is made by adding 50 centigrammes of tincture of amber to 100 grammes of syrup of opium. The remaining anodyne French syrups containing opium or morphia salts need not be mentioned. The B.P. Addendum of 1890 has added a chemical syrup, namely, *syrupus ferri subchloridi*, to the list.

This is prepared by the direct action of hydrochloric acid and water on iron wire, with subsequent addition of citric acid (10 grains to the pint), and though minus glycerin and hypophosphorous acid, seems to keep well. It has the advantage over the syrup of the perchloride, which rapidly changes, with loss of colour.

The exact value of citric acid in this case is not easy to determine; the syrup prepared with varied quantities of citric acid, and with its entire omission, seemed to present no points of difference therewith with respect to its keeping properties or as regards coloration.

I am relieved from entering at length into the history of the phosphate syrups owing to the excellent articles which have appeared in the *Pharmaceutical Journal*, entitled "The Introduction of Phosphorus and its Compounds into Pharmacy." I quote the following sentence (*Ph. J.*, p. 513, Dec. 21, 1895): "The syrups and chemical foods prepared by Parrish, Squire, Fellows, and Easton have been frequently discussed in works dealing with pharmacy, but the experience has been that it is almost impossible to produce a compound of regular and uniform composition from the prescriptions which have been published." Mr. Thomas Greenish, on April 9, 1851, at an evening meeting of the Pharmaceutical Society, my father as President, in the chair, drew attention to a preparation of iron which had been introduced to the medical profession by Dr. Routh in the January of that year. The process was thus described:—Add as much phosphate of iron to solution of metaphosphoric acid, as the latter, in a boiling state, will take up and allow it to cool. The solution was of a semi-transparent greenish hue, hardening on exposure to the air, soluble in water in all proportions, and free from inky taste. Mr. Greenish made a syrup of this salt: strength, 5 grains to a drachm.

At the suggestion of Mr. Phillips, at that time in the Laboratory in Jermyn Street, it was called "superphosphate of iron," waiting for a more definite term until its composition was better understood.

At that meeting at Bloomsbury Square it made its first appearance as a new remedial agent.

The preparation was improved as it was found that it contained more iron than could be held in solution.

The syrup of the superphosphate of iron was shown at the Great Exhibition of 1851, and since that date syrups known as compound syrup of the phosphates and hypophosphites form a long series which time would fail to describe.

Mr. Carteighe has proposed a method of preparing various syrups of the phosphates direct from any required phosphate, in a similar manner to his formula for

Syrupus Ferri Phosphatis. (Carteighe.)

Phosphate of iron.....	96 grs.
Water.....	℥ix.
Syrupy phosphoric acid (Sp. gr. 1.5)	℥vii.
Syrup	℥x.

Rub the phosphate of iron with the water in a glass mortar, add the phosphoric acid, and filter the mixture into the syrup. The ferri phosphas must be freshly made, as that kept in stock is not sufficiently soluble.

The B.P. (1885) *syrupus ferri phosphatis* is a manifest improvement on its predecessor, both in the strength of the acid and the substitution of the bicarbonate for the acetate of sodium. It seems too acid.

One wonders that in the finishing process the sugar and water are not made in the usual way into syrup, into which, when cooled, the acid solution should be filtered; or dissolve the sugar in the water without heat and into this filter the dissolved precipitate. The retarding influence of phosphoric acid on saccharin solution has not been taken into account. Possibly the text may bear this meaning and needs only a slight reconstruction.

This phosphate syrup combines beautifully with Easton's syrup made according to the modified formula adopted by the British Pharmaceutical Conference under the name of *syrupus ferri, quininae et strychninae phosphatum*, and by Guy's Hospital, under the far preferable title of *syrupus trium phosphatum*. Suppose we were to call tincture of rhubarb, *tinctura rhei, cardamomi seminum, coriandri fructus, croci et spiritus tenuioris*, we might fancy ourselves drifting into organic chemistry.

Dr. Easton, date 1863, proposed the syrup bearing his name, as an excellent general tonic. Dr. Aitken, in his 'Science and Practice of Medicine' (3rd edition, 1864), inserted the previously unpublished formula of his friend.

Strychnine in powder	5 grains.
Concentrated phosphoric acid (Sp. gr. 1.5)	75 minims.
Distilled water.....	225 minims.

Dissolve and add

Phosphate of quinine.....120 grains.

Dissolve by the aid of a gentle heat (?) and add syrup of phosphate of iron to 1 pint.

It has been stated that the quinine is apt to crystallise; I cannot confirm this. By treating the strychnine according to the method of gently smoothing out the crystalline structure between a fold of paper, the solubility is increased to such an extent that the least heat is required; on an experimental scale, none; the phosphate of quinine requires no additional heat, and the result seems all that can be desired.

We need not then dissolve the strychnine and phosphate of quinine in the solution of phosphate of iron, though the method is most ingenious; nor need we resort to the addition of hypophosphorous acid, as is sometimes the practice. Easton's syrup is also made by direct action on iron wire according to the following formula:—

Iron wire	grs. 65.
Strychnine	grs. 5.
Syrupy phosphoric acid	℥xi.
	(Sp. gr. 1.5.)

1.

Quinine phosphate.....	grs. 120.
Simple syrup	℥xiiij.
Water to	℥xx.

M.S.A.

A series of formulæ, suggestions, and variorum proposed amendments relating to this syrup will be found in current pharmaceutical literature.

Chemical food, that fertile subject for discussion, must be left undisturbed. It has been exhumed so often that there is not a vestige of novel treatment left.

Frequent reference is made in all manuals treating on galenical pharmacy to the preservation of syrups. In most cases this means suggestions for methods to be applied to the preservation of liquids containing organic matter, protected only by sugar. The protective substance itself is liable to undergo fermentation, and hence the precautions needed. One rule obtains throughout in pharmacy that preservation by any means, chemical or otherwise, should be of the simplest nature, and that any such addition made should not alter essential character.

All good methods have for their object the prevention of fermentation in syrups of vegetable construction; when once this has commenced, consign the preparation to the sink; chemical syrups are kept in an unaltered state by controlling decomposition or precipitation special to each particular case.

A long series of suggestions may be found scattered through periodicals, a few of which may be enumerated.

(a) Separation of albumin by heat, or (French method) clarification by albuminated water.

(b) Filtration by various means, notably by animal charcoal.

(c) Percolation, for which process there are strong advocates, chiefly insisting that no more sugar is dissolved than that which can be perfectly retained, and that excess is consequently avoided.

(d) Demarest's process. The syrup is beaten up with unsized paper made into a pulp, in the proportion of 1 gramme to 1 litre. The fluid is passed twice or oftener through a woollen filter bag. Syrup so treated must be maintained at a temperature of 35° C. to 40° C. [95° F. to 104° F.] and moleskin is recommended as the filtering material.

(e) The Via Frigida, a cold process; no heat to be applied in effecting the solution of the sugar. Great advantage is claimed by some; denied by others in view of fermentation. In the hands of an experienced pharmacist who uses judgment it is of service.

(f) The addition of rectified spirit of wine as in *syrupus mori* and *syrupus rhœados*; good pharmaceutically, but therapeutically doubtful.

Pharmacists of an earlier date used this method freely, the ordinary proportion being *sp. v. rectific. 4, syrup, 16*.

(g) Glycerin and water, equal parts; to replace syrup in the phosphate series; this will never do; the liquid is too thin, and a glycerole is not a syrup.

(h) Devices for iodide of iron syrup; their name is legion, a few selecta è præscriptis must suffice.

(1) Coil of iron wire.

(2) Thin supernatant layer of oil, preferably almond. Two theories are held respecting this—one, that it results in a loss of 3 per cent. of ferrous iodide; another, that the syrup becomes somewhat lighter in colour, while oil takes up only a minute trace of iodine even after long keeping.

(3) Dilute the syrup with a third of its volume of water, boil for a few minutes, filter, and reduce by evaporation to original bulk.

(4) Treating with hyposulphite and hypophosphorous acid—also

this: stir a few drops of liquor potassæ into the syrup previous to the addition of a trace of phosphoric acid. What an advantage it is to have learnt chemistry.

(5) Selection of some specially-manufactured sugar.

(6) The addition of pure glucose in the place of a corresponding amount of sugar.

(7) Beardsworth advises the addition of citric acid, 1 grain to an ounce, and exposure to a bright light, as being all that is required to clarify, decolorise, and keep the syrup in perfect condition.

(8) Messrs. Godfrey kept the syrup in small bottles, exposed to what sunshine London could afford.

(9) Mr. Carteighe states that if the sugar-syrup be heated rapidly to the boiling point before adding the iodide solution, the preparation has less colour than when made at the lowest temperature at which the sugar will dissolve.

No process should be slighted on account of its foreign origin. Our own British Pharmacopœia will compare favourably with any other as regards simplicity and arrangement; but while its formulæ may often be used with advantage by Continental authorities, we, on our side, may frequently adopt methods of manipulation and practice which commend themselves by their intrinsic excellence.

Appert's method for the preservation of syrups is specially serviceable in the case of those syrups which it is desirable to have in stock, but for which there is not much demand. I give my own student's note (translated):—

Take small bottles holding from 6 to 8 ounces each, fill them right up to the neck, immerse the bottles in water, and raise to the boiling point. To avoid breakage, the bottles must stand on wood placed at the bottom of the pan.

A slight expansion of the syrup will take place, but it will contract on cooling with formation of a partial vacuum, if corked while hot. Remove the source of heat, and let the bottles, still in the surrounding water and by no means removed, cool gradually down.

Reverse the bottles when stored else the corks may dry and leak. It is essential that the bottles used should have been absolutely dry, well corked and kept in a cool place. [Enfermez le sirop dans des bouteilles bien sèches, que vous boucherez exactement et que vous tiendrez couchées à la cave.]

No syrup can be made to keep for an indefinite period; by preservation is meant that it should retain its characteristics unimpaired for a reasonable length of time.

I believe the best general method for the preservation of a syrup is judgment in calculating the right proportion of sugar, and the management of heat.

DISTRIBUTION AND FUNCTION OF CAROTIN IN PLANTS.—Dr. H. Ritter Schrötter-Kristelli records the occurrence of carotin in the aril of *Azalia cuanzenensis*, belonging to the Leguminosæ, dissolved in a fatty oil, and not—as in all cases hitherto observed in flowering plants—in connection with the chromatophores. The author believes carotin to be nearly related to the group of cholesterins, and to have a function connected with the respiration of the plant. For the group of the yellow pigments of plants and animals to which carotin belongs, he proposes the name lipoxanthins. They occur in green leaves, and in autumn leaves in many flowers and fruits, in arils and in roots (as the carrot) also in algæ, fungi, lichens, bacteria, and myxomycetes. This group of yellow pigments must be carefully distinguished from others which occur dissolved in the cell-sap, and are not connected with the chromatophores (*Botanisches Centralblatt*, lx. (61), 33).

ALKALOIDS OF THE VERATRUMS.*

BY ALFRED H. ALLEN.

(Concluded from last volume, p. 243.)

Cevadine, $C_{32}H_{49}NO_9$, is the most abundant alkaloid of *cevadilla* or *sabadilla* seeds, and, according to Wright and Luff, is also present in the rhizome of *Veratrum viride*. It is identical with the 'veratrine' of Merck, and of Schmidt and Köppen, but that name is more appropriately given to the alkaloid first designated thus by Couerbe,† which yields veratric acid on saponification, whereas *cevadine* yields *cevadic acid* when similarly treated. But the nomenclature is liable to cause great confusion, even recent observers (*e.g.*, Ahrens, Bosetti, Merck) retaining the name "veratrine" for the base which yields *cevadic acid*, while the pharmacopœias apply the term "veratrine" to the mixture of alkaloids obtained from *cevadilla* seeds. *Cevadine* separates from alcohol in anhydrous needles, but from ether it separates only as a varnish, which becomes crystalline on moistening with slightly diluted alcohol and well stirring. The crystals are at first transparent, but on exposure to air become white and opaque, without material loss of weight. The alkaloid melts at 205° to 206° , or at a somewhat lower temperature if impure. *Cevadine* dissolves in acetic ether, acetone, chloroform, amylic alcohol, and carbon disulphide, but is only sparingly soluble in petroleum spirit, even when hot. The solutions are optically inactive.

Cevadine is extremely poisonous and exerts a peculiarly powerful action on the mucous membrane of the nose, the smallest particle producing violent sneezing.

Few of the salts of *cevadine* have been obtained crystallised. On adding auric chloride to a solution of *cevadine* in hydrochloric acid the aurichloride is thrown down as a very sparingly soluble yellow precipitate, which is amorphous at first, but soon becomes crystalline. When drained and boiled with slightly diluted alcohol it dissolves, and on cooling is deposited in small, well-defined needles containing

* This article is taken, with a few alterations, from advance-sheets of *Commercial Organic Analysis*, vol. iii., part 3.

† For the extraction of the alkaloids from *sabadilla*, Alder Wright and Luff (*Journ. Chem. Soc.*, xxxiii., 341) percolated the coarsely pulverised seeds with alcohol acidulated with tartaric acid (1 part of acid to 100 parts of seeds), evaporated the liquid to a small bulk, precipitated the resin by adding water, rendered the filtrate alkaline by sodium carbonate, and agitated with ether. The separated ether was then shaken with tartaric acid solution, and employed again. The acid liquid containing the alkaloids as tartrates was again treated with sodium carbonate, and agitated with ether, which completely dissolved the alkaloids. The ethereal solution was cautiously treated with benzoline previously diluted with a little ether until a permanent precipitate began to form, and then set aside, when the ether evaporating the more rapidly, the liquid became gradually richer in benzoline, and deposited first viscid masses of amorphous alkaloid and subsequently distinct crystals. These were stirred up with a few drops of alcohol, well drained, and slightly washed with alcohol on the filter-pump, and the nearly pure crystals of *cevadine* thus obtained purified by repeated recrystallisation from hot alcohol till they melted at 205° . On treating the viscid amorphous alkaloid with a quantity of ether insufficient for its complete solution, *cevadilline* remained behind, while on again treating the solution with benzoline and allowing it to evaporate more *cevadine* crystallised out. The resinoid precipitate which first separated was dissolved in dilute sulphuric acid, the liquid treated with ammonia, the precipitate drained on the filter-pump and partially dried by exposure to air. On stirring up the nearly dry base with dilute nitric acid in a mortar, a sticky mass was obtained, which was only partially soluble in water even on boiling. The insoluble portion gradually became granular, and was filtered off and purified by boiling two or three times with small quantities of water. On treating this product with sodium carbonate and ether, evaporating the ethereal liquid, and treating the alkaloidal residue with dilute sulphuric acid, fine crystals of veratrine sulphate resembling paper pulp formed on standing. These were collected and drained on the filter-pump. On spontaneous drying by exposure to air these became a resinoid mass of conchoidal fracture, but on dissolving this in water and allowing the solution to stand, crystals were again formed from which pure veratrine was obtained by treating the solution with sodium carbonate and ether.

$BHAuCl_4 + 2 \text{ aqua}$. The water of crystallisation is lost only slowly at 100° , and the salt melts at 182° . *Cevadine picrate*, $B, C_6H_5(NO_2)_3O$, forms stable crystals, which are very slightly soluble in water, but readily in alcohol, and blacken at 225° . The mercurichloride, BH_2HgCl_2 , crystallises in small silvery plates, which melt at 172° with decomposition, are readily soluble in alcohol, but very slightly so in water. The chloroplatinate is an amorphous precipitate, soluble in alcohol, but decomposed by water. Alder Wright and Luff found that when *cevadine* was heated to 100° with twice its weight of benzoic anhydride it was converted into mono-benzoyl-*cevadine*, $C_{32}H_{48}(C_7H_5O)NO_9$. From the formation of this body, the impossibility of obtaining a more highly benzoylated derivative, and the products of the saponification of *cevadine* by caustic alkali, Wright and Luff deduced the following constitutional formula for the alkaloid:—

When *cevadine* is boiled with concentrated hydrochloric acid it yields tiglic acid, $C_5H_8O_2$, and a lustrous, ruby-red, crystalline mass which is probably the hydrochloride of a new base. On treatment with nitric acid, *cevadine* is wholly oxidised; with alkaline potassium permanganate it yields acetic and oxalic acids; and with chromic acid, acetaldehyde and carbon dioxide.

When *cevadine* is heated in sealed tubes with water to 200° it undergoes saponification. The change occurs more readily when the alkaloid is boiled with alcoholic soda or baryta-water, and is also brought about by cold aqueous caustic potash or soda, and even, though more slowly, by cold dilute ammonia. The first reaction appears to consist in the formation of angelic acid and a new base called *cevine*, according to the equation—

The angelic acid changes with great facility into the isomeric *cevadic* or *tiglic acid*, which is, to some extent, split up into acetic acid, $C_2H_4O_2$, and propionic acid, $C_3H_6O_2$, while the *cevine* undergoes further decomposition with the formation of non-basic resinous products. The facility with which *cevadine* undergoes hydrolysis is the cause of the formation of much amorphous alkaloid and other products in the extraction of the alkaloids from *cevadilla* seeds.

To obtain the two chief products of the saponification of *cevadine*, Alder Wright and Luff boiled the alkaloid with alcoholic soda under a reflux condenser.* The liquid was then diluted with water, acidulated with dilute sulphuric acid, and distilled as long as any acid passed over. The distillate was neutralised with soda, evaporated to a small bulk, treated with sulphuric or phosphoric acid, and distilled. The distillate consisted partly of fluid acids, readily soluble in water, and partly of crystals or an oil becoming crystalline on standing. An alternative method is to acidulate the solution of the sodium salt with sulphuric acid, and agitate with ether. On distilling the separated ethereal layer after the ether had passed over, an acid liquid began to distil a little above 100° , the temperature quickly rising to 185° – 190° , when a fraction was obtained which solidified on cooling to a mass of crystals wetted by an acid liquid. On pressing this product between blotting-paper, pearly scales of *cevadic acid* were obtained, melting at 64° – 65° .

Tiglic acid, *Cevadic acid*, or *Methyl-crotonic acid*, $C_5H_8O_2$, forms triclinic prisms or scales, which melt at 64.5° , though a mixture of it with a somewhat greater weight of its isomeric, angelic acid,† is

* They continued the treatment for many hours, but this is manifestly undesirable, and half-an-hour's boiling with normal alcoholic soda is amply sufficient to effect complete saponification.

† Angelic Acid, or Pentenoic Acid, isomeric with tiglic acid, crystallises in long prisms having an aromatic smell, melting at 41° – 44.5° , and boiling at 185° . When boiled for some time, or when heated to 100° with sulphuric acid, it is converted into tiglic acid. Angelic acid is but

liquid at the ordinary temperature. Tiglic acid has an aromatic odour somewhat resembling butyric acid, but more pleasant, and boils at 198.5°, giving off a vapour which excites violent coughing. When fused with caustic potash it yields propionic and acetic acids. Calcium tiglate, $\text{Ca}(\text{C}_5\text{H}_7\text{O}_2)_2 + 3 \text{ aqua}$, is soluble in about 16 parts of cold water, but is much more soluble in hot water, and is deposited on cooling in white plates.

Cevine.— $\text{C}_{27}\text{H}_{43}\text{NO}_8$. In order to isolate the complementary alkaloidal product of the saponification of cevadine, Wright and Luff filtered the acid liquid left after distilling off the volatile acid, to separate resinous matter, rendered it alkaline with caustic soda, and agitated with amylic alcohol. The amylic layer, when separated, filtered, and evaporated, yielded a brownish varnish, which on solution in dilute acetic acid left resinous flakes. The filtrate from these, on fractional treatment with soda and amylic alcohol, gave an amber-coloured varnish of cevine perfectly soluble in acids. When heated in a capillary tube this did not frit below 140°, and fused at 145°. It dissolved readily in alcohol and amylic alcohol, sparingly in chloroform, and hardly perceptibly in ether. Neither free cevine, nor its salts were obtained crystallised. On adding Mayer's reagent to a solution of the base in acetic acid, nearly insoluble white flakes were precipitated, containing (after drying at 100°) BHHgI_3 . The aqueous solution of cevine becomes turbid on warming. Cevine does not attack the mucous membrane, gives a crimson colour with strong sulphuric acid, and a brown colour with sulphuric acid and sugar.

Veratridine, $\text{C}_{37}\text{H}_{53}\text{NO}_{11}$, occurs in sabadilla seeds, and possibly in minute quantity in the rhizomes of white and green hellebore. It is identical with Wright and Luff's "veratrine."

Veratridine free from cevadine has never been obtained crystallised. It melts in a capillary tube at 180° (Wright and Luff).

On triturating solid veratridine with dilute nitric acid a horny nitrate is formed, which is almost insoluble in water, even when boiling. Dilute sulphuric acid readily dissolves veratridine, and, on standing, the sulphate crystallises out in extremely fine needles, which, on drying, unite to form a horny translucent mass, reproducing crystals when dissolved in water and allowed to stand. The hydrochloride exhibits a similar behaviour, but the crystals are not so well marked and distinct. The aurichloride is obtained as a gelatinous yellow precipitate, which, when dried over sulphuric acid, becomes a translucent horny mass, not crystallisable from alcohol.

When boiled with alcoholic soda, veratridine undergoes saponification, with formation of veratric or dimethyl-procatechuic acid and verine, according to the equation:—

The acid is identical with that obtained by the saponification of pseudonitine. The basic product verine, or veratrine, presents a close resemblance to cevine, obtained in a similar manner from cevadine. The only recognisable distinctions are in the behaviour on heating and the elementary composition. Thus, verine fritted in the water bath or in a capillary tube at 95°, and on raising the temperature gradually became a thick viscid mass, exhibiting no distinct melting point, and not becoming completely fluid till heated to about

slightly soluble in cold water, but dissolves readily in hot water and alcohol, and is extracted from aqueous liquids by agitation with ether. When fused with caustic potash, angelic acid behaves like tiglic acid. Calcium angelate $\text{Ca}(\text{C}_5\text{H}_7\text{O}_2)_2 + 2 \text{ aqua}$, is much more soluble in cold water than in hot. A cold saturated solution contains about 23 per cent. of the salt, but when heated to 30°—40° glistening needles separate out, and at about 70° the whole becomes semi-solid. If air has been excluded the crystals dissolve completely again on cooling. The constitution of angelic and tiglic acids is probably represented by the following formulæ:—Angelic acid, $\text{CH}_2 : \text{C}(\text{CH}_3) \cdot \text{CH}_2 \cdot \text{COOH}$. Tiglic acid, $\text{CH}_3 \cdot \text{CH} : \text{C}(\text{CH}_3) \cdot \text{COOH}$.

130°; whilst cevine exhibited no sign of fritting below 140°, and completely fused at 145°.*

Bosetti (*Arch. Pharm.* [3], xxi., 81), attributes to veratridine the formula $\text{C}_{32}\text{H}_{49}\text{NO}_9$, and the melting point 150° to 155°. To the basic product of its saponification he gives the formula $\text{C}_{55}\text{H}_{92}\text{N}_2\text{O}_{16}$, and states its melting point at 143° to 148°.

Sabadine, $\text{C}_{29}\text{H}_{51}\text{NO}_8$, has been recently isolated from sabadilla seeds by E. Merck (*Chem. Zeit. Rep.*, xv., 48; *Jour. Soc. Chem. Ind.*, x., 481). It is deposited by the slow evaporation of its alcoholic solution in well-defined crystals, which melt with decomposition at 238° to 240° C., but the residue obtained by evaporating the ethereal solution has no definite melting point. The crystals are difficultly soluble in water and ether, and insoluble in petroleum spirit. With strong sulphuric acid, sabadine gives a yellowish coloration and green fluorescence, the colour subsequently changing to blood red, and finally to violet. Concentrated nitric acid appears to produce no change. BHCl crystallises with 2 aqua, but becomes anhydrous with decomposition at 282° to 284°. Sabadine is not precipitated on adding caustic alkalies, alkaline carbonates, or ammonia to cold solutions of its salts, but is separated in a flocculent form on warming the liquid. It can be extracted from the alkaline liquid by agitation with ether. Sabadine attacks the mucous membrane of the nose and causes sneezing, but in a less marked degree than cevadine.

Sabadinine, $\text{C}_{27}\text{H}_{45}\text{NO}_8$, behaves like sabadine with alkalies. It is best extracted by agitation with chloroform. From its ethereal solution it separates in hair-like needles, which commence to melt at 160°, and decompose at a higher temperature. The alkaloid is moderately soluble in water, sparingly in ether, but readily in alcohol. Concentrated sulphuric acid produces a permanent blood-red coloration, but nitric acid causes no visible change. BHCl forms crystals which contain water, and are readily soluble. Sabadinine does not occasion sneezing.

AINU MEDICINAL PLANTS.

The interest that is always attached to the useful plants of a new or little-known country is greatly enhanced when sufficient knowledge of the plants themselves exists to allow of their botanical identification, and still more so where the country is one that offers capabilities and promises of future development. Anything connected with Japan, therefore, or with matters worked out by such progressive people as the Japanese, is of sufficient interest to warrant a wider circulation than that which it would possibly have in a publication issued in a far-off land. Such, for instance, is the paper on Ainu Economic Plants, contributed by the Rev. John Batchelor and Dr. Kingo Miyabe, in the twenty-first volume of the 'Transactions of the Asiatic Society of Japan.' The authors point out that the study of the useful plants of the Ainus attracted the attention of the Japanese so long ago as the latter part of the eighteenth century, and contributions to the subject have been made from time to time since, all of which have been carefully studied by the present authors; but only those matters that have been examined and confirmed by them, with the aid of a native AINU, have been included in the paper mentioned, so that the uses of the plants referred to, as well as the identification of the

* Alder Wright and Luff, to whom the foregoing observations are due, point out that the numbers obtained by the analysis of veratrine are not incompatible with other formulæ differing but little from $\text{C}_{37}\text{H}_{53}\text{NO}_{11}$, which is that which agrees best with their results. But they add that the formula $\text{C}_{36}\text{H}_{51}\text{NO}_{11}$ would indicate cevine and verine as being identical, and cevadine and veratridine as containing a common radical when their formulæ are thus written:—

plants themselves, have the double value of actual confirmation by competent writers. Forty-four plants are enumerated, their scientific and common names given, and their uses in medicine stated. The authors are careful to point out that this is not an exhaustive list of Ainu medicinal plants, but that the subject has only just been commenced, and that they intend steadily to pursue their studies. The plants are arranged according to the sequence of the 'Genera lantarum' of Bentham and Hooker, though the natural orders are not given. The following are the principal plants referred to, the Ainu name in all cases standing first:—

Arikko (*Thalictrum aquilegifolium*, L.)—The bitter roots, either raw or roasted, are said to cure pains in the stomach. Sometimes, however, a decoction is made by steeping the roots in boiling water, and a good strong dose is taken. This is said to work wonders as a cure for stomach ache. Should a person wound his hand when at work, or thrust some sharp object into his foot when walking through the forest, he will take the roots of this plant, chew them to a paste, and apply to the wounded part to prevent suppuration. Some of the Ainu take the leaves, roll them between the hands to bruise and make them soft, and then plaster over any part of the body where there should be an internal pain or contusion.

Horap or Orap (*Paeonia obovata*, Maxim.)—The root is dug up, dried and preserved for medicinal purposes. It has a bitter taste. An Ainu will take a piece of the root and swallow it with water to cure stomach ache, and it is said to have an immediate effect. Chewed into a paste the root is sometimes applied to aching joints. For ordinary slight ailments a decoction is commonly recommended. In Mukawa and elsewhere the seeds are recommended as a remedy for sore eyes, for which purpose they are chewed up and put in a piece of clean white cloth and the juice then squeezed out into the eyes. In Usu when a person suffers from a pain in his ears the smoke from a mixture of tobacco and the powdered seeds is blown into them.

Opke-ni, or Omau kush-ni (*Magnolia kobus*, DC.)—The bark is the part used in medicine, a decoction of which is taken for colds. The bark is believed to have the mysterious power of driving away the demons of disease. In times of pestilence a piece of the bark is commonly put into the drinking water as a preventive. Branches are placed over doors and windows as a charm. A thin decoction is often made and drunk in place of tea.

Repnibat (*Schizandra chinensis*, Baill.)—The stems are mostly used in medicine, although the fruit is sometimes so used. It is believed by some of the Ainu to be a specific for colds: for this purpose a piece of the vine is rolled up and put into a cup of boiling water, and the thin decoction thus made is taken. It is also recommended by some Ainu as a remedy for sea-sickness.

Otompui-kina (*Chelidonium majus*, L.)—The stems and leaves, softened by dipping in hot water, are applied externally to any place where there are internal pains caused by a fall or contusion. Some Ainu believe that the yellow juice of this plant destroys warts, a belief that may possibly have been learnt from the Japanese. It is also believed to be an antidote against snake poisoning, and it is further used by some Ainu to relieve internal stomach pains. A most peculiar practice is when a child suffers from constipation, a small piece of bruised stem is placed in the anus, and it is said to have an immediate effect.

Riten-kina (*Stellaria media*, L.)—This common weed is widely used for external application to bruises or to any part of the body where the bones ache. The stems and leaves are steeped in hot water before being applied.

Kutchi-pungara (*Actinidia arguta*, Planch.)—In the spring, when the vine of this climber is cut, the sap flows out freely in

large quantities, and this is used in medicine and believed to be a good expectorant. The structure of this stem is peculiar, as it shows no annual rings or medullary rays, but presents a mass of large, clear, round, open pores, on which account cross sections of the trunk are used in Japan for making tobacco boxes, as sufficient air is admitted through it to prevent the tobacco becoming mouldy.

Shikerebe-ni (*Phellodendron amurense*, Rupr.)—The inner bark is much esteemed by the Ainu as a medicine. It is yellow and extremely bitter to the taste. It is applied externally over any portion of the body where there may be internal pain, particularly such as may have been caused by falling from a horse, or by any similar accident, it is also applied to burns, scalds, and sore eyes. The bark is bruised and made damp, either by chewing or with water, before it is used. Persons who travel in the interior, and who are called upon to wade streams the greater part of the day, suffer greatly from a skin disease called mizu-mushi by the Japanese. This disease attacks the spaces between the toes, quickly making them quite raw. An application or two of the inner bark of the shikerebe-ni is said to remove the malady. The berries are much prized by some Ainu as a medicine, and are said to be a good expectorant. In some places they are used where the muscles have been strained and caused to swell; a few berries are chewed into a pasty mass and put upon the affected part; they are also eaten as an article of food.

Shiu-ni, or Yuk-raige-ni (*Picrasma ailanthoides*, Planch.)—The bitter bark is believed by the Ainu to be poisonous, and a strong decoction is often used to kill lice; eruptions on the scalps of children are also sometimes washed with it. It is said that should deer eat the bark they die very soon after, hence the name, which means "Deer-killing tree."

Tochi-ni (*Aesculus turbinata* Bl.)—The nuts are collected and dried and often used in medicine; when required they are soaked and well scraped, and the scrapings steeped in water, when the decoction is used to wash wounds with. The Ainu often use it for washing the eyes of horses when they run water or discharge matter.

Oikara (*Pueraria thunbergiana*, Benth.)—The root is used as a remedy for aches and bruises, it is thoroughly roasted and the affected part of the body well rubbed with it. The root stock is rich in very fine starch, and is well known and much esteemed by the Japanese as an article of food, but the Ainu know nothing of it as such.

Chikube-ni (*Cladrastis amurensis*, Benth., var. *Buergeri*, Max.)—The bark of this tree is believed to have a poisonous property. It is externally applied to the body when there is internal pain.

Kikin-ni (*Prunus padus*, L.)—The bark is sometimes steeped in hot water and the decoction used as a remedy in stomach ache. The bark is also used as a beverage in place of tea. At Saru and elsewhere this plant is believed to have the power of driving away the demons of disease, and is, therefore, used as a charm.

Tokaomap (*Cicuta virosa*, L.)—The poisonous root-stock when charred is used by some Ainu for external application to pains in the bones.

(To be continued.)

CUPRIC OXIDE AS A VERMIFUGE.—In the *Wien Med. Prax.* Schmidt prescribes the following pills as a vermifuge:—Black oxide of copper, 6 grammes; prepared chalk, 2 grammes; French chalk, 12 grammes; glycerin, 10 grammes. Make into 120 pills; two pills four times a day for the first week, then three pills four times daily for another week (*Dub. Journ. Med. Sci.* [3], cclxxxviii., 5111).

ANOTHER OLD DRUG SHOP.

On reading the article in the Journal of January 11 on "An Old Drug Shop in Leeds," the writer thought that a few notes of personal experience of another more or less historic establishment of eighty years' standing in a town of the West Riding of Yorkshire, might be of some interest, principally by way of contrast between the style of business forty or fifty years ago, and at the present day. He was acquainted with the business referred to some fifty to sixty years ago, and has been connected with it as partner for over forty years. It has been mainly, and still is, a retail drug business, although drugs now form but a small item in the daily routine, being largely replaced by chemicals. It may also be interesting to state that the above business has been carried on without any break in the proprietorship since 1817, that is to say, the partnerships have overlapped each other during that time.

A doubt has often arisen as to whether our pharmaceutical "powers that be"—who assume that druggists or pharmacists are necessarily and primarily dispensers of physicians' prescriptions—can possibly realise the condition of things in a town of over 200,000 inhabitants, where there have been sometimes two, sometimes one, and sometimes no physicians writing prescriptions, and where nine-tenths of the medicine required is supplied by the medical practitioners. Of course there are prescriptions from London and elsewhere, but probably all these could be dispensed from one establishment without any great over-strain. As there are about a hundred chemists and druggists in the district, one naturally asks, Where does the pharmacy come in?

In the years 1820 to 1830 the then principal of this business was much interested in philanthropic matters. The shop was the depôt of the British and Foreign Bible Society, and the Bible room was the meeting place of those like-minded with himself, and many schemes for the good of the town and district were there inaugurated. Large warehouse room was a desideratum in those days. There was no sending for articles to London, as wanted, and having them in twenty-four hours, and this meant keeping a large stock. Representatives of London drug houses came once in six months and the goods were sent by sea and canal. These comprised bales of many drugs, duppas of castor oil, jars and half jars of olive oil, gourds of aloes, and carboys of other things—no "Winchesters." The visit of So-and-so's traveller was then an event looked forward to and prepared for weeks beforehand. Compare this happy (?) state of things with the present continual worry of travellers the day through! The proprietor of the business in 1820-30 had been in the habit of acting more or less as an apothecary prior to the passing of the Apothecaries Act, and in his later years prescribed for those who came to him; not visiting patients, but receiving them in the Bible room, and having his prescriptions dispensed downstairs. This prescribing was more or less continued by his immediate successors, but has long since ceased.

In the years about 1860 times were pretty good, mill hands were fairly well paid, and their hair, male as well as female, required much greasing for Sunday. Two "pipes" of ol. olivæ sublim. was then about the yearly purchase, and nearly all went for this purpose. Hair oil, at 2*d.* per fl. oz. in this quantity, even with a fair allowance of perfume, indicates, probably, good times gone by. The shop was often crowded on Saturday evenings up till 10 and 11 p.m., when the demands for hair oil would be varied by requests for "cipity" ointment, camomiles and poppy heads, pennyworths of jalap, salts and senna, "ikery pikery," brimstone and cream of tartar, and such like, all at good paying prices if in small quantities. Epsoms were *not* sold at 1*d.* per lb. Bear's grease became fashionable in later times. There were also a good many proprietary remedies peculiar to the establishment in those days. Of course it is well

known now that cordials are bad and wicked things to use for children, and yet, either the children of that day were of tougher stuff than those of later times, or from some other cause, hundreds of children in that town, who were dosed regularly with a carminative compound called "white mixture," have made good sturdy men and women. It was an article of faith in many households that this white mixture was a necessity in the rearing of children. Now; the stopper of the shop bottle is often set fast for want of use!

The writer joined the business as a partner in 1854, after a year at "the Square," then under the guidance of Pereira, Redwood, and Bentley as lecturers, with dear "old Braithwaite" as presiding genius over the laboratory in the cellar of No. 17. This was followed by a couple of years at the German Universities of Giessen and Munich, where Baron Liebig was then in the height of his fame. This is only mentioned to show the effect of the introduction of analytical and other chemistry into an old-fashioned drug business. One of the first changes in the character of the business was brought about by the introduction of photographic materials, an innovation then looked at very doubtfully by the seniors, who preferred the old steady drug, with oil and colour and candle trade. In process of time, other firms arose, dealing in drysalteries especially, and the value of this branch of the business was much lessened.

Another change, and one of a far-reaching and fatal character has been brought about by the transfer of the demand for simple drugs and own proprietary remedies to that for other "patents" fostered by the advertisement mania. We have, as a trade, ourselves to blame in this matter in that we have condescended to push this or that "patent," and have thus helped to bring about the present lamentable state of things.

The expansion of a large town has also had a great effect on the demand for domestic drugs from the older central establishments. The residential circle has widened, and many of the small general shops in the outskirts of the town sell drugs—of a sort. Independently of this, however, the value of salts and senna, jalap, camomiles, etc., are not "understood of the people" as they once were. Another change, and a very unpleasant one to the writer, is the transfer of the manufacture of pharmaceutical preparations to large establishments furnished with steam and other appliances. It is humiliating, but has to be admitted, that many of these can now be better bought than made by the ordinary retail druggist. For many years all the preparations of the business were made on the premises, and scores of apprentices have found it in this respect a very useful school.

The most recent change in the character of business has been brought about by the great extension of scientific teaching in the present day. This, and more especially the teaching of chemistry, added to the necessity experienced by manufacturers, dyers, and others, for the applications of chemistry in their processes, has caused a demand for chemicals in place of drugs and for scientific apparatus and materials of all kinds. Thus, at the present time the sulphur, of brimstone and treacle fame, has to be supplied as sulphuretted hydrogen, or as sulphurous or sulphuric acids, whilst the pennyworth of hair oil has given place to a pennyworth of glass tubing or a penny test-tube, and the purchase of bales of drugs to that of such things as compressed liquid chlorine and carbonic acid by the hundredweight. The very names of things not uncommonly asked for now, such as phenolphthalein, metaphenylene-diamine hydrochlorate, fluoresceine, and others are enough to take away the breath of one used to the old style of business.

What the character of the next changes will be one cannot foresee, but there does not appear to be, in the class of district to which these notes refer, any likelihood of much development of pure pharmacy.

CORRESPONDENCE.

[Letters to the Editor should be written as concisely as possible, on one side of the paper only, and preferably with name and address for publication.]

THE 'INDEX KEWENSIS.

Sir,—It was certainly with "surprise" that I read in your issue of Feb. 15, p. 130, that the 'Index Kewensis' is in no sense intended to be a standard of nomenclature, or to represent the views of Kew in the matter. I thought there must be some mistake, but I find that your statement is confirmed by the *Kew Bulletin* (Jan. 1896, p. 29), in which, however, the following two sentences appear, that to a certain extent modify the meaning of the passage quoted:—"Where it has been pointed out by competent authority that the names cited are 'synonyms,' the fact is indicated. As to the remainder, no attempt has been made to ascertain their validity. To have done this would have been to undertake a task that could not have been completed in a reasonable time even with the aid of a large staff of workers."

In the preface to the 'Index Kewensis' it is stated that Mr. Darwin intended his legacy to be, "in aid or furtherance of some work of utility to biological science. He further informed me (Sir J. D. Hooker) that the difficulties he had experienced in accurately designating the many plants which he had studied, and ascertaining their native countries, had suggested to him the compilation of an index to the names and authorities of all known flowering plants and their countries; as a work of supreme importance to students of systematic and geographical botany, and to horticulturists, and as a fitting mode of fulfilling his intentions, I have only to add that at his request I (Sir J. D. Hooker) undertook to direct and supervise such a work, and that it is being carried out at the Herbarium of the Royal Gardens, Kew, with the aid of the staff of that establishment."

We have here a distinct statement that the Index was compiled under the direction and supervision of the late Director of Kew Gardens, aided by the staff of the Kew Herbarium, and that it was intended by Mr. Darwin to aid students in accurately designating plants. Yet the present Director says it is in no sense intended to be a standard of nomenclature, or to represent the views of Kew in the matter. Under these circumstances, purchasers of the work have a right to ask—

1st. Does or does not the 'Index Kewensis' represent the views of the Kew Herbarium up to the date of the year 1885?

2nd. Who are the "competent" authorities who have "pointed out" that some names cited are "synonyms," and on what principles were they selected?

3rd. If the work is not to be considered as an expression of the views of Kew (the generally accepted leading authority on botanical matters in this country), why is there any distinction made in the type, indicating that the names of some genera and species are retained and others are not? and why is it stated that the work was done with the aid of the Herbarium staff?

4th. Why are dates of publication not given (as far as possible) for each species, so that the reader could exercise his judgment on the name he should select?

These are a few of the questions that naturally occur to the puzzled purchaser of what was supposed to be a standard work, and it is hoped that as there is no explanatory preface in the work the deficiency may be made good in the next *Kew Bulletin*. The January *Bulletin* states for what uses the work cannot be employed. Those who have the work would like to know for what purposes it can be used.

February 18, 1896.

PHARMACEUTICAL CHEMIST.

CLASS FEES FOR CHEMISTS' APPRENTICES.

Sir,—Would you allow me to thank, through the Journal, Mr. Henry Pollard, of Ryde, and those other correspondents who have kindly sent me particulars of the fees generally charged in the chemistry classes at schools of art? In the new school opened here last September, which has been described in your columns, the instruction given up to Christmas was theoretical and elementary only, owing to delay in procuring apparatus and chemicals. For this 5s. the term was charged for one hour per week, and an abatement was made to apprentices of one-half the fee, in common with the other science classes. For the current term this privilege is withdrawn from the chemistry class only; the elementary course is put at 5s. the term, the advanced course at 7s. 6d., while the laboratory or practical, of one and a half hours weekly, is £1.

Those advanced students, who, as suggested by their teacher, are taking two practical lessons weekly to make up for the time lost before Christmas, are called upon to pay £2 7s. 6d. This seemed so heavy an exaction from apprentices that I obtained an interview yesterday with the Technical Instruction Committee of the Council, in order to represent to them how disproportionate the charge was to those payable elsewhere, but the only concession I could gain was a promise to remit half the fees to those students who succeeded in passing the examination in May. With profound regret I recognised an unwillingness to allow those students who strive to qualify themselves for the practical application of chemistry in pharmacy, the aid and encouragement which is given, say, to a carpenter's apprentice learning mathematics.

Dover, February 19, 1896.

J. F. BROWN.

"CASH CHEMISTS."

Sir,—I note the inquiry by Mr. Leech, of Macclesfield, anent the using of the title "Cash Chemists," by limited companies. Has the question of their right to the title ever been settled by our Law Courts; I am aware our judges have found a way for companies to trade as chemists by ruling that "person" in the singular does not preclude persons as representing a limited company from trading as I said as chemists, but I do not remember to have seen it ruled that a company can adopt the title of chemists; whether cash chemists or credit chemists does not matter. It seems a plain and intentional device to defeat the purpose of the Act, which was to prevent ignorant and unqualified men deceiving the public by styling themselves chemists. If persons can call themselves cash chemists, cannot we have "Cash Doctors," and "Cash Dentists," or even "Cash Lawyers," and "Cash Doctors of Divinity"? Imagine the announcement that the Rev. John Jones (Cash D.D.) will preach next Sunday; it would save printers' ink, as it would be taken for granted that a cash D.D. would mean a collection after the sermon. I note, too, that some of our newly-fledged members are styling themselves "Cash Chemists." One knows what an analytical chemist is, and what a dispensing chemist is, but "Cash Chemist" is a new genus.

Blackpool, February 17, 1896.

J. JACKSON.

COMBINATION OF ANTIPYRINE AND TANNIN AS A STYPTIC.—Roswell Park has accidentally discovered that the gummy adhesive mass which forms on mixing strong solutions of antipyrine and tannin, is a most powerful and prompt hæmostatic. The only objection to its employment is the extremely tenacious hold which it takes upon the surface to which it is applied, so that its subsequent removal is a matter of some difficulty (*B. M. J. Epit.*, February, 1895, 90).

PHARMACEUTICAL JOURNAL.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, FEBRUARY 22, 1896.

DEATHS BY POISON IN 1894.

THE fifty-seventh annual report of the Registrar-General shows that, during the year 1894, there were 1091 deaths from the effects of poisons and poisonous vapours, as against 973 in the previous year. Of the 1091 cases, 588 (or 53.9 per cent.) were the result of accident or negligence, and 501 (or 45.9 per cent.) are attributed to suicide. There were two cases of murder, one of the victims—an infant under one month—being poisoned by ammonia, whilst a child of five years was poisoned by carbolic acid. In 1893, there were 597 fatal cases due to poisoning by accident or negligence, 370 suicidal deaths, one case of murder, and five of manslaughter.

Of the 588 persons poisoned by accident or negligence, 399 were males and 189 females, the figures for 1893 being 400 and 197 respectively. In 23 instances the kind of poison causing death is not stated, and 220 cases (140 males and 80 females) are attributed to poisons scheduled under the Pharmacy Act. Opium, laudanum, morphine, and chlorodyne are credited with 111 deaths; chloroform (presumably including cases where it was used as an anæsthetic), 58; chloral, 12; strychnine and nux vomica, 8; potassium cyanide, 6; prussic acid and oil of almonds, 5; arsenic, 5; oxalic acid, 4; belladonna, 4; aconite, 4; corrosive sublimate, 2; and cantharides, 1. Carbolic and other unscheduled acids caused 61 deaths, phosphorus 11, ammonia 9, creasote 2, and salt of lemons 1.

The suicidal deaths by poison numbered 299 males and 202 females, as against 209 males and 161 females in 1893. The kind of poison was not stated in 45 cases, and scheduled poisons caused 219 deaths—154 males and 65 females. Opium, laudanum, morphine, and chlorodyne lead with 85 fatalities; oxalic acid comes next with 45; then prussic acid and oil of almonds, 22; strychnine and nux vomica, 19; potassium cyanide, 17; vermin killer, 9; arsenic, 8; belladonna, 4; chloroform, 3; corrosive sublimate, 3; aconite, 3; and chloral, 1. Carbolic, sulphuric, hydrochloric, nitric, and chromic acids were taken with fatal results in 207 cases, the first-named alone being accountable for the death of 82 males and 85 females. Altogether, carbolic acid was responsible for 202 out of the 1091 deaths by poisoning that occurred in England during 1894, that is to say, for more than 18.5 per cent.

THE SALE OF ARSENICAL FLY-PAPERS.

As briefly indicated in last week's Supplement, it is unlikely that the appeal will be proceeded with in the fly-paper case that came before His Honour Judge BACON at the Bloomsbury County Court on January 21 (see *ante*, p. 62). This is unfortunate, as it is always much more satisfactory to have a High Court decision in such matters than a judgment in a court of first instance, which is not legally binding, except in that particular court. But, of course, as an expression of opinion the judgment carries a certain weight, and already there are indications that the natural result of the decision will be an exercise of greater care on the part of unregistered persons, in order to conform with the requirements of the Pharmacy Act, 1868. Thus, in the *Grocer* for February 15 some sensible advice is given to the members of the trade so well represented by our contemporary. It is pointed out that grocers who sell fly-papers prepared with poison will do well to note the result of the case which has recently been decided. This case, the *Grocer* remarks, makes the duty of the fly-paper-selling tradesman clear, if he be not a chemist. "He ought to obtain from the manufacturers of the articles which he stocks, an assurance, before he buys them, that they do not contain any scheduled poison, and a further assurance in writing, in every case, that in the event of the Pharmaceutical Society prosecuting him for selling the goods, the manufacturers will guarantee him against all costs arising from such sales. The only other course is to refuse to keep any doubtful articles of this character." This is well and wisely said, and should excuse the pettish allusions to the Pharmaceutical Society's "trade persecution" and "crusade for gathering heavy penalties from unsuspecting traders." The *Grocer*, however, should by this time be well aware why the Society is bound to proceed in such cases, and is surely sufficiently independent to be above catering to the passions of its readers like a certain section of the photographic press.

THE SALE OF FOOD AND DRUGS ACTS IN 1894.

THE twenty-fourth annual report of the Local Government Board shows that 238 appointments of analysts under the Sale of Food and Drugs Acts were approved during 1894. The total number of analyses during the same period was 39,516, or one to every 734 of the population, and an increase of nearly 2300 over the number made in 1893. The administration of the Acts is shown to be still very unequal. In Norwich, Yarmouth, Northampton, Stockport, Ipswich, and other large towns no serious attempt is made to suppress adulteration and, as might naturally be expected, many rural districts are in a similar position. In London, one sample was obtained for every 492 persons, and in the provinces generally one for every 801. Of the 39,516 articles examined, 4060 only were found to be adulterated. This is equivalent to 10.3 per cent., and indicates improvement as compared with the figures for 1893, which showed 12.9 per cent. of adulterated samples. Of 1116 samples of drugs analysed, 125 (or 11.2 per cent.) were reported impure. The report states that "As usual, the principal articles adulterated were nitre (36 out of 108); rhubarb (22 out of 148); cream of tartar (9 out of 59); and sulphur (8 out of 76). Of the remaining 725 samples, less than 7 per cent. were condemned. In 50 cases in which drugs were condemned, proceedings were taken,

and there were 39 penalties inflicted, amounting in all to £43 10s. 1d." It is a great pity that the authorities still continue to record the figures simply, without showing the sources from which the condemned samples were obtained. The unfairness of the omission has been repeatedly urged in these pages, yet it is again necessary to enter the same protest. For instance, it would be extremely interesting to know whether any of them were purchased from registered chemists and druggists. The public naturally associates chemists and druggists with the sale of drugs, and on the ground of the Local Government Board statistics it might be urged that whereas adulteration generally has been reduced, the adulteration of drugs has not. If, however, the number of samples of drugs obtained from grocers, hucksters, and others were deducted from the total, it is probable that the matter would bear a very different aspect so far as chemists are concerned.

GOVERNMENT SCIENCE.

THE total number of institutions where science was taught in connection with the Department of Science and Art increased from 1463 in 1884 to 2602 in 1894, the number of classes from 5001 to 9433, and the number of persons examined from 46,776 to 99,818. During the same period the direct payments on results increased from £56,533 to £140,390. In 1895 both the curriculum and method of payment of organised science schools, under the Department, were greatly modified, payments on results being greatly reduced, and a variable grant being introduced for each pupil who had qualified for an attendance grant, as well as certain other special grants for practical work. The payments on results, though still depending on the general examinations in May, are now only made in the advanced courses of the organised science school programme, and are on a different scale to what they were. The variable grant is based on the report made by the inspector after his inspection of the general work of the school. It is satisfactory to find that the authorities are at last awake to the evils of the old system, but much yet remains to be accomplished before the training received in the great majority of cases can be regarded as truly scientific and of any real and lasting value. The acquirement of a mere smattering of several sciences is virtually equivalent to little more than so much time and energy wasted, and in the case of students attending the Government classes, a loss is thus caused of much of the most valuable portion of the individual's life, for such, from an educational point of view, we must regard the years immediately subsequent to ordinary schooldays. However, changes having once been initiated, there is hope that a rational system of general scientific and technical education may ultimately be realised in the United Kingdom.

JAPANESE TRADE IN DRUGS AND CHEMICALS.

ACCORDING to Mr. GERALD LOWTHER'S report for the year 1894, drugs, medicines, and chemicals have, for many years, formed a very important item in the Japanese import trade, as there is a steadily increasing consumption in Japan. The values of drugs and chemicals imported for the past six years have been as shown in the following table:—

Year.	Value.
1889	£296,608
1890	331,208
1891	370,961
1892	363,760
1893	446,431
1894	393,343

It is stated that in each of these years Great Britain has had a valuable and important share in the trade. The principal items in the import list for 1894 were salicylic acid, bismuth sub-nitrate, amorphous phosphorus, potassium chlorate, sodium bicarbonate, caustic soda, alcohol, and saltpetre. Alcohol, silver nitrate, and salicylic acid were obtained almost exclusively from Germany, whilst caustic soda, sodium bicarbonate, potassium chlorate, and amorphous phosphorus were equally exclusively imported from England.

It will be noted that there was a considerable falling off in 1894, as compared with 1893, and during the first six months of 1895, there was, according to Mr. ERNEST SATOW, a further decrease in the value of drugs and chemicals imported, equivalent to 118,625 dollars, as compared with the corresponding period of 1894, but the next three months saw a change, a net increase being shown over the third quarter of 1894 of 206,318 dollars. The value of the October trade, which is the latest recorded, is described as having reached the highest total ever attained in any one month by Japan, the total imports being valued at 12,030,656 dollars, of which drugs and chemicals are credited with 280,314 dollars, as against 487,275 dollars for the whole of the preceding three months.

The Japanese import trade may therefore be regarded as having been during recent months in an exceedingly healthy condition. The most interesting item in the exports from Japan, camphor, was exported to the value of 1,023,956 dollars during 1894, 649,457 dollars in the first six months of 1895, and 391,438 dollars in the next three months, a constant increase being thus perceptible during the past year. The figures for the previous five years showed a steady falling off, and the quality of the product had deteriorated, but a guild was formed amongst the native sellers, and other steps have also been taken to effect a much needed reform in the quality of the drug.

THE BAOBAB TREE.

THE *Adansonia gregorii*, or Baobab tree, has always attracted attention on account of its singular gourd-like fruits, and because the pulp of the fruit is used to make an acid drink in fevers. Hitherto, only four species have been recognised by botanists, although the fruits differ considerably in size, and often in shape. Its name of "Cream of Tartar" fruit was shown by HECKEL and SCHLAGDENHAUFFEN to be correctly applied, since it contains 12 per cent. of bitartrate of potash, as well as 2 per cent. of free tartaric acid (*Pharm. Journ.* [3], xix., p. 246). Dr. C. GERBER has now made a careful histological examination of three species, *A. digitata*, *A. madagascariensis*, and *A. gregorii*. He finds that the structure is simplest in *A. gregorii*, is a little more complicated in *A. madagascariensis*, and is most complex in *A. digitata*. As *A. gregorii* is an Australian species, the author thinks that the genus must have originally started from that country, and that it travelled across a continent which has disappeared, but formerly united Australia and Madagascar, the species becoming modified as it proceeded westward. The author remarks in the *Annales de l'Institut Colonial de Marseille* that the "terra sigillata" of Lemnos probably owed its reputed medicinal value in the early part of the century to the dried pulp of the *Adansonia* fruit, of which it largely consisted.

ANNOTATIONS.

EVENING MEETING IN EDINBURGH.—On Friday next, February 28, an evening meeting of the Pharmaceutical Society will be held at 36, York Place, Edinburgh. Mr. W. L. Currie, of Glasgow, will take the chair at 8.30, and an interesting programme is promised. In the first place, "Notes from some Old Edinburgh Infirmary Case-books" will be communicated by Dr. A. Lockhart Gillespie. A paper on "Spiritus Ætheris Compositus, B.P." will then be contributed by Dr. W. Inglis Clark and Mr. D. B. Dott, and the latter will subsequently read a "Note on Papain," the next communication in order being a "Note on Commercial Litmus," by Mr. R. Rainy Brown. The palm for evening meeting programmes of interest to pharmacists generally apparently still remains with the North British Branch.

PRESENTATION TO MR. G. E. BRIDGE, OF BOURNEMOUTH.—Visitors to the Conference last year will remember the excellent arrangements made for the meetings and excursions, by which their convenience and enjoyment of the meeting was considerably enhanced, and it is with much pleasure we learn that those associated in that work with Mr. Bridge, the Chairman of the Local Committee, have presented him with a complimentary memento, in acknowledgment of the services rendered on that occasion.

THE NEW PHOTOGRAPHY.—The first practical demonstration in a London hospital of the use of the Röntgen rays in photographing the interior of a living subject was given last week at St. Thomas's Hospital, before the members of the Medical and Physical Society. Dr. Mackenzie, one of the assistant physicians, presided, and was largely supported. The experiments were conducted by Mr. A. F. Stanley Kent, late Demonstrator of Physiology, who briefly described the new process. The first experiment was a most interesting one to those present. The subject was a young medical student of St. Thomas's, who during the day had the misfortune to break one of the fingers of his right hand. This hand was photographed, and the plate when developed showed the exact position of the fracture in the bone of the finger. In the opinion of many medical men present the result was regarded as being very satisfactory, and as likely to lead to important developments in surgical and medical science. Other experiments followed, and it is the intention of the authorities of the hospital to enter more fully into the medical side of the discovery.

CHEMISTS' ASSISTANTS' ASSOCIATION.—Owing to indisposition, Mr. W. Manger was unable to read his paper on "Filtration" at the meeting of this Association on Thursday, and a musical and social evening was held instead. The eighteenth annual dinner of the Association will be held in the King's Hall, Holborn Restaurant, on Thursday, March 5, when the chair will be taken by the President, Mr. E. W. Hill, and it is hoped that a goodly number of the members and their friends will be present. Mr. George Roe, the honorary Secretary, will be glad to receive applications for tickets (5s. each), at 1A, Campden Grove, W., as early as possible.

HOW NOT TO LEARN THE ART OF PHARMACY.—A singular, and one would hope uncommon, method of learning the art of pharmacy is suggested in a recent advertisement in the *Burnley Express and Advertiser*. The business of a druggist and drysalter is offered for sale as a going concern, and as a special inducement it is stated that "the purchaser will be taught the business." It is to be hoped that no unsophisticated individual may burn his fingers by becoming a purchaser in this case.

SPECIAL ISSUE OF THE JOURNAL.—Next week's issue of the *Pharmaceutical Journal* will be sent to everyone on the Registers of Pharmaceutical Chemists and Chemists and Druggists, in addition to many other persons and firms connected with pharmacy in the United Kingdom and abroad. More than sixteen thousand copies will thus be distributed, being the largest number of any single issue of a paper addressing itself exclusively to individuals connected with British pharmacy. The subject matter of the special issue will, it is trusted, be found not unworthy of the occasion, the design being that the contents should prove both interesting and useful to readers. Amongst other matters treated will be the first complete historical account of what is probably the oldest London drug-house of which records are extant. This will be fully illustrated by the best modern processes. Local secretaries and others interested in the continued success of the Journal, will find this a fitting opportunity for advancing its claims to the support of the whole craft.

PRESENTATION AT COVENTRY.—There was an interesting gathering at the King's Head Hotel, Coventry, on Monday evening last, when Councillor Slingsby, churchwarden, gave a dinner to the choir and members of St. John's congregation. Mr. Slingsby presided, and Mr. Frederick Bird, chemist and druggist, was in the vice-chair, there being present a company numbering about fifty persons. Several complimentary toasts having been submitted and honoured, the Chairman proposed the health of Mr. Bird, and took the opportunity of presenting him with a handsome gold watch, on which was inscribed the words: "Presented to Frederick Bird by numerous friends of the congregation of St. John's, Coventry, in recognition of twenty-four years' faithful service as churchwarden." The Chairman spoke in the highest terms of the work of Mr. Bird in the parish. Mr. Poole added his expression of praise, and Mr. Bird heartily returned thanks for the present.

PHOTOGRAPHY AND ELECTRICITY.—At the last meeting of the Paris Academy of Sciences, M. H. Murat, of Havre, described results similar to those of Röntgen, obtained by the use of ordinary light. He places a sheet of copper in a photographic printing frame, next to this the object to be photographed, and then the sensitised gelatin plate. The frame is afterwards placed on a large sheet of copper, then covered with a sheet of lead, and the overlapping edges of the copper and lead sheets are folded over so as to enclose the frame completely, thus excluding ordinary light rays. After exposure of the whole to sunlight or lamplight, however, and subsequent development of the plate, distinct images are obtained of a similar nature to those of Röntgen. It has been found by M. Le Bon that electricity is generated during the formation of the photographic image, and Professors Righi, Bergmann, and Bergim find that the Röntgen rays have the property of electrically charging an insulated body, even if sheltered by means of a Faraday screen.

EXCHANGE NOTICES.—During the past twelve months opportunity has been afforded for readers of the Journal wishing to exchange surplus books, apparatus, etc., to insert notices to that effect in the Supplement. The necessity and utility of the "Exchange" have been proved by its increasing popularity, but it has now become necessary to adopt some means whereby undue occupation on our limited space might be prevented. A small charge will therefore be made for the insertion of such notices, and the conditions will be found on the last page of this week's Supplement. It will be noted that all communications in connection with the "Exchange" should henceforth be addressed to the publishing office, 5, Serle Street, W.C.

THE PRESCRIBING OF PIPERAZINE.—In the *Lancet* for February 8, Dr. E. D. Mapother recalls attention to the fact that some time ago he bore testimony to the utility of piperazine as a solvent for urates and a remedy for gout. It has since given satisfaction in most cases in which it has been employed, and the writer attributes its failure in some instances to the administration of the remedy in the presence of "vegetable tinctures or infusions." He says: "It appears that with these it is incompatible," and he imagines that adverse reports upon the drug may have been due to its combination with those preparations. He now urges that piperazine should always be dissolved in distilled water and taken by the patient on an empty stomach.

MISLEADING ABBREVIATIONS.—A correspondent of the *Western Morning News* appears to have experienced some inconvenience from the "ambiguity that exists in the abbreviations of 'Member of the Pharmaceutical Society' (M.P.S.), and 'Members (*sic*) of the Phonetic Society' (M.P.S.)." He calmly suggests therefore, that in the first-mentioned case the custom sanctioned by half a century's usage should be amended, by the substitution of the form "M.Phr.S." He continues "I think anyone of ordinary intelligence will perceive the judiciousness of the seemingly slight though somewhat necessary alteration." Though he is doubtless blessed with more than "ordinary" intelligence, it does not seem to have occurred to him that the greater may possess a higher degree of importance than the less, and that, as suggested by pharmaceutical correspondents to the paper in which his effusion appears, the members of an insignificant body of users of barbarous language may find it the simpler plan to avoid the misleading use of letters which have become inseparably associated with pharmacy. It is quite conceivable, too, that circumstances might arise which would render illegal the use of the letters "M.P.S." by any person not a member of the Pharmaceutical Society.

GOOD NEWS FOR BOTANICAL STUDENTS.—As evidence of the exceptional mildness of the season, it may be noted that *Daphne mezereum* came into flower in the Royal Botanic Garden, Edinburgh, on January 28. Last year it did not flower till March. The lesser celandine and other early flowering species have also come before their time in the London district.

NEWSPAPER ACCURACY.—It must always be satisfactory to pharmacists when they find that their proceedings are considered of sufficient general interest to be worthy of notice in the daily press, as on the occasion of the formal transfer of the Burroughs Memorial Fund last week, which was referred to in several of the London dailies. In one case, however, the paragraphist made sad work of the names, the *Morning* recording that "Mr. M. Corteighan (President of the Society) was presented by the committee of the Burroughs Memorial Fund with the sum of £850 for the purpose of endowing a scholarship to the memory of the late Mr. Sailas."

RANDIA DUMETORUM.—In "The Month" some years ago (*Ph. J.* [3], xxi., 881), reference was made to Sir James Sawyer's experiments with a tincture prepared from the fruit of *Randia dumetorum*. The drug had been suggested as a substitute for ipecacuanha, and its physiological action as a nervine calmative and anti-spasmodic was attributed to the presence of saponin and valeric acid. It is now being imported from Cawnpore by Messrs. John Haddon and Co., of Bouverie House, Salisbury Square, E.C., who are trying to place it on the English market, and have sent a sample to the Museum of the Pharmaceutical Society.

PROCEEDINGS OF SOCIETIES.

School of Pharmacy Students' Association.—A meeting was held on Thursday, February 13, Mr. H. A. D. Jowett, B.Sc., occupying the chair. The minutes of the previous meeting having been read and confirmed, the Chairman announced that the amended rules of the Association had received the sanction of the Council of the Pharmaceutical Society, and that, in accordance with the new rules, the Executive Committee had added to their number Messrs. H. Brown and H. Wilson. A discussion upon "A Student's Union for the School of Pharmacy" was then opened by Mr. T. A. Henry. In his introduction Mr. Henry remarked that pharmaceutical students lay under peculiar disadvantage, owing to the very short term they spent at a school of pharmacy. On this account it was difficult for them to take any great interest in the Association connected with the School. It was hoped that this would be remedied to some extent by the formation of a Students' Union. The working of a Students' Union was then briefly outlined, and some of the reforms which such a body might attempt were pointed out, in particular the securing of a common room for students, where they might hold meetings, instead of meeting on sufferance, as they did at present, in corners of the Laboratory or in the Library. A magazine for students was also advocated in order to keep up the interest of former students in the School. The discussion was taken part in by Messrs. Read, E. J. Eastes, Fothergill, Spurge, Payne, H. Brown, E. A. Umney, F. U. Stamp, Wilson, Lean Grier, and the Chairman, and general support was given to the proposal. A resolution to the effect that in the opinion of this Association it is eminently desirable that a Students' Union be formed was carried unanimously.

Midland Chemists' Assistants' Association.—At a meeting on Wednesday, February 12, at Exchange Rooms, Birmingham, the President (Mr. T. C. Clarke) occupied the chair, and the following paper was read:—

"LABORATORY NOTES."

BY JOHN BARCLAY, B.Sc.

Note 1.—*Liquid Extract of Pareira.*—The present official method of preparing the above is unsatisfactory on account of the partial insolubility of the aqueous extract in the aqueo-alcoholic menstruum and the resulting necessity for filtration, which involves considerable loss. Instead, therefore, of using 4 parts of the extract of pareira, as ordered by the Pharmacopœia, it has been found better to take an equivalent quantity (20 parts) of the root, and from it to prepare an extract by exhausting with a mixture of water, 3 parts, and methylated spirit, 1 part, the resulting extract being dissolved in sufficient of the official menstruum (rectified spirit, 1 part; water, 3 parts) to make 16 fluid parts. An extract so prepared dissolves completely to form a liquid containing about 20 per cent. of total solid matter. The same result might be obtained by percolating and re-percolating the root with the official menstruum, but the use of methylated spirit as above is found to be more economical.

Note 2.—*Colocynth Pulp.*—The determination of the percentage of ash in the powdered drug is useful for ascertaining its freedom from seeds. The Pharmacographia gives the ash of pulp dried at 100° C. as 11 per cent., of seeds 27 per cent. Squire gives for the former 8.6 to 14 per cent., for the latter 2.2 to 4 per cent. The writer found that 212 lbs. of peeled apples ground under small edge-running stones just so long as to crush the pulp without breaking the seeds, yielded 48 lbs. of pulp containing 12 per cent. of ash, and 164 lbs. of seeds containing 2.37 per cent. of ash. This method may, he recommended, be safely used for separating pulp from seeds. Eight samples of pulp obtained from various sources were incinerated and the results are given below.

Percentage of Ash Calculated on Drug Dried at 100° C.

1.	12.00	} Mean of 8 samples—11.45.
2.	10.10	
3.	12.40	
4.	11.40	
5.	11.20	
6.	11.70	
7.	11.70	
8.	11.20	
Whole apple	4.60	
Seeds	2.37	

Note 3.—*Compound Extract of Colocynth.*—An extract prepared according to the official formula and dried at 100° C. contains:—

Extract of aloes	59.6	per cent.	about.
Scammony resin	19.8	"	"
Curd soap (dried)	14.9	"	"
Cardamoms.....	4.5	"	"

Together with so much of the colocynth used as is soluble in proof spirit.

It might, therefore, be expected that a properly prepared extract would contain an amount of water-soluble matter equal to that of the extract of aloes and soap used (about 75 per cent.), plus a small percentage due to the colocynth and cardamoms, and that similarly the extract would yield about 20 per cent. to ether, that percentage representing the amount of scammony resin. Eleven samples of compound extract of colocynth obtained from various wholesale houses were examined with the following results:—

Compound Extract of Colocynth.

	Moisture.	Calculated on dry extract.			
		Ash.	Alkalinity as NaOH.	Soluble in water.	Soluble in ether.
1.	7.05	4.22	1.10	47.4	14.51
2.	11.59	6.33	1.81	69.6	18.86
3.	12.10	5.79	1.08	56.1	15.84
4.	7.18	6.50	1.88	60.7	13.55
5.	9.51	4.05	1.69	79.0	29.56
6.	19.85	5.37	1.58	77.0	15.90
7.	15.29	6.30	2.41	58.6	13.72
8.	8.14	5.03	2.28	82.4	16.20
9.* ...	2.73	6.62	1.45	62.0	9.55
10.† ...	4.24	6.80	2.70	55.8	22.39
11.† ...	3.50	3.30	.37	40.6	6.57

* A very old sample. † Dry extracts.

The alkalinity of the ash was taken with a view to arrive at the percentage of soap present. The dried curd soap used in preparing extract No. 10, was found to contain 6.92 per cent. of soda (NaOH), so that the ash of this extract would contain just over 1 per cent. of soda due to the soap, but the total alkalinity as soda of this sample was found to be 2.70, hence more than half of the alkalinity of the ash in the case was due to other ingredients. It will be seen that there is a very considerable variation amongst the samples in all the points examined. This is particularly the case with the ether soluble percentage, which may be regarded as fairly accurately representing the amount of scammony resin present.

The writer expressed his indebtedness to Mr. E. W. Mann for assistance given in making the experiments for the note, and in the discussion which resulted, the following members took part:—Messrs. Clarke, Williams, Arblaster, Shields, Jessop, and Bindloss. A hearty vote of thanks was accorded the speaker, in conveying which, the Chairman remarked that the Association was also greatly indebted to Mr. Barclay for the sound advice and suggestions he had offered the promoters, which had proved of immense service in the formation of the Association.

Chemists' Assistants' Association.—To the fact that the Junior Pharmacy Ball had been held the previous night may be ascribed the small attendance at 103, Great Russell Street on the 13th inst., when the President (Mr. E. W. Hill) occupied the chair. After the usual routine business, Mr. J. Castil Evans, F.I.C., F.C.S., Lecturer on Chemistry to City of London Guilds, gave an address upon "The Chemical Training of Pharmacists." He commenced by expressing his conviction that the evolution of chemistry was greatly due to representatives of pharmacy of bygone ages, who in their search for a myth in the shape of the philosopher's stone, laid the foundation of an exact science. Of late years there has been a revolution in methods of chemical teaching, as until recently a youth was very apt to imagine that he could learn the science without a course of systematic training, and that he could take for granted the methods of determination of molecular weights, being content if he simply committed to memory the necessary data. From his own experience in different parts of the country, Mr. Evans considered it was a great mistake to enforce the teaching of pure mathematics as the first step in a scientific curriculum. The axiom

that nothing should be taken for granted must always be borne in mind, for, chemistry being a purely inductive science, the laws and principles connected therewith ought to be worked out practically. He had no sympathy with a type of student that often came under his notice, whose only aim was to get through his work in a perfunctory manner, and was quite indifferent in regard to the accuracy of his results and methods of manipulation so long as he got some idea of the outlines of the process. The superficial nature of chemical training unfortunately pervades much of the current literature, and many of the results published are mere theory, owing to the way in which workers jump at conclusions. Of course every man has his own ideas as to the correct method of teaching chemistry, but undoubtedly the principle which should underly them all is to impress on students the necessity of continual observation and reasoning, and a teacher should be thoroughly qualified to carry out practically the ideas which he communicates as well as be an enthusiast in his work. Mr. Evans proceeded to enumerate what he regarded as cardinal points to tyros in chemistry:—A thorough knowledge of the features which distinguish elements from compounds, as well as the laws of combination both by weight and volume; a thorough acquaintance with the work which has been done by former investigators; a practical knowledge of the methods used in determining the equivalents of such of the elements as silver, copper, and chlorine; on this point he was of opinion that every student should carry out one or two of these methods for himself, for the man who is best qualified on leaving the school to engage in technical work is the one who has learnt the means of ascertaining facts by means of the processes which he has investigated, although he may not carry in his head a long string of dry facts. A student should also aim at proficiency in chemical reactions, being not only familiar with the mechanical details, but also the principles underlying the processes.

Every youth should know something of a physical science, preferably chemistry, since a study of it engenders care and exactitude. It is noteworthy that all good experimentalists in physical science have started as chemists. There was one branch of chemistry which Mr. Evans recommended to his audience in preference to all others to being conducive to the exercise of all the faculties, and that was blow-pipe analysis. He said that many men were fairly expert at wet analytical methods who were quite at sea with the dry reactions. Passing on to the subject of examinations, regret was expressed at the present-day tendency of studying with special reference to the requirements of examination schedules instead of for the sake of knowledge, and Mr. Evans said that the outcome of his experience as a teacher under the Science and Art Department, as well as at South Kensington and Finsbury, was that dissatisfaction—even from the point of view of percentage of passes—was the result of close observance of the requirements of the syllabus. At the present time there seems to be too much teaching and far too little individual learning, so that students think there is a "royal road to learning," instead of facing their difficulties and thereby acquiring self-reliance. In conclusion, Mr. Evans briefly summarised the points which he thought worthy of attention by his hearers.

The President (Mr. E. W. Hill) was of opinion that Mr. Evans had treated the subject of education rather exclusively from a theoretical standpoint, and he thought that some of the recommendations were impracticable to most pharmaceutical students, because of expenditure of time and money involved. Independently of those considerations, the training of pharmacists, as carried out at the present day, was as a rule exceedingly good. Messrs. Roe and Summers also joined in the discussion, and a cordial vote of thanks was awarded to the lecturer, on the proposal of Mr. R. G. Guyer, seconded by Mr. H. H. Robins.

It is understood that Mr. R. H. Jones, who for some time past has occupied a prominent position in connection with the Chemists' Assistants' Association, and filled the presidential chair during the session 1894-1895, is leaving Messrs. Savory and Moore in the course of a few days to take up a position in the Laboratory of Messrs. Brady and Martin, Newcastle-on-Tyne.

Midland Pharmaceutical Association.—A meeting of the above was held on Tuesday, February 11, at Mason College R. Darton Gibbs, President, in the chair, when F. H. Alcock, F.C.S. delivered a lecture on vegetable histology, illustrated with lantern views by Mr. J. Davis. There was present a numerous company of pharmacists and students. Mr. Alcock began by giving an outline

of the structure of the cell, and the various forms of cells found in vegetable tissue, with their contents, illustrating the varieties by sections from *Clematis vitalba*, *Hoya carnososa*, *Pinus*, *Tilia*, and garden rhubarb. The varieties of starch depositions were shown in potato, canna, arrowroot, and others; starch granules were also examined by polarised light. Raphides and other deposits in cells were shown, as also were lactiferous cells and vessels from euphorbia and dandelion. Leaving the morphology of the cell, a section of the stem of sun-flower showed the varieties of tissue that made the cortex, viz., sclerenchyma, phloem, cambium, xylem. The same section showed the chlorophyll grains, and also sieve tubes, another showed resin passages, epithelial cells, and fibro-vascular bundles, which were fully explained. A section of the leaf of cherry laurel gave examples of palisade parenchyma, chlorophyll, and stomata, the uses of which were pointed out. A section of the stem of *Ulmus campestris* showed the layers of cork tissue, inter-cellular spaces, pith, and medullary rays. A section from the root of *Hippuris vulgaris* showed the tissue in an aquatic plant. The structure of the embryo was dwelt upon in detail and illustrated by sections, followed by descriptions of the pollen, anthers, and stigma, the slides showing the difference in structure of monocotyledonous and dicotyledonous plants in their reproductive organs. At the conclusion of the lecture, a vote of thanks was proposed by the President, who hoped Mr. Alcock would occupy another evening this session: this was seconded by Mr. C. Thompson, who said the lecture carried him back to his old student days. Some lantern slides of a human hand, a living frog, a purse containing coins, and a razor in a case, obtained by the new Röntgen light, were exhibited by the Secretary, Mr. C. F. Jarvis, and gave rise to much interest.

Sheffield Microscopical Society.—Mr. Chas. Hoole assisted by Mr. Harrow, the curator of the Sheffield Botanical Gardens, on Friday last delivered a lecture to the members of the above Society on the "History, Cultivation, and Microscopic Structure of the *Victoria regia*." Mr. A. H. Allen, F.I.C., F.C.S., President of the Society, occupied the chair. The lecture throughout was of the most attractive character. An interesting point brought out was that the under surface of the leaves of this royal plant were of a deep crimson colour, and it has recently been proved that the effect of this is to change light rays into heat rays, and thus materially add to the maintenance of the internal temperature, which is so essential to the plant. After the lecture, Mr. Hoole, by the aid of a number of microscopes, kindly lent by Mr. Newsholme, showed a large number of microscopical sections taken from all parts of the plant. The warmest thanks of the Society were subsequently conveyed to Mr. Hoole and Mr. Harrow.

Royal Institution.—On Thursday, February 13, Professor H. Marshall Ward delivered the first of a series of three lectures on "Some Aspects of Modern Botany." The professor alluded first to the rise of descriptive and systematic botany, pointing out the advantage derived from the use of illustrations in describing plants, the recognition of the fact that the plants of one locality varied from those of another, the difficulty experienced in identifying them, and finally the necessity that was felt for some system of classification. In attempting to arrange plants, particular stress might be laid either upon the detection of minute differences or upon the recognition of resemblances. The older botanists followed the former of these two courses, whilst modern botanists were inclined to follow—perhaps, as the lecturer thought, too closely—the latter, and to lay too much stress upon the resemblances between various plants and the detection of transition forms. The object of modern systematic botanists was to compile a complete list of plants, all of which must be compared and contrasted with one another so as to build up a botanical genealogical tree; the difficulty of the task could be appreciated by remembering that on an average a new species arrives in this country every day.

Professor Ward then touched upon the question of variation and adaptation, and selected the Alpine edelweiss as an illustration of one direction in which work was being done. The hairy covering of this well-known plant might be thought to be a protection from cold. But hairy plants are extremely common in districts subjected to severe drought, as, for instance, the South American savannahs; now the edelweiss grows on ledges of rock which rapidly dry, and the plant might therefore easily suffer from excessive evaporation of the moisture it contains; the probability is that the dense covering of hairs obviates such an excessive evaporation of moisture, both in the Alpine edelweiss and the savannah plants, by surrounding the stomata with a quiescent layer of air.

By means of lantern slides the lecturer demonstrated the similarity in habit of growth that plants of widely different natural orders may assume when living under the same conditions, as well as the variation the different species of one and the same genus may exhibit when living under widely different conditions. To illustrate the latter case, an extremely interesting series of slides of various species belonging to the genus *Senecio* was exhibited, one having peltate leaves, another narrow recurved, and a third succulent leaves, whilst a fourth resembled a cactus in habit, a fifth was a climbing plant, and a sixth was a tree 30 feet high. The lecturer pointed out the effect of climate on various Indian species of *Senecio* that he had been investigating, and concluded by speaking in favourable terms of the value of descriptive botany as a means of teaching.

Western Chemists' Association.—At a meeting of this Association, held on Wednesday, February 19, a discussion was opened by the reading of the following paper, by the President:—

OUGHT THE BRITISH PHARMACOPŒIA TO BE USED AS A STANDARD UNDER THE SALE OF FOOD AND DRUGS ACTS?

BY J. C. HYSLOP.

Decidedly not. The first B.P. was published in 1864. The Sale of Food and Drugs Act was passed in 1875—eleven years afterwards—and the Act to amend it in 1879. Yet not a word is found as to the Pharmacopœia in either of the two Acts. Can it then be possible that the framers of those statutes had the least idea of making the Pharmacopœia a standard in their administration?

True the question is by no means a simple one, nor uninteresting, for the term "drug" occurs in the Act as often as the term "food," and one would naturally expect that where so much is said of "drugs" the Pharmacopœia would to some extent be recognised. Hence the omission becomes the more significant. But is there any standard mentioned for "food"? No. Why, then, should we expect to find one for "drugs"? The idea has arisen purely from the indolence and incapacity of those whose office it is to look up the sinners and mete out the punishment. They are down upon the poor milk-sellers, because they think it is so easy to determine the amount of water that has been mixed with the milk, and they are down upon the unfortunate chemist for a similar reason; he has a book in plain English, to be his one standard of strength and composition for the substances which the physician prescribes. So they are ever meddling with this book and with him in his dispensing business. Pity the Pharmacopœia is not still in Latin, which might confine men more to their true and proper callings.

Now this omission of any reference to standards was, it would seem, recognised very early as a defect in the working of the Act, hence the Sale of Food and Drugs Amendment Act of four years later had for its main object the adoption of certain standards with respect to brandy, whiskey, rum, and gin. The essential function of the Sale of Food and Drugs Act is evidently to come to the rescue of the purchaser, with reference to his lameness as to that time-honoured motto *caveat emptor*: "Let a buyer take care of himself." It was found that the tricks of trade were so guileful and varied that a buyer could not take enough care of himself, and this Act was passed to render his self-help more possible and easy. It has thus entirely to do with trade, and nothing whatever with the dispensing counter.

If a sausage maker uses up meat that is too bad for his dainty productions, even his offence may be punished by another Act of Parliament, but it does not come within the four corners of the Sale of Food and Drugs Act. Similarly, if a dispenser of medicines commits an offence against the B.P., he may be proceeded against under the provisions of the Pharmacy Act, 1868, Sec. 15., which reads thus:—"From and after the 31st day of December, 1868, any person who shall sell.....or use the title.....or shall fail to conform.....or who shall compound any medicines of the B.P., except according to the formularies of the said Pharmacopœia, shall for every such offence be liable to pay a penalty or sum of five pounds." If, therefore, I am asked for a seidlitz powder, or for a box of seidlitz powders, my only safe and proper course is to supply without a word of remark the "pulv. sodæ tart. efferves." of the B.P., for I am told in a footnote, where this formula occurs, enough to imply that this is what a consultant is most likely to mean by telling his patient to take a seidlitz powder. Now, if I give a larger dose, without being requested to do so, or a smaller one, I certainly disobey the clause just quoted from Section 15 of the Pharmacy Act, and I may, I suppose, be punished for so doing, but the offence surely has nothing to do with the provisions of the

Food and Drugs Act, the object of which is to prevent fraudulent and deleterious admixture with articles of food or physic.

In full support of this view it will suffice to note the schedule that accompanies the Act. This gives the form for the analyst's certificate, which must be produced in court; it runs thus:—

"To Mr....."

"I, the undersigned, public analyst for.....do certify that I received, on the.....from Mr.....a sample offor analysis, which then weighed.....and have analysed the same, and declare the result of my analysis to be as follows:—

"I am of opinion that the same is a sample of genuine....."

or

I am of opinion that the said sample contained the parts as under, or the percentages of foreign ingredients as under:

”

Then there comes a space for observations, with a foot-note to explain that "here the analyst may insert at his discretion (?) whether the mixture (if any) was for the purpose of rendering the article portable or palatable, or of preserving it, or of improving the appearance, or was unavoidable, and may state whether in excess of what is ordinary or otherwise, and whether the ingredients or materials mixed are, or are not injurious to health."

As witness my hand this.....day of.....

A. B.

at.....

These are some of the grounds on which rests my opinion that the Food and Drugs Act has nothing whatever to do with the B.P. or with the dispensing of medicines. Otherwise note a few of the incongruous results. Poor people on a Sunday, when other shops are closed, could not get their cheap carbolic acid because the chemist may not sell any but the B.P. article, for which he has to pay more than one shilling per pound.

What would my Lords of the Privy Council think of this? Burden the taxpayer perhaps, so that an article as useful for wrapping up dirtiness as for promoting suicides might be supplied gratis and *ad lib.* Then as to wax, white wax B.P. is bleached beeswax, but there is plenty of very useful white wax which is not the produce of bees, and in certain arts it is preferred for its suitability as well as its cheapness. In the laundry business, electrical engineers, engravers, etc., white wax is used, but beeswax would not suit even if it were cheaper. We chemists know people's respective wants in these matters better than other men, yet we are to be prohibited from selling these things if the same name also happens to occur in the B.P., with tests and a standard to determine the exact variety of the article that is to be used in medical dispensing.

Then there are the essential oils quite on all fours with the wax question. The oils of juniper, lavender, peppermint and rosemary for medical purposes we must pay from 3s. to 8s. per ounce for these, whilst the public requires an article worth from 6d. to 1s. an ounce. Are we not to supply these varieties because we happen to be chemists and although these are as good as the dearer kinds for the purposes required?

Indeed, gentlemen, it comes to the old, old, tale, a case of trade *versus* pharmacy. Mere buying and selling is always over-shadowed by the *caveat emptor* notion, joined of late with the threatenings of the Food and Drugs Act, as against the mere trader, who, by means fair or foul, will press for the uttermost farthing of profit.

The dispensing of medicines, whether by verbal or written directions is, on the contrary, illuminated by the special light of the B.P.: that is supplemented, perfected as far as may be, by the trained skill and competent experience of the dispenser, who, mindful of his high vocation, is half insulted when he meets with the *caveat emptor* idea across his own counter; he has more than enough of this in selecting his own drugs and the preparations which he has no time or convenience to prepare for himself. The ideas that guide his life's business come from quite another quarter, have quite a different ring about them; in the forefront stand leaders such as these:—

Caveat dispensator—Let the dispenser take the care.

Noblesse oblige—One's distinguished position involves great responsibilities.

Mr. W. Martindale remarked that he was placed in rather a delicate position on account of his connection with Pharmacopœia Revision Committee. He reminded his hearers that under the 15th Section of the Pharmacy Act of 1868, a chemist was bound to supply articles mentioned in the Pharmacopœia which were in strict accordance with its requirements, and he considered that an infringement

of the Section was bound to bring legal penalties. In regard to the seidlitz powder case referred to by Mr. Hyslop, a good deal depended upon the motive which influenced the sale of an article not in accordance with official requirements in this particular instance. From all accounts it seemed that a better article than the official tartarated soda powder had been sold at a higher rate of profit, but he was forced to the conclusion that the transaction savoured of over-reaching, and did not commend itself from an ethical standpoint. Another point to be remembered was that there are doubtless many cases in which the Pharmacopœia does not give a sufficient definition to the chemist, which will serve to bind him down to a hard-and-fast rule, and that was only to be expected, considering the length of time since the last edition had been issued. Convictions having reference to the sale of such articles as carbolic acid or soda water, which had been referred to by Mr. Hyslop, had never yet been attained, nor did he think they were likely to be so long as common sense was exercised and the customer understood what he was buying, but he must say emphatically that if a chemist is asked for a pharmacopœial article, and he supplies an article which is not up to the official standard, and at the same time neglects to inform the customer of the fact, he certainly comes within the pale of the law.

Mr. R. H. Parker said the subject which had been introduced by their President was of far more importance than they were likely to realise at the outset. To him the main difficulty seemed to be that the administration of the law is in the hands of those who are not conversant with the interpretations which should be put upon the pharmacopœial statements, and are often unacquainted with a pharmacist's calling, and hence are apt to act in a very erratic fashion. Had the authorities been men acquainted with those details, he would have said by all means maintain the pharmacopœial requirements strictly. He was of opinion that the strict application of the Food and Drugs Act should be limited to those articles which were sold for internal or external use by human beings, but should not hold good for articles of everyday use, which rendered explanation to individual customers burdensome. It was ridiculous to suppose a chemist would supply hyposulphite of soda in the pure state for photography; whilst many essential oils when used for external and commercial purposes, and other things readily suggested themselves. By all means let it continue to be compulsory to supply medicinal preparations intended for medicinal use in strict accordance with official requirements, but beyond that he was of opinion that considerable latitude should be allowed.

Mr. Robinson supported the arguments advanced by the President and Mr. Parker. He very much questioned whether the section of the Pharmacy Act quoted by Mr. Martindale would suffice to obtain a conviction; on the other hand, he was rather of opinion that the Food and Drugs Act would have the preference, seeing that it was passed subsequently to the Pharmacy Act. He strongly objected to the increasing tendency shown to adopt synonyms in the Pharmacopœia, and trusted that steps would be taken to delete those already in existence as far as possible. There was one argument which could be advanced in favour of chemists supplying all articles officially mentioned in strict accordance with pharmacopœial requirements, and that was that at the present time the public have been educated to look to chemists for the best, and only the best, drugs, and it was of course necessary that this feeling of confidence should be maintained. He was of opinion that it was quite absurd to expect a chemist to supply pharmacopœial articles only when the substances happened to be mentioned in the B.P. As far as lay in his power he always discouraged any attempts being made by the authorities to entrap chemists, by asking them to supply such articles as milk of sulphur, in the expectation of being supplied with the old preparation containing lime.

Mr. Martindale observed that convictions under the Food and Drugs Act were often based upon the poison having been left out of the preparation asked for, such as paregoric without opium, etc.

Another member said that it would be extremely inconvenient to many chemists if they were always expected to supply pharmacopœial articles to the public. At the present time there were many people who were accustomed to a particular strength of seidlitz powder and a particular flavour for their black draught, and they would have no other.

Mr. Marsh thought that the crucial point of the seidlitz powder case referred to was that it really resolved itself into a chemist having been convicted for selling a larger dose of an article than that specified in the Pharmacopœia, since it was not denied that the relative proportion of the ingredients was the same as in

the official powder. If the decision was upheld a chemist would be liable for selling a black draught of a larger dose than that prescribed in the Pharmacopœia. Further, he remarked upon the sale of arsenical soap by oilshops at the present time, as one which required the attention of the authorities.

In the course of the subsequent discussion, which was taken part in by Messrs. Martindale, Parker, Robinson, Andrews, Hinde, and others, it was at first intended that a motion should be put to the meeting—proposed by Mr. Robinson, seconded by Mr. Parker—to the effect that the Pharmacopœia should be regarded as a standard for the preparations named in it, which were used for medicinal purposes, but not necessarily for those sold for commercial use, but it was ultimately decided to adjourn the meeting *sine die*.

Cambridge Pharmaceutical Association.—On Friday, February 7, Mr. F. J. Stoakley, lecturer of chemistry at the Technical Institute, gave a lecture entitled "Alcohols," illustrated by experiments, at the Technical Institute, East Road. There were about thirty members and friends present. At the conclusion of this most interesting lecture Alderman Deck, F.C.S., moved a hearty vote of thanks to the lecturer; this was seconded by Mr. E. Saville Peck, and was appropriately responded to by Mr. Stoakley, and thus a most successful evening was brought to a close.

The lecturer gave a description of the synthetical production of methyl alcohol; he also said spirits of wine might be produced synthetically, but that it was usually prepared by the fermentation of sugar. He showed that sugar was decomposed by yeast into alcohol and CO₂. The lecturer gave a lucid description of the conversion of starch into sugar, and from thence into alcohol, and showed the rectification of alcohol from fermented liquids by distillation of a bottle of port wine, and thus obtaining alcohol. He then dealt with the conversion of starch into fermentable sugar by the action of—

- a. Infusion of malt.
- b. Boiling with dil. acid.

He enumerated the important and many uses of spirit in pharmacy and commercial work generally, and finished this most interesting and useful lecture with definitions (explained by experiments) of—

- Methylated spirit,
Proof spirit, etc.

ENGLISH NEWS.

NOTTINGHAM AND NOTTS. CHEMISTS' ASSOCIATION.—The annual dinner of this Association was held at the Masonic Hall, on Thursday, February 13, and was very well attended. Amongst those present were Ald. Gibson (Manchester), Councillor FitzHugh, Mr. S. Cook, Mr. T. Mason (Chairman), Messrs. J. Wilford, G. W. Gill (Vice-Chairman), C. A. Bolton, Middleton, Beverley, R. Widdowson, W. Widdowson, Beilby, Deaville, Sergeant, Turton, Dadley, Hare, H. Wilford, R. Jackson, Gascoyne, Vallance, Radford, Wilson, and A. Eberlin (Hon. Secretary).—After the loyal toasts had been honoured, the Chairman proposed "The Pharmaceutical Society of Great Britain," to which Mr. Bolton (Local Secretary) replied.—Ald. Gibson, in a forcible speech, proposed "The Public Bodies of Nottingham," and paid a high tribute to the work done by Mr. FitzHugh.—Mr. FitzHugh, in responding, said he felt it to be an honour to serve this town as a member of the Council, and hoped the time would come when all public bodies would be included in one Corporation, as he believed it would be to the advantage of the town.—Mr. S. Cook also responded, and dwelt upon the magnitude of the work done by the Board of Guardians.—"Success to the Nottingham and Notts. Chemists' Association" was given by Mr. Gascoyne, and responded to by Messrs. J. Wilford (Treasurer) and Eberlin.—"The Visitors" was proposed by Mr. Gill, and responded to by Mr. Deaville and Stevenson.—"The Chairman" was proposed by Mr. FitzHugh, and drunk with musical honours.—Mr. Mason suitably replied.—The proceedings were interspersed with songs, recitations, etc., by Mr. Turner, Mr. Vallance, Mr. Beverley, Mr. Winslow, Mr. A. W. Young, and several members of the company.—Mr. H. Woodhouse proved an able and sympathetic accompanist.

NEW PHARMACY BRANCH AT BEDMINSTER.—A new establishment, being the first of a series of branches proposed to be started

in connection with the Central Store of Messrs. Henry Hodder and Co., Limited, the well-known chemists of Broad Street, Bristol, has been opened at 79, East Street, Bedminster. The premises have been fitted up with every kind of pharmacy requisite.

THE MEANING OF THE VERB "TO KNOW."—The *Evening Standard* thus comments upon the fact that the Marylebone magistrate declares that the fact of a servant making a casual purchase at a shop, from time to time, does not justify the shopkeeper in assuming that he knows her:—"We cannot but think, with all respect, that it depends upon the meaning attached to that very indefinite verb 'to know.' A tradesman who understands his business does not allow the handmaiden of a well-to-do neighbour to depart without such little attentions as he has time to bestow. If, as in the case referred to, it be a small chemist's shop, and the servant be housekeeper to a thriving medical man in the next street, we would almost undertake to say that the shopkeeper 'knew' her before she paid her third visit. It was the interpretation of the 'Sale of Poisons Act' which raised this question. The law forbids a chemist to sell poison to anyone 'unknown' to him, unless introduced. This chemist believed that his acquaintance with the housekeeper was sufficient for all purposes, and 'he thought her master, the doctor, might be angry if she were refused.' So he supplied a composition to kill mice, containing 'thirteen per cent. of strychnine and any quantity of arsenic.' Disaster followed. For in her zeal to destroy the rodents she contrived to poison her master's favourite dog, and he avenged himself by denouncing the obliging but incautious chemist. It might have reasonably been argued that he 'knew' his customer, within the meaning of the Act; but this course was barred by his neglect to enter her name and address, though he fulfilled its requirements in other particulars. So a fine of ten shillings and costs was imposed, and the poor man is aware henceforward that acquaintanceship over the counter will not justify him in selling 'strychnine to any amount.'"

A FATAL DOSE OF BELLADONNA.—An extraordinary fatality was reported on Wednesday, February 12, at an inquest held by Mr. W. M. Glugan, at St. Mary's, Isles of Scilly, touching the death of Joseph Hicks, an inmate of the Union.—William J. Hicks, brother of the deceased, stated that on Tuesday evening he, with his wife and sister-in-law, called to see his brother, who had been ill for a long time, and after being with him a short time deceased asked him to give him some medicine, which he would find in a cupboard. He found a small bottle about half full of some mixture, and his brother told him to pour the whole of the contents into a glass and to add to it the contents of a smaller bottle, containing a teaspoonful, and a teaspoonful of a mixture contained in a third bottle. This he did, and his brother swallowed the mixture in the glass. Shortly afterwards his brother said, "You will call and see me in the morning, and I shall be dead. I have taken my last dose." Witness then looked at the labels on the bottles, and found they were marked "for external use only." Being very much alarmed he called the matron, who sent him for the doctor, returning with him in less than five minutes. This statement was borne out by Emily Gendal.—Mr. J. Thornton Michilin, M.D., stated that when he arrived deceased informed him that at his request his brother had given him several mixtures. The bottle taken from the [cupboard had contained a mixture which, from the label, he inferred was of a poisonous nature. Deceased had probably brought the bottle from Penzance some time ago, as it bore the name and address of a chemist there. The second bottle had contained a preparation of belladonna and glycerin, and the quantity taken was not more than a quarter of a grain of extract of belladonna. The third bottle contained a lotion, and the small quantity taken could have done no harm. He administered an emetic and an antidote to the belladonna. Deceased recovered somewhat from the effects of the belladonna, but although he made several attempts to speak, he could not properly articulate, and died some hours afterwards. Deceased had been in a consumptive state for at least eighteen months, and suffered considerably from an ulcer in the back. He could not probably have lived beyond a week or ten days. In his opinion death was caused by the effect of the belladonna and exhaustion caused by the means used to counteract them.—The jury returned a verdict that death was caused by belladonna, administered by the brother at deceased's request, and the brother was severely censured for his carelessness.

PARLIAMENTARY INTELLIGENCE.

ROYAL COMMISSION ON VACCINATION.—There are indications of some impatience over the delay in the report of this Commission. Petitions for the early presentation of that report have been received at the House of Commons from various midland towns, and have been consigned to that euphonious substitute for a parliamentary waste-paper basket—the table of the House. It will be remembered that the Commission includes the names of one or two gentlemen well known to the Pharmaceutical Society and its members, and one honorary member of the Society, Professor Michael Foster, F.R.S.

SHOPS (EARLY CLOSING) BILL.—Sir J. Lubbock reaped the advantage of the "lightning legislation" on Wednesday last by carrying his Bill through the ordeal of a second reading. The Bill is identical with that of last Session, and as it recognises the important relations between pharmacists and the public by the insertion of a saving clause in favour of pharmaceutical chemists and chemists and druggists, the measure does not call for opposition on the part of the trade. Among the sponsors for the Bill are found the names of Mr. H. E. Kearley (Kearley and Tong, tea dealers, Mitre Square, E.C.), who moved an amendment to the address on the subject of the importation of adulterated merchandise, and Dr. Farquharson, who has on several occasions taken charge of Pharmacy Act Amendment Bills.

PROCEEDINGS UNDER THE PHARMACY ACT.

ACTION BY THE PHARMACEUTICAL SOCIETY.

THE SALE OF FELLOWS' SYRUP.

In the Market Harboro' County Court on Monday, Feb. 17, the Pharmaceutical Society of Great Britain sued Messrs. Symington and Thwaites, local grocers, for one penalty of £5 for a breach of the law by retailing or dispensing a compound of strychnine known as Fellows' syrup of hypophosphites, contrary to the provisions of the Pharmacy Act, 1868. Mr. T. R. Grey, barrister (instructed by Messrs. Flux, Thompson, and Flux), appeared for the plaintiff Society; Mr. J. H. Douglass, solicitor, defended.

In opening the case Mr. Grey said Fellows' syrup is a proprietary medicine, and an analyst would prove that the bottle sold by defendants contained as much as 1 grain of strychnine, one of the most dangerous poisons mentioned in the Schedule to the Act. Of course, ignorance that it contained poison could not be accepted as a plea, because on the outside wrapper which enclosed the bottle were words setting forth what the Act required.

Mr. Douglass pointed out that the bottle produced (like the one sold) was in a thin plain outside wrapper over the other.

Mr. Grey said that would not affect the case, and he went on to add that the proceedings were taken under 31 and 32 Vic., chap. 121, an Act to regulate the sale of poisons. As stated in the preamble it was passed for the benefit of the public, so that no one should sell poisons unless he had a proper technical knowledge of the subject. Having read the Sections bearing on the case, counsel quoted the cases of the Pharmaceutical Society *v.* Piper, reported in 93, 1st Queen's Bench Division, page 686, and the same *v.* Armson, 94, 2nd Queen's Bench Division, page 720.

Arthur Foulds then gave evidence as to purchasing a quarter of a pound of tea and a bottle of Fellows' hypophosphites from defendant's shop and handing them to Mr. Moon.

Cross-examined: It was on December 28 he purchased the things. He came from Manchester. Could not say if anyone locally had given information. Defendant's assistant served him from a case behind the counter. Was quite sure he did not go upstairs for it.

Mr. Douglass said, after the evidence taken, he should not contest the case, but he was instructed that defendants only bought three bottles of the medicine specially for a customer, who took one, and the other two were kept upstairs. Defendants did not know of the sale, and could not trace who sold it.

The Judge: Is this a case of Mother Siegel?

Mr. Grey: No; that is not a scheduled medicine.

Mr. Douglass suggested that his Honour should reduce the penalty.

The Judge: Have I any power to do that?

Mr. Grey said No.

Judgment was then given for plaintiff for £5 and costs. Three witnesses were in attendance.

POLICE PROSECUTIONS UNDER SECTION 17.

THE SALE OF VERMIN-KILLER IN LONDON.

Mr. Herbert Ensell Carne, a chemist, carrying on business at 12, Wigmore Street, Cavendish Square, was summoned by Chief Inspector Shannon at the Marylebone Police Court, on February 13, for selling strychnine to Julia Hadler, who was unknown to him, and was not introduced by a person known to him. Mr. Beck was for the defence. Mrs. Hadler is housekeeper to Dr. Charles Stonham, of 4, Harley Street, Cavendish Square, and said that, being annoyed by mice, she on January 18 went to the defendant's shop, which is close by, and was supplied by him with sixpennyworth of poison to kill them. He entered the sale in a book, and she signed it, but he did not ask her name or address. She had been in Dr. Stonham's service eight years, and had been into the defendant's shop several times to make small purchases for herself, but not for her master. The defendant advised her as to how she was to use the stuff, and she followed his directions. Unfortunately, Dr. Stonham's dog got hold of some of the stuff, and died in half-an-hour. Dr. Stonham was greatly annoyed at the loss of his dog, and he had some of the unused poison analysed. The result showed 13 per cent. of strychnine and "any amount of arsenic." He informed the police of the matter, and defendant told them that he let Mrs. Hadler have the poison as she said she came from Dr. Stonham, and he thought the doctor might be angry if she was refused. He had seen the woman two or three times in the shop.—Mr. Curtis Bennett held that it would be idle to say that the fact of a person making a casual purchase at the shop, or even saying that she was servant to a doctor, was "knowing her." The defendant might have made inquiries and verified her statement, but he did not. Her statement, as it happened, was true, but for aught the defendant knew, purchaser might have had a criminal intent and made an untrue statement. He fined the defendant 10s., with 2s. costs.

THE SALE OF VERMIN-KILLER IN LEEDS.

On the same day Mr. J. W. Howard, chemist, of King's Road, Headingley, Leeds, was summoned at the Leeds Town Hall, before the Stipendiary Magistrate (Mr. C. M. Atkinson) for an offence under the Pharmacy Act. The proceedings arose out of the sale by defendant of a preparation containing strychnine to Mary Grierson, aged 13, of 6, Victoria Road, Headingley, who subsequently used it for the purpose of committing suicide at home.—Mr. Ward prosecuted, and Mr. Bowling defended.—The defendant pleaded guilty.—Mr. Ward stated that Section 17 of the Pharmacy Act, which required the vendor of a poison to enter the name and address of the purchaser, the name and quantity of the article bought, and the purpose for which it was required in a book specially kept for the purpose, had been infringed by defendant. On January 26, Mary Grierson went to defendant's shop, and purchased a packet of "Vermin-Killer." She then went to Sunday-school, and afterwards to her bedroom. It was shortly discovered that she had taken some of the poison, from the effects of which she died the same day. An inquest was held, and a verdict of "Suicide whilst of unsound mind" was returned.—For the defence, Mr. Bowling contended that it was unnecessary for defendant to take the girl's name, as he knew her to be the daughter of Mr. Grierson. Defendant was unaware of the composition of the "vermin-killer" until after the inquest, when he wrote to the maker of the preparation, who replied that the powder did contain strychnine. When the girl went to defendant's shop she asked for some rat powder, as her father wished to destroy some rats. Defendant was fined £3.

NOTES AND QUERIES.

Owing to pressure of matter, this column is unavoidably omitted this week, and the publication of several replies to correspondents is also deferred.

NOTICES TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

LETTERS.

DETECTION OF ACONITINE.

A READER says:—"Professor Dunstan will find that the purple precipitate of aconitine and potassium permanganate has been previously observed, and, indeed, indirectly described in *The Medical Times and Hospital Gazette* of December 8, 1894, page 798, under the head of 'Antidote to Alkaloid Poisons,' viz., one centim. (c.c.) of a 1 per cent. solution of aconitine was left with a tenth normal (half a milligramme of potassium permanganate in a weak acid solution) and after several hours the pink solution became colourless. This, diluted so as to contain one per twenty thousand of alkaloid, whilst still responding to the iodine reagents, did not give the sensory effects of aconitine, but the bitterness of aconine, although one per three thousand (dilution) afforded a strong tingling.' In the same series of articles it is recorded that the amorphous aconitine immediately decolorises acid permanganate, whilst the crystalline does not do so."

HOMŒOPATHIC PRESCRIPTION.

MR. W. H. EDWARDS, of Guy's Hospital, replies to the query in last week's Journal as follows:—"The homœopathic prescription—

℞ (1) Sulph. 2/30 1-11.
(2) " 2/200 2-12.

Mitte tales pulv., xii.

Sig.—A powder night and morning in a wineglass of water.

should be read:—(1) Sulphur: 2 grs. in each powder of attenuation number 30; number powders 1 to 11, viz., 1, 3, 5, 7, 9, 11. (2) Sulphur: 2 grs. in each powder, of attenuation number 200; number powders 2 to 12, viz., 2, 4, 6, 8, 10, 12. Send such powders, xii., viz., six of each kind. It would be preferable to add to the physician's directions: 'To be taken in numerical order.' Each powder, according to homœopathic etiquette (!) should be wrapped separately in tin foil (after paper) and numbered outside to preserve its properties (?). With regard to making attenuations required, attenuation No. 1 is 1 in 100; attenuation No. 2 is 1 in 1000, and so on. I leave it to your correspondent to work out the quantity of sulphur he will require. Sugar of milk is the diluent. I will also refer him to the homœopathic B.P. for *modus operandi*, which he will find a lengthy and arduous one (*experientia docuit*)."

MR. WALTER WHITE, of Newport, Isle of Wight, thinks "the homœopathic prescription should be dispensed as follows:—

℞ Sulph. gr. 2 of 30 dilution. Number 1, 3, 5, etc.
" gr. 2 of 200 dilution. Number 2, 4, 6, etc.

Send 12.

Label.—One to be taken, according to number, night and morning, etc.

"To prepare the dilutions, take 1 grain sulphur and triturate with 100 grains sacch. lactis. This forms No. 1 dilution. Take of No. 1 dilution 1 grain, and triturate with 100 grains sacch. lac. to form No. 2. Repeat the process till you arrive at No. 30 and No. 200, then dispense as above."

Mr. LOUIS JNO. WELLS, of Newmarket, says "To translate the prescription more fully, it reads thus:—

℞ Sulphur 30 grs. ij.
Ft. pulv. mitte vi.

Label the powders separately 1, 3, 5, 7, 9, 11.

℞ Sulph. 200 grs. ij.
Ft. pulv. mitte vi.

Label the powders separately 2, 4, 6, 8, 10, 12.

The twelve powders number from 1 to 12, one to be taken night and morning in a wineglass of water.

So it is really two prescriptions; containing two kinds of powders, and they are taken alternately, hence the numbering one lot odd

number and the second lot even, thus getting the series 1 to 12; the 30 and 200 show the strength of the powder, or the attenuation as it is called, but it is no use explaining this, as your correspondent would save time and trouble by buying it ready made. The twelve powders are dispensed together, under the directions, of course."

MR. T. A. OAKLEY HEALE thinks "it is intended to send one dozen four-grain powders, each to contain—

℞ Sulphur, No. 30 potency 2 grs.
" No. 200 " 2 grs.

unless the figures 1-11, 2-12, apply to size of pills, when it would mean two pills of each potency to be crushed and made into a powder, and one dozen such powders sent."

OIL OF WHITE PEPPERMINT.

MR. JOHN MOSS writes as follows:—"Will you permit a correction of your report of my remarks at the Evening Meeting on Tuesday last? I did not say that the above was used 'only' in high-class confectionery, but that it was 'mostly' so used. Nobody at the meeting needed to be told that the white oil is preferred and used by pharmacists, but as the requirements of the latter are smaller than those of confectioners, my statement was quite correct, and hardly, I thought, exposed me to the good-natured banter of the President. The matter is trifling enough, but being credited with implying that pharmacists do not use the best and most esteemed oil of peppermint, which is entirely at variance with my experience, I hope you will find space for this note."

MCDADE'S ANTISYPHILITIC MIXTURE.

MR. J. G. HARRIS, of Wimbledon, sends the following formula for this preparation, which is apparently the same as "Succus Alterans," referred to in the 'Extra Pharmacopœia,' 8th edition, page 397:—

℞ Fl. Ext. Smilax Sarsaparilla,
" " Stillingia Sylvatica,
" " Lappa Minor,
" " Phytolacca Decandra aa ʒij.
Tinct. Xanthoxylum Carolinianum ʒi. M.

He says:—"A teaspoonful in water three times a day before meals, gradually increasing the dose to a tablespoonful, is said to be beneficial in either primary, secondary, or tertiary syphilis. The extracts must be made from the freshly-gathered herbs." Messrs. Parke, Davis and Co., send similar information, together with a pamphlet containing medical opinions on the use of the mixture.

CALCIUM CARBIDE.

MR. W. A. BLUNT, of Shrewsbury, says:—"Your correspondent can obtain calcium carbide and all the necessary apparatus for generating and storing acetylene, from Messrs. Read, Holliday, and Sons, Limited, Huddersfield, who are making a specialty of this method of illumination." Mr. Richard Reynolds, of Leeds, and other correspondents write to the same effect. The price for small quantities of the carbide is said to be 8*d.* per lb. The firm above mentioned also makes an automatic acetylene gas generator.

SOLUTION OF MORPHINE ACETATE.

MR. G. W. BLYTHE, of Doddinghurst, Essex, suggests the following as an original way of making a strong and stable solution of morphine acetate, whether for administration by the stomach or hypodermically:—"Mix water, 3 parts (by measure), with glycerin, 1 part, and heat the acetate in the solution till dissolved."

ANSWERS.

"ALCOHOL."—We do not know of any remedy likely to fulfil the conditions you specify.

C.P.R. has omitted to enclose his name, and is referred to our rule with regard to anonymous communications.

"SUBSCRIBER."—Apply to the Secretary, Royal Veterinary College, Red Lion Square, London, W.C.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Barrow, Baxter, Bilbrough, Bindloss, Blunt, Bridge, Cocks, Connan, Conll, Edwards, Harris, Hill, Hyslop, Jackson, Jarvis, Jordan, Kirkby, Maish, Moss, Netting, Noak, Parker, Postlethwaite, Prescott, Purves, Reece, Reynolds, Rideal, Robinson, Row, Smith, Thomas, Thompson, Vogl, Wells, White, Wolff, Woodruff.

The publication of several communications is unavoidably deferred, owing to pressure on our space.

“THE MONTH.”

Thyro-iodin. Chemical investigation of the thyroid gland by Professor Baumann, of Freiburg, in conjunction with clinical trial of the product by Dr. Roos has led to the important result of obtaining from the thyroid glands of sheep a product amounting to from 0.2 to 0.5 per cent., which possesses in a high degree the peculiar therapeutic activity of the gland, and is almost as powerful as a corresponding quantity of the fresh gland. One of the most remarkable characters of this constituent of thyroid gland is that it is an iodine compound. According to the account given by Baumann, thyro-iodin is described as an amorphous brown powder, almost insoluble in water and readily soluble in alcohol. It is readily dissolved by alkalis and is again precipitated on adding an acid. When heated, it swells up and gives off an odour of pyridin. Thyro-iodin does not give any of the reactions of albumin; it always contains phosphoric acid corresponding to 0.4 or 0.5 per cent. of phosphorus, and possibly it may be a product derived from the nuclein acids of Kossel. By repeated purification a product has been obtained containing no less than 9.3 per cent. of iodine, but the proportion of phosphorus was not equally increased. Examination of the human thyroid gland showed that it contains a similar iodine compound in the normal condition, whereas in cases of goitre the amount of iodine appeared to be smaller. The discovery of this organic iodine compound appears to throw a light upon the use of iodine in the treatment of affections of the thyroid gland, and it offers an explanation of the fact observed by Kocher, that preparations of thyroid gland are much more rapidly effective than saline compounds of iodine. It is suggested that this difference is analogous to that observed in the assimilation of iron when administered in the form of organic compounds and in organic salts, etc. Professor Baumann speaks in a highly complimentary manner of the assistance that has been rendered to him in carrying out his investigation by Messrs. Fr. Bayer and Co., of Elberfeld, who have now undertaken the manufacture of the preparation for medicinal use (*Zeitschrift Physiol. Chem.*, xxi., 319).

Copper Silicide. M. Vigouroux has prepared a silicide of copper, SiCu_2 , by heating silicon and copper together in an electric furnace. The silicide is a very hard and brittle substance, of the density 6.9 at 18°. The halogens attack it with incandescence; fluorine acts upon it at the ordinary temperature, chlorine before it reaches red heat, and the others at higher temperatures. At a red heat dry oxygen or air converts it into a silicate, and moist air oxidises it in the cold. Hydracids also attack it, forming salts of copper and silica, potash in solution blackens it, and alkaline carbonates in a state of fusion decompose it if finely powdered. The vapour of water is reduced by the silicide (*Comp. rend.*, cxxii., 318).

Lactyltropheine. This preparation forms bundles of acicular needles, melting at 74° to 75° C. It is readily soluble in water, alcohol, ether or chloroform. The hydrochloride forms colourless crystals readily soluble in water or alcohol. The hydriodide is also crystalline, freely soluble in water, sparingly in alcohol. Lactyltropheine is obtained by heating an aqueous solution of equal parts

lactic acid, tropine, and hydrochloric acid (s.g. 1.12) to 70° or 100° C. for several days on a water bath, taking care to replace any hydrochloric acid evaporated. The liquid is then made alkaline, and the base is shaken out with chloroform, the residue left after evaporating down the separated chloroform solution being purified in the usual manner. Lactyltropheine has the composition represented by the formula: $\text{C}_8\text{H}_{14}\text{NO}\cdot\text{CO}\cdot\text{CH}(\text{OH})\cdot\text{CH}_3$ (*Pharm. Centralh.* xxxvii., 73).

Lithium Hydride. A compound of the formula LiH , has been obtained by M. Guntz, by heating lithium in an atmosphere of hydrogen. The hydride formed is decomposed by water, as follows:—

one kilogramme of the compound yielding 250 Gm., or 2780 lit. of hydrogen. Heated in a current of nitrogen, the hydride is decomposed, with formation of a nitride, and when heated in a current of air it burns, lithia being produced (*Comp. rend.*, cxxii., 244).

Theobromine Salicylate. E. Merck describes this salt as crystallising in well-defined needles of definite composition, and it is a very stable compound as compared with the double compound of theobromine sodium with sodium salicylate, known as diuretin, which is decomposed even by carbonic acid and is also objectionable on account of its alkaline taste, which is rendered still more disagreeable by the sweet taste of salicylic acid. The definite salicylate is therefore likely to be a preferable form for administration of theobromine (*Merck's Jahresbericht*).

Albumin in Urine. D. A. Jolles recommends the following reagent as a convenient test for albumin in urine:—

Mercuric chloride	10
Succinic acid	50
Sodium chloride	10
Water	500

The filtered urine—4 to 5 C.c.—is shaken with 1 C.c. of 30 per cent. of acetic acid, and then with 4 C.c. of the above test liquid. In order to make allowance for the presence of mucin, equal quantities of urine and acetic acid are shaken in a second tube, then mixed with 4 C.c. distilled water and again shaken. By comparing the two tubes the presence of a trace of albumin may be recognised with certainty. The test is said to be more delicate than that with ferrocyanide and to be capable of showing the presence of one part of albumin in 120,000 parts of urine (*Apotheker Zeitung*, xi., 96).

Triphenin. Under this name J. von Mering recommends as an antipyretic and antineuralgic, a compound homologous with phenacetine and obtained by heating *p*-phenetidine with propionic acid. It melts at 120° C., and is soluble in 2000 parts of cold water. A dose of from 7 to 9 grains is said to reduce the body temperature 2 or 3 degrees C. (*Pharm. Centralh.*, xxxvii., 73).

Separation of Albumose from Peptone. A. Bömer recommends the use of zinc sulphate as preferable to ammonium sulphate for the precipitation of albumose, as it obviates the difficulty encountered in quantitative operations from the presence of nitrogen in the precipitating agent. Albumose is completely precipitated by zinc sulphate, but in case the material operated upon contains ammonium salts, the possible formation of a sparingly

soluble double sulphate $(\text{NH}_4)_2\text{SO}_4 \cdot \text{ZnSO}_4 + 6\text{H}_2\text{O}$ must be borne in mind and provision made against consequent inaccuracy in determining albumose on the basis of the nitrogen in the precipitate (*Zeitsch. Analyt. Chem.*, 1895, 562).

Amygdophenine. This is a derivative of *p*-amidophenol, analogous to phenacetine in constitution, one atom of hydrogen in the amide group being replaced by a mandelic acid rest and one atom of the hydroxyl group by ethyl carbonate. It is a greyish-white voluminous crystalline powder, very sparingly soluble in water. R. Stüvel reports that it is serviceable in rheumatic affections of the joints, and is without objectionable action. It is anti-neuralgic, but of little value as an antipyretic. The daily dose is 92 grains (*Merck's Jahresbericht*, p. 43).

Iodates. Ruhemann has shown that sodium iodate, when brought into contact with the mucous membrane, eliminates iodine and he has recommended it as preferable to the organic iodine compounds commonly used. More recently he has extended his observations to other iodates, especially those of silver, lithium, mercury, and some of the alkaloids. Subcutaneous injection of 1.5 grain of the lithium salt has been found very efficacious in cases where there was copious elimination of uric acid and somewhat larger doses given internally have been useful in chronic gout. Scopolamine iodate is said to be three times as active as the other salts and it, as well as atropine iodate, produces mydriasis more rapidly than the other salts of those bases. The solution of atropine iodate can be kept for a long time unaltered without addition of any antiseptic (*Merck's Jahresbericht*, p. 33).

Volumetric Determination of Lead. A. S. Cushman and J. H. Campbell refer to the observation of Fresenius, that no really good method exists which can be generally employed for the volumetric determination of lead simply and exactly, and they describe a modification of Schwartz's method (*Dingl. Poly. Jour.*, clxix., 284), which they consider of value. The lead is precipitated as sulphate, ammonia added, then a slight excess of acetic acid, after which boil until the lead sulphate is dissolved. Moisten a filter with ammonia, pass the liquid through, and afterwards wash the filter, first with water containing ammonium acetate in solution, and finally once or twice with hot water. Cool the filtrate, and run in from a burette an excess of standard bichromate solution, stirring until the precipitate settles rapidly and the supernatant liquid has a yellow colour. Then allow to settle for a few minutes, filter under pressure, wash a few times, and titrate the filtrate against standard ammonio-ferrous sulphate. It is stated that, after a little practice, the method described can be carried out as detailed in about thirty minutes. In general, the results obtained are a trifle low, the mean of the amount of lead recovered in twenty determinations being 99.6 per cent. of that taken (*Journ. Amer. Chem. Soc.*, xvii., 901).

Cerotic and Melissic Acids. T. Marie, in a very lengthy paper, gives an account of a research, the results of which lead him to the conclusion that the body known as cerotic acid is a mixture of two distinct acids. One of these appears to be identical with the melissic acids obtained on oxidising myricic and melissic alcohols, and is present to the extent of 40 per cent. The name "cerotic acid" he proposes to retain for the body present in the larger proportion. Analyses of the two acids, and of their ethers, salts, and other derivatives, indicate that

the formula for melissic acid is $\text{C}_{30}\text{H}_{60}\text{O}_2$, and that of cerotic acid, $\text{C}_{25}\text{H}_{50}\text{O}_2$. Details are given concerning a number of derivatives of both acids (*Ann. de Chim. etc.* [7], vii., 145).

Assay of Benzoates. G. Rebière has devised a method of determining the proportion of base and benzoic acid in benzoates generally, and particularly in benzoates of the alkalies. By dissolving a weighed quantity of a benzoate in water, adding hydrochloric acid and evaporating to dryness, the base will alone remain in the form of chloride, and can be determined by volumetric solution of argentic nitrate. The same quantity of the benzoate is then again dissolved in water, and the amount of sulphuric acid requisite to exactly combine with the base calculated from the previous operation and added to the solution. The benzoic acid, previously in combination, will be liberated, and can be determined by volumetric alkali and phenolphthalein. The results obtained are said to agree with the calculated quantities. In the case of benzoate of ammonia a modification has to be made (*Journ. de Pharm. et de Chim.* [6], iii., 113).

Test for Nitrites. K. Gorter points out that in 1875 Plugge showed that mercurous nitrate does not give a red colour with phenol when free from nitrous acid, and that the minutest quantity of nitrous acid suffices to produce red coloration. Hence he suggests that in the test recommended by Denigés (see "Month," Nov., 1895, p. 365) the use of mercurous acetate is the only novelty, and that the reaction is really the same as that suggested by Plugge for detecting and determining nitrites (*Apotheker Zeitung*, xi., 95).

Tannoform. Under this name, E. Merck has introduced a condensation product of nut-gall tannin with formic aldehyde. Its composition is represented by the formula $\text{C}_{20}\text{H}_{20}\text{O}_{18}$. It is a reddish-white, light powder insoluble in water, but soluble in alkaline solutions. It melts at 230°C . with decomposition. Several eminent dermatologists have found this product to be very useful in the treatment of various forms of skin disease, and it is quite harmless. Constitutionally, tannoform may be regarded as a methylene ditannin, and its formation is represented by the following equation:—

Similar compounds obtained from other kinds of tannin are distinguished as oak bark tannoform, quebracho or rhatany tannoform, etc., according to the plant from which the tannin is obtained (*Merck's Jahresbericht*, 1895).

Bismal. This is a bismuth salt of methylene digallic acid, prepared by E. Merck. According to Dr. v. Oefele, it is a useful astringent for internal administration in cases of diarrhoea which are not influenced by opiates. The dose is from 1.5 grain to 4.5 grains (*Merck's Jahresbericht*, 1895).

Testing of Butter. The method of testing for adulteration by determinations of viscosity, suggested by Killing, has been subjected to examination by Pollenske, by direction of the German Sanitary Department, and the viscosity of butter fat has been found to vary so much that a very considerable admixture of margarine might escape detection (*Apotheker Zeitung*, xi., 97).

Testing of Medicines.

Dr. E. Lücker reports the following observations:—Ether frequently gives indications of the presence of hydrogen peroxide, and sometimes of vinyl-alcohol. Glycerin was often found to contain sulphuric acid and ammonia: on warming with dilute sulphuric acid, the odour of volatile fat acid was always observed. The samples tested always had a reducing action upon Nessler reagent. Copaiba balsam, capable of bearing the testing of the German *Arzeneibuch*, could not be obtained. Chloral hydrate sometimes contained an admixture of alcoholate. Sodid carbonate frequently contained not only more monocarbonate than it should do, but also chloride and sulphate. Calomel was not unfrequently found to contain some mercuric chloride (*Apotheker Zeitung*, xi., 104).

Hydrazide and Azide of Carbonic Acid.

Curtius and Heidenreich state that when hydrazine hydrate reacts with urea at 100° C., hydrazide carbamic acid is formed—

By heating carbonic ester with hydrazine hydrate to 100° C., carbonylhydrazide is formed, $\text{CO}\left\langle \begin{array}{l} \text{NHNH}_2 \\ \text{NHNH}_2 \end{array} \right.$ It melts at 152° C., is soluble in water with feeble alkaline reaction and forms salts with two equivalents of acid. By treating the hydrochloride in a water solution with two molecular proportions of sodium nitrite, the azide of carbonic acid, $\text{CO}\left\langle \begin{array}{l} \text{N} \\ \text{N}_3 \end{array} \right.$ is formed, a colourless oil, which explodes violently when touched with a glass rod. This compound is readily soluble in water, alcohol, or ether: it may be regarded as nitrogen carbonyl and related to chlorocarbonyl, COCl_2 , as hydrazotic acid is related to hydrochloric acid. When the oily product is shaken out with ether and the solution evaporated, the carbonylhydrazide remains in the form of spiky crystals, having a stupefying smell analogous to sulphuretted hydrogen (*Journ. Prakt. Chem.*, 52, 433).

Hydrazine.

This body has hitherto been known only in the state of hydrate, $\text{N}_2\text{H}_6\text{O}$, but it has now been obtained by L. de Bruyn in the free state, N_2H_4 , by decomposition of the hydrochloride with sodium methylate dissolved in methyl alcohol—

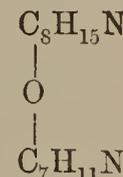

Hydrazine may also be obtained by heating the hydrate with baryta to 100° C. and distilling under reduced pressure. In the free state hydrazine is a liquid boiling at 113°·5 C. without decomposition; it solidifies when cooled below 0° C., and then melts at 1°·4 C. Hydrazine is a stable body and can be heated above 300° C. without decomposing: it reacts violently with the halogens: with solid sulphur it forms sulphuretted hydrogen: at the ordinary temperature it readily oxidises with elimination of nitrogen and, consequently, must not be exposed to the air (*Berichte*, xxviii., 3085).

Lupanine.

A comparative investigation conducted by Shermann Davis under the direction of Professor E. Schmidt has led to the conclusion that the alkaloids in the seed of *Lupinus angustifolius* and *L. albus* have a composition represented by the formula $\text{C}_{15}\text{H}_{24}\text{N}_2\text{O}$, as indicated by Siebert and Soldaini. The deliquescent base

obtained by Soldaini from white lupine seed is identical with the liquid base obtained from the same material, and both are identical with the liquid base obtained by Siebert from blue lupine seeds. The designations "liquid" and "deliquescent" are inappropriate, since all these products are readily crystallisable from petroleum spirit forming needles melting at 44° C. The aqueous solution of the base is dextro-rotatory. The solid base melting at 99° C. obtained by Soldaini from white lupine seed has also the formula $\text{C}_{15}\text{H}_{24}\text{N}_2\text{O}$, and it is a racemic compound of dextro- with lævo-lupanine, which can be separated into its components by converting them into sulphocyanides, and it can be reproduced by mixing in water solution equal parts of the dextro- and lævo-bases. These bases do not contain either a hydroxyl, methoxyl, ketone or aldehyde group. By the action of bromine the hydrochloride of dextro-lupanine is convertible by hydrolysis into two bases, $\text{C}_8\text{H}_{15}\text{NO}$ and $\text{C}_7\text{H}_{11}\text{NO}$, and since each of them contains one hydroxyl group, it is probable that the constitutional formula of lupanine may be represented by the accompanying formula—

—(*Apotheker Zeitung*, xi., 94).

Luteol.

This is the trivial name applied to oxychlor diphenylquinoxalin, a new indicator, which is described by W. Autenrieth as possessing certain advantages over phenolphthalein and litmus. The name must not be confused with that of the yellow colouring matter of *Reseda luteola*—luteolin—recently referred to by A. G. Perkin (*Proc. Chem. Soc.*, 160, 37). Luteol occurs in fine, woolly, yellowish needles (m. p. 246°), which are insoluble in water, sparingly soluble in cold alcohol, but readily soluble in hot alcohol and in ether. Luteol is also insoluble in dilute hydrochloric acid, only sparingly soluble in the concentrated acid, and forms a red solution in concentrated sulphuric acid, being re-precipitated from the latter solution on adding water. It expels carbonic acid from carbonates, and is readily dissolved by alkalies, a yellow solution being formed. A distinct yellow colour appears on adding a few drops of an alcoholic solution of luteol to 5 to 10 C.c. of a solution obtained by the addition of a drop of dilute soda-lye to one litre of water, the new indicator being therefore decidedly more sensitive than either phenolphthalein or litmus. Another advantage of luteol over phenolphthalein is that it is applicable in the presence of ammonia, whilst as compared with litmus there is no intermediate colour produced during the change (*Zeit. f. Anal. Chem.*, xxxv., 68).

Ergot.

As the result of an extended series of experiments, Beckurts and Grothe have confirmed the opinion previously expressed by Keller, that the ergot of Russia and Austria contains the largest amount of cornutine. It has also been found that the smaller-sized ergot contains most cornutine and is, therefore, preferable to the selected large grains. The authors recommend that in drying ergot it should not be exposed to heat, and they consider exposure over quicklime is the only method admissible (*Zeitschr. allg. Oesterr. Ap.*, V., 1896).

Juniper Tar.

In the South of France this tar is made by dry distillation from *Juniperus oxycedrus* and other varieties of juniper, but no tests are given for its identification or distinction from other kinds of tar in any of the pharmacopœias. Hirschsohn finds that the specific gravity of juniper tar varies from 0·978

to 1.102, and it is only partially soluble in alcohol of 95 per cent., but is perfectly soluble in aniline, while birch tar is only in part soluble. The aqueous extract of juniper tar gives no red coloration with aniline and sulphuric acid, and in this respect it differs from pine tar. With very dilute ferric chloride, the aqueous extract of juniper tar gives a reddish coloration, while birch tar extract gives a green colour (*Pharm. Zeitschr. f. Russland*, 1895, 52).

Influence of Light on Vegetation.

C. Flammarion has studied the action of different rays of the solar spectrum upon sensitive plants. The houses in which the plants were grown were glazed with red, green, and blue glass respectively, others being kept under ordinary white glass to serve as a check. It was found that the growth in height of the plants followed the order—red, green, white, blue, the difference being very marked in the case of the red. The action of red light was also most pronounced as affecting the vigour and activity of vegetation, white coming next in this case, then green, and blue again last. Red light is described as producing a similar effect to a chemical manure, while under blue glass development was almost stationary (*Comp. rend.*, cxxi., 957).

Boric Acid in Nature.

H. Jay deals with the prevalence of boric acid in nature, his observations possessing special value in connection with the use of the acid as an antiseptic in articles of food. The ash of fruits was found to contain from 1.5 Gm. to 6.4 Gm. of boric acid per kilo. Similarly, the ash of sea-weed, plane-tree leaves, wormwood tops, chrysanthemum flowers, and onions yielded from 2.1 Gm. to 4.6 Gm. per kilo. The plants which seem to absorb the acid with least facility are the cereals (wheat, barley, rice, and rye), certain fungi (*champignons de couche*), and cress, not more than 0.5 Gm. being found per kilo. of ash in those cases. The urine, milk, and blood of various animals have been examined for boric acid, but it was found in the urine only—to the extent of 0.0086 Gm. per litre in that of the cow, and 0.0075 Gm. in that of the horse. In conclusion, it is stated that boric acid is distributed over the chief part of the globe, if not the whole; both wild and cultivated plants absorb it from the soil and water whenever they meet with it, and most important of all, the acid is not assimilated when introduced into the animal stomach in small quantities, but is eliminated with the urine and other excretions (*Comp. rend.*, cxxi., 896).

Cod-Liver Oil.

W. Dulière has examined genuine cod-liver oil, and compared its characters with those of other oils. He finds the gravity stated by the Belgian Pharmacopœia (·920 to ·922) too low, and recommends the addition of a maximum acidity permissible, and limits within which the saponification number, iodine number, index of refraction and heat evolved with sulphuric acid should be stated (*Annales de Pharm.*, ii., 41).

Localisation of Daphnin.

L. Sauvan has investigated the localisation of the glucoside daphnin in *Daphne alpina* and *Daphne gnidium*; the reactions employed were the golden-yellow colour produced by solution of potash and the orange or blood-red by nitric acid, the results being confirmed by Errera's method with alcohol and alcohol acidified with tartaric acid. Sauvan has found that the root contains but little daphnin; the stem is much richer in the glucoside, which is principally contained in the outer cell-layers of the

cortex and in the bast, and is present most abundantly when the plant is flowering and fruiting. Both petiole and lamina of the leaf yield the reactions, but the fruit and the seed coats contain more of the glucoside than any other part of the plant. *D. alpina* appears to contain daphnin more than *D. gnidium* (*Répert. de Pharm.* [3], vii., 55).

Preparations of Kola.

J. Jean has determined the proportion of kolanin and caffeine (including theobromine) contained in various samples of kola seeds, as well as in certain galenical preparations made from them. The alkaloids were determined by the lime and chloroform method, but details of the determination of the kolanin are not given. The best seeds were those from Sierra Leone, which contained as much as 2.4 per cent. of caffeine and theobromine and 1.2 per cent. of kolanin. As the best preparation, the author recommends the tincture, since it contains practically all the kolanin, together with the majority of the alkaloids; upon the presence of kolanin particular stress is to be laid by reason of its decomposition in the stomach and consequent presentation of the alkaloids in a nascent condition. Of the extracts of kola examined, that prepared according to the directions of the Codex alone represented the drug, and such an extract should be the only one used for the preparation of a liquid extract (*Rép. de Pharm.* [3], vii., 49).

Oil of Russian Anise.

G. Bouchardat and M. Tardy have examined the essential oil of Russian anise to ascertain what it consists of, in addition to anethol, the chief constituent. As a result they have been able to separate two compounds—aniseic aldehyde and a ketone (*acétone anisique*). The first occurred more abundantly, 22 kilos. of oil yielding 80 Gm., whilst only about 20 Gm. of the ketone was obtained. The aldehyde has an odour resembling that of hawthorn or dry hay; its density at zero is 1.141, and its formula is $C_{16}H_{18}O_4$. It does not affect the plane of polarisation, and it combines with sodium bisulphite to form laminated and pearly crystals. On oxidation, the crystals yield a product identical with aniseic acid, $C_{16}H_{18}O_6$, crystallising from ether in needles that melt at 182°. Like the aldehyde, the ketone exists naturally in the oil, being derived from estragol or its isomer—anethol—by oxidation. It is optically inactive, has a density at 0° of 1.095, and an odour recalling that of the aldehyde. It also forms crystals of similar appearance with sodium bisulphite, but they contain a little less sodium. The composition of the ketone accords with the formula $C_{20}H_{30}O_4$ or $C_{20}H_{32}O_4$. Its oxidation results in the formation of aniseic acid as the chief product, together with traces of oxalic acid and a volatile acid as yet undetermined. A small proportion of aniseic acid was naturally present in the oil, and also traces of a liquid, the odour of which recalled that of cuminic aldehyde. Further particulars concerning the composition of the oil will be published later (*Comp. rend.*, cxxii., 198).

Oil of Pycnanthemum Lanceolatum.

W. G. Correll has examined a specimen of the oil distilled from *Pycnanthemum lanceolatum*, Pursh., collected whilst in full bloom, and found the specific gravity was 0.9135 at 20°, whilst the specific rotatory power indicated was $[\alpha]_D = +3^\circ.25$. Oil distilled from the same plant before blossoming had a specific gravity of 0.9160, and $[\alpha]_D = +0^\circ.88$. Carvacrol was isolated from the first oil to the extent of 7.2 per cent., whilst 9 per cent. was indicated in

the second specimen. Negative results were yielded by tests for pulegone, though duplicate experiments were performed successfully with oil of pennyroyal (*Pharm. Review*, xiv., 32).

Test for Thymol and Carvacrol.

The presence of carvacrol in the oil of *Pycnanthemum lanceolatum* was indicated in W. G. Correll's experiments by the beautiful purple-red colour produced on heating 0.01 Gm. of oil with 0.01 Gm. of caustic potash and 20 drops of chloroform. Commercial carvacrol and thymol both gave a similar purple-red colour with this test, as did also the oils of monarda and thyme, which are known to contain those phenols. Three samples of pennyroyal oil were examined; two each of spearmint and turpentine oils; and one each of the oils of spike, lavender, rosemary, balm, peppermint, juniper, savin, cedar, balsam fir, and white spruce, but none of them gave this characteristic reaction for carvacrol and thymol (*Pharm. Review*, xiv., 33).

Lignosulphite. This is a liquid obtained in the production of wood pulp for paper-making by treating pine wood with a boiling solution of lime and sulphurous acid. The liquor extracts ethereal oil, resin, and the balsamic constituents of the wood, as well as other substances produced by the action of sulphurous acid, and it has an agreeable aromatic odour. The use to which it has been applied by Dr. Hartmann, Professor Schrötter, and other physicians in Austria is for inhalation in the treatment of diseases of the lungs and respiratory organs (*Merck's Jahresbericht*, p. 95).

Umbellaria Californica, Nutt.

At the last meeting of the Berlin Pharmaceutical Society, Dr. Busse gave an account of the leaves of this plant, which are erroneously stated to be used in the preparation of Bay rum. They have a strong narcotic odour and are capable of producing toxic effects. An oil is obtained from the leaves, yielding at 167° to 168° C. a fraction of pleasant odour resembling terpinol, and having a composition represented by the formula $C_{20}H_{32} \cdot H_2O$. The fraction distilling at 215° to 216° C. is narcotic, and dissolves in concentrated sulphuric acid with red colour. This is named umbillol, and its composition is represented by the formula $C_8H_{12}O$ (*Apotheker Zeitung*, xi., 108).

Paper-making in Corea.

It is not generally known that the best kinds of paper met with in China and Japan are the produce of Korea. Varat says that "the Corean paper excels the very best that is made in China and Japan." It is produced entirely by manual labour and without the use of any machinery. The raw material used for the better kinds is obtained from the bark of *Broussonetia papyrifera*, which is collected in spring and beaten in water containing a large admixture of wood ashes until reduced to thick pulp. This is taken in large ladles and spread upon frames of bamboo so as to form thin sheets. Another kind of paper is made from old scraps trodden into pulp much in the same way that grape juice is expressed in some countries and though this process of pulping is slow, it has the advantage of not breaking the fibre so much as when machinery is used. After the pulp has been made into paper the sheets are piled up to a height of six feet, and then cut into pieces, to be again subjected to the stamping with the feet. At the same time the roots and seeds of a plant called "tackpoul" are added, the soluble parts of which are supposed to give tenacity and toughness to the paper (*Apotheker Zeitung*, xi., 107).

Analyses of Honey.

F. B. Guthrie publishes the results of the analyses of four samples of Australian honey, the origin of which was more or less definitely known. No. 4 was a sample in comb, and appeared to have granulated slightly, the left-handed sugar being consequently in excess of the dextrose. A considerable quantity of pollen, wax, etc., was present in the same sample, the large quantity of ash being thus explained. The approximate composition of the samples was as follows:—

Sample.	Water at 100° C.	Ash.	Dextrose.	Levu'ose.	Cane Sugar.	Combined Water and Unknown.
No. 1....	21.62	.23	37.21	32.23	3.70	5.01
„ 2....	19.2	.19	38.16	33.24	1.80	7.59
„ 3....	16.20	.03	32.30	31.80	13.60	6.07
„ 4....	21.56	.42	35.57	36.90	1.20	4.35

The third sample was regarded with some suspicion by bee-keepers, and the abnormal amount of cane sugar present rendered its purity doubtful. At the same time it is well known that bees fed on cane sugar yield honey containing an excess of that substance, and Guthrie considers it would be unsafe to assert positively that the sample represented an adulterated article (*Agricult. Gaz. of N. S. Wales*, vi., 793).

New Theory of Sight.

H. M. Bernard has been engaged for the past ten years in endeavouring to find an explanation of light sensations, and has at last worked out a theory which he considers capable of connecting and explaining most of the phenomena. He hopes also to prove that it is capable of demonstration, and is now engaged in arranging the evidence. Meanwhile, a short abstract is published of the conclusions arrived at, the development of visual organs in the animal kingdom being briefly described as follows:—Under the influence of light certain organisms travelling toward the light seek either to leave the Metazoan body altogether or else to discharge their contents at the surface. Such emigration cannot take place without the cognisance of the nervous system, and in the most frequently illuminated parts of the body complications arise between the fugitives and the other tissues, notably the peripheral nerves. Bernard's suggestion is that out of these complications all the known eyes of the animal kingdom, the most complicated as well as the most simple, have arisen in one way or another (*Mag. of Nat. Hist.* [6], xvii., 162).

Australian Fungi.

D. McAlpine has carefully tabulated all the Australian fungi known up to the end of the year 1894, and finds that the total number of species is 2284, West Australia contributing 242, South Australia 262, Tasmania 339, Victoria 1070, New South Wales 406, and Queensland 1060. He proposes now to put on record all fungi coming under his notice, whether they are new to science, new to Australia, new to particular colonies, or are found in new localities or on new host plants. After means have thus been supplied for the discrimination and correct classification of species, he trusts that vegetable pathologists will supply the requisite practical application of this knowledge by studying the life history of the fungi and their influence upon the well-being of other plants. The species so far known are classified and several new species described, and their spores illustrated (*Agricult. Gaz. of N. S. Wales*, vi., 752).

THE OLD FIRM OF GODFREY.

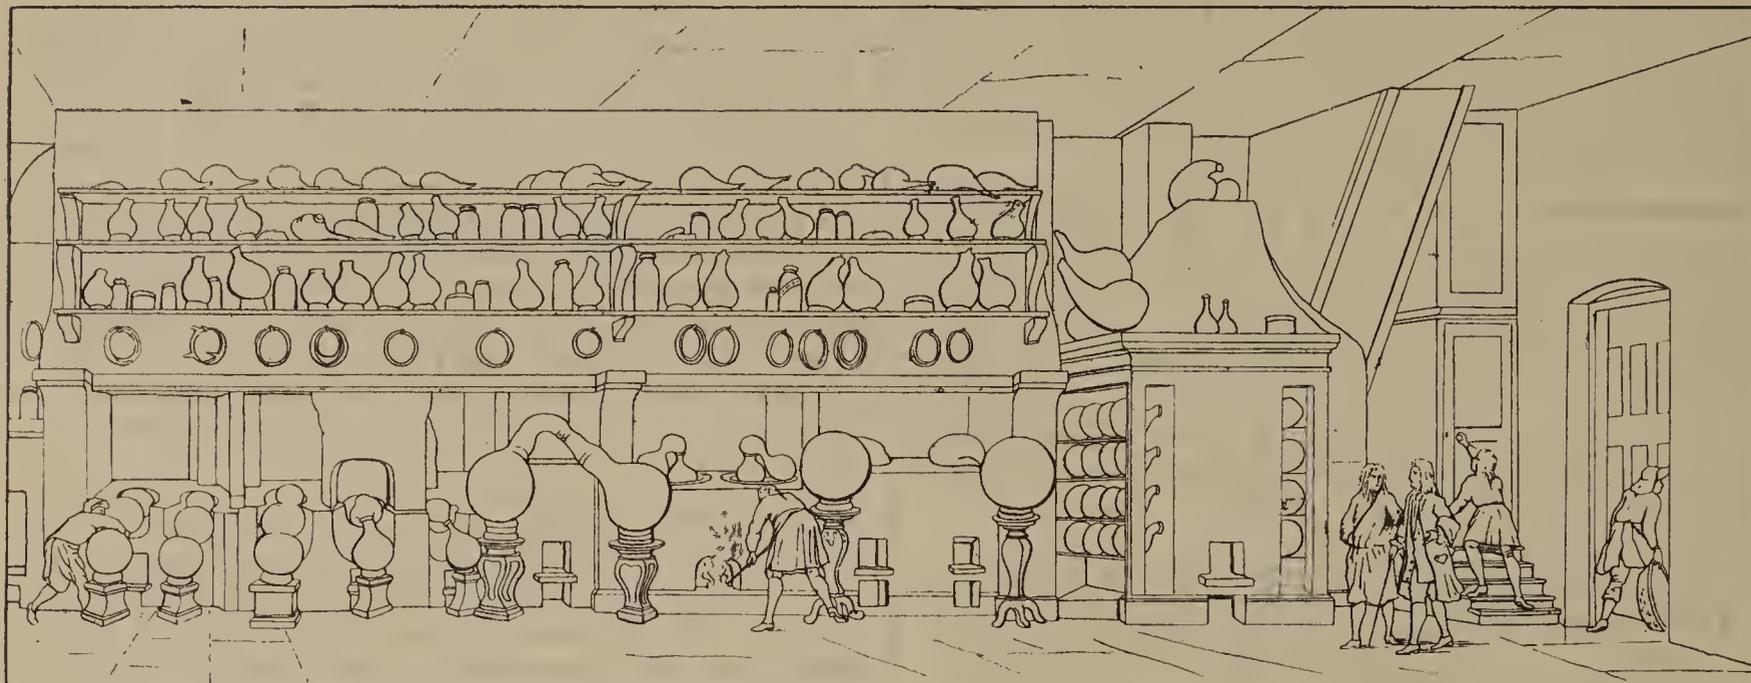

BY JOSEPH INCE.

Late Director of Godfrey's Laboratory.

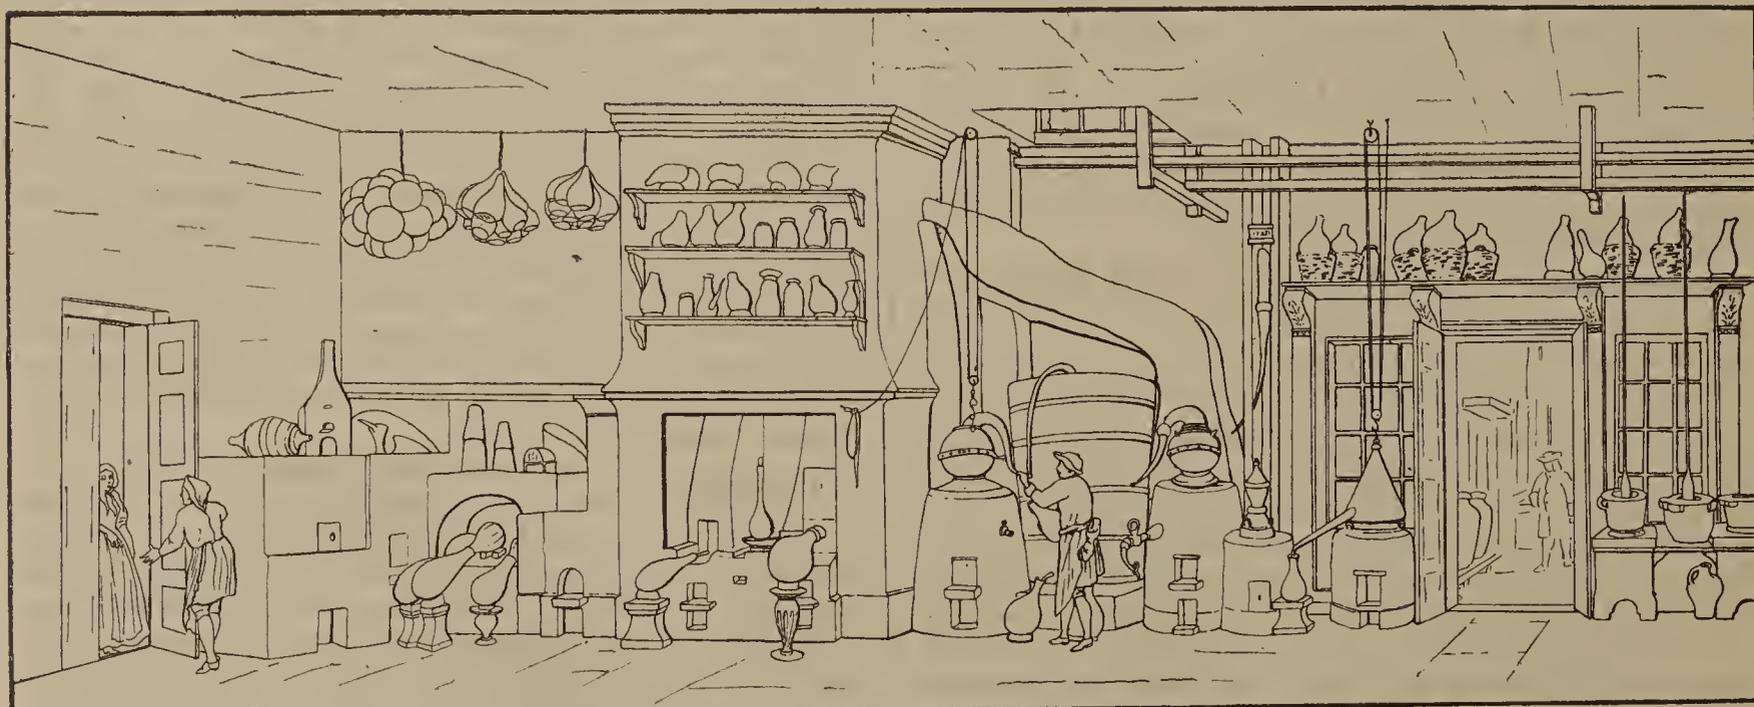

The mediæval history of this ancient house, dating from 1680 as a business, has been told so often,* that a brief outline of its earliest period will be sufficient. This is the story. The Honourable Robert Boyle devoted himself to the cultivation of science, particularly to the study of chemistry, natural philosophy, and theology.

On these three subjects he wrote many books, which in their day were held in great esteem.

mental evidence. So Boyle brought his young German friend* to London as his assistant, and some time about the year 1660 they built between them a long, lofty, straggling laboratory which opened into Maiden Lane, and extended down towards the Strand to the westward of the site, where the houses forming Southampton Street were subsequently built. The accompanying illustrations are taken from prints representing the laboratory at a later period when it was used for manufacturing purposes. The first represents the whole process of making phosphorus. The second shows unwieldy stills and retorts in full operation, and the third represents various pharmaceutical processes.

GODFREY'S LABORATORY—THE DISTILLATION OF PHOSPHORUS.

GODFREY'S LABORATORY—STILLS AND FURNACES.

Boyle lived for six years on the Continent, which inspired him with a love of foreign travel, and on one of his wanderings he met with a young German, Ambrose Godfrey Hanckwitz. A strong bond of fellowship drew the philosopher and the youth together—both were enthusiastic workers; the latter was plodding and industrious, and though Boyle occasionally saw visions, his rare love of truth led him to distrust theories not based on experi-

In this last illustration the open door of a vestibule to the right discloses a spacious garden which was a fashionable resort in the afternoon, and on certain occasions popular experiments were performed for the amusement of visitors.

In the history of the firm of Godfrey the usual order of things was reversed, a chemical laboratory entirely up to the science of the day was established first; it was devoted exclusively to experi-

* *Pharmaceutical Journal*, xviii., 126, *et seq.*

* The surname Hanckwitz being difficult to pronounce, and quite as hard to spell, it was eventually dropped.

ment and research; trade was an afterthought and an adaptation; only long afterwards was the old firm established.

I have been at pains to trace the exact origin of the business subsequently established, and it appears to have been this:—there was a great stir about phosphorus, heralded as one of the Arcana or mysteries of alchemy. It was the wondrous lumen, the *agens intrinsicum*, and many other things vaunted by the discoverer (Brandt) and his followers.

Boyle heard of phosphorus by "lytterall" correspondence; got a specimen from Saxony, and gave it to his head chymist, Mr. Bilger, who was to experiment and then instruct Godfrey how to make it. But Godfrey produced it first and made his fortune at the same time. He had been living in obscure lodgings in Chandos Street, with a wife, a family, and very slender income. He was immediately promoted to Boyle's friendship, and was engaged at once in the production of phosphorus. Afterwards he was sent on a travelling expedition to Holland, France, Italy and Germany, to display his specimens and to promote their sale. Then it occurred to Godfrey that science might be allied to trade, and the house in Southampton Street was built. I can find no evidence to show that Boyle had any connection whatever with its business career. He died a few years after and left his former assistant, Godfrey, in full possession of the situation.

heads; alembics of various pattern; curious receivers and glass vessels of strange shapes, the probable use of which it was difficult to determine. Much is it to be regretted that a fire, arising from the overflowing of a spirit still, destroyed most of these antiquarian relics. Beneath the whole flooring ran the cellarge, arranged in separate arched vaults—the receptacle for ammonia salts, ether, phosphorus, strong acids and essential oils—as well as for whatever might come under the denomination of dangerous chemicals.

The ground-plan of the chief section of the laboratory may be traced in the church of Corpus Christi, which has been built upon the exact site; the walls have followed the old line of construction. Modern improvements swept away much that was additional and external, but the out-house, which held the larger tinctures and an extensive assortment of snakes and adders, was the last to disappear. A plane tree, which adorned the yard and cast a grateful shadow in the summer, continued to flourish in spite of its untoward surroundings, smoky and unpropitious, until cut down by ignorant hands while the present writer was abroad. Communism is not limited to Paris.

Yet a lover of the past, standing on the steps of the church in Maiden Lane, may note that the right and left entrances mark the position of the phosphorus furnaces which Boyle, Godfrey's "honoured master," built. Their fate proves the mutability of all

At the time the writer of this article became acquainted with the laboratory of Godfrey, it had probably undergone much alteration from its original condition when used only for purposes of scientific experiment. In its construction whatever was wanting in symmetry was amply compensated for by height and space; ground had not risen to its modern value, hence the building was roomy and irregularly spacious, and was in time provided with two huge vats, supplied with water from the main which served as condensers to worms of similar dimension, attached to those ponderous stills, the memory of which survives in old prints. Big metal mortars were served by iron pestles, fixed to a long, wooden spring beam, suspended at the further end by a chain and ring. Much later in date came two sublimers for ammonia; one much resembling the usual form of apparatus—with a second which was an unwieldy leaden receiver, cooled by means of running water, and when possible encased with snow. Winter work was a sore trial for the men, since on all the laboratory premises there was not a solitary fireplace. On the shelves was an array of still-

earthly things; three on the left were demolished to make way for a coal-shed, two on the right were pulled down to accommodate a truck, the third lingered as a charcoal-burner until the business migrated to the West end, its last operation being to calcine acacia wood, which was manufactured into a *poudre dentifrice* for the then Empress of the French.

When the priest addresses his congregation he is probably not aware that the pulpit stands upon the spot once occupied by the Drying Chamber. This was a room arranged when ventilation and air currents were little understood, and it resembled, in its main features, the furnace seven times heated, of sacred history. It was equally ineffective in accomplishing the desired purpose. The modern drying-closet, one-fourth the size, offers a far better method of desiccation. The high-altar of the Church stands on the spot once appropriated to the manufacture of carmine, with rows of precipitation basins arranged on shelves and the store of silver grey cochineal. A particular feature of this room was the admission of light only from above.

It would be tedious once more to recapitulate the scientific transactions of the period between 1660 and 1741, full particulars of which will be found in the earlier numbers of the *Pharmaceutical Journal*. The record shows that Godfrey first produced sulphuric ether in saleable quantity, a circumstance pointed out to me by Professor Redwood. The statement must be taken without prejudice to the share that Sir Isaac Newton, Boyle himself and a certain Dr. Frobenius had in the discovery. Next came researches upon Ambergris, which he pronounced to be a substance analogous to, but not identical with, Amber.

The more important matter for present purposes is the date at which, in 1680, Godfrey became a business man and issued an elaborate advertisement, which will be dealt with in the next article. Then chemistry was no longer an abstract science, but bore a direct reference to the till.

There are two portraits of Godfrey extant: one by Vertue, dated 1718, is reproduced at page 168: it represents him as the "Chymist at the Sign of the Phoenix," of whom mention is made in Brandes' 'Chemistry' as being the founder of "Godfrey's" in Southampton Street, Covent Garden.

(To be continued.)

PHOTOGRAPHY FOR CHEMISTS.

BLACK AND WHITE.

One or two queries that have been sent by correspondents, on the subject of failures in successfully reproducing black and white subjects, such as line diagrams or printed matter, either as prints or lantern slides, suggest that primarily the cause of failure lies in the making of the negative and that this point is deserving of treatment at some length.

First, as to the lens. Almost any lens may be used, even a single or landscape lens, because, as a rule, we do not use the whole of the field, merely the centre, and there distortion of marginal lines does not become apparent; on the other hand, a doublet is preferable, and undoubtedly the newer lenses, such as the Concentric, Collinear, Zeiss, Goerz, or Cooke, give superior results, because of their flatter fields and greater freedom from astigmatism. The focus of the lens is immaterial, provided always it is not so long that it will not allow of a sharp image being obtained when copying full size or nearly so, because it must be remembered that the nearer you get to your object, so the focal length for the time increases, and if you have two or more lenses the necessary distances should be calculated out so that you do not get into a difficulty by using a lens of too long focus, or one too short. The rule to find these distances is, divide the longer base of original by longer base of plate, add one, and multiply by the focus of lens; for copying, this gives the distance between lens and object. To find the distance between lens and sensitive plate, divide the distance between lens and object by the number expressing the ratio of image to object. We want to copy a diagram or page of a book measuring 9 x 5 ins. so that we can make a lantern slide by contact; the lantern plate measures $3\frac{1}{4} \times 3\frac{1}{4}$ ins.; $\therefore 9 \div 3\frac{1}{4} =$ the amount of reduction, or ratio of image to object. Using an 8-inch focus lens we have a very simple sum:—

$$[(9 \div 3\frac{1}{4}) + 1] \times 8 = \frac{40}{3} \times 8 = 30\frac{2}{3} \text{ ins.}$$

This is the distance from lens to object; then—

$$30\frac{2}{3} \div [9 \div 3\frac{1}{4}] = 10\frac{2}{3} \text{ ins.,}$$

which is the distance between lens and plate. It may be added that in doublet lenses these distances should practically be measured from the diaphragm slot, and with single lenses from the front surface of the lens. There is one important point which must not be

forgotten; taking the above case we find that the focus is increased to 11 ins. practically, but our diaphragms or stops, which have an important bearing on exposure, are calculated out on a basis of 8 in. focus. The result will be that they are reduced in value, and, therefore, the exposure should be proportionately lengthened; for instance, the diameter of F/8 with an 8-in. lens is obviously 1 in.; therefore, with 11 in. focus it is no longer F/8, but F/11; and as the exposures with these two apertures are as $8^2 : 11^2$, or practically as 1 : 2, it is obvious we must take this into consideration,

Now for the treatment of the object. Suppose we have a page of a book, a diagram, or engraving to copy, and it is impossible to tear it out of the book, what is the best way to go to work? As a rule one does not care to tear up one's own books, though we may not be so careful of other people's; but even they would object probably to have, perhaps, a valuable book mutilated merely because you want to copy something. Obtain two pieces of plate glass, or even old negative glasses will do, as long as they are quite clean, some stout india-rubber bands or American wooden clips. Place your book flat on the table, open at the particular leaf. Hold this leaf up straight, place one glass behind it and one in front, slip two india-rubber bands over the glasses and leaf, one near the centre of book, the other at the edge of page, and you will have a perfectly flat surface, and only need place a box or pile of books behind to keep this upright and in a position for copying.

The next point is, where is it to be copied? Naturally, we have a totally different subject to a living subject. We want no half tones, no modelling, nothing but black and white, consequently as flat and even a lighting as possible. This does not seem a very difficult thing to obtain, but it is far more difficult than one would suppose. Placing the book exactly opposite the window of the room is satisfactory as long as too short a focus lens is not used, or else the camera casts a shadow, and photography is far more sensitive to varying lighting than our eyes. If it is not possible to do this or to copy the book out of doors, then place it as nearly as possible at an angle of 45° with the window, and to equalise matters, use a good-sized bedroom mirror to reflect the light on to the side further from the window. Now set up your camera approximately at the distance found by above rule, and focus sharply with full aperture of the lens, and now look out for reflections; if you can on the ground glass see the slightest reflection you may be quite sure that it will appear in the negative and spoil your results. If you cannot get rid of them in any other way—and it will be found that it generally is possible to do it by a slight shifting of the book and camera—then you must erect a framework of tissue paper all round the book, for this breaks up the light, so that no distinct reflections are visible.

Before leaving the question of the subject, it must be distinctly understood that the camera must be parallel to the object, or parallel lines in a diagram will appear to be convergent. This is particularly important when making negatives for lantern slide work.

One of the principal advantages of rapid plates is their power of reproducing correctly the vary tones or gradations which exist in nature, but in copying black and white this very power is a great drawback, because we want no tones, no gradations, merely black and white, and, therefore, rapid plates possess a quality we do not want. The only plates to use for this work are the so-called photo-mechanical or process plates, which are specially made for the purpose, and have but little or no scale of gradation, but merely two tones.

With regard to exposure, but little help can be given, the only thing to do is to make a trial as follows:—Pull out the shutter of your dark slide, and uncap the lens for thirty seconds, cap the lens

push sliding shutter in about one-fourth, give fifteen seconds more; repeat this operation till the whole plate has been exposed in strips with thirty, forty-five, sixty, and seventy-five seconds, exposure; on development, a good guide will be obtained as to something like the correct exposure. Practical trial alone can teach this.

The particular method of development is not of much moment, pyro., hydroquinone, glycine, or even metol and hydroquinone.

A very good pyro, formula is—

Pyro.	4 grains.
Metabisulphite of potash ...	4 „
Potassium bromide	4 „
Distilled water	1 oz.
Sodium tribasic phosphate	40 grs.

or hydroquinone—

Hydroquinone	4 grs.
Metabisulphite	4 „
Bromide	2 „
Citric acid	2 „
Distilled water	1 oz.
Sodium tribasic phosphate.....	40 grs.

Glycine may be used instead of the hydroquinone in the last formula, and equally good results obtained. For beginners pyro. should be avoided.

In developing, the main point to be observed is clear lines; density is quite of secondary importance, though if the two can be obtained in one operation, so much the better. Continue development as long as you can, but on the slightest sign of the lines veiling wash and fix. When thoroughly fixed, rinse and take out into the light and examine. If the lines, when the negative is laid on white paper, do not show as absolutely bare glass, flood the negative with Belitski's potassium ferric oxalate reducer till the lines are cleared, and then well wash. Treat the negative to an acid and alum bath, or one of anthion, and again wash. If the ground is not dense enough, intensification must be resorted to. A very little experience will tell the operator this; in fact, after making, say, a couple of negatives and printing from them, he will know about how dense the negative should be.

There are two methods of intensification which are very suitable, the one bleaching with mercuric chloride, thorough washing and blackening with Monckhoven's potassio-silver-cyanide solution; the other mercuric chloride, followed after thorough washing with a 5 per cent. solution of Schlippe's salt, sulphantimonite of soda. The latter is to be preferred because the resultant image is bright red, and therefore of an extremely non-actinic colour.

Attention to details and a little care is all that is required to enable anyone to make negatives on dry plates fully up to the standard of those turned out by the old wet collodion process, which is the process always used by professionals for this work, and till last year was used exclusively by the writer for this work.

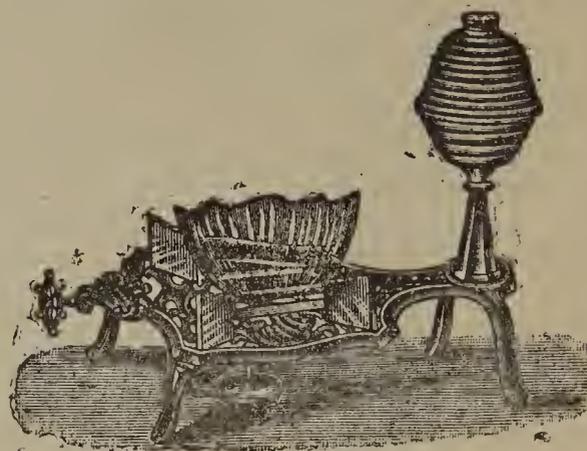

Now a note as to printing such results; for paper prints, bromide or platinotype paper must be used. It is hopeless to expect to get satisfactory results on any silver printing-out paper. For lantern slides, slow plates specially made for black tones must be used.

Particular stress has been laid upon those points in which the beginner in copying is likely to fail, but it is hoped readers have not been impressed with an idea that there are enormous or insuperable difficulties. By constant practice some have become so perfect in this process—and anybody else may do the same—that in preference to copying long extracts, particularly if accompanied by diagrams from books or papers, they now photograph them and make a print in a few minutes on bromide paper, with considerable saving of time and labour,

NOVELTIES IN PHARMACEUTICAL APPARATUS.

A SIMPLE SPIRIT STOVE.

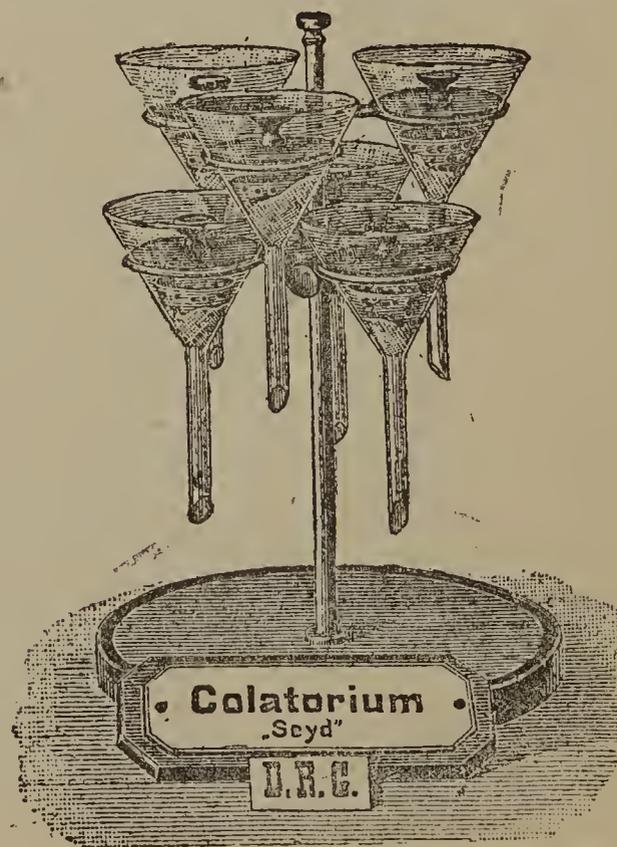

A German firm has introduced and patented an elegant and simple spirit-stove. A steady stand with four feet carries a brass globe holding about half a pint of spirit. By turning a small wheel

a little spirit is allowed to overflow into a dish below the stand; this is then ignited, but before it has quite burnt out the wheel is again turned; the spirit that flows is now converted into vapour, and burns with a blue and intensely hot flame. The spirit burnt costs about a penny per hour, and the heat is sufficient to boil a litre of water in from four to five minutes.

A NEW COLATORIUM.

Seyd's colatorium appears to be specially adapted for straining mucilaginous infusions, such as that of marshmallow root, etc. The straining material consists of a layer of cotton-wool backed with muslin, and is sold in rolls. A square piece is cut off, placed

in the funnel, wool outwards, kept in position by a perforated porcelain cone and protected by an earthenware cover. Six such funnels can be arranged on a single stand,

PHARMACEUTICAL JOURNAL.

THE BENEVOLENT FUND.

THE attention of everyone legally qualified to practise pharmacy in Great Britain is this week directed to the Benevolent Fund administered by the Council of the Pharmaceutical Society. The extreme catholicity of this Fund should suffice, without further recommendation, to attract to it the practical sympathy of all included within its sphere of operations, but it may serve a useful purpose to point out that, between 1872 and 1894, the total amount received by annuitants was £12,975, and that there are now forty-seven persons in receipt of annuities from the Fund, whilst nearly £2700 has been expended in payment of annuities and casual grants during the past year. The subscription of so small a sum as half-a-crown entitles an individual to take part in the election of annuitants, and it is believed that, were every non-subscribing chemist and druggist to devote that small amount annually to the purposes of the Fund, all cases of need in connection with the craft could be amply provided for. It must be borne in mind, too, that the payment of annuities alone now necessitates the disbursement of £2245 per annum. Whilst, therefore, it is hoped that all former subscribers will continue to assist the Fund to the best of their ability, those who have not yet borne their share in securing their unfortunate fellows against the need of outside charity, are urged to begin at once, remembering that gifts in such a cause are valuable in proportion as they are given quickly.

WHAT THE SOCIETY HAS DONE.

THE present issue of the *Pharmaceutical Journal* will be sent to every person entitled under the Pharmacy Act, 1868, to pursue the calling of pharmacy in Great Britain, and it would, therefore, seem particularly fitting that some prominence should be given to considerations affecting the interests of those persons. From the report recently presented to the Council by the Registrar, it appears that there are now 15,078 names on the Register of Chemists and Druggists, and one cannot but be impressed with the possibilities which so large a body of individuals might accomplish if they chose to regard community of calling and identity of interests as a reason for mutual association and concerted action. But the pharmaceutical millennium is still

only *in posse*, and the chemists and druggists of Great Britain are as much divided amongst themselves as were those hypothetical men of science whom the influence of a subtle phenol compound revealed to Professor MICHAEL FOSTER. Unless there be some malign influence in medicaments—some inherent spirit of discord in the art of dispensing—it is difficult to account for this infinite isolation of individuals engaged in the same daily avocation. It is not unlikely that “the fault is not in our stars but in ourselves that we are underlings,” and if that be so, it might be well to recognise, at once, the force of making the most of existing means of defence or advancement and the futility of cursing the horoscope.

Happily, chemists have no need to painfully evolve or laboriously execute plans for the erection of a barrier against antagonistic forces; the loyalty and earnestness of a past generation of pharmacists accomplished all that for them more than fifty years ago, and to-day there is—available to stand between pharmacy and those that threaten its existence—the Pharmaceutical Society, the sole means of resistance and the only hope of safety. Remarks of similar purport to this may have been made before, but even as a sermon, according to WHITFIELD, is good for nothing till it has been preached forty times, so one may be inclined to doubt the efficacy of pharmaceutical arguments until they have been well seasoned by repetition. Who shall say, too, that after the fiftieth time chemists and druggists may not begin to think there is “something in it”? One may hope to be forgiven, therefore, for again urging upon chemists the vital necessity of making their only safeguard a strong and sufficient one. What real motive chemists may have for not joining the Society is difficult to discover, but the expressed reasons, if they were not lamentable indications of ignorance and indifference, would be humorous. When a registered man declines to join—as was actually the case quite recently—on discovering that as a member he would only get two votes for the Benevolent Fund, one is apt to take a pessimistic view of the future of our calling. Equally difficult is it, at times, to divine the actual reason of a member's retirement from the Society.

There is little doubt, however, that the chief cause of secession from the Society and abstention from joining it is a want of knowledge of the Society's work. “What has the Society done?” is a familiar and perfectly natural question. In the hope of dispelling some misconceptions and galvanising to activity some indifferent minds, the inquiry may again be briefly answered. To urge gratitude for past work as a reason for present loyalty, is perhaps not in accord with *fin-de-siècle* philosophy, and the fact that chemists and druggists have shared in whatever good may have accrued from the Society's fifty years' of steady effort is, therefore, passed over. The past year's work alone is sufficient to gauge the value of the Pharmaceutical Society to all qualified persons.

In the first place some £1500 was spent in prosecuting persons infringing the law. True, this is a public duty and it is imposed in the interest of public safety, but it should not be forgotten that, from the business point of view, every action against an unregistered man tends to enhance the value of personal qualification; the ten thousand registered men who are unconnected with the Society being as much interested in upholding that value; benefiting as much by its maintenance, as the four thousand members of the Society who paid the bill. Of course, it might be

argued quite plausibly, "Why should I join in prosecuting these people when someone else will do it and find the money?" To those who would employ this sophistry the converse of the argument may be commended; the question may be asked what will be their position when the present members conclude to bear no longer the burdens of the whole calling? The privileges already won may be far from what the education and training of a chemist entitle him to hope for, but is he prepared to forego even that which he has?

The administration of the Pharmacy Acts, and the consequent training of the public mind in respect for the qualification provided by those Acts, though the chief, is not the only item in the record of the Pharmaceutical Society's work. As a voluntary association of qualified persons it has expended during 1895 a very considerable sum in endeavouring to secure the educational fitness of those who follow, or who seek to enter upon, a pharmaceutical career. The maintenance of the Libraries, Museums, and Laboratories in a state of efficiency is a factor of no inconsiderable value in the elevation of the status of the qualified chemist. The Society's work in that direction is of indirect benefit to all chemists and has been of immediate advantage to many who have availed themselves fully of the opportunities offered. The Society has also to perform and does frequently perform, services which by their very nature cannot be immediately made public. Allusion may be made to the strenuous efforts which have been continued for some time past by the Council to direct the attention of the Government to the abuses practised under shelter of the Companies Acts. Those efforts had naturally to be made diplomatically; it should be clear to every thoughtful person that it is not always expedient in such matters to herald one's intentions by bold advertisement. During the year, the Council has made representations to more than one Government Department on such questions as the qualification of Poor Law dispensers, the Metric System of Weights and Measures, the Adulteration of Food and Drugs and other matters affecting the business of a chemist and druggist; and it is certainly unjust, however natural it may appear, to assume that nothing has been done because there have been no banners on the outer walls. No doubt the representations of the Council are not always successful, but they would be more frequently effectual if the strength of the Society were commensurate with the number of chemists on the Register.

There can be no danger of general adherence to the Pharmaceutical Society tending to destroy or even to weaken in any degree the individuality of chemists and druggists. The founders of the Society were mindful of the fact that with many men there must be many fancies; they drew up a constitution broad enough to allow for all sorts of opinions arising from a healthy and virile personality. It is the possession of this broad constitution—more democratic than most of the institutions specially devoted to the cult of Demos—that should render the Pharmaceutical Society beyond suspicion by the most hypersensitive pharmaceutical *sans-culotte*. Registered men are not asked to join a select body of superior people who will take all the subscriptions and make regulations for self-advancement, but to associate with fellow-craftsmen in the attainment of common privileges. If the Society's half century of work has been on wrong lines, let the advocates of a new policy come in and effect the desired change; on the other hand, if the

past has been productive of good so much the stronger reason is there for guarding well the heritage that has wrought the good. Let the chemists and druggists of the two kingdoms ponder well these things.

THE VALUE OF A PHARMACEUTICAL JOURNAL.

IN a paper read before the Connecticut Pharmaceutical Association, R. H. KIMBALL points out that the pharmacist who desires to keep up in the race needs to be posted regarding new remedies and many other matters, concerning which he can nowhere find immediate information except in the pages of his drug journal. Without such information he may often find himself in the awkward position of being unable to reply to a customer's question, this being especially annoying when the querist is a physician. In many such directions journals of pharmacy are of inestimable value to working pharmacists, and the writer of the paper referred to observes that he would as soon think of trying to conduct the business of a pharmacist without a pharmacopœia, a dispensatory or other books of reference, as without a journal of pharmacy. He therefore urges every pharmacist, every assistant, and every student to buy and read some such publication. It may be added, to fitly apply his concluding words, that in no way can they invest so small an amount and get better or more valuable returns than in subscribing for the *Pharmaceutical Journal*. Every effort has been made, for some time past, to meet the legitimate requirements of the trade in these pages and, as the organisation for this purpose becomes more and more perfect, it is anticipated that the Journal will come to fully satisfy the needs of readers generally.

PHILADELPHIA COLLEGE OF PHARMACY.

AT the first pharmaceutical meeting of the present year, a long paper was read by Mr. F. B. KILMER on "Kola and Kolanin": it does not add much to the knowledge of this subject, and is for the most part a recapitulation of the statements already published. In dealing with the use of kola as a stimulant and medicinal agent, the author assumed the existence of the substance, to which the name kolanin has been applied and attributed to it a greater efficacy than either caffeine or theobromine possess; but the ground for this opinion was purely speculative and, as Professor TRIMBLE pointed out in the discussion, there is much reason for doubting the romantic accounts of kolanin, the existence of which is far from having been satisfactorily proved. The second paper read was on "The Influence of Medicines upon the Character of Urine," by Mr. F. W. HAUSSMANN, and it gave evidence of much observation in reference to a subject which requires careful attention and study. The third paper related to "Comparative Examinations of Methods for the Assay of Cinchona Bark," by Mr. LYMAN F. KEBLER. Abstracts of both these papers will be published in the Journal. The January number of the *American Journal of Pharmacy* contains the first of a series of articles upon the "Coniferæ of North America," by Professors BASTIN and TRIMBLE, and there is a second article in the February number. These articles contain descriptions of the botanical characters of the plants, their chemical constituents and economic uses, with excellent illustrations of the microscopic structure of the roots, leaves, etc.

EXPERIMENTS ON TRANSPIRATION.

IN the *Botanische Zeitung*, E. STAHL has described a number of interesting experiments, on the results of which he bases a method by means of which it can be demonstrated to the eye whether a plant loses water by transpiration, and also through what parts of its surface the loss takes place. For this purpose A. MARGET had formerly employed white paper impregnated with a mixture of mercurous and palladous chlorides, or with palladous and ferrous chlorides and tartaric acid. In the dry state the paper was whitish-yellow, but it became darker, and finally black as it absorbed water. When applied to the transpiring surface the loss of water could be estimated by the change in colour, and at any point the colour could be fixed by simply dipping the paper in solution of ferric chloride. Other investigators, however, have found MARGET's method unsatisfactory, and STAHL has resorted to the use of cobalt salts, especially cobalt chloride. He soaks strips of Swedish filter paper in an aqueous solution (1 to 5 per cent.) of this salt and dries them, their colour then varying from light to deep blue, according to the strength of the solution employed. As the paper becomes moist, the colour changes to pink and then to white. In use a small piece of the cobalt paper is thoroughly dried, placed in position on the plant, then held firmly against the surface, and protected from the air by means of a thin piece of glass or mica, which is held in place by small clamps. In cases where leaves have stomata on the under side only, cobalt paper on that side is reddened very quickly, often in a few seconds, while that on the upper side of the same leaf may retain its original colour for several hours. Where stomata occur on both sides, the reddening is proportionate to the number, and in the case of *Trifolium repens*, the leaves of which have more stomata on the upper than the under side, the paper fades more rapidly on that side. No reddening occurs in the case of slightly wilted leaves or in any instance where the stomata are closed on account of an insufficiency of water in the plant, even when the leaves are exposed to the sun. The slight extent to which evaporation through cuticularised epidermis takes place is thus demonstrated, whilst fully turgescient leaves supplied with water are said to illustrate the same fact.

RHODINOL OR GERANIOL.

THE principal liquid constituent of rose oil was first isolated by MARKOWNIKOFF in a state of purity sufficient for approximately determining its composition and molecular weight. Then POLECK and ECKART gave it the name of rhodinol, and showed that it is a primary unsaturated alcohol of the fat series, having the composition represented by the formula, $C_{10}H_{17}OH$, and being readily convertible into terpene derivatives. MONNET and BARBIER ascertained the presence of rhodinol in French geranium oil from *Pelargonium odoratissimum*, and described the method of preparing it from that material. BERTRAM and GILDEMEISTER prepared the very unstable compound of rhodinol with calcium chloride, and showed the probable existence of rhodinol in Palmarosa oil from which JAKOBSEN had in 1871 obtained an alcohol, $C_{10}H_{18}O$, by means of calcium chloride.

The essential agreement of these results did not prevent the expression of different views. While MARKOWNIKOFF and REFORMATSKY adopted the formula $C_{10}H_{20}O$ as representing the composition of rhodinol and, consequently, regarded it as

different from the alcohol of palmarosa oil, HESSE held that rhodinol, although having a composition represented by $C_{10}H_{18}O$, was a mixture of two isomeric compounds, one of which, obtained from the geranium oil of Reunion, he named reuniol.

ERDMANN and HUTH have since then studied the products from all the different sources, and obtained evidence of the chemical identity of the alcohol obtained from all of them. They therefore suggest, in the *Journal für praktische Chemie*, the retention of the name rhodinol for scientific purposes, although for trade purposes the terms "rhodinol" or "geraniol" may be useful, as indicating the different sources of commercial varieties of this alcohol and the very sensible differences in the odour of the alcohol, according as it may be obtained from rose oil, geranium oil, palmarosa, or citronella. Chemically it is not possible to ascertain what is the cause of the honey-like odour of rose oil, the sweet smell of the rhodinol from *Pelargonium odoratissimum*, or the faint smell of that from palmarosa or citronella, though these materials bear the same relation to each other as the alcohol from wine, corn, potatoes, or beetroot.

TURKISH AND PERSIAN OPIUMS.

THE consular report for the district of Salonica, dated January 7 last, embodies somewhat belated information regarding the opium trade of Macedonia. This trade is described as being of growing importance, the cultivation of the poppy having largely increased in Macedonia, and it is anticipated that as the Salonica and Constantinople varieties of opium are most in demand in foreign countries, the annual harvest will before long rival that of Asia Minor. The poppy crop of 1893 was very small, and a comparatively small amount of seed was exported (500 tons), but an improvement took place in 1894 (900 tons). In the former year the weight of opium exported from Salonica was 37,500 pounds, the price free on board varying from 10s. 2d. to 10s. 10d. per pound; during 1894 the quantity exported rose to 157,500 pounds, and the price varied from 9s. 6d. to 13s. 7d. per pound. The United States takes the largest proportion of the drug, London coming next, followed at a considerable distance by the markets of Germany and France.

The report for the year 1894-95, on the trade of Ispahan and Yezd, shows that the total output of opium in the Ispahan district reached about 390,000 lbs, the quantity exported from Ispahan—1600 boxes—being valued at about £125,000. European exports of the drug were absolutely *nil*, the price being too high, ranging at the time of writing the report, from 7s to 11s. per pound. China probably takes the bulk of the product. European merchants are also hampered by having to pay 5 per cent. *ad valorem* duty on their cases, whereas the natives pay but a nominal duty. From Yezd, 530 tin-lined cases of opium in cake form, valued at £31,800, were exported to China. Each case weighs about 130 pounds. The crop has been a failure for some years past, but since Yezd opium has a special reputation in Persia, large quantities are imported in the raw state from Ispahan and other places, then exported after preparation as Yezd opium. The stick opium, which is very carefully prepared in Yezd, is mainly preferred in Persia, and brings a higher price than the ordinary variety in cakes. Tested on the spot, the highest yield of morphine from Persian opium, according to this report, is 12 per cent.

ANNOTATIONS.

"THE DISCOVERY OF OXYGEN."—The reprints of the articles dealing with the life and work of Scheele, Priestley, Cavendish, and Lavoisier—with special reference to their connection with the discovery of oxygen—are now ready, and readers can obtain copies from the *Pharmaceutical Journal* Office, 5, Serle Street, W.C. The book contains sixty octavo pages, and is illustrated with portraits of the famous chemists whose labours are delineated, together with sketches of the apparatus they employed. Copies are supplied at one shilling each, post free.

BACTERIA IN AGRICULTURE.—The Berlin correspondent of the *Daily Telegraph* reports that at the last meeting of the German Agricultural Society, Dr. Thiel, of the Prussian Ministry of Agriculture, stated that experiments which have been carried on for a long time past by Herren Hall, Riegel, Notbe, and others, with a view to ascertaining how the bacteria of the soil may be rendered useful, have been crowned with success, so far as the bacteria necessary for the assimilation of nitrogen and the successful cultivation of leguminous plants dependent upon it are concerned. Herr Notbe has succeeded in cultivating these bacteria on a large scale, and he is convinced that the sowing of these bacteria will make soils which need them more productive in a cheaper and more convenient way than the method of inoculating suitable earth invented some years ago.

THE PROPRIETARY ARTICLES TRADE ASSOCIATION.—A meeting of retail chemists in Bristol and its neighbourhood was held at the University College, Bristol, on Wednesday last, under the auspices of the Bristol Pharmaceutical Association, to consider what action should be taken by it in regard to the Proprietary Articles Trade Association, and was attended by some members of the Council of the latter Association.

UNIVERSITY COLLEGE, LIVERPOOL.—Extensive alterations and additions are at present being carried out in connection with the chemical, medical, physiological, and pathological departments of University College, Liverpool, the total cost to be incurred being estimated at about £30,000. As to the chemical department, there is now in course of construction, at a cost of some £7000, a handsome building adjoining those erected in the year 1885-6 in Brownlow Street. This wing, which will do much to supply the extra accommodation required by the students of chemistry, is the gift of Messrs. William Gossage and Son, and is being erected in memory of the founder of that firm, Mr. William Gossage. It has been decided that an additional metallurgical furnace room shall be provided in the new Gossage Laboratory, and a still more important want supplied by the new building is the enlargement of the professors' laboratory, which is entirely devoted to original research. In the present small room assistants are engaged in research work—one endeavouring to solve an exceedingly difficult problem in theoretical chemistry, aided by a grant from the Royal Society, whilst the others are producing new substances or solving problems, many of which will be of practical importance.

ANTI-CUTTING DISCUSSION AT PLYMOUTH.—On Wednesday, March 4, a meeting of chemists and druggists will be held at Plymouth to hear an address by Mr. Glyn-Jones on recent proposals for dealing with the "cutting" evil. The meeting will be held at 3 p.m., and several large manufacturers have notified their intention of being present.

THE ANNUAL DINNER.—A meeting will be held at 17, Bloomsbury Square, W.C., on Wednesday, March 11, at 11.30 a.m. precisely, for the purpose of making preliminary arrangements for the annual dinner of the Members of the Pharmaceutical Society and their friends. The President of the Society, Mr. Michael Carteighe, will take the chair, and gentlemen interested in the annual gathering are invited to attend.

THE EARLY SPRING.—A correspondent mentions as evidence of an advanced season that he saw, a day or two ago, in a garden in Edinburgh, *Anemone pulsatilla* with the buds quite through the ground and well advanced. At this stage, he says, birds are very fond of the buds, and frequently tear the plants to pieces unless they are protected by a net. Who can explain this?

THE PRODUCTION OF ALUMINIUM.—The Hall process for producing aluminium—as described by Mr. Alfred E. Hunt before the Institution of Civil Engineers—involves the direct electrolysis of alumina, dissolved in a molten bath of the mixed fluorides of aluminium, calcium, and sodium. One cubic foot of the solvent serves for an hourly production of one pound of aluminium, and as the fluorides remain unchanged, the operation is continuous. The carbon anodes are consumed at nearly the same rate as the metal is produced.

PHOTO-MICROGRAPHY.—The articles published in the *Journal* under the heading of "Photography for Chemists," have been greatly appreciated, and in the present number the series is continued. A practical, illustrated article on "Photo-Micrography" is in course of preparation, and will appear shortly. This, it is hoped, will prove of considerable value to pharmacists who desire to have permanent records of interesting objects, in which the personal equation of the observer will be eliminated.

SCHOOL OF PHARMACY STUDENTS' DINNER.—The annual dinner of the Pharmaceutical Football and Cricket Club will take place at the Holborn Restaurant on Wednesday, March 18, at 7 o'clock, when Professor Attfield, F.R.S., President of the Club, will once more occupy the chair that he has for so many years dignified. It is hoped that all past and present students of the School of Pharmacy who can conveniently attend will be present on this occasion. Tickets (5s. each) may be obtained from either of the following members of the Dinner Committee:—Messrs. Senter, Stamp, or Tickle, 17, Bloomsbury Square, W.C.

THE SYNTHESIS OF FOODS.—In the *Asclepiad*, Sir B. W. Richardson suggests that if foods could be theoretically constructed that would perform every necessary purpose for the body of man in every season, and under all varieties of rest and work, the art of feeding could be transformed into one that would develop an ideal system and a more perfect race. To flesh feeders, meals prepared in chemical laboratories would be more than equal in matter of quantity, equal in quality and taste, and could be prepared with infinitely greater economy than now exists. Vegetables, fruits, and herbs would form the basis of the new system, and the artificially-prepared foods would not fluctuate in supply under adverse seasons and blights. They would also be free from the risk of disease incident to the diseases of animals, and would be altogether assimilable by the body, leaving no constituents to be excreted, thus conserving the strength and activity of the body.

PROCEEDINGS OF SOCIETIES.

Chemical Society.—An ordinary meeting of the Society was held on February 20, Mr. A. G. Vernon-Harcourt, President, in the chair. It was a ballot night, but in spite of the inclemency of the weather, there was a strong muster of fellows. The greater part of the evening was taken up with the consideration of subjects relating but remotely to pharmacy. The first on the list was read by Professor Armstrong, F.R.S., on "The Origin of Colour; the yellow, 2: 3—hydroxynaphthoic Acid." This is a continuation of a series of papers by the Professor on the subject of the origin of colour. The hydroxynaphthoic acid has peculiar properties, and is strongly coloured—deep yellow, and its salts are also yellow. The ethereal salts likewise are peculiar and dissolve in alkalies with the production of yellow derivatives. Professor Armstrong commented on the structure of naphthalene and of benzene, and dealt with the relationship of formula and colour. In the course of his remarks he said that aniline and bromine always yield tribromaniline. It is exceedingly difficult to stop the reaction and to obtain the monobromide. Dimethylaniline, however, readily yields the monobromide.

Dr. Kipping said that Professor Armstrong's attribution of the origin of colour to a quinonoid structure was quite inadmissible, and he especially objected to NO_2 being considered as quinonoid. Iodoform, he said, was coloured, but chloroform with a similar molecule was colourless.

Dr. Perkin was asked to speak, but would not commit himself as he was at present writing a paper on the subject.

Professor Armstrong replying to Dr. Kipping maintained that iodoform was an absolutely quinonoid form. Chloroform was not sufficiently refractive to become coloured.

The next paper was by the same author on "The relation of Pinene to Citrene." From what Professor Armstrong said, it would appear that these two bodies are not very closely related. Pinene is distinctly divalent, and citrene trivalent, and they belong to very different groups. Pinene should be capable of definite combination. It may be a trimethylene derivative. The formula of pinene cannot be made to harmonise with any arguments.

A paper on "The Formation of Naphthaline and Isoquinoline Derivatives from Dehydracetic Acid," by Dr. Collie, and Mr. W. Wilsmore followed. The authors had already studied this question and the present paper further treated of the condensation products of diacetylacetone. They had succeeded in obtaining yellow derivatives closely allied to naphthaline compounds. They described chiefly the production of yellow crystalline compounds by combination of diacetylacetone with barium. Mr. Wilsmore, who read the paper, stated that one of the bodies they had obtained was submitted to Dr. Schäfer, of University College, for physiological examination, as it had given distinct evidence of having alkaloidal properties. Only one experiment so far had been performed, and that was a subcutaneous injection on a frog which died.

By the time this paper had been read the interest of the audience seemed to be flagging. But the next paper by Professor Dunstan and Mr. F. H. Carr revived matters considerably. This was "On a Difficulty Encountered in the Determination of Nitrogen by the Absolute Method." The substance in question, said Professor Dunstan, was aconitine whose formula is $\text{C}_{23}\text{H}_{45}\text{NO}_{12}$, and this equals 2.1 per cent. of nitrogen. On burning aconitine with copper and the oxide the percentage obtained was nearly twice the theoretical yield, and there seemed something curious in these results. Using the base they obtained nearly 4.4 per cent. Professor Dunstan gave the figures obtained by several other methods. By the Dumas method—4.4 to 5.1 per cent. The vacuum method yielded 3.79 per cent., and the soda-lime method 2.4 to 2.6 per cent. Other alkaloids, strychnine, for instance, were all right in giving up their nitrogen, but aconitine seemed to behave in an altogether anomalous way. Methane was found to be the body accompanying the nitrogen, and great difficulty was experienced in oxidising the Marsh gas.

Dr. Perkin asked if the authors had tried lead chromate, and Dr. Bernard Dyer inquired if Kjeldahl's method had been tried, to both of which questions Professor Dunstan replied in the affirmative.

This concluded the business for the evening, and the following papers remained unread:—"Mixed Diazoamides Containing an Orthonitro Group," by Professor Meldola and Mr. F. W. Streatfield; "Allyl-p-Dinitrodiazo-Amidobenzene: A Study of the Relations Between Melting Point and Constitution," by Professor Meldola and Mr. F. W. Streatfield.

Linnean Society of London.—At the meeting held on February 6, Mr. C. B. Clarke, F.R.S., President, in the chair, the Rev. E. Woodruffe-Peacock and Mr. William Cole were admitted, and Messrs. J. Backhouse, Gilbert Christy, and Ivor Richards were elected Fellows of the Society.

Sir W. H. Flower, K.C.B., F.R.S., presented to the Society, on behalf of the subscribers, a portrait of Mr. William Carruthers, F.R.S., Ex-President of the Linnean Society, painted by Mr. J. Hay. On the motion of Mr. J. G. Baker, F.R.S., it was resolved *nem. con.* that the portrait be accepted, and that a cordial vote of thanks to the donors be recorded.

Professor C. Stewart, F.L.S., exhibited a series of dissections of skulls, illustrating the development of air cavities. The skull of a herring, carefully dissected, to show the relations of the ampullæ of the pneumatocyst to the cranial bones; of a crocodile, to show those of the extra tympanic cavity and siphonium; of a rook, to show the limitations and relationships of the vesicular and other strata of the cranial roof; and of a chinchilla and a *phascolarctus*, to illustrate the variations and development of the "bullæ" and of its associated structures, were the chief objects shown. Professor Stewart expressed himself favourable to the belief that the parts mentioned in the herring are functional for acoustic purposes. In this he was supported by Professor Howes, who referred in detail to the arrangements occurring in *Hyodon* and *Mormyrus* as substantiating this conclusion.

On behalf of Mr. B. G. Cormack, Dr. D. H. Scott, F.L.S., gave the substance of a paper on polystelic roots of certain palms. He remarked that with scarcely any exception roots show one normal vascular bundle or stele. The author, utilising material from Ceylon, found that in *Areca catechu*, Linn., *Cocos nucifera*, Linn., and a species of *Verschaffeltia*, the young roots agree with this condition, but on examining older and thicker portions of the same roots, he found many steles present. After discussing the origin of this, the author considered the change to be primary, not secondary, and suggested that these roots might serve as props to the stem. The paper was criticised by Mr. George Murray and Prof. Trail, Dr. Scott replying to objections.

Mr. R. Morton Middleton, F.L.S., read a paper on a remarkable use for ants in Asia Minor, communicated by Mr. Miltiades Issigonis of Smyrna. It was stated that the Greek barber-surgeons of the Levant employed a large species of ant for the purpose of holding together the edges of an incised wound. The ant held with a forceps opens its mandibles wide, and being then permitted, seizes the edges of the cut which are held together for the purpose; as soon as a firm grip is obtained the head is severed from the body. Mr. Issigonis had seen natives with wounds in course of healing with the assistance of seven or eight ants' heads. The ant referred to was a large-headed species of *Camponotus*, not unlike one found in India.

Mr. Middleton recalled the fact that a similar observation concerning a species of ant in Brazil had been recorded many years ago by M. Mocquerys of Rouen (*Ann. Soc. Entom. France*, 2 sér., ii., lxvii.), as quoted by Sir John Lubbock in his work on ants, bees, and wasps; but the observation had not been confirmed either by Bates or Wallace during their travels in South America.

Dr. John Lowe, commented upon the irritation generally caused by the bite of an ant, and remarked that in this operation apparently no attention was paid to the usual antiseptic precautions which are regarded as indispensable in modern surgery.

Sir William Flower considered the observation of interest from an ethnological point of view, as showing the independent existence of the same custom in countries so far apart as Brazil and Asia Minor.

Royal Institution.—Dr. E. Frankland's lecture on the "Past, Present, and Future Water Supply of London" attracted a very representative audience on the 21st inst. At the outset reference was made to the fact that the Royal Institution had always been prominently connected with official work on the subject, through the person of some of the professors of chemistry for the time being, and it was therefore not unfitting that for the third time he should tell his hearers something of the present position of affairs. Before going further it was interesting to note that in 1829 there was absolutely no system of filtration applied to the water supplies of the metropolis, and although some twenty years after three of the companies voluntarily adopted some system for the purpose, it was not until 1856 that it became compulsory. This satisfactory state of things was doubtless greatly due to Dr. Snow, who had seven years before declared that cholera epidemics in this country were

undoubtedly directly traceable to impure water, and although his statements were received with incredulity at first, their truth was proved by the fact that no case of Asiatic cholera has been traced to this source since the compulsory adoption of filtration. After brief allusion to the sources and characteristics of the present water supply, Dr. Frankland passed on to a description of modern methods of water analysis by means of determination of the colonies as enunciated by Koch. The fact that cholera is propagated by bacilli existing in the water, and not by the presence of ordinary organic impurities, led the latter chemist to devote attention to the isolation of microbes and spores in a given volume of water, which gave a method for their determination with quantitative exactness. For this purpose a nutrient material is prepared by dissolving gelatin in beef tea and effecting complete sterilisation of the product by keeping it at a temperature of 99° C. for three days. The sample of water which has been collected by breaking off the end of a vacuum tube at a considerable depth below the surface, is added to the gelatin peptone, and placed in a circular glass dish, which is afterwards kept at a temperature of 20° C. in an incubator for several days. The product is examined microscopically at intervals, quantitative results being obtained by observing the number of colonies present in an area of 1 square centimetre, as it would usually be impossible to count those present in the whole slide. The development is somewhat slow, three days being usually required for perfect growth.

A large number of slides were shown on the screen and illustrated the various stages of development. The lecturer, in drawing attention to the beautiful way in which some of these colonies are built up, amused his audience by remarking that it was possible that some enquiring microbes had become so enamoured with the architecture of London that they had made up their minds to emulate it in the space of forty hours. The efficiency of the system of filtration adopted at the present time by the different water companies was duly acknowledged; indeed, the results in some cases are simply astonishing, a case being cited in which one drop of ordinary river water contained 3000 colonies, this number after ordinary sand filtration being reduced to 50, 30, 20, 10, and in some cases to zero. The water from the Kent Company's new well at Deptford seems to lead the van, no colonies whatever being perceptible after one week's incubation, but river water is not far behind, and it is but seldom that the standard fixed by Frankland and Koch—which allows the presence of fifty microbes in a cubic centimetre—is infringed, nor is it often approached within 50 per cent. Some interesting results were shown of analyses which had been carried out to ascertain the truth of the statements advanced by some observers that sunlight is of great importance in its destructive action upon bacterial growths. These show that a beneficial action results only when the exposure to sunlight has taken place at not more than six inches below the surface of the water, as at a greater depth the number of colonies gradually increases.

Turning to the question of the future of the metropolitan water supply, Dr. Frankland said that it was absurd to entertain any fear as to the necessity of recourse being made to the watersheds of Cumberland, Westmoreland, Wales, the Severn or the Wye, as had been proposed at various times, as the evidence given before the Royal Commission showed there was no necessity, and it is satisfactory that no river water in Great Britain affords such a good supply as the Thames. It would be necessary, however, to have additional reservoirs constructed, and to improve the present system of filtration by using a finer sand for the purpose. Slides were shown which demonstrated that storage decreases the bacterial growths enormously, a sample which contained 11,560 when first drawn containing only 1360 after an interval of thirteen days. In conclusion, it was remarked that the London water supply would not be surpassed by any in the world for fifty years at least. Dr. Frankland expressed his indebtedness to Mr. Burgess for executing the diagrams, etc., which illustrated the lecture.

Chemists' Assistants' Association.—Owing to Mr. Manger being unable to read his promised paper on "Filtration" on the 20th inst., a musical and social evening was held instead, and in spite of the short notice given, proved a great success. This was due to the energy displayed by the President (Mr. E. W. Hill) and Secretary (Mr. R. Glode Guyer), who put themselves to considerable pains to ensure a good attendance and enjoyable programme. Amongst those who contributed to the evening's entertainment were Messrs. Bellamy, Burgess (violin), Barrett, Dawson, Latreille, Morley, Pasco, Taylor, Robins, Roberts, and Walton,

whilst Mr. Ellis gave satisfaction as accompanist. During the evening Professor J. Reynolds Green, F.R.S., Sc.D., Messrs. Peter Squire and P. MacEwan were duly elected patrons of the Association.

Midland Chemists' Assistants' Association.—At a meeting held on Wednesday, February 19, at Exchange Rooms, Birmingham, Mr. T. Clarke (President) in the chair, the following paper was read—

"COAL—IN RELATION TO PHARMACY."—PART II.

BY H. JESSOP.

In opening the subject he remarked that most of the members present were aware that this paper was the sequel to one read by him on January 15, yet for the benefit of those who were not present on that occasion, and in order to make the paper quite intelligible, he proposed to recapitulate very briefly the more important points of his first paper, which were in connection with the manufacture of coal gas. The gas manufacturer found that the coals that suited him best were those belonging to the bituminous class; this class comprising caking-coal and the different varieties of cannel. The reason these coals were chosen was that other things being equal, they contain a comparatively small percentage of oxygen in proportion to hydrogen. The gas maker well knows that for every 16 parts of oxygen present, 2 parts of hydrogen combine to form 18 parts of water, so that it is only that hydrogen which is over and above that required by the oxygen which is available for the production of hydrocarbons. The most suitable coal having been chosen it is introduced into the retorts and subjected to a red heat for six hours, during which time distillation goes on. The charge is now drawn and the residue is coke, a comparatively pure form of carbon. It is found that an average coal will yield for every 100 lbs. distilled, about $22\frac{1}{2}$ lbs. of gas, $8\frac{1}{2}$ lbs. of tar, $9\frac{1}{2}$ lbs. of ammonia water, and $59\frac{3}{4}$ lbs. of coke.

Among the gaseous constituents are:—Water vapour (formed by combination of the H and O of coal), marsh gas, olefiant gas, small quantities of acetylene, benzene and other hydrocarbons, ammonia (formed by combination of N and H of coal), cyanogen, sulphuretted hydrogen, sulphur dioxide, carbon bisulphide, carbon dioxide, carbon monoxide, and free hydrogen. Apart from coal gas itself almost the only gaseous constituent related to pharmacy is ammonia.

Ammonia is removed from other gaseous products by a system of washing with water. By this means the ammonia is obtained as ammonium hydrate (NH_4HO) together with a somewhat considerable quantity of sulphide and carbonate formed by the combination of a portion of the ammonia with H_2S and CO_2 . The ammoniacal liquor is then sold to be converted into sulphate or nitrate of ammonia, both of which are useful as artificial manures, or it may be converted into carbonate, resublimed, and thus find its way into our shops.

Passing on to the consideration of crude coal tar, it was shown that, during the destructive distillation of coal, the lower the temperature at which distillation was effected the larger the yield of liquid and solid hydrocarbons, but the lower the yield of gas, which, however, was of a better quality. Thus tars vary a great deal according to the coal used, the temperature of distillation, the manner of working, etc. An average coal tar contains the following constituents:—Gasses of marsh gas (CH_4) and olefiant gas (C_2H_2) families dissolved in the liquid tar. Benzene and its isomerides (C_6H_6) and higher hydrocarbons, of which styrolene (C_8H_8) is an example. Naphthalene (C_{10}H_8), anthracene ($\text{C}_{14}\text{H}_{10}$), and other bodies of that class.

Wood spirit (CH_3HO) and acetic acid ($\text{C}_6\text{H}_5\text{HO}$) occur, but neither of them in workable quantities. Then there are carbolic acid ($\text{C}_6\text{H}_5\text{HO}$), cresylic alcohol ($\text{C}_7\text{H}_7\text{HO}$), nitrogenous bodies as ammonia (NH_3), methylamine (NCH_3), pyridine bases, among which are pyridine ($\text{C}_5\text{H}_5\text{N}$), picoline ($\text{C}_6\text{H}_7\text{N}$), lutidine, and numerous others. Also, the leukoline bases, of which leukoline itself ($\text{C}_9\text{H}_7\text{N}$) is a type, and lastly the non-volatile residue which we call pitch. Many of the above substances do not actually occur as such, but are formed during the subsequent processes to which the tar is subjected. Of all these substances the lecturer said he would refer only to those which are interesting to pharmacists.

The tar, as it comes from the gas works, always has more or less water in suspension, to free it from which it is pumped into large iron tanks, allowed to stand for some time, when the water rises to the top and is pumped off. This liquid often contains a

fair percentage of ammonia compounds. The tar is then run off into enormous stills, and subjected to a steam heat; by this means any water vapour, ammonia, permanent gases, and the more volatile constituents of the tar pass over and are collected separately. This fraction is known as "first light oils," and in a 1200 gallon charge would amount to about 70 gallons, of which under one-half would be naphtha and the rest water containing various substances in solution.

The temperature is now raised when the break occurs (at this point the still almost ceases working, little else but water vapour passing over for about an hour). As the temperature rises the still comes off the rattle—a term used by the workmen probably on account of the peculiar noise made by the water vapour issuing—and about 20 gallons of an oil lighter than water are collected. The temperature is now continually being raised.

After a short time an oil which is heavier than water is being collected; when this occurs the shoot (or receiver) is changed and the first heavy oil is collected separately. This oil distils for about three hours and about 300 gallons distilled off. The first portion consists chiefly of naphthalene, so that considerable care must be exercised in order to prevent the worm of the still becoming blocked. The second portion of the distillate is called "sharp, soft oil," the naphthalene which distils over now is wholly soluble in the oil running. When the oils begin to thicken the shoot is again changed, and the still is said to be on the anthracene oil, of which about 50 gallons are collected. The fire is now drawn and the still cooled; the residue is pitch. Now returning to the first fractions obtained, the "first light oils" are allowed to stand and the oils drawn off from the water and run into another still and fractionated. The portion passing over below 80° C. is often sold as naphtha for dissolving rubber, etc.

The next fraction (taken between 80° and 115° C.) is commercial benzene. The portion remaining in the still is added to the second light oils. The second light oils (as are the other oils) are now subjected to a wet process, *i.e.*, they are washed with hydrochloric acid, then with water, next with a solution of caustic soda, and again with water. These washings are put aside and used for the manufacture of carbolic acid, as will be shown later. The second light oil is now fractionated, that passing below 140° C. is added to another batch of first light oils, that passing between 140° and 190° C. being collected. The first portion of the heavy oil is used to prepare naphthalene, and the second portion (together with any other oils which are unworkable) are sold to railway companies for creosoting timber sleepers, telegraph poles, etc., to prevent decay and the attacks of insects.

The anthracene oil has of late years become very valuable on account of the artificial production of alizarin from anthracene. The anthracene is extracted by a system of cold and hot pressing, subliming, and condensing. In this condition (yellow flakes) it is sold to the colour maker, who converts it into alizarin. Returning now to benzene, which we had obtained in a crude state—this hydrocarbon was first discovered by Faraday in 1825, who termed it bi-carburet of hydrogen, under the supposition that its empirical formula was C_2H_2 . Later, Hofmann discovered its existence in coal tar. Soon after its discovery in coal tar its use for the removal of grease from cotton, wool, oil-cake, seeds of various kinds, clothes, etc., became known. Finally, the discovery of aniline dyes caused a great increase in the trade of this substance.

The crude benzene obtained contains, in addition to benzene, a substance, toluene, of some interest to pharmacists on account of its being also contained in "Dragon's blood" and tolu balsam; and the fact that this substance is the one from which saccharin is prepared. To obtain the benzene in a pure condition it is only necessary to re-distil, collecting that which passes over at about 80° C. (Benzene boiling at that point.) In order to obtain aniline, which is the starting point of the manufacture of an immense number of beautiful dyes, it is necessary to convert the benzene into nitro-benzole or oil of mirbane. This oil of mirbane is an oily liquid having the odour of oil of bitter almonds. It is obtained by allowing a mixture of nitric and sulphuric acids to slowly trickle into a cylinder of benzene, the cylinder being constantly rotated. When the nitration is complete the cylinder is allowed to stand, when the nitro-benzole rises to the top, and is drawn off, washed with water, then with caustic soda solution to neutralise any acid left, and finally re-washed with water. The purified nitro-benzole is now converted into aniline by nascent hydrogen by adding it to hydrochloric acid and iron trimmings. On distillation the aniline passes over and condenses as a colour-

less liquid, which rapidly changes colour and solidifies at a low temperature.

Having now obtained aniline the next step is to convert it into rosaniline, from which the countless number of dyes are made. It is converted by a process of oxidation, to effect which numerous substances have been used, but principally arsenic acid.

The aniline and arsenic acid are heated together, the product dissolved in alcohol, then acetic or hydrochloric acid is added and the alcohol distilled off, leaving rosaniline (or fuchsine) behind. By heating rosaniline with iodide of methyl or ethyl several shades of blue can be formed; these are known as Hofmann's blues, and so on by various means almost all the colours can be formed from rosaniline.

Aniline was first discovered by distilling indigo. Several of the recent remedies are obtained from aniline, antifebrin for example, which is obtained by the action of glacial acetic acid upon it, and subsequent purification. For the preparation of carbolic acid from the washings (as previously spoken about) the caustic soda used converts the carbolic acid into sodium carbolate and is run off. This solution is treated with HCl, the carbolic acid (which rises to the surface) is treated with chloride of calcium to deprive it of water, distilled and re-distilled, when a crystalline mass of pure carbolic acid is collected, melting at about 33°, and boiling at 183° C.

From carbolic acid several substances are obtained of interest to pharmacists, notably salicylic acid, phenacetine, and picric acid.

Salicylic acid is formed by the combination of the elements of carbolic and carbonic acids.

Picric acid is obtained by the continued action of nitric acid on phenol.

Saccharin or gluside was first discovered by Fallberg in 1879, and if prepared from toluene by heating with strong sulphuric acid at a temperature below 100° C. This product is subjected to oxidation, equal parts of para and ortho sulpho benzoic acids being formed. These are converted into potassium salts and then converted into di-chlorides by the action of chlorine in the presence of phosphorous tri-chloride. After the phosphorous oxychloride has been distilled off, the di-chlorides are treated with ammonia in an atmosphere of CO_2 . The para salt is insoluble and is filtered off, whilst the filtrate which contains the ortho salt is treated with acid, when saccharin is formed.

Saccharin is only sparingly soluble in water, so that for use it is usually converted into the sodium salt either by the action of sodium hydrate or, as is more usually by mixing with an equal quantity of bicarbonate of soda.

Liverpool Pharmaceutical Students' Society.—This Society held its usual meeting at University College on Thursday, the 20th inst.

A practical demonstration of suppository making by cold compression was given by the President, Mr. T. S. Wokes, who used a small "Perfection" machine for the purpose capable of making three suppositories at a time. The mixed cocoa butter and drug were passed through the machine once or twice until homogeneous, after the style of "milling soap," and then were pressed into the moulds. Upon removal of the cover at the base of these moulds, and the application of further pressure, the suppositories were ejected at the extremity of a thin rod of the mass, from which they were detached by means of a knife. Pessaries of about 2 drachm size, suppositories of 15, 30, and 60 grains, and bougies were rapidly made, all being irreproachable both in shape and consistence.

A couple of prescriptions worthy of comment were brought under the notice of the meeting by Mr. R. H. Mitchell.

The first contained the following ingredients:—

R̄ Ferri et Quin. Cit.	80 gra.
Croton Chloral Hyd.	ʒiiss.
Tinct. Gelsem.	ʒii.
Aquæ ad.	ʒviii.

On mixing they separated, the croton, chloral, and citrate of iron and quinine forming a solid mass, leaving the liquid nearly colourless. Mucilage had to be used to get a presentable mixture.

The second was for pills—

Ext. Hyoscyami,	
Zinci Valerianatis	aa gr. iiss.

The mass was deliquescent, and took a large quantity of *P. glycyrrhizæ* to make it cut nicely.

It was advised by the members that Mr. Mitchell should try a dry extract similar to the U.S.P. abstractum instead of the usual B.P. ext. hyoscyami.

A string of "issue peas" made from minute unripe orange fruit was passed round for inspection by Mr. Pickering, who stated that they were still used in Cornwall.

Then followed an address of a very interesting character, by F. C. Larkin, Esq., F.R.C.S., upon "Facts," in the course of which various phenomena or facts were reviewed, and the mental and other processes by which we became aware of them were thoroughly gone into and explained. Dr. Larkin has always been ready to assist the Students' Society, and each session since its formation has contributed a lecture to its syllabus, invariably of a novel and valuable scientific nature, so that the vote of thanks accorded him at the close was well deserved by him, and was given by the students with flattering vigour.

Cambridge Pharmaceutical Association.—A meeting of the above was held on Friday, February 21, Mr. Alderman Deck, F.C.S., in the chair, and Mr. Arthur S. Shrubbs, of the University Herbarium read two papers:—(a) "Ancient and Mediæval Materia Medica." Sundry quaint old recipes for various diseases, and accounts of the extraordinary errors which crept into the writings of the early herbalist were given, being illustrated (by means of lantern slides) by the sheep tree or Tartarian lamb and the Barnacle or Goose Tree. This was supposed by the people of the north in the 16th century to have brought forth little living creatures which, dropping into the water, gave rise to feathered fowls, and these they considered accounted for the large number of geese in the rivers at certain seasons. (b) "The Medicinal Plants of Cambridge-shire," was illustrated by plants collected by Mr. Shrubbs, and preserved as herbarium specimens. He mentioned their various medicinal properties, and some of the diseases for which they were used. The Chairman proposed a hearty vote of thanks to the lecturer for thus affording such an instructive and interesting evening. This was seconded by Mr. A. S. Campkin, J.P., and endorsed by Messrs. C. S. Addison, and E. Saville Peck.

PROCEEDINGS UNDER THE PHARMACY ACT.

THE UNLAWFUL SALE OF POISON.

At the Liverpool County Court on Tuesday, before His Honour Judge Shand, an action was heard in which the Pharmaceutical Society of Great Britain sought to recover a penalty of £5 from J. Bainbridge, an assistant employed at the Park Lane Pharmacy, Liverpool, for having sold poison contrary to Section 15 of the Pharmacy Act, 1868, he not being registered as a chemist under the Act. Mr. T. R. Grey, barrister (instructed by Messrs. Flux, Thomson, and Flux), appeared for the Pharmaceutical Society, and the defendant appeared in person.

Mr. Grey said the action was one to recover a penalty for the sale of poison under the Pharmacy Act of 1868. The poison sold on this occasion was a preparation containing opium, and it was sold at 158, Park Lane by the defendant on November 25 last. As his Honour knew, a preparation of opium was a poison within the schedule of the Pharmacy Act. That Act was passed for the safety of the public and to absolutely exclude all persons from selling poisons unless they had passed an examination under the Pharmacy Act. The Act made it unlawful for any person to sell or keep open shop for the sale, dispensing, or compounding of poisons, and it declared that the several articles entered in the schedule were to be deemed poisonous. Section 13 of the Act made the register which he now put in proper evidence—that was to say if the defendant's name did not appear in that register, it was evidence against him that he was not qualified unless he could prove to the contrary. The penalty provided for by the Act in the case of an unqualified person selling poison was £5. Counsel then cited a case decided in the Queen's Bench Division, where it was held that if an unqualified chemist's assistant sold poison he was liable to the penalty, notwithstanding that he effected the sale on behalf of his master, and that his master was duly registered.

The Registrar (to defendant): You admit your liability, do you?—Yes, sir. I admit selling the poison.

The Registrar: And you admit that you were not qualified?—Yes, sir.

The Judge: That is sufficient. The penalty is £5.

NEW REMEDIES.

[The notes given under this heading embody recent suggestions in therapeutics. They cover both new drugs and preparations, and old ones under new aspects. The word "parts" is used to represent parts by weight, both for solids and liquids.]

VIBURNUM PRUNIFOLIUM IN DYSMENORRHOEA.—In a paper read before the Edinburgh Obstetrical Society, Dr. Spennan reported on an investigation of *Viburnum prunifolium*. He concludes that it acts as a sedative in neurotic and hysterical conditions, this action being partly due to the valerianic acid present and partly to an alkaloidal substance. The preparations most convenient for use are the fluid extract, and an inspissated extract obtained by evaporating the former to one-sixth its volume, *in vacuo*, or at a low temperature. This thickened extract may be conveniently enclosed in capsules. In nervous cases he finds that it is at least as efficacious as opium; it does not produce constipation, and is practically non-toxic. In the discussion which followed, Dr. Craig stated that he knew no drug so efficacious as *Viburnum* for threatened abortions. Other authorities confirmed this view (*Lancet*, II., 95, 1626).

PHENOCOLL HYDROCHLORIDE IN MALARIA.—Dr. Ludewig has found phenocoll hydrochloride of marked service in the treatment of malaria, known locally in tropical Mexico as "calentura." In nine adult cases the treatment which proved successful consisted in the administration of 15 grains of the hydrochloride three times a day; in three infantile cases, 15 grains dissolved in a quart of water was given in three portions during the day. As a prophylactic, one dose daily of 15 grains is sufficient, even in subjects who are refractory to quinine. The author considers phenocoll hydrochloride to be a quick and reliable remedy, and a certain preventive in cases of tropical malaria (*Therapist*, v., 96).

ANTIPYRINE IN INFANTILE DIARRHOEA.—In the diarrhoea of children, not due to toxic causes, the following has been suggested:—Antipyrine, 7 grains; syrup, 1½ ounce; water, 1½ ounce. One teaspoonful every two hours.

SALOPHEN IN ACUTE RHEUMATISM AND IN CHOREA.—Huot has confirmed the usefulness of salophen in cases of acute articular rheumatism, in which it is preferable to salicylate of sodium, since it exercises no irritant action on the stomach or the kidneys; it seems to act on the bowels as a gentle laxative. Marie has obtained a complete cure in a case of Sydenham's chorea in eight days with the use of salophen. From its freedom from taste it is readily taken either suspended in fluid or in cachets. The usual daily dose is from 3 to 4 grammes, advantageous taken in five or six separate portions at intervals (*Rev. de Thérap. Méd. Chirurg.*, lxii., 763).

VALERIANIC ETHER IN PERSISTENT HICCOUGH.—Valerianic ether is claimed to be a specific in persistent hiccough and other spasmodic disorders. It should be given in capsules in doses of 2 minims (*Med. Times*).

PELLETIERINE FOR TAPEWORM.—Prospero speaks strongly of the value of this alkaloid in the treatment of the two larger varieties of *tenia*. He administers it in doses of 20 centigrammes of the sulphate with 25 centigrammes of tannin in syrup, to be followed by an aperient next morning. Extract of male-fern is unreliable in its effects, and may be poisonous. For the *ankylostoma*, thymol is the best vermifuge. In one case proglottides of the *tenia mediocanellata* were voided through the mouth, and that without any severe vomiting (*Brit. Med. Jour. Epit.*, February, 1895, 88).

CHLORAL IN ACUTE CORYZA.—The following pigment, applied to the mucous membrane after cleansing the surface is said to arrest the secretion and calm the irritated surface, as well as the accompanying headache:—Chloral, 10 grains; castor oil, 4 drachms. Ft. pigmentum (*Practitioner*, lv., 517).

MENTHOLATED CHLOROFORM IN CORYZA.—The inhalation of a 5 or 10 per cent. solution of menthol in chloroform will, according to Wünsche, cut short an acute attack of coryza. A few drops of the solution are sprinkled on the hands, which are held before the mouth and nose and five or six deep inspirations are made (*Rev. Medico. Pharm.*, ii., 296).

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulæ for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

DISPENSING LANOLINE.

A. P. S. has made several unsuccessful attempts to incorporate the ingredients in the following prescription, and only succeeded in turning out a presentable ointment at last by adding two grains of tragacanth :—

R Lanolini	3ij.
Aq. Rosæ.....	3ij.
Zinci Oleat.....	3ij.
Glyc. Amyli	3ij.

Misce bene. Sign. "The Cream."

The addition of tragacanth was quite unnecessary. Warm the mortar, avoiding too much heat. Mix together the solid ingredients, and very gently stir in the rose water by circular manipulation. This is best effected by means of a spatula, and not with the pestle, as the latter exerts too much pressure.

COVERING THE ODOUR OF IODOFORM.

It is probably not possible to mask the odour of iodoform entirely, for it is so persistent that it reveals itself after the odour of any added substance has been dissipated. Amongst the additions recommended at different times for temporary or partial deodorisation are the following :—(1) Squire, in the 'Companion,' says geranium oil, 5 minims to 2 drachms, is most effective; (2) carbolic acid, $\frac{1}{2}$ per cent., and peppermint oil, 1 per cent.; (3) coriander oil, 8 drops to 1 drachm of iodoform; (4) menthol is said to produce the desired effect if enclosed in a bottle with the iodoform for an hour or two; (5) coumarin, preferably the synthetic product, answers to some extent; (6) camphor disguises the odour, especially if the iodoform be dissolved in Rubini's solution, or Martindale's camphoid; (7) eucalyptus oil; (8) anise oil; (9) tannic acid; (10) balsam of Peru. [Reply to Iodoform.]

PILL-COATING WITH PARAFFIN.

C. De Houck finds that pills can easily be coated with paraffin by heating them to about 80° C. in a capsule and adding the paraffin in shavings and rotating; 2 or 3 grammes of paraffin are sufficient to coat 1000 pills. The coating in no way interferes with the action of the pills, since they disintegrate easily in the mouth (*Annales de Pharm.*, ii., 66).

INK FOR WRITING ON GLASS.

Dissolve 36 grammes of fluoride of sodium and 7 grammes of sulphate of potassium in 500 grammes of water. Dissolve 14 grammes of chloride of zinc in 500 grammes of water, and add 65 grammes of hydrochloric acid. Mix equal quantities of these solutions, and apply with a pen or brush. In half an hour the surface covered will be etched (*Annales de Pharm.*, ii., 81).

COLOUR OF DARK-ROOM WALLS.

J. E. Appleby asks regarding the treatment of the walls of a dark-room. Provided the light admitted by window or emitted from a lamp is safe, white is by far the best colour, as it reflects all the light, and consequently makes it easy to see and move about.

MICROSCOPIC FIXING SOLUTION.

Zenker recommends the following fixing material for vegetable tissue; it penetrates the tissue readily without producing any shrinking: Distilled water, 100 parts; mercuric chloride, 5 parts; bichromate of potassium, 2.5 parts; sulphate of sodium, 1 part; glacial acetic acid, 5 parts (*Intern. Journ. Micro. Sci.* [3], vi., 91, after *Munich Med. Woch.*).

ERLICH'S TRIPLE STAIN.

Reinbach gives the following formula for the triple stain as improved by Erlich (*Arch. f. Klin. Chirurg.*). Saturated solution of orange G., 120 parts; saturated solution of acid rubin, 80 parts; saturated solution of methyl-green, 100 parts; water, 300 parts; absolute alcohol, 180 parts; glycerin, 50 parts. The aqueous solutions of the dyes must be thoroughly saturated. The mixture is not to be shaken before use.

NOTICES TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

LETTERS.

MEMBERSHIP OF THE SOCIETY.

Sir,—Another year has passed since the report of the Registrar was made in the Journal, showing the numerical strength of the Society, and this strengthens the opinion I expressed in my letter in the Journal the corresponding period of last year. The members of the Society are decreasing at a very fast rate, sixty-two having disappeared out of 2000 since last year; and it must be understood that the governing portion of the Society is drawn only from the members of the Society, which means, in time, that there will be very few members left to form a council. Why cannot a bye-law be made that associates in business after a certain number of years be allowed to be enrolled as members? Surely after a number of years in business they can show sufficient ability to assist in keeping the Society together, besides being an inducement for the whole of the trade to become associates. It is plainly shown that raising the fee for one examination and reducing the fee of the other has not had the desired effect. I think I remember one of the aspirants for Council honours said he would try and do something in the right direction. Hoping to hear the opinions of others on the subject.

Chester, February 19, 1896.

J. H. THOMAS.

UNDUE CUTTING IN THE RETAIL TRADE.

Sir,—I have read the remarks by Mr. E. J. Smith and others on the above subject, but fail to grasp the proposed mode of action. My impression is that anything that may be done for the benefit of the pharmacist must be for the benefit of the public also, otherwise the project will fail. If the pharmacist desires the public to come to him in preference to his opponents, he must make himself useful to the public.

The trouble in prices has been caused entirely by the so-called "patent" medicines, the plan followed being usually as follows:—The cutter prospects for a good business position, secures a suitable shop, puts in stock, issues a price-list, quotes patents at about cost price, and drugs at a very low figure. Result: A big turnover from the first or opening day. As a matter of fact, he secures his connection with his quack medicines, and so runs the shops in his vicinity more or less dry, and ultimately secures a portion of their drug trade and dispensing. I contend that if the same man opened the same shop without patents, and cut drugs only, he would not be able to pay rent and wages out of the profits for some considerable time.

This systematic cutting is a very serious matter to chemists and druggists. It not only reduces a man's income to starvation point, but if he wishes to sell his business, instead of getting a substantial goodwill, he cannot sell even at valuation; and very often the business has to be broken up. If a man reduces prices to absolute cost, such trading must ultimately result in a loss, but a cutter or drug store that is in the ring, and knows the ropes, can reduce patents to the level of the ordinary wholesale price-list and still make a substantial profit, out of which he could live and pay his way without selling a single crude drug, whereas a chemist buying in normal quantities would never see invoice price back if he competed with such a man.

This, I think, proves my point that quack medicines are a dead branch on pharmacy, and if not removed will prove its utter ruin. The Inland Revenue returns, 1894-5, show that medicine stamps were sold amounting to £234,881. These would stamp 37,580,960 *ls.* $1\frac{1}{2}d.$ packages of medicine, which, if sold at the reduced price of $9\frac{1}{2}d.$, would amount to about £1,487,579.

There are about 14,000 registered chemists in Great Britain, and about 2000 in Ireland. Nine or ten thousand of these are in business, and a small percentage of them are making a living from advertised quack medicines of their own manufacture, whilst perhaps fifteen or twenty are making a fortune. Further, about two-thirds in value of the quack medicines are owned by men with no legal connection with pharmacy or the drug trade.

Now with regard to the remedy, I would first ask each chemist and druggist to give the whole of his support to any movement for the general good of pharmacy; in fact, to co-operate on all broad questions that affect the trade generally. Commence by forming a company with a suitable capital, say £5000 to £10,000 in £1 shares, establish a central analytical laboratory, and at once commence to analyse all advertised "patent" medicines at the rate of ten or fifteen per month. Subsequently, where practicable, give a working recipe for each article analysed, and publish each month's work on a suitable sheet or pamphlet, leaving the front page blank for the shareholders to print their own business announcements, previous to circulating to the public in their respective districts. Assuming that there are 5000 chemists unconnected with the "patent" medicine trade, and that each one became a shareholder and purchased only 1000 pamphlets monthly, this would give a circulation of 5,000,000 monthly, or 60,000,000 per annum, of a pamphlet that would be eagerly looked for and widely read by the public. On the quantity required, if the company charged a profit of 25 per cent. on cast, they would still be able to print each chemist's announcements on the front and supply the entire pamphlet for less money than he would have to pay for 1000 counter bills like the front page. The company would have many other sources of profit, but it is not necessary to go into detail at present.

"Patent" medicines are, roughly, of three classes—useful, pernicious, and fraudulent. By this system we could stamp out the pernicious and fraudulent, and so elevate the drug trade, and gain the confidence and respect of the public. In many cases they would ask chemists to compound the recipes that had been pointed out as useful. A further source of profit would arise from the fact that we should thus paralyse the backbone of the cutter's trade, and increase each shareholder's returns by reducing the cutter's.

In conclusion, I strongly advise pharmacists to unite and be solid on this one idea—to clear out so-called "patent" medicines, which serve as the decoy duck of the cutter, and with which he undermines your business. Hitherto the cutter has posed as a public benefactor to the extent of $33\frac{1}{3}$ per cent., or fourpence in the shilling. If you utilise your knowledge you are in a position to go one better, and educate the public to the fact that the ingredients of a successful *ls.* $1\frac{1}{2}d.$ patent medicine often only costs the fraction of one penny, and seldom over twopence; and that you are ready to compound quite a large package of the stuff for *6d.* or *1s.* You would also be able to help the medical man with the host of secret remedies that crowd your cupboards and beset his path; lastly, you would be able to help yourselves.

56, *Cheapside, E.C., February, 1896.*

WILLIAM FERGUSON.

SOLUTION OF MORPHINE HYDROCHLORATE.

MR. G. W. BLYTHE, of Manor Cottage, Doddinghurst, Essex, points out that "a strong solution of morphine hydrochlorate (48 grains in the fluid ounce) can also be made in the same way as that of the acetate referred to last week (p. 160), except that sufficient tartaric acid must be added to keep the morphine salt dissolved after the sol. has cooled."

ANSWERS.

"CARYOPH."—The words you specify could not be registered as they would be regarded as descriptive of the article to which they were applied. With regard to the other point you raise, apply to the Comptroller, Patent Office, 25, Southampton Buildings, Curator Street, Chancery Lane, London, E.C.

J. PENDLEBURY.—Straw hats are renovated by applying a spirit varnish, after thoroughly removing all traces of moisture. The yellow varnish is ordinary French polish, the black is a spirit varnish containing some form of vegetable black in suspension, and a green preparation can be made by dissolving an aniline green in a clear spirit varnish.

"SODA."—The cleanliest and most convenient apparatus a retail chemist and druggist can employ for preparing his own aerated waters is one in which compressed gas is employed for aeration. Such a machine is supplied by the Volcanic Aeration Co., 203, Great College Street, London, N.W., or by Barnett and Foster, 26T, Eagle Wharf Road, London, N. One outfit by the first-named maker has cost only a few shillings for maintenance and repairs during the last five years, though it has been in continual use. It is worked by a man of "less" than ordinary intelligence, and has been proved to work very economically.

J. K. W.—Try Hopkin and Williams, chemical manufacturers, Cross Street, Hatton Garden, London.

QUERY.

REFINING GELATIN.—C.P.R. wishes to know how gelatin is refined. His experience is that when it comes out of the press it is very clondy, and he desires to know the simplest way of getting it as clear as possible.

OBITUARY.

PUMPHREY.—On February 10, J. H. Pumphrey, Pharmaceutical Chemist, Evesham. (Aged 40.) Mr. Pumphrey had been a Member of the Society since 1879, and was a former Student in the Society's School of Pharmacy.

COOPER.—On February 14, George Cooper, Chemist and Druggist, Branscombe. (Aged 84).

HODSON.—On February 15, Edwin Hodson, Chemist and Druggist, Burton-on-Trent. (Aged 53).

BUSH.—On February 18, William Bush, Chemist and Druggist, Walworth. (Aged 74).

OLIVER.—On February 19, John Oliver, Pharmaceutical Chemist, Liverpool. (Aged 78).

COLVIN.—On February 22, J. T. Colvin, Chemist and Druggist, Peckham. (Aged 51).

STEWART.—On February 23, John Stewart, Chemist and Druggist, Birkenhead. (Aged 61).

NOTE ON COMMERCIAL LITMUS.

BY D. RAINY BROWN.

The manufacture of litmus is carried on chiefly in Holland, and is prepared from various species of *Rocella*, *Variolaria*, and *Lecanora*, and also from other lichens, for the most part natives of the Mediterranean and Channel Islands. There is very little published information to be had regarding the preparation of litmus, as the process of manufacture is kept in the hands of the makers, but the process is somewhat as follows:—

The lichens are made into a paste with water, and are allowed to ferment in the presence of ammonia, as in the preparation of archil. When the mixture has acquired a purple tint, stale urine and potassium carbonate are added, and fermentation is then allowed to proceed until the blue colour produced is considered to be of the correct tint. It is stated that the best product is obtained in about forty days. The blue liquor is then mixed with chalk, gypsum, or sand, and, according to some authorities, alum, in order to give it consistency. After moulding into pieces of the desired dimensions it is more or less thoroughly dried.

This addition of chalk, sand, gypsum, and alum to the blue liquor, to give it consistency, is surely a doubtful proceeding, and very likely to be attended with loss of colouring matter from the formation of an insoluble lake. It would be better to send the litmus into the market either in the form of a liquid extract similar to archil, or else to acidify the solution and precipitate the colouring matter with excess of alcohol, and offer the product in the dry state.

Apparently indigo is sometimes added in the process of manufacture to improve the colour of the product. I did not observe any indications of it in the samples which I examined, and, if present, it must have been in very small quantity. This addition of indigo is not to be commended from the analyst's point of view. Indeed, from any point of view it should be objected to as a sophistication, but it is a practice quite on a level with the indefinite crude and unscientific methods which, so far as can be ascertained, characterise the production of the commercial article. Wartha suggests that the presence of indigo might result from the fermentations of the lichens at the expense of the urine added.

The blue colour of commercial litmus is due to varying proportions of a pigment called azolitmin in combination with potash. Azolitmin is a weak acid, and combines with alkalies forming blue salts. It is soluble in water, but insoluble in alcohol.

According to De Luynes, azolitmin may be prepared from orcinol by the treatment of that substance with sodium carbonate and ammonia by keeping the mixture in a closed vessel with water for four or five days at a temperature of 60°–80° C. On acidifying this solution what is considered to be pure azolitmin is precipitated this substance is soluble in alcohol, and nearly insoluble in water (Allen, 'Comm. Organic Analysis,' vol. iii., part i., page 325).

The substance which I have separated and consider as azolitmin was quite soluble in water, but insoluble in alcohol. It cannot, therefore, be the same substance as that described by De Luynes as azolitmin, but it is undoubtedly the colouring matter of litmus, and agrees with the descriptions of that substance given by Kane (*Royal Soc. Trans.*, 1840, p. 298), and Wartha (*Berichte*, 9, p. 217).

Besides azolitmin there are three other colouring matters in litmus—spaniolitmin (which occurs very rarely), erythrolein and erythrolitmin, but as they are of no value as indicators they need not be spoken of here.

I have estimated the azolitmin in nine samples of commercial litmus and get fairly constant results from each sample. The finely powdered sample is exhausted with boiling water so long as any colouring matter is extracted; the water extract is evaporated to

small bulk, and after acidifying with acetic acid, the evaporation is continued until the extract is nearly to dryness. The object of adding acetic acid is to form potassium and ammonium acetates, which are both soluble in alcohol. A large excess of 85 per cent. alcohol is added to the acidified solution, which precipitates the azolitmin in a crude state; after standing for twelve hours the precipitate is collected on a filter, and when dry is washed through, with the smallest possible quantity of boiling water, into alcohol. After standing over night the precipitate is filtered off, and is dried and weighed.

In order to check the results the samples were re-assayed by a slightly different method. The finely powdered sample was heated on a water bath with excess of acetic acid, and it was then exhausted with warm alcohol; the residue insoluble in alcohol is extracted with boiling water, which, after evaporating to small bulk, is precipitated with alcohol in large excess. The precipitate is collected, and after exhausting with warm alcohol, is dried and weighed. The products obtained were free from inorganic matter.

Sample. No.	Per cent. moisture.	Per cent. insoluble in boiling water.	Per cent. azolitmin.	
			First assay.	Second assay.
1	2.8	84.3	5.21	5.09
2	4.0	73.6	5.84	5.83
3	2.0	83.3	4.92	5.02
4	1.2	89.8	3.40	3.30
5	6.4	60.0	13.55	13.10
6	1.6	87.9	4.79	4.75
7	2.0	86.4	4.31	4.46
8	1.8	89.6	3.82	3.70
9	10.1	46.0	14.22	13.98

According to the only analysis I have seen (Mitchell, *Chem. News*, 1876, p. 140), litmus is stated to contain 2.2 per cent. of azolitmin.

Seven samples—Nos. 1, 2, 3, 4, 6, 7, 8—give an average of 4.6 per cent., which is a much higher percentage than that found by Mitchell. It will at once be seen that Nos. 5 and 9 contrast strongly with all the others. They both indicate a high percentage of moisture, a low percentage of insoluble matter, and a high percentage of azolitmin. Even to look at they appeared to contain a much larger percentage of pigment, and one naturally concludes that the process by which they were prepared must have been different from and superior to that of the others. It will also be seen that the lower the percentage of moisture in the samples, the higher is the percentage of insoluble matter, and the lower is the percentage of azolitmin. This seems to indicate that the quantity of chalk, gypsum, etc., added to the blue liquor to give it consistency is not regulated in any uniform way. The insoluble matter ranges from 46–89.8 per cent., and surely it ought not to be difficult to attain a higher and more uniform standard for commercial litmus than the results found indicate.

In the process given for the preparation of litmus solution in the appendix to the B.P., it is directed to boil the powdered litmus with successive quantities of alcohol, and then to make a water solution. The treatment with alcohol will remove erythrolein, erythrolitmin, and ammonium carbonate, and the water extract will contain azolitmin and potassium carbonate. The presence of the latter is objectionable, because by its alkalinity it may affect the analytical result, and it will render the indicator much less sensitive, as the presence of carbonic acid in titrating interferes greatly with the production of the blue colour.

In place of the official formula I would suggest that a method should be given for the preparation of pure azolitmin, of which a suitable solution could readily be prepared.

PAPAIN AS A DIGESTIVE AGENT.

BY D. B. DOTT, PH.C., F.I.C.

On a former occasion* I contributed a brief note on this subject, showing that papain compares very unfavourably with pepsin, when these are tested by their solvent and peptonising effects on egg albumin under the usual conditions. Since then Dr. Rideal has published a paper† in which he endeavours to make out a good case for papain, and attributes unfavourable results to the mistake of supposing that papain should be tested under the same conditions that hold good for pepsin. He notes that papain differs from pepsin in so far as the former acts fairly well in an alkaline solution, while the latter does not, and more particularly that the proportion of fluid to albumin must be much less in the case of papain than is required with pepsin. That may be correct, but it is permissible to point out that Rideal's proportion of one albumin to three of liquid does not greatly differ from the B.P. proportion of one to four and a third. I have recently tried a few experiments on Dr. Rideal's lines, with the result that they confirm in all essentials what I previously stated. The experiments are not supposed to be very precise, indeed, the methods employed are not capable of great precision, but they are quite sufficient for the purpose in hand; some sources of slight error are very obvious. When working with such a substance as moist sifted albumin, which rapidly loses moisture to the air, absolute accuracy is scarcely possible, and as 14 parts dry albumin are equal to 100 parts of the moist, a slight error, due to variation in the desiccation is very considerably magnified when the dry is calculated into the moist. But the principal source of error appears to be in the filtration. Calico is impracticable. Dr. Rideal recommends muslin, which is a little indefinite, as muslin varies in fineness. I have used a double fold of common muslin, such as is used for straining purposes, and it was scarcely possible to avoid small portions of the more finely-divided substance passing through the filter, particularly in some of the experiments. It is believed rightly or wrongly, that some of the proprietary papains contain a certain proportion of pepsin in order to enhance their power. There is, in a sense, no objection to this addition, but it would never do to assume that the total action of a commercial papain is due to a constituent of papaw juice. Dr. Rideal does not seem to have taken into account the solubility of the albumin in the menstruum employed, which is very considerable, but to have assumed that the difference between the albumin employed and that remaining at the end of the experiment was due to the action of the enzyme.

The following experiments may be noted:—

1. 15 gramme of the enzyme was used in each case, being added to 15 grammes moist sifted albumin in 45 C.c. water containing .5 per cent. hydrochloric acid, at 40° C. After digestion for 1½ hour the undissolved albumin was collected on filter, washed with a little cold water, dried, and weighed. A represents dried papaw juice from Ceylon; B another sample of same; C is pepsin. The numbers indicate the percentage of albumin apparently dissolved.

A	B	C
12.9	11.3	99.6

2. In these experiments 12 grammes of albumin were used, 45 C.c. of water, .15 gramme of enzyme, digested at 40° C. for 1½ hour. In alkaline solution the water contained .5 per cent. NaHCO₃; in the acid solution .5 per cent. HCl.

A=commercial papain in acid solution. B=same in alkaline solution. C=papain powder in alkaline solution. The result of A was particularly difficult to filter, the viscous mass having a tendency to choke, and also to ooze through the filter.

A	B	C
66	7.8	10

per cent. apparently dissolved.

3. Same proportions (Rideal's) as in No. 1, but digestion continued for three hours before filtering.

A=papain specially prepared from papaw powder; B=papain powder with 1/8th part pepsin; C=blank experiment, *i.e.*, albumin with acid solution alone, no enzyme added. Numbers indicate percentage of albumin apparently dissolved.

A	B	C
25.4	84.3	20

4. Same proportions and conditions as No. 3, but in alkaline solution the water containing .5 per cent. of NaHCO₃. A=papain powder; B=commercial papain; C=blank experiment.

A	B	C
23.0	20.9	17.8

These results are confessedly incomplete, but seem sufficient to show:—

1. That the solvent action of the menstruum alone must be taken into account in experiments conducted on the above lines.
2. That dried papaw juice, and the papain prepared from it by purification and precipitation, have very little solvent action on albumin, either in alkaline or acid solution.
3. That one brand of commercial papain has very slight solvent action in alkaline solution, but considerable action in acid solution, in these respects resembling a mixture of papain and pepsin.
4. That even the commercial papain has not nearly the solvent action on albumin which is possessed by pepsin.

It has to be noted that in the case of the experiment 1 C, the amount of albumin dissolved would have been greater had excess been present. What remained consisted of small traces, insoluble *débris* from the albumin and pepsin. It is not intended to undervalue papain in certain of its applications. It has undoubtedly a disintegrating and special action of its own on animal tissues; but as an aid to digestion it appears to be altogether inferior to pepsin.

SPIRITUS ÆTHERIS COMPOSITUS.

BY W. INGLIS CLARK, D.S.C. AND D. B. DOTT, F.I.C.

The formula for "Hoffmann's anodyne" now official in the British Pharmacopœia differs very slightly from that given in the old London Pharmacopœia. Briefly stated the older directions are: to distil 2 lbs. spirit with 4 lbs. sulphuric acid till black froth rises in the retort, separate the light fluid from the heavier, expose it for a day to the air, agitate with sufficiency of potash solution, separate the ethereal oil which subsides, and wash it well.

The product was oleum æthereum. The spiritus ætheris sulphurici compositus was made by mixing 3 fl. drms. of the oil with 8 fl. ozs. of ether and 16 fl. ozs. of spirit. It was certainly a more definite and intelligible formula than that which is now authoritative. According to the present instructions, there is no separation of the ethereal distillate from the strongly acid watery portion. Lime water, though eminently unsuited on account of its weakness, is used to neutralise. The direction simply "to expose to the air for about twelve hours," must give a less definite result than when "exposed for a day" and afterwards "well washed." The U.S. Pharmacopœia process is on similar lines, but more specific and detailed. Shortly described, the process is; to distil together 1 litre alcohol with 1 litre sulphuric acid at 150°–160°, until oily drops cease to come over; separate the ethereal liquid and expose it for twenty-four hours in a shallow capsule; transfer to a wet filter, and wash the oil with 25 C.c. cold water; mix the oil with an equal volume of ether. The spiritus is prepared by mixing 25 C.c. of the oil with 325 C.c. ether and 650 C.c. alcohol. Some of the defects of

* Pharm. Journ. [3], xxiv., 758.

† Ibid. [3], xxv., 183.

these processes have been previously discussed (*Pharm. Journ.* [3]. xvii., 316, and xxii., 614, and other papers). In order to further elucidate the subject the following experiments were tried.

(1) 80 fl. ozs. of rectified spirit, and 72 fl. ozs. sulphuric acid were mixed, and after twenty-four hours distilled. The distillation was continued as far as practicable, that is, until the black liquid began to froth up in the flask, and large quantities of sulphur dioxide were being evolved. The distillate consisted of an ethereal portion (27 fl. ozs.), and an aqueous portion (6 fl. ozs.). To neutralise an intensely acid liquid with lime water is not a reasonable method, and the use of caustic alkali seems contra-indicated on account of its decomposing influence on compound ethers, on the presence of which the virtues of this preparation at least partly depend. We therefore used bicarbonate of soda. It required about 6 ounces to neutralise. After neutralisation the ethereal liquid was separated and filtered. It amounted to 26 $\frac{3}{4}$ fl. ozs.

(a) 100 C.c. exposed in shallow basin in warm laboratory for fifteen hours. The residue was 7.5 C.c. (5 C.c. being oily heavy layer, and 2.5 C.c. upper layer). It was mixed with 160 C.c. ether and 320 C.c. rectified spirit; sp. gr. = .8167.

(b) 100 C.c., without any evaporation, diluted in the same proportion as "a," i.e., to 167 C.c. with ether, and then 320 C.c. spirit added; sp. gr. = .8184.

(c) 100 C.c. placed in cylindrical glass dish, four inches diameter, two inches deep, in cold room. After fifteen hours the residue was = 25 C.c. This was mixed with 530 C.c. ether, and 1060 C.c. rectified spirit; "a" and "b" differ slightly, though appreciably in odour and taste. Although "c" is a literal fulfilling of the law, the result is as might be expected, too purely ethereal and spirituous.

(2) In this experiment the same proportions were used as in No. 1, a thermometer being inserted with bulb dipping in the liquid, and the distillate collected in fractions:—

135°-147°	= 170 C.c. ethereal;	13 C.c. aqueous.
147°-157°	= 162 C.c.	" 21 "
157°-167°	= 155 C.c.	" 39 "
167°-170°	= 148 C.c.	" 67 "

Each fraction was neutralised with sodium bicarbonate; first required 10 grammes, second required 20 grammes, third required 35 grammes, fourth required 50 grammes. After neutralisation:—

1st	=	145 C.c.
2nd	=	127 C.c.
3rd	=	90 C.c.
4th	=	85 C.c.

These left by "spontaneous" evaporation:—

1st	=	3.0 C.c.
2nd	=	4.0 C.c.
3rd	=	5.0 C.c.
4th	=	12.4 C.c.

(3) 320 C.c. rectified spirit and 288 C.c. sulphuric acid were mixed, and after twenty-four hours distilled, the distillation commencing at 134° and continuing to 173° C. The temperature was only for a few seconds so high as 173°, but a considerable amount distilled at 170-171°. The distillate consisted of 125 C.c. ethereal and 10 C.c. aqueous. The ethereal portion was mixed with 10 C.c. water and 10 grammes sodium bicarbonate, which was sufficient to render nearly neutral. When separated and filtered it measured 108 C.c.

(a) 50 C.c. were exposed in a glass cylindrical dish for fifteen hours, leaving a residue of 3.3 C.c. This was diluted with 70 C.c. ether and 140 C.c. S.V.R.; sp. gr., .8088.

(b) 50 C.c. were simply diluted with 20 C.c. ether and 143 C.c. spirit; sp. gr., .8116.

Several experiments were tried in evaporating quantities of the two solutions for different periods of time, and in capsules of varying dimensions. The average percentage of residue was:—

$$"a" = .39 \quad "b" = .59.$$

We have arrived at the general conclusion that the evaporation of the distillate merely causes loss of material, without serving any useful purpose. The only difference that can be detected in the spirit prepared by direct dilution, as in "b," from that prepared in the old method, as in "a," is that the former is rather stronger. There is no evidence, or any probability of an objectionable element, which is got rid of by the wasteful evaporation. It is only necessary that the neutralisation should be properly conducted so that no sulphurous acid gets into the finished preparation. We are, therefore, of opinion that a method on the lines suggested by experiment "3b" should be adopted for the preparation of compound spirit of ether. The distillation should not be pushed to its utmost extent, as there is then a tendency to an empyreumatic odour in the product. The following formula might be suitable. Mix 80 fl. ozs. alcohol with 72 fl. ozs. sulphuric acid. After a day, distil slowly with thermometer in the liquid till the temperature rises to 340° F. Then separate the liquids, rejecting the lower or aqueous distillate. The ethereal liquid is now mixed with 3 ozs. water and sufficient sodium bicarbonate to render neutral or nearly so. Decant the liquid, add 10 fl. ozs. ether, and 80 fl. ozs. alcohol, mix, and filter.

NOTES FROM SOME OLD EDINBURGH INFIRMARY CASE-BOOKS.

BY A. LOCKHART GILLESPIE, M.D.,
Medical Registrar, Royal Infirmary.

While looking over some of the old registers of the Edinburgh Royal Infirmary the other day, I came across two of the case-books of Dr. W. Cullen, and one which is probably from his ward also, although it is not indexed. On one of the pages of the third volume the name of Cullen's son, afterwards Dr. Henry Cullen, occurs, perhaps as clerk of the case, if clinical clerks were known in those days. The earliest of these journals, the earliest, in fact, of any preserved in the Infirmary, bears the date of July 16, 1755, and belongs to Dr. Cullen's female ward. The second dates from 1787 and bears the inscription "Dr. Cullen's Women's Journal," begun August 28, 1787. The third and doubtful number is dated 1773 and begins on November 24 of that year. Pages 15 and 16 have been cut out of this journal, a piece being left, on which the signature of Mr. H. Cullen may be seen. On page 61 a case is signed "Thos. Jamieson, stud. of Physic," probably the same Dr. T. Jamieson who became a fellow of the College of Physicians, Edinburgh, in 1800. This third volume may therefore with reason be ascribed to Dr. W. Cullen's wards.

I do not for a moment suppose that I am mentioning anything new when I describe some of the prescriptions in these old journals. Many much older books exist. For physicians and chemists in Edinburgh, however, anything that pertains to the great Cullen must have a great and absorbing interest. Cullen was without doubt one of the greatest pioneers of modern medicine. One hundred and forty years is not so very long a period of this world's history, but just think of the huge strides made in these few years in the science of medicine alone. Cullen originated much of this. Probably if Cullen had never been born, someone else would have done so, but that does not detract in the slightest degree from the honour due to him. Someone has said that genius consists in the power of taking infinite pains. It is far better described as the power of taking infinite pains originally. Hard

work with a small amount of originality is priceless compared with the most painstaking toil performed by previous rule. Cullen was not only a hard worker—witness his voluminous writings—but an original worker, and any records left by him must always be of interest. I would propose to dip at random into these case-books of his and endeavour to extract some facts of interest and instruction as I proceed, giving details of a number of interesting cases with the treatment employed. The first was a case of Jacksonian epilepsy, in which the patient got 10 grains of a laxative pill containing soap, rhubarb, aloes, and syrup of roses. This was followed by 1 oz. castor oil and $\frac{1}{2}$ oz. compound tincture of senna; the laxative pill was again given, and a blister was at the same time applied round the arm. This was followed by 2 grain doses of opium twice daily for four days, and the patient was then dismissed cured.

A case of acute rheumatism was treated with $\frac{1}{2}$ -oz. doses of a solution of tartar emetic (2 grains to 1 fl. oz.), followed by a diaphoretic jalap containing aqua alexeteria (distilled from elder flowers and fresh angelica leaves), Mindererus' spirit, carbonate of ammonia, and sugar. A yeast poultice was at the same time applied to the breast, and enema salinum (sodium chloride, 2 table-spoonfuls, in 16 fl. ozs. of warm water), administered and repeated whenever fever recurred. The patient soon recovered.

A case of hysteria was treated first with a bolus containing 2 grains calomel, 6 grains jalap, and confection of roses, *q.s.*; this was followed by a kind of spirit of sal volatile, to be applied to the nostrils, and a few drops to be given by the mouth on the advent of a hysterical attack. Afterwards a mistura anti-hysterica was given of the following composition:—

R̄ Aq. fontis.....	ʒii.
Sp. vol. fetid.	gtt. 100
Sacch. alb.	ʒii. M.
Cujus capiat ʒss. urgente paroxysm.	

This stopped the fits, but the treatment next prescribed consisted of $\frac{1}{2}$ -drachm doses of powdered metallic tin at bedtime, indicating the belief that worms were the cause of the hysteria, as pubis stanni was chiefly employed as a remedy for tape-worm. Dr. Alston recommended 1 oz. powdered tin, to be taken on an empty stomach, mixed with 4 ozs. molasses; $\frac{1}{2}$ oz. the second day and $\frac{1}{2}$ oz. the third day, then a cathartic. The next treatment consisted of julapium salinum, containing peppermint water, syrup of lemon, and sal absinthii (potassium carbonate obtained from wormwood). Then followed julapium foetidum, containing water of rue, of asafoetida, anti-hysterical water (valerian, levisticum or lovage seeds, savin, and brandy), oil of hartshorn, and white sugar. The result of this case is not recorded. A girl with sore throat was subjected to the following heroic treatment:—A saline enema, a gargle of infusion of roses, six leeches to the fauces, solution of tartar emetic till vomiting was induced, and an ounce of saline julep every third hour. Next day a note was made that the symptoms were relieved.

A case of erysipelas in the legs was treated by applying three leeches and giving a scruple of ipecacuanha and potum acidi mineralis (weak solution of hydrochloric acid) *ad libitum*. The legs were to be rubbed with wheaten flour, and in the morning a draught was given containing 1 oz. Glauber's salt and $\frac{1}{2}$ oz. cream of tartar, and the treatment succeeded in removing the redness of the legs. Suppuration supervened in the great toe, and for this a decoction of cinchona bark with elixir vitrioli (gentian root, $\frac{1}{2}$ oz.; orange peel, $\frac{3}{4}$ oz.; cochinill (*sic*), grs. 15; brandy, 1 lb.; oil of vitriol, 4 ozs.) was given. The subsequent treatment included ipecacuanha, tincture of opium, and emollient enema (palm oil, $1\frac{1}{2}$ oz., yolk of one egg, milk, $\frac{1}{2}$ lb.), soluble tartar, emulsio arabica (sweet almonds, 1 oz.; water, 2 lbs.; sugar, 2 drachms; gum arabic, $\frac{1}{2}$ oz.), julapium

cardiacum (aqua alexeteria, ʒiv.; aqua aromat., ʒii.; spirit. vol. oleos., ʒii.; tinct. croci, ʒii.; sacchar. alb., ʒss.). Aqua aromatica contained canella bark, lemon peel, cardamoms, or Jamaica pepper and brandy. Spiritus volatilis oleosus contained oils of rosemary and amber, carbonate of ammonia, and brandy. Milk seemed to be a favourite ingredient of enemata with Dr. Cullen, one curious example containing milk, $\frac{1}{2}$ lb.; red sugar and olive oil, 1 ounce of each. Why red sugar (red rose petal juice and white sugar) should have been used in an enema was a mystery. One instance of curious spelling is opodeldoc, which is spelled "oppodeltoch." In a case of faltering of the speech, a local gargle is prescribed which could hardly be expected to influence a central affection of speech. The rest of the treatment, however, is more in accordance with modern ideas. "Let a kettleful of cold water be poured upon her left shoulder every morning, the arm afterwards to be carefully rubbed with dry flannel." Here was a foretaste of the now fashionable massage. Then, "let very slight electrical shocks be given from the top of the shoulder to the points of the fingers, and from the top of the thigh to the toes." What more would we do now except half poison the patient with iodide of potassium? In a case of acute rheumatism, cerevisia tenuis (small beer) is ordered to be given *ad libitum*.

Cullen was by no means so severe on his patients as many of his contemporaries were, as the following case, from Dr. Cheyne's book on 'The English Malady *vulgo* Megrim, shows:—"I first took 20 grains of what is called Prince's powder, which gave me twelve vomits and near twice the number of stools, and I certainly would have perished under the operation but for an overdose of laudanum after it." After that he took 10 grains of calomel daily for ten days, and although much lighter he found himself no better, a result which I for one am not surprised at. As megrim is without doubt a disease, chiefly of nervous origin, the exhibition of drastic purgatives, even if they should happen to remove the exciting cause of the "nerve storm," to use Liveing's term, must necessarily lower the nervous tone and predispose to further attacks.

The study of these old journals has made it plain to me the physicians of Cullen's time were excellent prescribers, and probably knew more of the art of prescribing than many of the present-day practitioners, who are nourished on theory, brought up on "tabloids," and reach their prime dependent on the manufacturing chemist for the proper dosage of the drugs they wish to administer. If I have aroused as much interest by the presentment of these bold glimpses of bygone days as I experienced in its preparation, I shall be amply rewarded.

MISTURA FERRI COMPOSITA—A WRINKLE.

BY W. JOHNSTON.

Dissolve the sugar with the iron sulphate instead of mixing it with the myrrh and potassium carbonate. This seems a very little trifle to take notice of, and yet it is surprising what a difference "little trifles" sometimes make. Dear old Redwood used to tell us that sugar was unfriendly to emulsions; and, acting on that hint the writer tried a little departure from the letter of the law, on the lines above named. The result justified the experiment. The emulsion of myrrh, pot. carb., and rose water was more easily formed and more milky without the sugar; and not a little irritation in future was saved. To get a really good emulsion, the myrrh (nice, oily pieces) should be rubbed hard with the alkali till it becomes not only pulverulent but pasty, before adding any rose water. When that is done, the emulsion can (when diluted) be safely strained through coarse muslin, to remove bits of bark, etc. If not too late, the Pharmacopœia revisers might take note of this.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

MEETING OF THE COUNCIL.

WEDNESDAY, MARCH 4, 1896.

Present:

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. JOHN HARRISON, VICE-PRESIDENT.

Messrs. Allen, Atkins, Bottle, Corder, Gostling, Grose, Hampson, Hills, Martin, Martindale, Newsholme, Savory, Schacht, Southall, Storrar, Warren, and Young.

The minutes of the previous meeting were read and confirmed.

THE BURROUGHS MEMORIAL FUND.

The PRESIDENT officially reported that as President of the Society he had received a cheque for the amount raised for this Fund, which would be invested in the course of a week or so, and the trust deed duly signed.

ELECTION OF A MEMBER.

The following having passed the Major examination and tendered his subscription for the current year, was elected a "Member" of the Society:—

Gill, Joseph William, Pendleton.

ELECTION OF ASSOCIATES IN BUSINESS.

The following having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Amiss, Albert Edward, Shipdham.
Armstrong, Benjamin, Malvern.
Arthur, Arthur, Carmarthen.
Banks, Charles Henry, Paddington.
Boreham, Walter H., Manor Park.
Cameron, John M., Edinburgh.
Churchyard, O. George, S. Tottenham.
Dent, John Wallace, Swaffham.

Dunston, Alfred, Farnham.
Green, George Edward, Southborough.
Herman, Robert Charles, Liverpool.
Hill, Blair, Edinburgh.
Hogg, George, Edinburgh.
McMurtrie, John, Maeduff.
Pilling, John William, Halifax.
Smith, Wm. John, Old Swindon.

ELECTION OF ASSOCIATES.

The following having passed the Minor examination, and tendered or paid as "Students" their subscriptions for the current year, were elected "Associates" of the Society:—

Arthur, Harvey Phillips, Glasgow.
Barron, Robert, Turriff.
Bell, Charles, Wolverhampton.
Bickle, William J., Newport Pagnell.
Bramley, William Miles, Birmingham.
Fairlee, Alfred Jas., Carlisle.
Holt, William, Seunthorpe.
McDonald, David Baird, Glasgow.

Plekworth, George B., Congleton.
Robertson, Daniel Coutts, Galashiels.
Sinclair, George, St. Andrews.
Sisson, Edwin, Carlisle.
Slater, Thomas Sutcliffe, Burnley.
Volans, John Russell, Sunderland.
Wilson, Thomas, Burntisland.
Wright, Robert Edwin, Redditch.

ELECTION OF STUDENTS.

The following having passed the First examination and tendered their subscriptions for the current year, were elected "Students" of the Society:—

Allan, David Houldsworth, Govan.
Arnott, William John, Topcliffe.
Bellingham, Edgar S., Blackburn.
Benham, Reginald Reuben, Chichester.
Brown, Thomas Frederick, Gravesend.
Campkin, Francis Sidney, Cambridge.
Casson, Frank, Birmingham.
Chapman, Edward John, Hull.
Davis, Henry, Riverhead.
Dewhurst, John Arthur, Halifax.
Douthwaite, Percival Few, Newport.
Endicott, William Bassett, London.
Field, William J., Cambridge.
Fisher, Percy, Bradford.
Green, George Winifred, Tadeaster.

Haddock, John, West Bromwich.
Hallgarth, Arthur, Thorne.
Hewitt, Neville Charles, Cowes.
Hitt, Thomas Gabriel, Long Eaton.
Hunter, John, Maybole.
James, Ernest Henry, Guisborough.
Jean, Ernest Albert, Jersey.
Jeffrey, John Edwin, London.
Johnson, Robert Clitherow, Scawby.
Jowett, Hugh Hamilton, Aylesbury.
Kember, George Norman, Pittenweem.
Kent, Charles Wesley, Louth.
Knowles, John Thos., Lancaster.
Leak, William, Beursil.
Leseher, Thomas Edward, London.

Maedonald, Robert, Elgin.
Magan, Frances, Hampstead.
Nelson, William Brown, Harrogate.
Nicholson, William Henry, Guildford.
Oxendale, Thomas T. R., Edinburgh.
Pearson, George Ernest, Wakefield.
Pinson, Percy J., Willenhall.
Plenderleith, John Wm., Edinburgh.
Pring, William Wallace, Bromyard.
Ramshaw, Harold, Sunderland.
Ridge, Percy Littlewood, Selby.

Rogers, James William, Sheffield.
Sargeant, Fred Pilkington, Chorley.
Shaw, Henry Woolhouse, London.
Smith, James W. M., Alexandria.
Stewart, Jeanie, Dumbarton.
Swift, Herbert Henry, Barnsbury.
Teffel, Leonard John, Newcastle-on-T.
Thompson, John, York.
Turner, John Scriven, London.
Tweedy, Sidney C. G., Northwich.
Wileman, Frederick Walter, Lincoln.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who have severally made the required declarations, and paid the restoration fee, were restored to the Register of Chemists and Druggists:—

James Walker Howard, 23, King's Road, Leeds.
David Stevenson Reid, Anstruther, N.B.
Henry Smith, 46, High Street, Evesham.
Robert Walter Somers, 99, Mile End Road, E.

Several persons were restored to their former status in the Society upon payment of the current year's subscription, and a nominal restoration fee of one shilling.

FINANCE COMMITTEE.

The report of this Committee was read, recommending sundry accounts for payment.

The PRESIDENT (as Chairman of the Committee) moved the adoption of the report and recommendations. He said there was nothing calling for special notice. During the present and following month the largest portion of the income from subscriptions was received. The payments were of the usual character. With regard to the Benevolent Fund, about £250 had been received on current account, and during March and April it was hoped that a large amount of subscriptions would come in. It might be considered satisfactory, he thought, that the Society was able to spend judiciously all the money subscribed for benevolent purposes. He should add that the accounts of the Executive of the North British Branch had been forwarded to the Committee and examined, and it was satisfactory to find that the expenditure on keeping up the building, cleaning, lighting, etc., which would be a permanent charge, was very moderate, and that their friends in the North were keeping the expenditure as low as possible. Of course a little more would have to be paid each year in taxes and cleaning, but the figures showed that a very wise and careful judgment had been exercised. The chief expenditure, apart from the building itself, had been for extra furniture and chemicals, and apparatus for the use of the Examiners, so that it was really in the nature of capital expenditure.

Mr. STORRAR asked if he correctly understood the President to say that the principal part of the income came from subscriptions? He thought the examination fees formed the major portion of their receipts, and came in more or less constantly throughout the year.

The PRESIDENT said that was so. He only said that the larger portion of the income from subscriptions came in during March and April.

BENEVOLENT FUND COMMITTEE.

The report of this Committee included the recommendation of grants amounting to £15 to the following cases:—

The widow of a member and subscriber who was formerly a local secretary of the Society. Applicant is trying to establish a private school for the support of herself and family. A grant was made on behalf of applicant's husband in February last year.

The widow of a registered chemist and druggist who has had nine previous grants from the Fund, amounting to £85. She is burdened with an invalid daughter, and her other children cannot render adequate assistance.

One case had been deferred.

Mr. BOTTLE, as Chairman of the Committee, in moving the adoption of the report, said he thought the meeting of the Committee yesterday was a record one as to the minimum amount they voted, and he trusted that it might be regarded as an indication of the prevalence of better times. Their recommendations called for no observations, but there were two other subjects which he should like to bring to the notice of the Council. The first was one advantage which had accrued to the Society from the establishment a few years ago of a list of corresponding members.

Their Secretary had taken advantage of the fact that one of these corresponding members lived in Sydney to hand over a small sum from the Benevolent Fund to a widow of one of their members, who was in search of her brother, and had through their corresponding member's exertions succeeded in that object. An effort was now being made to find her some position, and he thought the Council would be gratified to know the service that their corresponding and honorary members might be able, as they were willing, to render to those connected with the Society. The other subject to which he desired to call attention was the case of Miss Alice Coulson, the daughter of a deceased chemist and druggist, who having been in the position of a governess at Worthing found her school collapse through the outbreak of typhoid there. Under the Society's old charter he thought they might have been able to entertain an application for some temporary relief, but the existing regulations for administering the Fund limited their relief to orphan children—a designation under which this lady did not come. But though they had failed to help her in this direction it might be that either members of the Council or their friends might be able to secure her assistance in another quarter. Consequent on her bad state of health she was a candidate for admission to the British Home for Incurables at Streatham, and should any chemist and druggists or their friends be able to promote her candidature by their votes, he trusted they might see their way clear to do so.

LIBRARY, MUSEUM, SCHOOL, AND HOUSE COMMITTEE.

Library.

The report of the Librarian had been received, including the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
January	Day	419	28	5	16
	Evening.....	153	14	3	7
Circulation of Books.	Total.	Town.	Country.	Carriage paid.	
January.....	187	99	88	£1 3s. 11d.	

Donations to the Library had been announced (*Pharm. Journ.*, Feb. 15, p. 125), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

The Committee had recommended that the undermentioned books be purchased:—

For the Library in London:—

Caspari, Treatise on Pharmacy, 1895.
 Scoville, The Art of Compounding, 1895.
 Thorpe, Inorganic Chemistry, new ed., 1896.
 Pearmain and Moor, Aids to the Analysis of Food and Drugs.
 Flügel-Schmidt-Tanger, German and English Dictionary, 1896.
 Zimmermann, Die Morphologie und Physiologie der Pflanzenzelle, 1887.

For the Library in Edinburgh:—

Richter, Inorganic Chemistry.
 Allen, Chemistry of Urine.
 Pearmain and Moor, Analysis of Food and Drugs.

Museum.

The Curator's report had been received, and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
January	Day.....	545	31	6	20
	Evening.....	47	8	1	2

Donations to the Museum had been received (*Pharm. Journ.*, Feb. 15, p. 125), and the Committee recommended that the usual letter of thanks be sent to the respective donors.

The Committee recommended, in consequence of the decrease in the interest received from the Hills Fund, that after the present session the gift of books to second and third prizemen be discontinued.

The PRESIDENT, in moving the adoption of the report and recommendations, said the principal part of the proceedings of the Committee were purely administrative. The reference to the Hills Fund arose in consequence of the universal fall in the rate of interest, which had been going on for some time, and the Committee thought the best way of dealing with the difficulty was to confine the gift of books to the first prize-man. The other prizes were really valuable in themselves, and it was not believed that withholding the books would have any influence on the competition.

The resolution was then carried unanimously.

THE ANNUAL REPORT AND ANNUAL MEETING.

It was resolved that the preparation of the annual report be referred to the Library, Museum, and School Committee. Also that the annual meeting be held on Wednesday, May 20, at 12 o'clock.

LAW AND PARLIAMENTARY COMMITTEE.

The report of this Committee recommended the appointment of a small standing committee to watch the progress of Parliamentary business, and take such steps as might be necessary. Such committee to consist of the President, Vice-President, and Messrs. Allen, Hills, Martindale, Savory, and Warren.

The PRESIDENT, in moving the adoption of the report and recommendations, said this was a reversion to a plan which was very general many years ago, of having a small committee of London members available at any moment to interview members of Parliament who had charge of Bills which might affect the trade. A reference was made in the Queen's Speech to a Bill for the amendment of the Companies Acts, and such a Bill was in course of preparation, based on the report of the Special Committee appointed by the Board of Trade last year. That report included the evidence given by himself and the documents put in, and since its publication, he in association with the representatives of the dentists, veterinary surgeons, and others affected by the Companies Acts, had considered what steps should be taken to impress on the President of the Board of Trade the importance of amending the Acts in certain directions. A long conference had been held with Mr. Ritchie, the President of the Board of Trade, in which their opinions were fully expressed, and whether they were adopted or not it was quite certain that Mr. Ritchie understood the question from beginning to end. He was not in a position to state the result of the conference, for though it was usual in some cases when a deputation waited on a Minister to publish a report of what took place, it was felt that in this particular case it was rather to their interest to ascertain the views of the President of the Board of Trade and his subordinates, and from long experience they knew that if a Minister ever would express himself freely, it was to a private deputation—not a public one. By adopting this course they were not able to let their friends in the country know exactly what was going on, but he might say that they were in touch with the Board of Trade, and he hoped in a few days to have a reply to a communication which had been sent, which would place them in a position to know whether they could accept what was suggested, to seek another interview, to apply to the Privy Council, or whether it was desirable to take any other steps to remedy the grievances under which they laboured. In this position of affairs it was very desirable that a small committee should be at hand, ready to act with the President, and to enlist support when the Bill was introduced, if thought desirable. The chief difficulty in dealing with the matter was the magnitude of the financial interests involved in any legislation affecting limited liability companies; on the other hand, the injurious working of the Act on certain professions and callings was such that it behoved the Council and the bodies with which it was acting to see if they could not insert a general clause, which would materially lessen the difficulties he had referred to. It must be remembered, however, that no legislation would ever interfere with the general distribution of goods in certain ways by limited liability companies. There was fierce competition in every form of trade, and they could only hope to deal with that which bore upon titles and the dispensing and sale of poisons. Whatever measure of success might be achieved, either through Parliament or otherwise, it must be borne in mind that competition on ordinary trade lines with regard to everything which did not come within the domain of poisons, would probably remain as it was. However, he thought, in any case, the effect of the Bill for amending the Companies Acts, whether it specially dealt with the points mentioned in his statement to the Committee or not, would be to benefit the trade at large, because the facilities for the formation of companies would almost certainly be materially lessened. Then there was the Early Closing Bill, which it was desirable that the Sub-Committee should watch and see if any amendments were necessary. Their brethren were probably divided in opinion with regard to that measure. The Bill introduced by Sir John Lubbock dealt with chemists and druggists very much on the lines suggested by himself some years ago. Many thought chemists should be exempted entirely from the operation of the Bill, while many others thought on the whole it would be beneficial, and with such divided opinions he thought it would be impossible to produce any effect on Parlia-

ment, except in the direction of securing the safety of the public. The principle of the Bill was somewhat new, because it sought to protect grown-up people by legislation in a way which had heretofore been confined to protecting women and children, but one could not lose sight of the fact that the tendency was to employ young people for a good many hours, and very many people besides Sir John Lubbock were beginning to think that the principle underlying the inspection of factories and workshops should be extended to retail businesses. A Select Committee had been appointed to deal with the law relating to adulteration, and probably evidence would have to be given before the Committee. Another Committee had been appointed to enquire into the working of the Petroleum Acts, in which many of the trade were interested, and on that matter also evidence might have to be collected and offered. Under all these circumstances he hoped it would be considered that the Parliamentary Committee had acted wisely in recommending the appointment of this Sub-Committee to watch the interests of chemists and druggists in parliamentary matters.

Mr. STORRAR said he supposed it might be understood that the delay in producing a Pharmacy Act Amendment Bill arose from the desire to see what was done directly or indirectly by any Government Bill which might be introduced, but it was just as well that it should be stated that this was the case, and that in the opinion of the Parliamentary Committee it was the wisest course to pursue.

Mr. MARTINDALE remarked that in some respects pharmacists and the proprietors of stores stood in an entirely different position. The latter looked simply to the total amount of turnover to be obtained on their capital and wished to make it as large as possible, whereas the chemist recognised that with regard to certain articles in which he dealt, such as poisons and nostrums containing poisons, certain restrictions on their sale were necessary in the interest of public safety, and that the sale ought not to be pushed by every possible means, regardless of consequences. It was very desirable that co-operative stores and limited companies should be bound to strictly observe the letter of the law in the distribution of such articles.

Mr. HAMPSON very much regretted that the Committee was content, so far as any expression of opinion went at present, not to oppose Sir J. Lubbock's Early Closing Bill. He altogether objected—not merely as a chemist, but from the point of view of an ordinary trader—to the interference with liberty which would arise if this Bill were passed. He understood the promoter of this Bill was very tender with regard to the sale of tobacco and newspapers, and the sellers of drink were also to be exempt from its operation, but it appeared to him to be a very unsatisfactory and abject position for the Council to assume, simply folding its hands and doing nothing in the interests of chemists and druggists. The members should at least attempt to do something, though he very much doubted if they would be able to. There was a great tendency at present, whatever Government was in office, to pander to the taste for State interference and the restriction of individual liberty and the natural growth of manhood. In every direction this was seen, but he thought it degrading for any class of English people to acquiesce in it. For many years it had been supposed that English people were able to take care of themselves without this grandmotherly interference, but nowadays the old flag of liberty was being furled, and men were content to be legislated for as to what time they should begin business, when they should shut up, and eventually, no doubt, at what price their goods should be sold.

Mr. ATKINS, in presence of the difference of opinion which notoriously prevailed throughout the country on these subjects, feared that unless they could present a more united front their influence would be largely nullified. He thought the peculiar needs of their craft might well be urged in the House of Commons, and was glad to have heard what the President had said, because there was a good deal of anxiety in the country and some expectancy as to what might become of this Bill, and as to their action in regard to it. He gathered from what their President had said that their position was recognised by what he believed to be one of the ablest men of the present day, Mr. Ritchie. At the same time he agreed with the President that they must not expect too much in regard to the excessive, and he would venture to say, unfair competition to which the trade is exposed; he thought their President exercised a wise discrimination in guarding them from expecting too much relief in respect to the Companies Acts. The matter being *sub judice*, he was glad of

the proposed appointment of what he might call a watch committee, who, he trusted, would be strengthened by the advice and co-operation of the members of the Council resident in London, and he heartily agreed to its appointment.

Mr. NEWSHOLME regretted to find himself in what he feared would prove a hopeless minority on this question. Side by side with a desire for earlier closing he felt there was so much difference as to details in various localities that without some kind of legislation there was no prospect of anything like unanimity. In reference to their own profession there was a saving clause. He did think they could carry out their business in very much less time than was now the case, but he also thought some means could be devised for meeting their special needs as chemists and druggists.

Mr. SOUTHALL agreed with Mr. Newsholme that chemists wanted a little of what had been styled grandmotherly legislation. Women and children were now being protected, and he thought it time that something should be done in the same direction for men. They were so little united as chemists and druggists that he thought the law might come in and make them a little more united. It was nothing short of dreadful to see the poor chemist and druggist regularly open till nine and ten o'clock, and suitable legislation might remedy that state of things to a considerable extent.

Mr. MARTIN said he entirely agreed with the President. He did not see how it was possible to draw the exact line in their trade where medicine ended and other sales begun, as for instance in the case of a bottle of eau-de-Cologne being asked for simultaneously with the making up of a prescription, and he thought it would be placing pharmacists in an invidious and humiliating position to be subjected to the surveillance of an inspector. Other trades could take care of themselves, and on this ground alone he should have hoped the Council would have opposed the suggested legislation. There were already so many flaws in the administration of the Pharmacy Act that he should have thought they might have proceeded in a more direct manner, and not wait for any amendment of the Companies Acts.

The VICE-PRESIDENT said he did not agree with the view that the Law and Parliamentary Committee showed any want of wisdom in deferring the matter until they had heard the decision of the President of the Board of Trade. If the evils from which they at present suffered should be accentuated, so much the better, as perhaps leading them to combine with others in demanding a remedy, and so approaching the Legislature with a force greater than they themselves could command, and with a greater prospect of success. He believed this was the first time a Government department had been officially made aware of their needs, and that there were such grievous defects in the Companies Acts. With other bodies similarly affected, they would have greater justification in asking Parliament for a remedy, and, for his part, he was content to wait till they got an answer from the Board of Trade and the decision of what had been described as one of the best business men of the day, before attempting to proceed with legislation on their own account. With other bodies similarly affected as themselves it might be that they could incorporate their whole needs in one measure. As to early closing, he had listened with great interest to what he might call the sermonette of their Treasurer, for it was long since he had heard anything finer than his protest on behalf of liberty against the restriction of the growth of manhood. Although he was not quite sure what that magniloquent phrase meant, he thought it very finely expressed a state of things not consistent with present-day tendencies, and so far he was in accord with it. But there was another tyranny besides Parliamentary enactment which he thought it important equally to guard against—namely, the refusal on the part of certain ill-regulated members of society to give the reasonable and proper relaxation which was necessary, and the people had a right to demand. He could not help thinking that in this matter a uniform system would be one of extreme difficulty, and that perhaps something more on the lines of local option would be preferable. There being so much to be said for and against questions of this kind, he hoped the Committee, which he felt sure would be appointed, would look very carefully indeed into the question, specially as it affected chemists and druggists. The result of excluding them from supplying medicine at any hour of the day and night would probably be that doctors would open departments to supply that which properly belonged to the chemist to provide.

Mr. ALLEN said he had not intended to take part in the discussion, but as one of those suggested to form a sort of committee to watch measures passing through Parliament affecting their

trade, he should have pleasure in giving as open a mind as possible to any question brought before it. As regarded early closing, as pharmacists he thought they were specially affected, and that they might reasonably ask for separate treatment from other shops, seeing that illnesses would occur at all times and hours, and that it was necessary in the public interest to be able to secure medicines accordingly.

Mr. HILLS, as one of those named for the watch committee, agreed with Mr. Atkins that they should not expect too much from an alteration of the law; but competition, especially from what were called drug stores, seemed to call for some amendment of the law, though at the same time he agreed with those who thought what was called grandmotherly legislation should be avoided. He agreed that pharmacists required, in the matter of early closing, special attention as compared with other businesses, but that did not prevent him from sympathising with the desire for more time for relaxation than now prevailed. For this he looked to a healthier state of public opinion, not only as regarded shops, but as the question bore on other occupations.

Mr. GOSTLING said he was quite in accord with the Treasurer.

The PRESIDENT, in closing the discussion, said in view of the fact that the intentions of the Government were not yet known he hoped the Council would appreciate the fact that it would be of advantage to have the ear of the Government in legislating on subjects which appealed to them as chemists and druggists; and he thought it would be unwise of them not to encourage every effort which should tend to that end.

The resolution was then put and carried unanimously.

DIVISIONAL SECRETARY.

Mr. A. J. Wing, of Powis Street, Woolwich, was appointed Divisional Secretary for Woolwich, in place of Mr. Carter.

LOCAL SECRETARY.

Mr. D. L. Lewis, of the Broadway, Ealing, was appointed Local Secretary, in the room of Mr. Curtis, who had left the neighbourhood.

The PRESIDENT in putting the motion, referred to the services rendered by Mr. Curtis, who was not only a good pharmacist, but had a good knowledge of affairs generally.

CORRESPONDENCE.

The PRESIDENT said a letter had been received from the Secretary of the Bristol Pharmaceutical Association enclosing the following resolution which had been passed at a large meeting, representative of the chemists in the district. The resolution would be referred to the Law and Parliamentary Committee—

“That this meeting of registered chemists pledges itself to support the Council of the Pharmaceutical Society in its efforts to amend the proposed Companies Acts Amendment Bill, which it is intended to introduce into Parliament during the present session.”

The PRESIDENT then read the following memorial, forwarded by Mr. J. Anderson Russell, of Glasgow:—

“In view of the very great and increasing evils connected with proprietary medicines, more particularly with the prescribing of these by medical men, we, the members of the Glasgow and West of Scotland Pharmaceutical Association, urge the Council of the Pharmaceutical Society of Great Britain to take the matter into its very serious consideration. We are aware it is a matter for which the medical profession is more directly responsible, and to that body we must look for effectually dealing with it, nevertheless, as it is a procedure having a most baneful influence upon the practice of pharmacy, as well as upon ‘medical’ practice, it appears to be the duty of pharmacists to grapple with it. Since it affects both callings we respectfully suggest that the Pharmaceutical Society’s Council, as officially representing pharmacy, should direct the attention of the General Medical Council to this matter, and in combating the evil should use its influence to secure the sympathy and co-operation of medical organisations and governing bodies throughout the country. We further suggest that it would be advisable were the Pharmaceutical Council through the facilities at its disposal, and with the approval of the General Medical Council, authoritatively to compile and publish formulæ for medicinal preparations for which considerable demand had arisen.”

The PRESIDENT suggested that the above be referred to the General Purposes Committee for consideration and report. The memorial covered a good deal of ground, and some important principles were involved;

This was agreed to.

RETIREMENT OF A MEMBER OF COUNCIL.

The PRESIDENT said he had to read a letter which had been in his possession for forty-eight hours, although he had not mentioned its existence, and before doing so he ought to say that he had conferred with the writer, who desired to adhere to it, and wished it to be taken as his deliberate decision.

The letter was as follows:—

“1, Windsor Terrace, Clifton.

“March 1, 1896.

“The President of the Pharmaceutical Society.

“Sir,—The time has again arrived when in due rotation I have to retire from the Council, and I beg to state that it is not my intention to offer myself for re-election.

“My chief reason for this conclusion is the feeling that, being no longer in any way connected with the business of pharmacy, I do not consider myself to be in the list of fittest persons to represent pharmacists on the Society’s Council.

“I take leave of my duties with regret, for I have learned to believe that in fulfilling them I was helping to provide some good for others, and much wholesome training for myself.

“I take leave of my colleagues with a pain that would be great indeed were it not for the hope that I carried with me some measure of their esteem and, perhaps, some of their affection—sentiments which I earnestly assure you I sincerely cherish for them.

“I shrink from the trial of making this announcement in person, and therefore, sir, beg you to receive it and to read these few lines to my old friends and colleagues, and thus add one more to the many courtesies for which I am your debtor and which I most gratefully acknowledge.

“Believe me to be, dear Sir,

“Yours very sincerely,

“G. F. SCHACHT.”

“Michael Carteighe, Esq.”

The PRESIDENT said it was not usual to move any resolution in such cases until the term of office had expired, but as Mr. Schacht’s retirement from the Council room a few minutes ago was actually his retirement from the Council, he would move:—

“That this Council deeply regrets the proposed retirement of Mr. G. F. Schacht, and desires to give expression to its high appreciation of the valuable services he has rendered in every department of pharmaceutical work. As a member of the Board of Examiners, as member of the Council for twenty-five years, and as Vice-President of the Society for three terms, he has devoted the highest powers of a vigorous and well-endowed mind to the furtherance of the best interests of pharmacy. The unwearying efforts of Mr. Schacht in the cause of pharmaceutical education will be always gratefully remembered by every member and associate of the Society.”

No words of his could express in suitable form what they all felt for Mr. Schacht, but, in proposing the resolution, he would remind the younger members that Mr. Schacht was one of the earliest examined men, in fact, the earliest one still living, and he had shown that he possessed not only great natural gifts, but that he had made good use of his early education in that house. He followed the science of chemistry and other sciences bearing on pharmacy with continuous interest all through his life, and probably one of his greatest regrets in early life was that in leaving London he was going away, as he thought, from the centre of scientific activity. Those who had been associated with him at meetings of the Conference and socially, knew him as a man of strong will and of considerable personality. He was gifted with great power of observation, and it was a matter of deep regret that he had thought it necessary to retire now, as he still possessed those gifts to a marvellous degree, and in the deliberations of the committees yesterday he showed his usual activity and knowledge. However, as he had said, Mr. Schacht was a man of strong will, and, having carefully thought this out, he had deliberately come to the conclusion that it was the proper time for him to retire, and he had authorised him to say that this was his final decision. In reviewing the work he had done, he should be disposed to regard him as one of the most successful and most elegant adapters of

scientific methods in pharmacy they had had amongst their numbers. The preparations with which his name was associated evidenced a considerable amount of originality and chemical skill, but the features of all others that endeared him to his colleagues were his *bonhomie* and his unwearied exertions to be perfectly just and true to everybody; in fact, sometimes he appeared to be almost too conscientiously just to others. He knew no man who could receive a mild castigation, either privately or in public, with so much consideration, or who was so free to admit where differences of opinion prevailed that he might be wrong. It would be inappropriate to say more on this occasion, and he should be sorry to say anything which would imply that Mr. Schacht in retiring from the Council would cease to take an interest in pharmacy; on the contrary, he believed that as long as Mr. Schacht lived he would exert himself as far as practicable with pharmacy, especially in its educational aspects. In his own neighbourhood he was highly respected. He was treasurer of the Bristol University College, and visitor of some of the local schools connected with it, was leading an active educational life there, and was highly esteemed by all around him.

The VICE-PRESIDENT said, as a very unworthy occupant of the chair which Mr. Schacht held for some time with great distinction, he felt he ought to second the motion. They were called upon to bear a very serious loss, for it was not every day they could find a man with the educational attainments, scientific ability, and courteous character to be found in Mr. Schacht. He had been brought into close contact with him for some time, and could endorse every word in the resolution, though he deplored the necessity for passing it.

Mr. BOTTLE said he could only express his extreme regret at the loss of a member of the Council, of such attainments and abilities. He had rather thought that he (Mr. Bottle) would be the first to retire, and that Mr. Schacht would continue his work there for many years to come, because he was almost a boy compared to him, remembering him as he did as a student. If he thought he could influence him in any way he would do anything and everything he could to induce him to reconsider the matter, for his usefulness, especially in connection with educational matters, was beyond expression.

Mr. ATKINS said he hoped the retirement of Mr. Bottle might long be deferred. It was difficult to say what one felt on this matter, on the spur of the moment, coming as it did so unexpectedly. He felt, without any disrespect to his colleagues, that no small part of the pleasure with which he looked forward to these meetings would be gone when he knew that he should no longer meet Mr. Schacht there, for he knew of no man for whom he cherished a deeper respect and affection. The one thing which had impressed him most through many years' friendship was the absolute honesty with which he expressed himself and transacted all public business. The President had borne testimony to the position which Mr. Schacht had occupied in pharmacy for so many years, and, in truth, he might be said to be a typical pharmacist. He hoped his retirement did not involve the conclusion that all who had retired from business should follow his example, and as there was no abatement of his natural force or clearness of judgment, he hoped that his services to the Society would still be continued for many years. His loss it was impossible to exaggerate; it was to him a most painful bereavement, and he could only give very imperfect utterance to the feelings of his heart.

Mr. HILLS said he could not let the occasion pass without echoing what had been said in much better terms than he could use. He was sorry that they had not known what was coming, so that they might all have had an opportunity to use what little influence they possessed with Mr. Schacht to make him reconsider his determination. The Council would be much poorer by the absence of Mr. Schacht, for whom he had the greatest veneration, both as a pharmacist and a man.

Mr. HAMPSON thought the word bereavement was scarcely an appropriate one to use, for it was quite possible that Mr. Schacht in leaving his duties there would have more leisure, and be able to increase his usefulness in his own locality. He could not believe for a moment that a man of his calibre would cease his efforts for the good of a cause which he had so much at heart. He could only say that he should miss him very much, and he thought Mr. Hills' last observation covered the whole ground.

Mr. MARTIN said the shock of this announcement was so great that he felt it impossible to express what he felt in fitting words. Personally Mr. Schacht had been to him for twenty-five years his ideal. Though they had often differed in opinion, he always felt

that he was dealing with a man who was absolutely honest in his opinions, and having served pharmacy as he had, he had a right to his own opinion. He thought the fact of his being no longer in business was rather an advantage than otherwise for a member of Council, as it left him more leisure, but they were bound to respect his decision, which he was sure had not been arrived at lightly. He was sure that his sympathies and affection would always be with the Society, and that he would do everything he could to promote its best interests.

Mr. YOUNG, at the risk of saying imperfectly what had been already gracefully expressed, felt it only right, as one of the younger members, to express his own sincere sense of personal loss. Since he first knew Mr. Schacht he had felt that if an object lesson were needed to indicate that which was lofty, high-minded, free from all pettiness, scholarly, and fair, it was to be found in Mr. Schacht, and since his closer acquaintance with him at the Council table that feeling had been accentuated.

Mr. GOSTLING also expressed in a few words his deep sense of the loss which the Council had sustained.

The resolution was then put, and carried unanimously.

GENERAL PURPOSES COMMITTEE.

The Council, as usual, went into Committee to consider the report of this Committee, which dealt with legal matters only. On resuming, the report and recommendations were adopted, and special resolutions were passed authorising the Registrar to take proceedings against certain persons named therein.

EVENING MEETING IN EDINBURGH.

Friday, February, 28, 1896.

MR. W. L. CURRIE IN THE CHAIR.

The third evening meeting of the present session was held in the Society's hall, 36, York Place, on Friday, Feb. 28, at 8.30.

The minutes of last meeting having been read and approved, apologies for absence were intimated from Messrs. Coull, Ewing, Fraser, Garvie, Heron, McGibbon, Maclaren, Macpherson, Nesbit, Noble, Stephenson, and Wylie. Mr. Ewing in his letter expressed his indebtedness to Mr. Currie for coming from Glasgow to take the chair in his unavoidable absence, and said he was sure the meeting would give a cordial welcome to one who has done so much to advance the interests of pharmacy in the west of Scotland.

The CHAIRMAN then briefly introduced Dr. Lockhart Gillespie, who contributed the first communication, "Notes from Some old Edinburgh Case-Books," which is printed at page 183.

Mr. BOA said he had greatly enjoyed this paper. It was one thing to read these old recipes in a book and another thing to hear their application presented in such an interesting way as had been done by Dr. Gillespie. With regard to the *vinum domesticum* mentioned by Dr. Gillespie, he thought it would probably be a generic name for any of the home-brewed wines, such as gooseberry, raspberry, elderberry, or ginger wine.

Mr. HILL said Dr. Gillespie had made an apology on the ground that he had a great many matters in hand, and he could well appreciate that, for the other night he listened to a most elaborate and interesting paper read by him before the Royal Society of Edinburgh on a subject in which pharmacists took considerable interest, namely, the relationship between weather conditions and disease. That paper had been completely misunderstood by some casual readers, who came to the conclusion that Edinburgh must be a very dreadful place to live in, because when they had cyclonic weather people suffered from coughs and colds, and when they had anti-cyclonic weather they had influenza. They knew, as pharmacists, that such a statement was groundless, for though they had had a great deal of anti-cyclonic weather in Edinburgh this winter, they had practically no influenza, and he doubted if ever the chemists had had less dispensing to do. He believed Dr. Gillespie was continuing his researches, and they would follow his work with very great interest. He might mention that they had in the North British Branch Library a large number of those old pharmacopœias, many of them annotated in handwriting which might be that of Dr. Cullen or others of similar eminence, and anyone inclined for antiquarian research in that department would find

ample material in that Library With regard to the remark made by Dr. Gillespie as to the recent published statement that a firm in Edinburgh had been supplied with the stalks of *Angelica* from the garden at Croft-au-Righ, beside Holyrood Palace, it was interesting to remember that the celebrated Dr. Sibbald, one of the founders of the Royal College of Physicians in Edinburgh, was the means of having a garden established just about that spot by the Royal College, and in that garden all kinds of medicinal plants were cultivated. This angelica might very probably be a survival from that old garden. One could not help being struck by the great size of the pills prescribed in Cullen's time. If such pills were sent out now they would be returned with an intimation that nobody could swallow them, and that we did not know how to dispense pills. Brandy seemed to have been very commonly used, and one wondered why so potent and popular a remedy had almost entirely disappeared from the Pharmacopœia. He was inclined to agree with Mr. Boa as to the meaning of the term vinum domesticum. It would mean a wine made by fermentation of a saccharine solution, as distinguished from natural wine imported from foreign countries.

The CHAIRMAN said he had been struck by the extraordinary doses mentioned in the paper. He was reminded of a story told in Glasgow about a certain Dr. McEwan who carried with him an antimony bullet or perpetual pill. It had been administered to a patient suffering from constipation, and after twenty-four hours had produced no effect. The patient expressed a fear that the bullet would never be seen again, but Dr. McEwan promptly dispelled the fear by assuring his patient that it had already passed through at least one hundred, and would certainly not fail now. As he listened to the paper he thought some of them would prefer even now to have the various concoctions referred to to dispense rather than the factory-made, elegant preparation of to-day. He also was at a loss to know why brandy had so entirely disappeared from pharmacy.

Dr. GILLESPIE in replying, said as medical registrar at the Infirmary, he had come across these curious prescriptions, and Mr. Alexander, the chief dispenser, had told him they would be of interest, and he was very pleased to have given them. With regard to vinum domesticum, they had to remember that these case-books were dated just ten years after the time of Prince Charlie, when French wines were drunk in Scotland not by the bottle but by hogsheads, and possibly a light claret might go by the name of vinum domesticum. It was a London newspaper which represented him as saying Edinburgh was a dreadful place to live in, and it was predicted that rents would immediately fall. They knew how wide of the mark such an idea was, and for this winter the experience of doctors, he suspected, was very like that of pharmacists. It was interesting to note that Dr. Cullen came from Glasgow in 1755, and was at once put in charge of wards in the Royal Infirmary. Nowadays a man might wait thirty or forty years to get such a chance. As to the size of pills, he had seen a recent case in which an experienced prescriber ordered pills with 10 grains of quinine in each. He thought brandy had disappeared because whiskey was better.

The next communication was on "Spiritus Ætheris Compositus, B.P.," by W. Inglis Clark, D.Sc., and D. B. Dott, F.I.C., F.R.S.E., and is printed at p. 182.

The next communication was a "Note on Papain," by D. B. Dott, F.I.C., F.R.S., and is also printed at p. 182.

Mr. HILL said they might be inclined to ask why the spirit referred to should be retained in the Pharmacopœia, but it was not their duty to settle such a question. If it was to be retained, it was desirable that they should have a formula which would give a definite and uniform result in an economical and reasonable way. This, he thought, the process now suggested would do, and no doubt it would receive due notice, and be utilised in the proper quarter. With regard to papain, they in Edinburgh were specially interested, for they had been prominent in adversely criticising its alleged powers as a digestive agent resembling pepsin. He had felt, on hearing Dr. Rideal's paper, that he would like to have some further work done before feeling quite satisfied that the matter was clear. He had only had very limited experience of papain, but what he had seen tended to confirm Mr. Dott's conclusions. He thought papain might possess medicinal value, indeed they knew it had a very special value in the treatment of diphtheria, though a more recent remedy might have slightly displaced it in that department, but it did not seem to be a powerful agent in the digestion of albuminoid substances. That side of the question seemed pretty well settled by Mr. Dott's results.

The CHAIRMAN said doubts might well arise as to retaining the

spiritus ætheris compositus in the B.P. He had only seen it once prescribed in five or six years in the west. Recently, when it was prescribed he found his stock unsatisfactory and had to procure a fresh supply. The B.P. directions struck him as incomplete and the mode of preparation suggested in this paper was a distinct gain. With regard to papain he could not speak of its use as a digestive agent but he had seen a lot of it used for eliminating the diseased growth in diphtheria. It was used in five per cent. solution in glycerin and removed the growth in ten or twelve hours, and was followed by antiseptic treatment.

Mr. DOTT, in replying, said that the spiritus ætheris compositus had been condemned as a discredit to the Pharmacopœia, but when this was brought under the notice of the Committee they said it could not be left out. He regretted that Dr. Clark had not been able to come to the meeting that night.

Mr. BOA asked the Chairman how often the papain solution was applied, and the Chairman said "every three hours." As to the spiritus ætheris compositus, he often dispensed it. In conversation with a medical man the other day, he was told he got better results from it than from the simple spirit of ether. Then in Ireland he had seen it prescribed almost every day, and sometimes almost in every other prescription under the name liquor Hoffmani. He did not think, under these circumstances, it could be left out.

The last communication was a "Note on Commercial Litmus," by D. Rainy Brown, and is printed at p. 181.

Mr. DOTT said there could be no doubt commercial litmus did vary very much, and some samples were very difficult to filter. A neutral solution prepared from the aqueous extract of litmus he found to answer very well, but it might, perhaps, be desirable to work with a more definite substance.

Mr. HILL said one striking point in Mr. Brown's results was the great disproportion in percentage of colouring matter between samples 5 and 9, and all the other samples examined. These two were very close to one another, and it almost seemed as if they had been made by the same process. There did seem to be an absence of science in any of the methods of preparing this substance which he had seen. The gypsum, sand, etc., seemed to be added in a haphazard way, and there was probably a needless waste of colouring matter. A very pure azolitmin could be prepared with comparatively little trouble, and as it was always best to work with definite substances when these could be conveniently had, he thought that substance should be adopted for the preparation of a standard litmus solution for analytical purposes.

The CHAIRMAN said they were much indebted to Mr. Brown for this practical note.

Mr. BROWN, in replying, said he could not give the history of samples 5 and 9 further than that the former was obtained from a German firm, and the latter from an English firm.

The ASSISTANT SECRETARY then exhibited a specimen of a new mineral which had been found on the Calton Hill, Edinburgh, when excavating the foundation for an addition to the observatory buildings. The mineral had not been identified. Some thought it was agathite, but a very rough examination which he had made of it showed that to be impossible. It had also been described as obsidienne, but that also did not appear to be correct. It occurs in laminated crystals of a bluish-green to steel-grey appearance, and is very brittle and infusible. It seems to float on strong sulphuric acid (sp. gr. 1.843) which it colours deep brown, but it does not sensibly dissolve, nor is it dissolved on the addition of potassium bichromate. It yields a trace of iron to hydrochloric acid, but is not dissolved either by it or by nitro-hydrochloric acid. Strongly heated in the blow-pipe it seems to be slowly burned away, and on attempting to fuse it with sodium carbonate and potassium nitrate, it seemed to deflagrate like carbon. The examination was only very superficial, but pointed to a graphite form of carbon though different from any descriptions of graphite he had seen. A gentleman who had been in the South African diamond fields said had he not been told what it was, he would immediately have called it a specimen of diamond matrix. The specimen had been kindly lent by Mr. William Hume.

The ASSISTANT SECRETARY then drew attention to the books recently added to the Library.

On the motion of the Chairman, votes of thanks were awarded to the authors of papers and the donors of books.

Mr. BOA, in moving a vote of thanks to the Chairman, said he believed this was the first occasion on which a Glasgow man had presided at their evening meetings. He hoped this new departure would be continued.

The vote of thanks was cordially awarded, and the meeting closed.

PHARMACEUTICAL JOURNAL.

LONDON: SATURDAY, MARCH 7, 1896.

THE COUNCIL MEETING.

At the opening of the meeting on Wednesday last, after the reading of the minutes of the previous meeting, the PRESIDENT announced that as President of the Society he had received a cheque for the amount raised for the Burroughs Memorial, and that in due course the money would be invested.

The additions to the Society comprised one Member, thirty-two Associates, and fifty-two students.

The report of the Finance Committee was without any exceptional feature. It stated that the accounts of the Executive of the Society's North British Branch had been received, examined, and found satisfactory. The chief expenditure, apart from that for the new buildings, has been for furniture and equipments for the use of the examiners. In answer to an inquiry by Mr. STORRAR respecting the income of the Society, the PRESIDENT explained that, in speaking of the subscriptions as the largest part of the Society's income, he referred especially to the receipts during the months of March and April.

On the recommendation of the Benevolent Fund Committee two grants were ordered to be paid, one of £10 and one of £5. Mr. BOTTLE, as acting Chairman of the Committee, remarked that he believed the report was a record one in regard to the amount voted in grants being less than on any previous occasion, and he hoped that might be regarded as a sign of better times. He also mentioned the assistance that has been rendered, in connection with the administration of the Benevolent Fund, by a corresponding member of the Society residing in Sydney, as an instance of advantage derived from the appointment of corresponding members. Attention was called to the case of Miss ALICE COULSON, the daughter of a deceased chemist and druggist, who, though an orphan, is not eligible under the existing regulations for relief from the Fund for orphans, and Mr. BOTTLE solicited on her behalf the assistance of any members or their friends who may be able to promote her candidature for admission to the British Home for Incurables at Streatham.

The report of the Library, Museum, School and House Committee furnished the usual statistics of attendances at

the Library and Museum, a statement of donations received, recommendations for the purchase of books, and for the discontinuance of the gift of books to the second and third prizemen. The decrease in the interest received from the Hills Fund has rendered that course necessary, but it is not anticipated that it will entail a loss of interest in the prizes awarded.

It was resolved that the preparation of the Annual Report should be referred to the Library, etc., Committee, and that the annual meeting of the Society shall be held at noon on Wednesday, May 20, next.

On the recommendation of the Law and Parliamentary Committee it was resolved that the PRESIDENT and Vice-President, with MESSRS. ALLEN, HILL, MARTINDALE, SAVORY, and WARREN should form a Sub-Committee to watch the progress of Parliamentary business, and be empowered to take such steps as might be necessary in regard to any measure affecting the trade. In reference to this arrangement a long discussion took place chiefly relating to the attitude of the Council to particular measures before Parliament. The PRESIDENT pointed out that it is a reversion to the plan which was generally adopted some years ago in order that the London members of Council might interview members of Parliament at any moment. At the present time several measures are before Parliament in which the trade is interested. The Bill to amend the Companies Acts is of especial importance, and, in association with representatives of dentists, veterinary surgeons, and others, the views held on the subject of amendment of the Companies Acts have been fully expressed to the President of the Board of Trade, at a conference with him, so that it is at least certain they are understood by him. Though not at present in a position to state the result of the interview, the PRESIDENT hopes to have a reply to a communication that has been sent to the Board of Trade, by which future procedure may be regulated. Under such conditions it is desirable that a small Committee should be readily available to act with the PRESIDENT as occasion may require. That is also the case in regard to the Early Closing Bill which proposes to deal with chemists and druggists. On the subjects of adulteration of food and drugs and petroleum, committees have been appointed, and probably there will be necessity for evidence to be given in relation to those matters.

In connection with the Companies Bill, Mr. STORRAR explained that the delay in producing a Pharmacy Act Amendment Bill has arisen from the desire to see what is done by any Government measure, and though that might be understood, he thought the statement should be made. Mr. MARTINDALE drew attention to the different positions of proprietors of stores and pharmacists, the former being influenced only by trade considerations, while the latter recognise the necessity of restrictions, in dealing with certain articles, out of regard for public safety. Mr. ATKINS and Mr. HILLS, in referring to the evils of company trading and to the feeling of expectancy prevailing in regard to the amendment of company law, expressed the opinion that, although the peculiar needs of the craft have been recognised by Mr. RITCHIE, the trade should not look to the Government for much relief in respect of the Companies Acts, unless the influence of a more united front could be brought to bear. The Vice-President, while approving postponement of action by the Council until the decision

of the Board of Trade is made known, thought that in any event there would be greater probability of combination among those suffering from the evils now complained of, and a consequently greater prospect of success in seeking to obtain a remedy from the Legislature.

On the subject of Sir JOHN LUBBOCK'S Early Closing Bill, the differences of opinion prevailing in the trade were fully represented, Mr. HAMPSON uttering a protest against State interference with individual liberty, in which he had the concurrence of Messrs. MARTIN, ALLEN, HILLS, and GOSTLING. While in apparent opposition to Mr. HAMPSON'S belief that Englishmen should be able to take care of themselves, Mr. SOUTHALL was in favour of extending even grandmotherly protection to the "poor chemist," and the Vice-President humorously criticised Mr. HAMPSON'S "sermonette" upon the restriction of the growth of manhood.

The reading of a letter from Mr. SCHACHT, announcing his intention of retiring from office, produced an entirely unprecedented sensation in the Council. After inquiries by Mr. BOTTLE and Mr. SOUTHALL, as to the possibility of inducing Mr. SCHACHT to alter his decision, had been replied to by the PRESIDENT, to the effect that his efforts in that direction had failed, a resolution was passed expressing regret at Mr. SCHACHT'S retirement and high appreciation of his long services in connection with the Society. This was warmly supported by several members of the Council, who spoke of Mr. SCHACHT and his work in highly eulogistic terms.

EARLY CLOSING FOR CHEMISTS.

LAST week reference was made to the curiously varied and sometimes humorous reasons advanced by chemists for objecting to support the Pharmaceutical Society, and on page 200 of this week's Journal will be found a letter which affords ready confirmation of the statements then made. The writer's name, it may be observed, appears in the Society's Calendar as an associate not in business and, presumably, he is engaged as an assistant in the place where he undergoes what he is pleased to term "slavery." Under the circumstances, therefore, his expression of opinion may be somewhat excusable, since he probably suffers under an arrangement in the making of which he has no voice. It must be pointed out, however, that an assistant is usually a free agent, and not bound to continue in a place where the conditions are objectionable to him. That the conditions prevailing in any given situation which it suits the convenience of an individual to fill for the time being, are not always to his liking, is but natural. If, however, in such a case the strain becomes intolerable, would it not be much simpler for that individual to effect a change than to have a special Act of Parliament passed to relieve him? Would it not also be wiser for him to help himself in the manner indicated than to sit down and call in question the attitude of the governing body of his craft, without first ascertaining the extent of his ignorance respecting matters that he ought to be fully conversant with?

Chemists' assistants have yet much to learn from workers at other crafts, more especially in regard to the preservation of professional dignity and to combination for self-defence. It yet remains to be told also why so large a proportion of registered chemists, who suffered under grievous restrictions when assistants, persist in maintaining the old obnoxious

system when themselves in a position to arrange matters differently. Perhaps it is reserved for "Early Closing" to inaugurate a new era in this respect, in his particular district, when he commences business on his own account. The reason usually alleged for long hours, and now repeated by our correspondent, is "because others keep open," but this is not in any degree a valid reason. Besides savouring too much of a jealous and parsimonious spirit to be at all worthy of members of a semi-professional body, many who, under similar circumstances to those detailed by "Early Closing," have boldly faced the difficulty and closed their establishments at a reasonable hour, save for cases of urgency, have proved by their experience that the dread of other shops remaining open is for the most part a harmless bogey.

With regard to our correspondent's complaint of lukewarmness on the part of the Journal in connection with the Shops (Early Closing) Bill, no expression of opinion on the Bill appeared in the paragraph referred to, though the language employed fairly represents the position taken up by many leading pharmacists. Moreover, it should be clear that the Editor is in the hands of his readers in this matter. The Bill, as a whole, proposes legal restraints upon trade. The question, then, naturally arises are chemists inclined to quietly submit to such restraints? So far, we are not aware that they have taken any action in the matter worth mentioning, though the Pharmaceutical Council would doubtless be glad to receive general expressions of opinion on this point, as on all other matters affecting pharmacy, and the columns of the Journal are open week after week for similar expressions of opinion. If, out of the fifteen thousand registered chemists in Great Britain, not half a dozen trouble their heads about a matter of vital importance to the craft, it can hardly be wondered at if they find apparent lukewarmness manifested on the part of those who are only too anxious to be instructed regarding the wishes of the whole body. But would it not be well for "Early Closing" and others to act upon the view expressed by Mr. HAMPSON and do something in this matter for themselves before they condemn others for assumed inaction?

THE RETIREMENT OF MR. SCHACHT.

THE announcement made at the Council meeting on Wednesday will undoubtedly be received with profound regret and, as an event of more than ordinary importance, Mr. SCHACHT'S retirement from office also calls for brief mention of the fact being placed on record in this place. As a student in the Society's School during its earliest days, as one of the Society's first graduates, and as having for many years held important official positions, Mr. SCHACHT occupies an almost unique position as a bond of personal connection between the present and the past. Without disparagement of his colleagues, it may be said that he has been the most zealous promoter of the educational principle by which the Pharmaceutical Society has acquired its present position. His whole career has furnished eloquent testimony to the soundness of that principle and it may with confidence be predicted that when, in time, nothing shall remain of the past but history, the name of GEORGE FREDERICK SCHACHT will still continue to stand out prominently as one of its most distinguished landmarks.

ANNOTATIONS.

THE ANNUAL DINNER.—As briefly announced last week, the preliminary arrangements in connection with the annual dinner of the members of the Pharmaceutical Society and their friends will be discussed at a meeting to be held at 17, Bloomsbury Square, W.C., on Wednesday next, March 11. Former stewards and others interested in the success of the annual gathering are invited to support the President, Mr. Michael Carteighe, who will take the chair on this occasion at 11.30 a.m. precisely.

KINNINMONT PRIZE, 1896.—Intending competitors for this prize are reminded that the examination will be held in May or June, and that their names should be sent to the Secretary, Mr. W. L. Currie, Dowanhill, Glasgow, before the end of April. All information in connection with the prize will be sent by him on application.

SEEING THE INVISIBLE.—By the use of a similar arrangement to that recently described by Professor Salvioni, of Perugia, Mr. A. A. C. Swinton has succeeded in rendering visible coins inside a closed leather purse, and metal instruments in a wood and leather case, besides being enabled to see a coin through a piece of wood half an inch thick or a sheet of aluminium. A tube of opaque pasteboard was employed, with a simple aperture at one end, to which the eye was applied. The other end was provided with an opaque diaphragm of double black paper, upon the inner side of which was laid a piece of blotting paper impregnated with barium platino-cyanide in a crystalline state. On holding the purse or other object against this diaphragm, and directing the rays from a Crookes' tube upon it, a shadow of the coins, etc., was cast upon the platino-cyanide paper, which fluoresced brightly under the stimulus of the rays, and so rendered visible the form of the metallic object. Non-metallic objects were less clearly seen, their greater transparency to the Röntgen rays causing the images to be more faint.

"PHARMACEUTICAL EDUCATION IN A COUNTRY TOWN."—Considerable interest was manifested in the article by Mr. George Vogt with the above title, published in the *Pharmaceutical Journal* for September 14 last. The writer showed that, with satisfactory local arrangements, it is quite possible for chemists' apprentices to prepare themselves for the qualifying examination during the period of pupilage without the necessity of attending a special school. It was pointed out, too, that "the knowledge gained by this steady process during the apprenticeship contrasts vividly in its solidity against the flimsiness of the six months' education or cram." Pleasing testimony of this fact, and at the same time a clue to the reason of the success attained, is now afforded by the report of the inspector under the Department of Science and Art, who, speaking of the chemistry class conducted by Mr. Vogt at the Kendal Science and Art School, says: "This is one of the best classes, if not the very best, in elementary practical chemistry that I have seen. Simple preparations, devised with a view to encourage observation, and simple quantitative determinations were done by all the students before analysis was attempted. I was assured by the teacher that the analytical work is now done much more thoroughly and with much more interest and ease as a result of the preliminary training gone through. I examined the work of several of the students, and I am of opinion that the instruction is in every way highly satisfactory."

EVENING MEETING IN LONDON.—A meeting of the Pharmaceutical Society will be held at 17, Bloomsbury Square, W.C., on Tuesday next, March 10, at 8 p.m., the President in the chair, and a paper on "The Pharmacy of Phosphorus" will then be read by Mr. William Martindale.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.—This is the youngest of our local associations and, naturally, one of the most active. Great promise has been shown by its work up to the present, and now it is proposed to celebrate the triumphs of the first session by the inevitable dinner. This will be held at the Colonnade Hotel, Birmingham, on Wednesday, March 25, and tickets (3s. each) may be obtained from the honorary secretary, Mr. H. M. Bindloss, 17, Bull Street, Birmingham, or from any other member of the Committee of the Association.

THE ANTITOXIN TREATMENT.—The delay of the report on the antitoxin treatment of diphtheria in the hospitals of the Metropolitan Asylums Board may be unavoidable, observes the editor of *the Practitioner*, but it is none the less unfortunate. The apparent reticence is regarded in certain quarters as implying that the results are the reverse of brilliant. It is noted, too, that whilst Mr. Boulger has stated in the *Contemporary Review* that he has reason to think the special report, when issued, will show a higher rate of mortality for the "antitoxined" patients than for those not so treated, so far his statement has not elicited any contradiction.

HUXLEY FROM A DISCIPLE'S POINT OF VIEW.—In the current issue of *Natural Science*, Professor T. J. Parker, F.R.S., of Dunedin, N.Z., points out that it is obviously upon Huxley's technical and non-popular writings, and upon the character of his teaching, that his reputation as a man of science must stand or fall. He considers that, judged by Huxley's original contributions to science, there can be no doubt that the late professor's performance falls far short of his capabilities, and that there is hardly a man of first-class ability among his contemporaries who has not produced more. The names of Leuckart, Koelliker, Haeckel, and Gegenbaur are mentioned in this connection as those of contemporary professional zoologists who have left deeper marks upon zoology than Huxley, and looking at the matter from rather a narrow and professional standpoint, the writer is inclined to think that modern biology owes a larger debt to Huxley the teacher than to Huxley the investigator. "His lectures were like his writings, luminously clear, without the faintest disposition to descend to the level of his audience; eloquent, but with no trace of the empty rhetoric which so often does duty for that quality; full of a high seriousness, but with no suspicion of pedantry; lightened by occasional epigrams or flashes of caustic humour, but with none of the small jocularities in which it is such a temptation to a lecturer to indulge." Huxley's iconoclastic tendencies peeped out in his lectures, the mitral valve of the heart being explained by him as deriving its name from a supposed resemblance to a bishop's mitre. "You know the sort of thing I mean—a sort of cross between a fool's cap and a crown." Likewise, he observed that when he was a student, he always remembered which side the mitral valve was on by saying to himself "a bishop's never in the right." In] conclusion, Dr. Parker states that he has never ceased to be impressed with the manliness and sincerity of Huxley's character, his complete honesty of purpose, his high moral standard, his scorn of everything mean or shifty, his firm determination to speak what he held to be truth at whatever cost of popularity.

CYLINDERS FOR COMPRESSED GASES.—After the explosion at Fenchurch Street Station, Mr. Asquith appointed a Departmental Committee of inquiry into the causes of such explosions, and the precautions necessary to ensure safety in dealing with cylinders of compressed gas. The Committee, which consisted of Professors Unwin, Boys, and Dixon, with Mr. Dupré and the Rev. T. J. Smith (Lecturer on Mechanics, Oxford), has just issued its report and recommendations. A general official inspection of all factories manufacturing compressed or liquefied gases is recommended as being desirable, and it is suggested that such inspection might be conducted under the Factory Department of the Home Office, or even by a department of the Board of Trade.

RECOMMENDATIONS REGARDING GAS CYLINDERS.—For cylinders intended to contain oxygen, hydrogen, or coal-gas, the greatest working pressure recommended by the Committee is 120 atmospheres, or 1800 lbs. per square inch, the cylinders to be permanently marked with a rotation number, a manufacturer's or owner's mark, an annealing mark with date, and a test mark with date. Testing is recommended to be repeated every two years, and annealing at least every four years, a record being kept of all tests. Hydrogen and coal-gas cylinders should have left-handed threads, and be painted red, whilst a minimum weight should be fixed for each size of cylinder in accordance with its required thickness. The greatest working pressure recommended for cylinders for carbonic acid is also 120 atmospheres, and it is stated that no cylinder ought to contain more than $\frac{3}{4}$ lb. of carbonic acid per pound of water capacity, if for this country, or $\frac{2}{3}$ lb. if for the tropics. A notice ought to be affixed to the cylinder stating that it contains carbonic acid and should be kept cool, and not exposed to the sun. Ammonia cylinders are recommended to have a working pressure not exceeding 1000 lbs. per square inch, and they should not contain more than $\frac{1}{2}$ lb. of ammonia per pound of water capacity, whilst a similar notice should be affixed to that recommended for carbonic acid cylinders. No oil or similar lubricant should be used for cylinder valves, pressure gauges, regulators, or other fittings; pressure gauges should have a check to prevent a sudden inrush of gas, and those for hydrogen and coal-gas should have left-handed screws and be painted red. Several other recommendations are made with regard to minor details, and it is stated that, subject to a reasonable guarantee that all the specified conditions are complied with, the Committee will be prepared to recommend that cylinders should be distributed by road or rail unpacked.

"REQUIREMENTS" REGISTRY.—With the object of affording Fellows of the Imperial Institute and the general public resident in the United Kingdom an opportunity of making known special "wants" or "needs" in the British Colonies, India, and foreign countries, space is to be regularly devoted in the *Imperial Institute Journal* to approved notices in a column reserved for that purpose. Announcements are not to exceed twenty-five words in length, and advertisers may have their replies addressed to them direct, or care of the Imperial Institute, London, S. W., under a distinctive number and initials.

FESTIVITIES AT BIARRITZ.—On Shrove Tuesday evening the Central Hotel, Biarritz, was brilliantly illuminated and decorated with flowers, the occasion being a *soirée* given by the employés of the English pharmacists of the town. More than 150 invitations were accepted, and dancing to the strains of a fine orchestra continued until early morning, supper being served about one o'clock at small detached tables. The singing of the English national anthem brought the proceedings to a close, general satisfaction being expressed at the manner in which the affair had been organised.

PROCEEDINGS OF SOCIETIES.

Chemists' Assistants' Association.—At the meeting held on the 27th ult., when the President (Mr. E. W. Hill) occupied the chair, Mr. R. H. Jones read a paper entitled "The Digestive Ferments of the Pancreas."

After a brief description of the pancreas itself, the processes involved in the digestion of food after leaving the stomach were described. The chyme, as this partially digested food is called, on entering the small intestine, excites the pouring out of the alkaline secretions of the pancreas, which neutralise the acidity previously acquired from contact with the gastric juice. These secretions are four in number, namely, the diastatic, proteolytic, fat-splitting, and milk-curdling enzymes. The first of these, to which the name amylopsin is applied, appears to have been first studied by Bouchardat and Sandras in 1845, but attempts to separate the ferment in a state of perfect freedom from the other enzymes have so far proved unsuccessful, although Wittich claims to be able to prepare a solution free from the proteolytic enzyme by dehydrating the divided pancreas with boiling alcohol, and then macerating in glycerin. The fact that a solution can be thus obtained far more rich in one particular enzyme than the other points to the independence of the two ferments, as does the fact that the richness, absolute and relative, differs in different animals, being ten times more active in the pig than the sheep. Although zymogens of pepsin and trypsin have been obtained, conclusive proof is yet required of the existence of a zymogen of amylopsin, but it is considered probable that one does exist. The diastatic action of this enzyme is almost identical with that of the enzyme of the saliva, the greater portion of the final product of digestion being maltose, although some small amount is transformed into dextrose in contradistinction to malt diastase, the final product of which is entirely maltose. It may be noted that a prolonged digestion of starch with salivary diastase is said to yield a similar result to amylopsin, a small proportion of dextrin being formed. The latter enzyme is capable of hydrolysing dry starch, whilst it has also been observed that the most favourable temperature for digestion is between 30° to 45° C., which is quite the reverse of malt diastase, which acts most favourably up to 60° C.

The proteolytic enzyme of the pancreas, called trypsin, was discovered in 1836, but it was left for Heidenham to show that this body does not exist in the pancreas ready formed (except in traces), but is formed from the corresponding zymogen by the action of acids or alkalis. It is said to be insoluble in pure glycerin, whilst an aqueous solution can be maintained at 40° C. for a long period without decomposition, but when boiled yields 20 per cent. of albumin and 80 per cent. of peptone. Alkalis up to 1 per cent. aid digestion, whilst over 0.5 per cent. acidity has an inhibitory effect. According to Roberts, the activity of trypsin increases up to 60° C., but Mr. Jones' experiments point to the conclusion that above 54° C. the activity decreases.

The existence of a fat decomposing enzyme in the pancreas was first indicated by Eberle in 1837, but although it seems likely that such a ferment really does exist, from the fact that activity is affected by temperature, some well-known workers, amongst them Roberts, have expressed doubts upon the subject. However this may be, there is no doubt but that the pancreatic juice has a most important part to play in regard to the assimilation of fat, this fact being clearly proved by cases in which the pancreas has been removed from animals, when it was noted that no absorption whatever of fat took place.

Mr. Jones devoted the latter part of his paper to the use of the pancreatic ferments in medicine, the so-called pancreatin, which is a mixture of the enzymes, being taken as a typical representative. The fact that this preparation appears to gain ground but slowly in this country as a medicine seems to be due to the uncertainty which exists as to the destruction of the enzymes when it is taken by the mouth. The author's experience was that several well-known physicians prescribed it regularly, with alkalis and aromatics as well as alone, without any keratin coating, from which it was to be concluded that the good results which apparently accrued were due to its proteolytic property, since the action of the trypsin would not be destroyed so long as the medium did not contain above 0.5 per cent. of acid. On the other hand it should be borne in mind that the action of the pepsin, especially if a large amount of proteid were present at the same time, would probably have a deterrent influence upon the pancreatin. This point has unfortunately never been cleared up, although Schweitzer (*Ph. J.*, August 20, 1887, p. 149) published some results carried on *in vitro*

which are not conclusive. The characters and tests applied to pancreatin in the last edition of the U.S.P. were, in Mr. Jones' experience, not a success. He had never met with a single sample which was odourless or completely soluble in water, although several of American manufacture were guaranteed to be up to or above the standard. For the purpose of carrying out the valuation of pancreatin, he had been accustomed to use the following modification of the U.S.P. test:—The milk and most of the water, with the soda dissolved in it, is raised to a temperature of 52° 5 C., when the pancreatin, previously mixed with the remainder of the water, is added, the whole being maintained at the above temperature. From time to time a measured quantity is added to a measured quantity of acid in a test tube. When no coagulation occurs the time is noted, a comparison being thus established between samples. No sample has been examined complying with the U.S.P. test, which appears to be too stringent. This state of things is probably due to the interpretation put upon the word coagulation, since many would disregard a separation of fine curd and take the operation as finished when bulky coagulation ceases. Mr. Jones suggested that the temperature of 52° 5 C. would be an improvement, as being the most favourable to digestion, that half quantities of water, milk, and pancreatin should be used, and that a fixed quantity should be tested with acid every five minutes in a test tube. When no coagulation was apparent on standing for ten minutes digestion was regarded as complete, since the whole of the casein was converted into peptone, which is not precipitated from its solution by acids. Some idea of the power of starch digestion would also have been an improvement, *e.g.*, "should digest 100 times its weight in 30 minutes." The sample should not give a nauseous taste to milk, and the reference to rancidity applies to this also. The result of an examination of a number of samples by the U.S.P. test are given below:—

1. Took 90 minutes.
2. " 90 "
3. Not done in 4 hours.
4. " " 65 "
5. " " 50 "

Midland Chemists' Assistants' Association.—At the meeting held on Wednesday, February 26, at Exchange Rooms, Birmingham, the President, Mr. T. C. Clarke, occupied the chair, and a paper, entitled "A Botanical Romance," by Mr. A. McDonald Cobban, was, in the unavoidable absence of the author, read by Mr. R. M. Williams.

In the paper the author explained that it was his endeavour to show a few of the romantic instances of the diversities of plant life. He would first take a few instances of the vast, and then give a brief description of the infinitesimal.

Among the mammoths of plant life, he was sure most of his hearers had, in their junior days, made acquaintance with the Ratan cane, and had had its striking peculiarities impressed upon them by their various schoolmasters. Yet this short instrument of torture was only a small portion of a long trailing palm, growing in Continental and Insular India to the length of over 5000 feet, trailing on the ground and ascending trees, never increasing in thickness, and each of its nodes marking where foliage had been. This peculiar lengthening was also noticed in certain seaweeds, the *Nereocystis*, growing on the N.W. shores of America, having an unbranched stem 300 feet long, no thicker than whipcord, and bearing at its summit, growing from a bladder-like enlargement, upwards of fifty forked leaves, each from 30 to 40 feet long.

The *Macrocystis*, another seaweed, exceeded this by rising to the surface of the ocean by many branchings from a depth of as much as 1500 feet, and forming a floating mass of foliage, some hundreds of yards in extent. The Baobab, a native of the tropics, had a trunk sometimes seventy to eighty feet in circumference, yet the height was little more. The branches, which were of great length, drooped to the ground, and at a distance gave the appearance of a green hillock. In Australia one specimen of *Eucalyptus robusta* (measuring two feet from the ground) was 102 feet in circumference. In the district of Calaveras (Upper California), known as "Mammoth Tree Valley," were a group of some ninety trees, not one less than 90 feet in circumference, and a clear stem for from 150 to 200 feet from the ground. One specimen which was blown down had a hollow centre for about 200 feet, large enough for a person to ride through on horseback. After describing many other giant specimens, the paper went on to describe two floral wonders, one, the *Rafflesia arnoldi*, bearing a flower of fungoid texture, 3 feet across,

weighing 14 lbs., and emitting a most offensive odour; the other the *Aristolochia gigas*, which flowered last year at the Sheffield Botanical Gardens. One flower was over 23 inches in diameter, and the bottom edge of the petal was elongated into a tail-like appendage some 31 inches longer.

The author then went on to consider the other side of the picture, the minute organisms. Until recent years it was the subject of much controversy as to whether certain of the flowerless plants, particularly the natural order Diatomaceæ, with its sub-orders Diatomæ and Desmidiæ, were really plants or not. It was now conceded that these minute inferior organisms were plants, and were found to exist both in fresh and salt water all over the world, presenting a diversity of species as well as of colour and marking. They consist of a glassy shell of a silicious nature, enclosing a soft coloured substance of a golden or brown hue, called endochrome. Henfrey mentions this peculiarity of the Diatomaceæ, the existence of a silicious deposit in their cell walls, which remains as a skeleton after the plant decayed. It has been stated by Dr. Barclay Montgomery that the bed of the ocean was made up of these bodies. The town of Richmond, U.S.A., has been built of a stratum of these bodies, 20 feet in thickness. These minute organisms form the principal food of the minor aquatic animals. The stomachs of shrimps have been found filled with them.

The members desired that a hearty vote of thanks be conveyed to Mr. Cobban for the interesting paper; after the reading of which Mr. F. Casson demonstrated and explained a quick method for the detection and estimation of lead in tartaric acid. The analyses of forty-two samples were shown, which varied from .0016 to .0065 per cent. of lead, with an average of .0037.

Royal Institution.—On Thursdays, February 20 and 27, Professor Marshall Ward concluded his lectures on "Some Aspects of Modern Botany." He first dealt with the physiology of plants, and showed how plants had been used as subjects for experiments. Pointing out the tendency to select external stimulating influences, and, by varying the conditions under which they were allowed to act, to determine their effect upon the plant, light was taken as an illustration and its influence on the plant under certain conditions was explained. The lecturer then proceeded to speak of the life histories of the lowest plants, pointing out the care with which they had been studied, and describing the methods adopted for separating these minute plant forms from all others with which they might be associated, and for studying their development. After alluding to the effect of the stratum upon which a fungi is cultivated, Professor Ward showed that the hyphæ of a fungus could be induced to enter the tissues of a particular leaf, which would otherwise be left uninjured, by injecting certain substances, as, for instance, sugar into the tissues of that leaf; by cultivating on artificial media, such hyphæ exhibited the power of discriminating between media containing different proportions of sugar. Even the enzyme ferment secreted by the cells appeared to vary with variation of the substance upon which they grew.

The aspect of modern botany to forestry was demonstrated by an account of the life-history of a species of *Polyporus* that attacks pine trees and destroys the timber by penetrating the cell-walls. The means the botanists had proposed for preventing the spread of the disease had been found unsuccessful by foresters; such failures had led to further investigation of the life-history of the fungus, and the discovery of other facts. Professor Ward concluded his lectures by a lucid explanation in a few words of the division of the cell-nucleus and the light such knowledge threw upon the facts of heredity.

Bristol Pharmaceutical Association.—The members of this Association held a meeting to discuss the recent developments of company pharmacy on Wednesday evening, February 26, Mr. Allen presiding. All registered chemists in the district, including Bath, Clevedon, and Weston-super-Mare, were invited, and a large and representative meeting assembled. A discussion took place on the question of company pharmacy, and the efforts that were being made by the Pharmaceutical Society to amend the new Bill dealing with limited companies, and on the motion of Mr. Plumley a resolution was passed pledging the meeting to support the Pharmaceutical Council in any action it might take towards amending the Bill. The resolution, which was seconded by Mr. Hart (Cleve-

don), supported by Messrs. Isaac, Young, Keen, and others, and carried unanimously, was in the following terms: "That this meeting of registered chemists pledges itself to support the Council of the Pharmaceutical Society in its efforts to amend the 'Companies Act Amendment Bill,' which it is intended to introduce into Parliament during the present session." Mr. Glyn-Jones, Secretary of the Proprietary Articles Trade Association, and Mr. G. R. Barclay, of the firm of Barclay and Sons, Limited, Farringdon Street, and Mr. Norris, of the Condal Water Company, afterwards addressed the meeting on the anti-cutting movement and the advantages to be derived from supporting the Association named with respect thereto. Co-operation was strongly advocated, and Mr. Glyn-Jones argued that as retailers their goodwill was of infinite value to proprietors, and that if the latter ensured fair profits, the interests of the retailer lay in the direction of willingly distributing their articles; that if the articles were allowed to be sold without profit they must expect retail chemists to use their skill in pushing articles the sale of which would help to pay their expenses. A discussion followed, and a resolution was unanimously passed pledging the meeting to support the Proprietary Articles Trade Association. The Council of the Bristol Pharmaceutical Association was also asked to consider the advisability of co-operating with the London Association in the matter. At the close of the meeting a vote of thanks was passed to the representatives of the Trade Association.

ENGLISH NEWS.

THE SALE OF CHLORODYNE.—At Darwen, on Monday, February 24, an inquest was held on the body of Florence Ainsworth, aged one year and eleven months. It appeared from the evidence that deceased was recovering from measles, and had been given some chlorodyne, from the effects of which she died. A Mr. Grime, described as a chemist, but not registered as a chemist and druggist, said his traveller sold the chlorodyne wholesale to a Mrs. Leach, who gave some of it to the mother of the deceased child. He made it a rule when selling chlorodyne to caution people, and put red labels on the bottles. Mrs. Leach, however, deposed that there was not any red label on the bottle. The jury returned a verdict of "death from narcotic poisoning," and exonerated Mr. Grime from any responsibility in the matter.

LORD RAYLEIGH ON LIGHT.—In the second of his course of lectures at the Royal Institution on Saturday afternoon last, Lord Rayleigh made further interesting experiments to illustrate the qualities of light. In the first instance, he went back to the principle by which the colours of the spectrum may be cut away—red and orange by sulphate of copper, and blue by bichromate of potash. Having also shown how yellow might be produced by mixing, he went on to say that if they considered the action of a single coloured body upon light, the question might arise, How were they to define with accuracy the colour of any given body? If they began with that body in extremely thin layers or in an extremely diluted state, they would begin with a light that differed only a little from white. As they increased the thickness of the layer, however, the colour would deepen. If they began with a piece of blue glass and then made that glass thicker and thicker, they would find at last that it turned to an extremely deep red. The glass apparently changed colour according to the thickness that the light had to penetrate. He illustrated this with a liquid of a light green colour, which, on being gradually thickened became red. Which, he asked, was the colour of the liquid? Red, because red was the part of the spectrum to which the liquid was most transparent, and therefore asserted itself most when the liquid was increased. In a brief allusion to the effect of light in photography, he said the theory that blue and violet rays were exclusively or chiefly photographic rays was an error. He showed, however, that on photographic paper blue had a much greater effect than any other colour. He had spoken in his previous lecture of the law of refraction and its formulation as the law of sines by Snell and Descartes. He now remarked that if they took water and caused light to penetrate it obliquely, they would find the ray bent or refracted at the point where it entered the water. If they took the sines of the angles of incidence and refraction, then the ratio was called the refractive index of the substance. What did that mean from the point of view of the wave theory? The interpretation was that light moved less quickly in water than in air, so that a wave of light, if it met water, was retarded. The effect of that might easily

be traced in what was usually considered the simplest case—where light passed from a large body of air to a large body of water without a break. But they were most concerned with refraction when light went into water or glass and came out again; and the interpretation from the point of view of the wave theory was somewhat easier in that case. Lord Rayleigh gave an illustration of this by a prism of small angle. The wave of light was bent on passing through the prism, and always away from the thin end. The effect was much the same with a lens, which, thicker in the middle than at the edges, turned the light inwards till it met at the focus. Why? Because the part of the wave of light which passed through the thick part of the lens was retarded more than that which passed through the thin ends, and of course they were enabled to calculate the focal length of a lens. Lord Rayleigh then went on to consider another effect of the various component rays of the spectrum—the production of heat. All the rays of the spectrum produced heat in different degrees. By an interesting experiment with the spectrum and thermal pile, he showed that the heat effect of the violet ray was least, green coming next, then red, the region of the ultra-red being decidedly the most powerful. This last point had given rise to much speculation, and upon it he gave the views of Young, Sir W. Herschel, Professor Langley, and others. Another matter to which he drew attention was the way in which powdered glass could be mixed with a liquid of the same refractive index as itself so as to have almost the same effect as one continuous body.—*Daily News.*

AN OVERDOSE OF MORPHINE.—Mr. A. C. L. Glubb, County Coroner, held an inquest at the Guildhall, Saltash, Cornwall, on Monday morning, respecting the death of Dr. Richard C. Revell (Mayor of Saltash), aged 40, of Alexandra House, who died last Sunday. It was stated in evidence that deceased was in the habit of taking sleeping draughts, and on a previous occasion he had taken too much morphine. Dr. Robert Thornton Meadows said deceased had died through an overdose of morphine, and a verdict of death from an overdose of morphine, taken by misadventure, was returned by the jury.

ACCIDENT WITH VITRIOL IN A CHEMIST'S SHOP.—A boy named William Stanmore, aged 13, an errand boy in the employ of Mr. W. Mingot Tucker, chemist, of Fore Street, Knightsbridge, had a narrow escape of being seriously injured on Saturday last, February 29. He was in the act of carrying a half-gallon bottle of oil of vitriol from the shop to the stores at the back, when he walked, while looking backwards, against a wall. The bottle was smashed, and a portion of the contents went over the boy. His cries brought Mrs. Cove, a neighbour, and the boy's employer to his aid, and they put the poor lad under a pump which was close by, and so stopped the progress of the burning fluid. Meanwhile, Dr. W. H. Webb was sent for, and, on examination, it was found that both the lad's eyes were badly burnt, and both wrists scorched. The wounds were dressed, and the lad was put to bed, and he is now making favourable progress towards recovery. Mr. Tucker himself burnt his wrists rather badly while in the act of assisting the boy.

WHAT IS WHITE WAX.—One of the anomalies of the law was beautifully illustrated the other day when a St. Pancras and Marylebone chemist was fined £2 for selling white wax, stated to be adulterated to the extent of 38 per cent. with paraffin. Although it was shown that the article was only sold for laundry and artificial flower-making purposes, and not at all for pharmaceutical use, the defendant was fined as stated. He had on his premises pure beeswax, which was sold to the general public when asked for. Both kinds were labelled "white wax." This seemed to have been the gravamen of the offence. But how were they to be otherwise described? Would you have a man describe an article which is white as black? It was admitted by the prosecution that the same article sold by Mr. Jefferson Dodd (the defendant) could be sold in an ordinary oil-shop without risk of prosecution. Here is a gentleman who has passed the examinations of the Pharmaceutical Society, who is experienced in drugs and is possessed of a liberal education, subjected to the indignity of a fine, while a man with the knowledge of an opossum is at liberty to sell the same article (at perhaps a higher price) with impunity.—*St. Pancras Guardian.*

RESEARCHES AT LOW TEMPERATURES.—It was not to be wondered at that Professor Dewar would sit calmly down beneath the storm of criticism regarding the priority of his researches on low temperature. In a recent paper read before the Chemical

Society, he reviews all the forms of apparatus which have been used since Pictet liquefied oxygen in 1878, and places the originality of his own modification in a strong light. He refers to the fantastic claim put forward by Professor Olszewski, of Cracow, that because he used in 1890 a steel tube combined with a stopcock to draw off liquid oxygen, he had taught the world, to use his own language, "the method of getting large quantities of liquid gases." But when, in addition, Olszewski alleges, four years after the event, that the experiments made at the Royal Institution since 1891 are chiefly borrowed from Cracow, and that he is entitled to the credit of all low temperature research subsequent to 1891, because of his steel tube and stopcock invention, one can only wonder at the meagre additions to knowledge that in our time are unhesitatingly brought forward as original, and more especially that scientific men could be got to give them any currency in this country. Such persons should read the late Professor Wroblewski's pamphlet entitled 'Comment l'air a été liquéfié' (Paris: Libraire du Luxembourg, 1885), and make themselves generally acquainted with his work before coming to hasty conclusions on claims of priority brought forward by the Professor of Chemistry at Cracow. In the discussion which followed, Lord Playfair, Professor Armstrong, and others paid well-deserved homage to Professor Dewar on account of his magnificent researches on the liquefaction of gases.—*Electrical Review*.

AMMONIA FOR WINE.—A singular accident occurred on February 27, at Bolton-le-Sands, near Lancaster. James Higginson, 77 years of age, was about to leave home for work, after having taken his wife a cup of tea upstairs, when, at the latter's suggestion, he went to the cupboard to get a glass of wine, as the morning was raw and cold. He got hold by mistake of a bottle containing liquid ammonia, and did not find out his error until he had drunk a glassful. The bottles were very much alike, but the one containing ammonia had a label on, and was marked "poison." An emetic was given to the patient, a doctor was sent for, and ordered plenty of oil to be given. This was done, but the old man died three hours after the occurrence.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday, the 2nd inst., Sir James Crichton-Browne presiding. The following were elected members:—Mr. H. J. Allcroft, Mr. R. L. Andrews, Dr. Ernest Clarke, F.R.C.S., Mr. Mayo Collier, F.R.C.S., Mr. H. E. Fry, Mrs. Francis Gaskell, Mr. E. Gimmingham, Mr. A. Glegg, Sir Cameron Gull, Bart., M.P., Miss Catherine Imray, Mr. C. W. Keighley, Dr. Edward Law, M.R.C.S., Mr. C. Letts, Mr. M. Micholls, Mr. R. E. Middleton, M. Inst. C.E., Dr. A. Paine, Mr. G. H. Sykes, M. Inst. C.E., and Mr. W. L. Wise, J.P.

SHEFFIELD COLLEGE OF PHARMACY.—On Thursday last, the students of the Sheffield College of Pharmacy, accompanied by one of the principals, had their second botanical outing this term. After taking train to Totley, they walked across the moors, passing over Totley tunnel (the second longest in England) to Fox-House, thence forward to Hathersage (the burial place of Little John, of Robin Hood fame). A substantial tea was had at the Station Hotel. The return journey was made by train after a very enjoyable day.

DEATH OF A WELL-KNOWN "PILL DOCTOR."—Doctor Gilbert, well known throughout the Western Counties as a "pill doctor" and herbalist, died on Monday last in Bridport Workhouse, in his 104th year, after an apoplectic seizure. He was, it is believed, a native of Wincanton and was married at Totnes. He has travelled throughout the south-west of England ever since he was twenty years old, and the distances he covered on foot were remarkable. His uncle was the late Dr. Gilbert, author of 'The History of Cornwall.'

THE DISPENSING OF DRUGS AT EXETER WORKHOUSE.—The Exeter Corporation of the Poor, at their weekly meeting on Tuesday afternoon (March 3), discussed the question of the dispensing of drugs at the city workhouse, on a report being brought up by the Management Committee on the subject. It appears that the present male nurse (Mr. Clarke) has always assisted the medical officer (Dr. J. Woodman) in dispensing the drugs, but Mr. Clarke and his wife (the female nurse) have obtained the appointments of master and matron of the Okehampton Workhouse, and the committee having resolved to recommend the Board to employ only female nurses in future, Dr. Woodman brought forward the matter of dispensing for the committee's consideration. Having discussed

the matter at some length the committee decided to recommend that if the medical officer required assistance in dispensing, the duties should be performed by a person from outside the workhouse and not by nurses. On the recommendation coming up for adoption at the Tuesday meeting of the Board, Mr. H. P. O. Hamlin (the deputy governor) stated that the remuneration of the proposed new dispenser had not yet been fixed, but the question could be easily got over. The committee had partly considered the matter, and they were in a position to name a person who would do the duties at "a very trifling cost." The recommendation was adopted, and the appointment will be made in due course.

SCOTTISH NEWS.

MESSERS. DUNCAN, FLOCKHART, AND COMPANY, of Edinburgh, are opening a wholesale depot for their specialties at 38, Snow Hill, London. Mr. A. Proctor Atkinson, their present city traveller, leaves next week to act as manager.

A DANGEROUS TRAP.—Before Sheriff Henderson at Cupar, on February 25, David Peebles, farmer, Belliston, Carnbee, was charged with leaving the carcass of a sheep, impregnated with strychnine or poison, exposed on Greenhill Farm. A collie was found dead next morning beside the carcass. Peebles pled guilty, stating that he had had much trouble with dogs worrying sheep, but was now sorry for what he had done. The Sheriff said the consequences might have been far-reaching and dangerous. He fined Peebles £3, with an alternative of twenty-one days' imprisonment.

IRISH NEWS.

THE NATIONAL HOSPITAL FOR CONSUMPTION FOR IRELAND, at Newcastle, county Wicklow, is to be opened on the 19th inst.

DR. R. J. MONTGOMERY, F.R.C.S., lately Botany and Materia Medica Examiner to the Pharmaceutical Society, has been unanimously appointed Ophthalmic Surgeon to Drumcondra Hospital, Dublin.

FOREIGN NEWS.

LITHIUM AS BALLAST.—In connection with the researches of M. Moissan it is interesting to note the proposed utilisation of that savant's discoveries by M. Andrée during his projected aerial voyage to the North Pole. Consequent on the publication by M. Moissan of a method for manufacturing by the electric process lithium in large quantities, the idea occurred to M. Andrée that this metal might be utilised as ballast for his aerial machine on account of its light specific gravity and its enormous power of generating hydrogen when in contact with water (1 kilogramme of the metal yielding 1600 litres of the pure gas). M. Berthelot was applied to for his opinion on this matter, and his reply was read before the last meeting of the French Aerial Navigation Society. The eminent scientist, while considering the idea good in theory, considered that the advantage gained by the small weight of the metal would be more than counterbalanced by its bulk and difficulty of manipulation, as a cage to submerge it in water would be necessary when the chemical action was required. Magnesium he thought might be advantageously substituted. Its greater specific gravity obviated the use of a cage and would compensate for the increased weight.

THE PRESERVATION OF SURGICAL DRESSINGS.—The French troops for Madagascar were furnished for the first time with packets of surgical dressings, ordered by the Government to be supplied to each soldier and to be carried by him with his kit. Drs. Baille and Chavigny have tested dressings which have undergone the vicissitudes of the campaign in order to ascertain if any deterioration had taken place. They found only a very small percentage out of the numerous samples examined to be well preserved, the remainder having become completely useless from water, rough usage, etc. Of those well preserved, the wool, bandages, and gauze remained aseptic and still retained some of their antiseptic properties. A curious effect, however, was observed to have taken place in the different dressings, the materials in the centre of the packets retaining a small proportion only of the

corrosive sublimate originally present, whilst the remainder of it was found in the impermeable material in which the dressings were enclosed. The result was to leave the gauze, etc., with insufficient sublimate to be actively antiseptic. The perchloride of mercury had undergone no chemical change, and until the cause of its displacement is known and can be remedied it is proposed to increase the strength of medication.

PHOSPHORUS-FREE MATCHES.—It will be remembered that a Commission was appointed by the French Government to investigate processes for manufacturing matches free from phosphorus. The manipulation of this substance had such deleterious effects on the health of the workpeople engaged in the industry, that legislative action was found necessary. As an outcome, the Commission recommended the products of M. Haebecke and M. Delpy for trial, and consequently the public has been supplied during the last two months with matches prepared according to the process of M. Haebecke. The experiment has not proved entirely successful, several accidents having occurred from sparks flying in the user's face, unopened boxes suddenly exploding, and the matches have also the disadvantage of not readily igniting with slight friction. The method of M. Delpy is said to be very similar to the above, and both are considered objectionable on account of salts of lead entering into their composition. A process has, however, been invented by M. Pouteaux, of Dijon, which is entirely innocuous to workers, and no phosphorus or other poisonous or explosive chemicals are employed. Experiments have been made at the Pantin factory, and the matches proved to be easily made whilst possessing a fragrant instead of a disagreeable smell, due to the acetate of amyl, which, with permanganate of potassium, enters into the composition used. M. Pouteaux has generously made a gift of his discovery to the Government, and a test supply will shortly be issued for sale.

CERIUM CARBIDE.—At the Académie de Sciences, M. Moissan stated that he had obtained carbide of cerium in the crystalline state by heating in the electric furnace oxide of cerium with carbon. Carbide of cerium decomposes water at ordinary temperatures, with production of 75 per cent. acetylene, 20 per cent. methane, and 5 per cent. of other hydrogen carbides. Variation of temperature and the presence of hydrochloric or sulphuric acid affect the proportion of acetylene generated. He has likewise obtained carbide of lithium by means of the electric furnace and by heating the metal in a current of acetylene. Carbon is present in this compound in the proportion of 66 per cent. Carbide of lithium burns in iodine or sulphur vapour, and decomposes water with production of pure acetylene; 1000 grammes yields 387 litres of the gas.

PROCEEDINGS UNDER THE PHARMACY ACT.

CASE UNDER SECTION 17.

At Tenbury Petty Sessions, on Tuesday, February 18, George Turley, of Teme Street, Tenbury, was charged by P.S. Hardwick with keeping an open shop for the retailing of poison, not being a duly qualified pharmaceutical chemist or chemist and druggist, and with selling to one Francis Edwards, a quantity of "strychnine," without labelling the bottle or cover in which it was contained, with the name of the article, the word "poison," and the name and address of the seller.—Francis Edwards, of Broadfields, Little Hereford, farmer, said that on January 13 last he purchased a shilling's worth of strychnine at Mr. Turley's shop. Defendant said he would say he had not sold him any strychnine. He did not see any label on it. Superintendent Long took the bottle from him at the Swan Hotel in the presence of Mr. Hardeman and two other officers.—P.S. Hardwick said he and Superintendent Long visited defendant's shop on the 15th, and asked Turley to produce his poison book, but he replied that he had not one.—Mr. Long said "You sell poison."—Defendant said he did not.—Superintendent Long said, "You sold some to a gentleman a few days ago," and defendant said, "He said I sold it, did he?" On January 20, the witness received the bottle produced.—At this stage the Bench adjourned the case until March 17 next, as there was no evidence to show whether the article sold was a solution of strychnine, water, or any other fluid.

PARLIAMENTARY INTELLIGENCE.

EXPORTS TO JAPAN.—A Blue Book has just been issued giving the supplementary convention between Great Britain and Japan, respecting the duties to be charged on British goods imported into Japan. The convention re-adjusts the *ad valorem* tariff of a Protocol of 1894, and was ratified in November last. The following duties are now enforced:—

Caoutchouc, manufactures of	<i>Ad val.</i> , 10 per cent.
Indigo, dry	12 953 yen per 100 cattiee.
Leather, other than sole leather	<i>Ad val.</i> , 10 per cent.
Mercury or quicksilver	5·048 yen per 100 cattiee.
Paraffin oil	<i>Ad val.</i> , 10 per cent.
Paint in oil	1·304 yen per 100 cattiee.
Salt tre (nitrate of potash)	0·490 yen per 100 cattiee.
Wax, paraffin	0·544 yen per 100 cattiee.

A catty is equal to 600 grammes, and the silver yen is equivalent to about 4s. 3d. English money.

FOOD PRODUCTS ADULTERATION.—Sir W. Walrond's Committee of inquiry into the law relating to adulteration, to which allusion was made last week (Supp., p. liii.), has now been constituted. The members of Committee are:—Capt. J. F. Bagot (C), Kendal; T. B. Bolitho (U), St. Ives, Cornwall; R. K. Causton (L), West Southwark (a Treasury Lord in the late Administration); F. A. Channing (L.), Northampton, E.; E. C. Colston (C.), Thornbury Division of Gloucester; Lewis Fry (U.), Bristol, W. (J. S. Fry and Sons); A. F. Jeffreys (C.), Basingstoke; H. E. Kearley (L.), Devonport (Kearley and Tong); W. Kilbride (N), Galway, N.; G. Lambert (L), South Molton; Sir John Leng (L.), Dundee; P. A. M'Hugh (N.), Leitrim, N.; F. A. Newdigate (C.), Nuneaton; D. N. Nicol (C.), Argyll; Herbert Roberts (L.), Denbighshire, W.; T. W. Russell (U.), Tyrone, S. (Secretary Local Government Board); Sir Mark Stewart (C.), Kirkcubright; J. A. Willox (C.), Everton Division of Liverpool; and R. A. Yerburgh (C.), Chester. It will be seen that very little regard for party has been exercised in the selection of the Committee, and that each division of the United Kingdom is represented. All the members, with the exception of Mr. Fry and Mr. Nicol, have sat in previous Parliaments.

COMPANIES ACTS—WINDING UP.—Sir Seymour King (C.), Hull Central, has moved for the introduction of a Bill to sanction the publication, by official receivers and other persons, of official reports and observations in winding-up proceedings under the Companies Acts. The knowledge that free publication can be given to official discoveries would possibly do something towards raising the standard of commercial morality among limited liability companies.

SHOPS (EARLY CLOSING) BILL.—Amendments to this Bill have multiplied rapidly, and the conviction that a measure of this kind needs very careful handling has become so general in Parliamentary circles that by agreement the order for commitment was on Friday last read and discharged, and the Bill referred to the Standing Committee on Trade.

PETROLEUM.—A Select Committee has been appointed to inquire into the working of the law relating to the keeping, sale, use, and conveyance of petroleum and other inflammable liquids. Doubtless the inquiry will have a special bearing on the question of accidents arising from the use of petroleum lamps, but the terms of reference are broad enough to make the labours of the Committee of the highest interest to those who deal in or use inflammable liquids. The Committee will consist of thirteen members, who will be selected in due course, and power is given to take evidence from experts on the subject under enquiry. It is satisfactory to learn that the interests of chemists in this respect will be carefully safeguarded by the Law and Parliamentary Sub-Committee of the Pharmaceutical Society, which has just been appointed.

PHENOCOLL HYDROCHLORIDE IN PERTUSSIS.—Vargas reports that with phenocoll hydrochloride he has obtained more prompt relief and quicker cure in whooping-cough than with any other remedy. It is given in daily doses of 15 to 30 grains, water or mucilage being the vehicle, and 2½ grains being given at a time, repeated every two hours (*Therapist*, vi., 14).

NOTES AND QUERIES.

[The information given in this column includes both notes of practical interest to pharmacists, and replies to queries which seem to possess sufficient interest to readers generally. Readers requiring working formulæ for special preparations should intimate their wants to the Editor, who will be pleased to assist them to the best of his ability. The word "parts" invariably indicates parts by weight.]

MALTED FOOD FOR INFANTS.

Practice appears to vary considerably with regard to the amount of malt in prepared infants' foods, as little as 5 per cent. being used in some cases. Probably the following formula, or some modification of it, may serve your purpose:—

Baked wheat flour	10 oz.
Ground malt	2 oz.
Sugar of milk.....	4 oz.

There is no necessity to add phosphates. A more palatable food can be prepared by adding desiccated milk, but this, of course, is not essential, as fresh milk is always added before use. Dry all the ingredients before mixing, by spreading on large flat dishes in a moderately cool oven. [Reply to A. Russell.]

PETROLEUM EMULSION.

The following formula is given in the 'Extra Pharmacopœia':—Mix soft paraffin, 5 oz., and powdered acacia, 2½ oz., then add water, 4 oz. Next dissolve sodium and calcium hypophosphites, each 2 drachms, in water, 6 oz., and add to the paraffin, with constant trituration. Finally, make up to 15 oz. by adding water. An alternative formula is as follows: Mix liquid petroleum, 4 oz., with powdered acacia, 2 oz., then add water, 5 oz., all at once. Dissolve sodium and calcium hypophosphites, each 1-2 drachms, in water, 2½ oz., add glycerin, 1 oz., and add to the emulsion, finally making up to 15 fl. oz. with water. A third formula (*vide Era Formulary*) is: Liquid petrolatum, 4 oz.; oil of sweet almonds, 2 oz.; powdered acacia, 1½ oz.; glycerin, 1½ oz.; sodium and calcium hypophosphites, each 128 grains; lime water, enough to make 1 pint. A peculiarity of petroleum emulsions is that they are rendered more permanent by continued stirring. For this purpose a mechanical stirrer is preferable. [Reply to Quæsta.]

BALSAM VARNISH FOR DENTISTRY.

The antiseptic varnish recommended by Dr. Howard consists, according to the *Dental Practitioner*, of Canada balsam heated to drive off its volatile constituents, then dissolved in chloroform, after which mercuric chloride and thymol are added. The varnish is intended to aid in the adaptation of fillings, and to act as an anti-thermal and protective coating.

IMPROVED MOLYBDIC REAGENT.

Meillère employs the following formula for preparing molybdic test reagent, which he finds more stable and more delicate than that usually employed (*Journ. de Pharm.* [6], iii., 61). It can, moreover, be kept raised to a temperature of 100° C. for some time without undergoing decomposition. Solution of ammonium molybdate, 15 per cent., 200 parts; sulphuric acid, 50 per cent. by volume, 20 parts; mix and add pure nitric acid, 30 parts.

INCOMPATIBILITY OF NEW REMEDIES.

Mœrck points out that TRICHLORIDE OF IODINE is decomposed by alcohol and partially by water; the aqueous solution liberates iodine from iodides; ammonia added to it forms the explosive iodide of nitrogen; reducing agents liberate the iodine; and many organic bodies, among others the fatty oils and alcohol, decompose it. HYDROXYLAMINE HYDROCHLORATE is very unstable, and readily forms explosive mixtures; it is a powerful reducing agent; alkalis liberate the base, which is unstable and explosive. FORMALIN is incompatible with ammonia, the alkaline bisulphites, and reduces alkaline metallic solutions, and gelatin becomes insoluble through its action. IODOPHENIN is decomposed by water, liberating iodine. As it readily parts with its iodine, it should not be mixed with any body which has a strong affinity for that metalloid. (*Journ. de Pharm.* [6], ii., 536).

NOTICES TO CORRESPONDENTS.

All Articles, Letters, Notices, and Reports intended for publication in the Journal, Books for Review, and communications respecting Editorial matters generally must be Addressed "Editor, 17, Bloomsbury Square, London," and not in any case to individuals supposed to be connected with the Editorial Staff. Communications for the Current Week's Journal should reach the Office not later than Wednesday, but news can be Received by Telegraph until 4 p.m. on Thursday.

ANY INSTRUCTIONS from Members, Associates, and Students of the Pharmaceutical Society, with reference to the transmission of the Journal, should be sent to the Secretary—Mr. Richard Bremridge,—17, Bloomsbury Square, London.

BUSINESS communications—including advertisements, orders for copies of the JOURNAL, and instructions from Subscribers respecting transmission of same—must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London. Cheques and money orders should be made payable to "Street Brothers."

CORRESPONDENTS who wish notice to be taken of their communications must write in ink, on one side of the paper only, and should authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS for illustrations should be executed twice the desired size; clean, sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

QUERIES addressed to the "Editor" will be replied to in the Journal as early as possible after receipt; answers of sufficient general interest being given under the heading "Notes and Queries." The Editor cannot undertake to reply to queries through the post.

REPRINTS of articles cannot be supplied unless authors communicate with the Editor before publication.

LETTERS.

UNDUE CUTTING IN THE RETAIL TRADE.

Sir,—Unfortunately for us analysis has not yet reached the high standard of perfection which Mr. Ferguson suggests as a remedy for extreme cutting. How would he propose to make an accurate and undisputable determination of, say, a complex organic chemical compound in combination with perhaps half a score of remote difficulties in the way of the vegetable side of materia medica. As long as isomerism and polymerism have to be reckoned with and a host of other difficulties, both microscopical and chemical, in a complicated mixture, analyses, to be of any real value, are impossible. Then what about the consequences of a published mistake?

March 1, 1896.

ANALYST.

Sir,—You published in the *Pharmaceutical Journal* of date February 29 a very interesting letter on the above, by Mr. Ferguson, of Cheapside. It is not my intention at present to criticise his proposals either one way or another, but rather to draw a moral from them. The letter, readers will remember, suggested the formation of a company of chemists, the objects of which should be the analysis of proprietary medicines and publication of the results. This scheme is, to my mind, one more illustration of the antagonism which cutting has aroused amongst retailers against proprietaries, the owners of which allow them to be cut. It is an additional evidence that retailers are ripe for a revolution of some sort. Fifteen or twenty years ago, when a living profit was obtainable, such a scheme would scarcely have been dreamed of, far less published. Now, I do not know if Mr. Ferguson is a worker or only a talker, but I am bound to say that if his powers of initiation and organisation are equal to his ingenuity, and he makes an attempt to float his company, he will meet with considerable support from the more exasperated members of the retail drug trade. In view of such a possibility, I wish to ask proprietors if it would not be good policy on their part to get ahead of Mr. Ferguson. In the matter of catering for retail favour, they have a decided advantage over him in the fact that there is a "goodwill development association" all ready to hand for their immediate use. I refer, of course, to "The Proprietary Articles Trade Association," of 2, Stonecutter Street, London. Whether this big analytical order ever gets executed or not, there remains abundance of reason why advertisers of patent medicines, foods, etc., should try to conciliate the retail trade. Substitution, at once the retailer's life-blood and the proprietor's bane, is more rife than ever, and is now directly fostered by several large houses, which put up neatly packed goods

for the very purpose. If proprietors want a remedy, they have it in their own hands. When they forbid undue cutting and ensure a fair profit, substitution will dwindle and goodwill return. I do not mean that the chemist will cease to advertise and push his own specialties; I mean that he will cease to set them up as direct barriers between the proprietor and the public. Therefore I say again, "Join the anti-cutting brotherhood, good sirs, and we will forgive and forget the past." I warrant those who do that they will steal the wind from Ferguson's sails, and that their own "sales" will be fuller thereby.

69, Loughborough Road, Brixton, S.W. WILLIAM JOHNSTON.
March 2, 1896.

EARLY CLOSING FOR CHEMISTS.

Sir,—I was not a little surprised when I read your remarks in the column headed "Parliamentary Intelligence" anent the "Shops Early Closing Bill," and am very much disappointed to find you throwing cold water on what would be a real *magnum bonum* for the majority of chemists. I have turned up the indices of the Journal for the last two vols., and can neither find a word of praise nor of support for a measure which so materially affects the interests of chemists. You need not be surprised at so few becoming connected with the Society when it does so little for the sake of the trade. True you say it has petitioned in favour of certain measures enumerated on page 172; it has also consistently promoted the higher education of chemists, but how can that be accomplished except by having shorter hours, and therefore time for study? I must say, further, you can have the interests of the trade very little at heart when you find "it difficult to see why chemists should not enjoy the same degree of freedom from the pains and penalties of the Bill as that accorded to refreshment house keepers, publicans, tobacconists, and newsagents." Well, after this, I can only think of your higher education fads as a delusion, for to class an intelligent body of men like chemists along with publicans, etc., passes my comprehension. Why should chemists be exempted from the provisions of the Bill, and where is the freedom they would have in being exempted, and what time is there for freedom after nine, and, in some cases, nearly ten o'clock at night? Freedom you call by the wrong name, I would call it slavery. Here am I engaged every night until after nine, Saturdays until eleven, all because others keep open, besides Sunday duty. Where is the time for freedom or recreation even after hours like these, either here or anywhere else? I sincerely trust that the saving clause for chemists will not be deleted, but will pass in spite of the protest (*sic*) of the *Pharmaceutical Journal*. In conclusion, I will earnestly consider whether or not I ought to renew my subscription to the Society for the current year.

Dundee, March 3, 1896.

EARLY CLOSING.

"CASH CHEMISTS."

Sir,—Mr. Leech's query and Mr. Jackson's reply to the question whether or not limited liability companies can legally use the title of "chemists" opens up an interesting and important subject. Lord Selborne and Lord Blackburn decided in the famous case of *Pharmaceutical Society v. London and Provincial Supply Association*, that limited liability companies could sell poisons, provided they did so by means of a qualified assistant, and as the use of titles and the selling of poisons are referred to in the same sections of the Act it might appear that this decision covered both points. There is, however, a difference between the two cases, and this difference might, in my view, influence the decision of the matter should a case be brought forward. Had Lord Selborne and Lord Blackburn decided that the limited companies were the sellers and could sell poisons then it appears to me such companies could use the titles of chemists, druggists, etc. The decision, however, was to the effect that the qualified assistant was *de facto* the seller, and the question arises, Are limited liability companies *de facto* chemists? Surely not. In the one case the public are so far protected by the poison being sold by the hands of a qualified chemist. In the other case the public are misled and deceived when "Smith, Jones, and Robertson, Limited," use the title of "chemists," when none of them has passed the necessary examinations. If these companies can use the titles of "chemists" or "druggists," what is to hinder them also using those of "pharmaceutical chemists" or "pharmacists"? The evil is spreading, and it seems to me that the sooner a test case is proceeded with to settle the point, the more easily will it be settled in the end.

Edinburgh, February 24, 1896.

CLAUDE F. HENRY.

"CASH CHEMISTS."

Sir,—I think the above title requires further attention than it has yet received, so far as limited companies are concerned. Although the House of Lords ruled that a Corporation could carry on the business of chemists without qualification, providing they did so under qualified management, these limited companies can scarcely be acting legally when they use the word chemist in connection with any of their establishments which are not under qualified management. To my mind, the decision of the Lords was never intended to apply to companies composed of seven unqualified individuals only (in many cases one-man companies), but to such concerns as the Civil Service or Army and Navy Stores, where perhaps a thousand or more shareholders are trading with themselves, and where the drug department is under the management of a chemist whose name appears on all the labels sent out from that department. If this is the correct reading of the law there should be plenty of scope for action, the sooner the better. Whilst dealing with this subject of company trading, there is one little matter connected with it which I have never seen or heard satisfactorily answered; and that is the labelling of poisons. As a rule, the labels of these proprietors of many shops bear only the name of the company, followed by a list of towns in which they have establishments. Whilst an individual chemist is compelled to exhibit his name and address on the label attached to each article sold. How is it these companies are not compelled to do the same? For the sake of argument we will suppose a case of poisoning occurs in some remote village, and the article employed bears the name of a Drug Company, with shops in perhaps twenty different towns, without any address except perhaps the names of half a dozen of the principal towns, etc.; how are the authorities going to trace the sale? This may seem only a trifling matter, but the trade throughout is hampered by trifles, and I do not see why these companies should go clear of them. The remarks of Mr. Jackson, of Blackpool, in a recent issue, as to our "newly-fledged" members adopting the title of "cash chemist" are uncalled for. When we are fully protected, as are the professions he mentions, we will then avoid these "distasteful" titles.

Hull, February 25, 1896.

A. RICHARDSON.

ANSWERS.

"QUESTA."—The date of publication is very uncertain. A sufficient interval is always allowed to elapse before it is used in the connection you mention. See answer to other question under "Notes and Queries."

T. W. WHITE.—We fail to recall the statement you refer to. The salt you require is the acid potassium metantimonate, $K_2H_2Sb_2O_7 \cdot 6H_2O$.

ERRATA.

BENEVOLENT FUND.—The Secretary of the Pharmaceutical Society requests us to note that in the list of subscribers to the Benevolent Fund, published as a special supplement to last week's issue of the *Pharmaceutical Journal*, the following names were omitted:—Halifax, Brierley, J. B., 2s. 6d.; London, Dunn, E. B., 5s.; Winchcombe, R.S.O., Hall, A. L., 10s.; Wolverhampton, Weaver, A. C., 10s. 6d. The following amendments are also necessary:—Page xv., Wells, A. J., Great Yarmouth, 10s. 6d. instead of 2s. 6d.; page ii., Watts, J. W., should be under Bristol, not Beaminster.

OBITUARY.

SMITH.—On February 29, Walter Smith, Chemist and Druggist, Glasgow. (Aged 41.)

WARDROPPER.—On February 29, Paul Wardropper, Chemist and Druggist, Cullercoats. (Aged 92.) Mr. Wardropper was a native of Sunderland, and until a short while ago took an active part in business. It is said that he was the oldest chemist and druggist in the United Kingdom. The veteran pharmacist was of the most kindly sort, and when a circular calling the trade together reached him, never failed to express his regret that he could not meet his fellow pharmacist. He has been able to say "I am too old to be out of my home at night" for a wondrously long time.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Bennett, Bindloss, Brown, Clague, Clarke, Grierson, Harrison, Henry, Hill, Johnston, Keen, Knight, Morris, Parkinson, Polley, Reynolds, Russell, Turner, Walker, Wretts.

THE PHARMACY OF PHOSPHORUS.

BY W. MARTINDALE, F.C.S.

Phosphorus and its compounds have been used for about a century and a half as medicinal agents. Interesting papers have lately appeared* on the history of the use of phosphorus in medicine and pharmacy, but my intention is to refer more particularly to its present use.

The compounds of the oxides of phosphorus—phosphates, pyrophosphates, phosphites, and hypophosphites, and also those of its chemical ally arsenic, which it somewhat resembles in its therapeutic action in skin and other diseases, and of which, commercially, it is apt to contain traces of impurity—are relatively not so poisonous as the elements in their free state; in fact, the higher oxides of both are comparatively non-poisonous as compared with the pure metalloids.

Phosphorus exists in two, or probably three, allotropic conditions, but in pharmacy we only use phosphorus in its ordinary condition as stick or vitreous phosphorus. The red or amorphous phosphorus is rarely prescribed, and is supposed to be, if pure, physiologically inert.

The salts of the oxygen compounds are mostly soluble, there is no difficulty in dispensing them in aqueous solution, and on the whole they are comparatively palatable, but the administration of phosphorus in a free state, or in solution in a free state rather than chemically combined, presents pharmaceutical difficulties, as it is an acrid poison and causes gastric derangement with unpleasant eructations, which render its agreeable administration in large doses hardly possible.

Phosphorus does not melt below 111° F., and unless it be administered in the state of solution, or in very fine sub-division by emulsion or otherwise, it is doubtful whether it is completely assimilated or produces all its therapeutic effect. It would be preferable to administer it in solution if the solvent were otherwise suitable. At the ordinary temperature it requires about 320 volumes of absolute alcohol, 200 volumes of absolute ether, 50 volumes of chloroform, 100 of Dutch liquid, and about 100 parts of most fixed oils and fats to dissolve it, but the exact solubilities are difficult to ascertain. Being insoluble in water, it is thrown out of solution when added to this as a vehicle for administration, if the solvent be miscible with water. It is soluble also in, or rather combines with, several essential oils, such as those of turpentine, peppermint, neroli, bergamot, lavender, rosemary, etc. It is also soluble in melted resins, but not unchanged in some. These, therefore, essential oils and many resins would appear to be incompatible with phosphorus, either as excipients or correctives.

My first pharmaceutical experience in working with it was for the use of the lower animals, making phosphorus paste, in fact, for the purpose of destroying rats, mice, and blackbeetles. This was composed of phosphorus, comminuted by shaking it in hot water until cold, and mixed with sugar, lard, and oatmeal. This compound is said to prevent the mal-odour of decomposition.

Since then we have had preparations of it in the free condition made official in the British Pharmacopœia, two formulæ for phosphorated oil and also two for phosphorus pill.

The Unofficial Formulary of the British Pharmaceutical Conference has a compound tincture and an elixir, and the United States Pharmacopœia has an elixir, a pill, and a spirit or tincture. I mention also in the 'Extra Pharmacopœia' the following as being used medicinally:—Æther phosphoratus (French Codex, 1839), perles of phosphorated oil, phosphorated cod-liver oil, a phosphorus pill (special), sebum phosphoratum, and compound pills of this containing iron, quinine, and strychnine or nux vomica.

Some of the before-mentioned are liquid preparations, and on this account, notwithstanding their being active therapeutically, are repugnant to the taste and stomach, and generally considered unpalatable. Others are in a pilular form, or perles, and are apt to be quickly oxidised from the great affinity of phosphorus for oxygen, unless well protected from the air, or, if so protected, the composition or covering may be so perfect that it may withstand the digestive action of the system when it is administered, as was the case with the pill in the 'Additions to the British Pharmacopœia' of 1874 (*Ph. J.* [3], iv., 902).

Phosphorated Oil.—Of the liquid preparations, this, which is official—containing about 1 per cent. of phosphorus dissolved in prepared almond oil, and the dose of which is stated to be 5 to 10 minims (greatly too much)—is exceedingly nauseous, administer it as you will. Dr. Redwood suggested its being emulsified with yolk of egg, liquor potassæ, syrup of tolu, and chloroform water (*Ph. J.* [3], iv., 991), but it is never employed medicinally. It may be used as a toy, exhibiting its peculiar phosphorescence, or for producing evanescent "writing on the wall," but the medical profession and the public refuse it. It appears to be a nearly saturated solution at the ordinary temperature; although as much as 2 per cent. of phosphorus can be dissolved by the aid of heat and the exclusion of air, nearly one-half crystallises out on cooling. It, however, may be conveniently administered in the form of perles or capsules, which are largely used, containing a dose equal to 1/100th, 1/65th, or 1/32nd grain of phosphorus respectively; but, unfortunately, they are irregular both in size and in the amount of contents, still they are well protected from the air.

Phosphorated Cod-Liver Oil contains about 1/100th grain in a drachm. It may be made by adding one volume of the official phosphorated oil to fifty-nine volumes of cod-liver oil. It is unpalatable, and quickly oxidises and coats the sides of the bottle. Still it may be kept reasonably stable in capsules, containing one drachm in each.

Æther Phosphoratus.—This is best prepared by comminuting the phosphorus, 1 part, in warm absolute alcohol, 4; decanting and adding absolute ether 20; then macerating one month, and decanting. It is better to decant it when dispensed, keeping the excess of phosphorus in the bottle; about 1 part in 200 volumes is dissolved. It is an active but an unstable preparation, and has been deleted from the last edition of the French Codex.

Spirit of Phosphorus, U.S.P., contains 0.12 per cent., dissolved in absolute alcohol; it too is unstable. A similar preparation has been recommended here (*Ph. J.* [3], xi., 468), but as it quickly oxidises it is an unsatisfactory preparation.

Compound Tincture of Phosphorus, B.P.C., is prepared by dissolving phosphorus, 1 part, in chloroform, 30 volumes, and adding it to absolute alcohol so as to contain 1 part of phosphorus in 600 volumes. Although it keeps without depositing, it becomes acid, and requires to be freshly prepared. When diluted with four volumes of glycerin, it forms the *Elixir of Phosphorus*, B.P.C., which contains 1/50th grain in a fluid drachm. If freshly prepared this is palatable and well borne by the stomach.

Various other formulæ for liquid preparations of phosphorus have been suggested. The late Mr. John Williams recommended (*Ph. J.* [3], v., 210) a solution of phosphorus in glycerin, to which an equal volume of absolute alcohol was added, containing about 1/30th grain in a fluid drachm. It was a modification of a formula recommended by Mr. Ashburton Thompson (*Ph. J.* [3], iv., 684). It is more difficult to prepare, and even more unstable, than the B.P.C. elixir.

Phosphorus appears to form compounds with albumin, which preserves it from oxidation as well as from phosphorescence when

* *Pharm. Journ.* [4], i., 433, 513.

in solution, and Mr. Urwick has suggested a formula in which albumin, cane and milk sugars, and glycerin, are combined with phosphorus to make a comparatively palatable preparation—liquor phosphori albumatus (*Ph. J.* [3], viii., 253).

The avidity that phosphorus has for oxygen renders it necessary that liquid preparations should be as freshly prepared as possible. They should also be kept from the light in a cool place in perfectly closed bottles. The same remarks in a less degree apply to phosphorus in a pilular form.

Pilula Phosphori.—The official pill is composed of phosphorus incorporated with balsam of tolu and yellow wax under hot water. This is directed to be kept under water, and two parts are to be incorporated with one of curd soap when dispensed. It contains about 1 in 90. The addition of soap has been made, as the previously official pill was, as I showed, completely undigested (*Ph. J.* [3], iv., 920). Still, it has never found favour; the mass becomes hydrated by being kept under water, and the pills of special manufacturers, some of which are beyond reproach, while others are at times insoluble, meet with greater demand.

Messrs. J. Bell and Co. had previously published (*Ph. J.* [2], vii., 615), a formula for phosphorus pills made by dissolving 1 per cent. of phosphorus in melted suet, and coating the pills with gelatine; these were very tedious to prepare. As an improvement, in 1866 I devised a mass, using prepared cacao-butter in place of suet, for the late Dr. Tilbury Fox. This contains 1 per cent. of the drug (*Ph. J.* [3], i., 414), the pills of which I cover with sandarach solution. These masses contain the phosphorus in perfect solution, still for general dispensing they are not altogether satisfactory, as they require an even temperature both to make and to keep them, and to be well excluded from the air and light.

As phosphorus dissolves in less than its own weight of bisulphide of carbon, advantage has been taken of such a solution to mix it with an inert powder or suitable mass, so as to obtain the drug in a finely comminuted condition, perfectly distributed through the mass, on the evaporation of the bisulphide. While traces of it are present in the mass it acts as a preservative and checks phosphorescence or oxidation. Some may object to the use of bisulphide of carbon on account of its disagreeable odour, yet if purified it is not so disagreeable, but has an agreeable chloroform-like taste, and I think it is not so deleterious as has been supposed.

Mr. R. H. Parker suggests the employment of such a solution by diffusing it through liquorice powder, as in the following formula (*Ph. J.* [3], xxv., 197):—

Phosphorus.....	The prescribed quantity for 24 pills.
Bisulphide of carbon	30 minims.
Liquorice root in powder	24 grains.
Glycerin	4 minims.
Tragacanth in powder.....	2 grains.
Syrup	A sufficient quantity.

This formula has the disadvantage of using a large excess of the bisulphide, and the tendency to deflagration of the phosphorus as the latter evaporates. It is true the pills apparently keep well, as after nearly seven years I find they still contain phosphorus in its free condition. Probably some of the bisulphide gets locked up in the interior of the pills, and thus fixes the phosphorus, as they have the aromatic taste of the bisulphide still, and if cut in two are phosphorescent in the dark.

Messrs. Allen and Hanburys also published a formula, in which they employed the phosphorus solution in bisulphide. This mass, I am told, works well on a large scale, but it is not advisable, as I have before mentioned, that phosphorus should be combined with resins, which may interfere with its therapeutic activity. These pills are better adapted for pearl-coating than for covering with varnish

extemporaneously. Pearl-coating covers a multitude of imperfections. The formula is as follows (*Ph. J.* [3], vi., 921):—

Pil. Phosphori cum Sapone.

Phosphorus	2 grains.
Bisulphide of carbon	10 minims, or <i>q.s.</i>
Hard soap in powder,	
Guaiacum resin in powder, of each ..	35 grains.
Glycerin	12 drops.
Liquorice root in powder	12 grains, or <i>q.s.</i>

to make a mass of 100 grains. To be divided into pills of the strength required, and varnished or "coated" in the ordinary way.

Many pharmacists have written on the subject of phosphorus pills, including Messrs. Proctor, A. C. Abraham, Gerrard, Haffenden, Appleby, and Millhouse, most of whom recommend the use of bisulphide of carbon as a first solvent. Many of their formulæ I have tried, but to meet the requirements of an official formula, after numerous tentative experiments, I suggest the following:—

Pilula Phosphori.

Phosphorus.....	10 grains.
Oil of theobroma, cut small	490 grains.
Bisulphide of carbon	200 fluid grains.

Dissolve the phosphorus in the bisulphide of carbon contained in an amber-coloured stoppered phial, add the oil of theobroma, and dissolve by agitation aided by the heat of the hand: then, if necessary, increase the volume to 750 fluid grains by the addition of more bisulphide of carbon. This solution will contain 1 part by weight of phosphorus in 75 fluid parts. If cooled below 59° F. it partially solidifies, but readily liquefies at a slightly higher temperature.

When dispensed, after liquefaction by the warmth of the hand, take of—

Above solution.....	54 fluid grains.
Gum acacia in powder	18 grains.
Syrup, by weight.....	18 grains.

Mix the solution quickly with the acacia, add the syrup, triturate into a uniform mass, and when most of the bisulphide has evaporated, roll it into twenty-four pills.

The mass of which these pills are composed will contain about 1 per cent., and each pill about 1/33rd grain of phosphorus. Pills of other strengths may be prepared by dividing the mass into a proportionate number of pills.

The pills, after a little exposure to allow still more of the bisulphide of carbon to escape, may be coated with an alcoholic solution of sandarach, or other covering; they should be freshly prepared, and kept in a dark place in well-closed amber-coloured bottles.

The quantity of syrup I have suggested is 18 grains; this may be added from a dropping tube after ascertaining the weight of a drop. In practice, I find a large drop weighs 2 grains.

If varnished, the pills should be thoroughly dried before being bottled, else the traces of bisulphide left remaining in them may soften the coating, and cause them to adhere. They keep well if the covering be perfect. They take a pearl coating without much difficulty. They should, of course, be kept cool, and not carried in the waistcoat pocket, or the grease may permeate the coating.

These pills have the advantage over the ordinary cacao-butter pills that they are much more easily made, and are more gradually assimilated; and as they are not so quickly dissolved they are less likely to upset the stomach. More than half of the phosphorus will be in solution in the cacao-butter, the remainder with the cacao-butter solution forms a solid emulsion with the acacia and syrup.

It may be objected that the quantity of bisulphide of carbon recommended is excessive. I tried experiments to lessen this by using an equal quantity of the bisulphide to that of the phosphorus and adding the cacao-butter, melted at 100° F., to this solution contained in a bottle, and shaking well. At first a perfect solution was obtained, but gradually about one-third, apparently, of the

phosphorus separated out in a solid granular condition. I tried even three times this quantity of bisulphide, but still much of the phosphorus separated. As I before said, the solubility of phosphorus, although difficult to ascertain, is only slightly over 1 per cent. in such a fat as cacao-butter. In the pill mass, it is true, it is present to the extent of 2 per cent. of the fat in it, or about 1 per cent. of the whole, but what has separated will be in a very finely comminuted condition. If a small quantity of the bisulphide would have answered, the mass could have been weighed when dispensed; this would have been more convenient. Less, I dare say, may answer the purpose, but my desire is to make a mixed liquid solution containing 1 part of phosphorus in 75 volumes, which on evaporation of the bisulphide will yield 2 per cent. in the cacao-butter, and 1 per cent. in the finished mass. Then again there is the uncertainty of the strength of the cacao-butter and bisulphide solution after having been frequently warmed; still, this can vary but little, as the warmth of the hand, as I have said, is sufficient to liquefy the mixture, and the fat will have a tendency to prevent quick evaporation. Working on a large scale, the rounding of the pills might be difficult, as they want body, and the pearl-coating of them might not be so easily done as of pills containing resin; they might in fact if slightly heated during this process, stick together owing to the melting of the cacao-butter. The use of syrupy glucose to replace the syrup and part of the acacia would give more "body" to the pills, and enable the mass to be better worked in quantity; glucose is much in favour with the large pill-makers, but it is not official, and not easily defined, still it might be used as an excipient.

This mass is best worked at a temperature a little over 60° F.; there might be an objection to their being not easily prepared in warm climates. I find, practically, if coated with sandarach, they soften about 90° F. in water, but are probably much more permanent in the air.

The difficulties in exhibiting phosphorus in pilular form are numerous, and the above is the best I can suggest for the practical retail pharmacist. In this formula he has a solution in which the phosphorus is kept from oxidation, is fairly stable, and can be dispensed into pills in a short time. Furthermore, the excipients acacia and syrup may be lessened to give place to other medicaments that the prescriber wishes to combine with phosphorus.

Sevum Phosphoratum (10 per cent.).—This I have recommended elsewhere for preparing a mass to blend with other medicaments with which the phosphorus may be prescribed. It is prepared by dissolving phosphorus, 1 part, in bisulphide of carbon, 5 parts, adding suet, 9 parts, mixing thoroughly, and allowing the bisulphide to evaporate. It contains the phosphorus in a finely comminuted condition, and if mixed with an equal quantity of compound tragacanth powder, together with the other drug—quinine, reduced iron, or strychnine—adding a few drops of chloroform, the vapour of which prevents phosphorescence or oxidation—it can be readily massed by the addition of mucilage of acacia or syrup. Such pills, if covered with sandarach solution or pearl-coated, will keep a reasonable time, but the suet, like the liquid preparations of phosphorus, and all pills containing phosphorus, are better freshly prepared. This phosphorated suet is unnecessarily strong, and for making compound pills might be replaced by a 4 per cent. oil of theobroma solution produced by bisulphide, similar to the 2 per cent. solution previously recommended for an official pill of phosphorus alone.

I had intended to chemically test the preparations as to their strength, but pressure of other work, and the short time I have had to prepare my paper, have prevented my doing so.

NOTES ON THE PREPARATIONS AND FORMULÆ OF THE BRITISH PHARMACOPŒIA.

SYRUPS.*

The syrups of the Pharmacopœia form a group of preparations of considerable importance both to the medical practitioner and the pharmacist. Whilst several of their number rank amongst the most frequently prescribed of official galenicals, a glance at the indexes of current pharmaceutical literature reveals the fact that many of their formulæ are found more or less imperfect and demand revision. Indeed, the *syrupus ferri iodidi* may be said to divide the honours with *spiritus ætheris nitrosi* in periodically furnishing food for pharmaceutic thought or discussion.

Many of the syrups are extremely prone to undergo decomposition or fermentation. In order, therefore, to avoid the vexatious inconvenience and loss incidental to such changes it is essential, firstly, that the official formulæ be as perfect as possible, and, secondly, that strict attention be paid not only to the methods of preparation indicated, but also to the subsequent storage of the syrups themselves. With a few exceptions the present formulæ are susceptible of improvement either in permanence, elegance, or palatability.

The Pharmacopœia makes no reference to the storage of syrups, although in many cases this point is almost as important as care in manufacture. Generally it may be said that the finished syrup should be allowed to become quite cold, and the specific gravity adjusted, if necessary, before being bottled. The bottles should be quite dry, filled almost to the neck, well corked, and stored in a place not subject to any great variation of temperature. If a syrup be bottled whilst warm, aqueous vapour condenses on the upper interior surface of the vessel, and, trickling down on to the syrup, forms a weak saccharine layer, extremely favourable to fermentative change. A similar result is brought about by the influences of light and heat, as is often noticed in the case of partially filled bottles of syrup kept in exposed positions.

Syrupus.—The most suitable sugar for use in the preparation of "simple syrup" is that known as "granulated pure cane sugar," and not lump sugar, which constitutes the official variety. It should be practically free from glucose by the sulphate of copper test, and should be dissolved at a gentle heat in the distilled water, the latter having been previously well boiled and poured on the sugar whilst warm. Boiling the syrup itself, as is sometimes recommended, is not advisable, unless care be taken to maintain the gravity low by the occasional addition of water during ebullition, otherwise a certain amount of darkening in colour is liable to take place. It is quite exceptional to meet with a commercial sugar which answers to the Pharmacopœia description of "forming a clear bright syrup" by mere solution in water.

Clarification by filtration is at once the simplest and best means of ensuring a brilliant product. The following method works well, even with small quantities:—Add to the warm syrup pulped white filtering paper, with a very little washed French chalk in fine powder. Pour the mixture on to a moistened flannel bag or strainer, returning the first portions which come through until the syrup passes bright. Finally wash the strainer with boiled distilled water to make up the required weight. The contrast between two syrups prepared by the simple admixture of a chemical or other solution (see suggested formula for *syr. ferri phosph.*), in the one case with filtered and in the other with unfiltered simple syrup, is very marked; absolute brilliancy can only be secured by careful filtration. The preparation of syrups by cold percolation is given as an alternative process in the U.S. Pharmacopœia, but

* This article has been in type several weeks, but publication has been deferred through lack of space.—[Ed. *Pharm. Journal*.]

trial in this country has not shown it to possess any advantage over the foregoing.

Syrupus Aurantii.—This syrup is a great favourite with the medical practitioner, being more frequently prescribed than any other official syrup. A more palatable article might be prepared by using tincture of fresh orange peel in the place of the present tincture. This produces a more aromatic and less bitter preparation, somewhat approaching that given in the United States Pharmacopœia, which is made from the rind of the sweet orange. An elegant and finer-flavoured preparation may be made by the following formula:—

Simple syrup 7 fl. ozs., 5 fl. drs.
 Concentrated infusion of orange peel 2 fl. drs.
 Soluble essence of bitter orange 1 fl. dr.

Mix thoroughly.

Concentrated infusions (or "essences") will, it is hoped, find a place in the forthcoming Pharmacopœia.

Syrupus Aurantii Floris.—This formula does not appear to call for any alteration. It might, however, be as well to state under "Aqua flor. aurant." that the kind intended to be used for the syrup is that known commercially as "triple," the present B.P. description being somewhat ambiguous. This syrup is not much in vogue, which is somewhat remarkable, seeing that the "water" is so popular as a medicinal flavouring agent. Perhaps this may be due to the method of preparation, which does not commend itself to the pharmacist or to the prescriber on account of its weakness of flavour.

A distinctly pleasant syrup can be made by dissolving the sugar without heat in the water of triple strength as imported, without dilution:—

R. Aq. flor. aurant. trip. 2 parts.
 Sacchar. alb. 3 "

This will produce a syrup of a similar gravity to that now used, but decidedly stronger in flavour, and since it contains a larger percentage of oil of neroli, of a superior keeping property.

Syrupus Chloral.—This form possesses many good points. It is a simple preparation and accurate; this last feature is a great desideratum in dealing with a more or less potent substance, such as chloral. It lacks one thing, that is, delicacy of flavour, which is of paramount importance with this class of galenicals. The syrup does not cover the nauseous taste, and invariably some flavouring agent is added to mask the pungency. The palatability of this syrup might be increased and the peculiar acrid taste of the chloral hydrate better disguised, either by the substitution of syrup of orange flower for the simple syrup in the formula, or the addition of a flavouring agent, such as tincture of lemon peel. Mr. C. Umney, as far back as 1870, proposed that it should be flavoured with cinnamon, nor is precedence wanting with regard to flavouring this syrup, for the French 'Codex' and the Belgian Pharmacopœia have theirs flavoured with peppermint, also the Dutch Society for Advancement of Pharmacy have one made with oil of curled mint, and in America a flavoured syrup has been advocated (*American Journ. Pharm.*, Sept., 1881). It would not therefore be a very radical innovation if the B.P. syrup were flavoured. This would effectually mask the unpleasant taste, described in the B.P. as a "pungent bitter flavour." The neroli flavour has not that distinctly medicinal taste which is so characteristic of cinnamon, etc.

Syrupus Ferri Iodidi.—Many and varied have been the plans suggested for overcoming the instability of this troublesome member of the group of official syrups, and although the present formula is to a certain extent an improvement on the 1867 one, it has not been quite as successful as was anticipated, and will bear further revision. The chief objections to the B.P. process as it stands are these:—(1) The direction to boil the solution of ferrous

iodide with a portion of the syrup is of questionable utility as a means of preservation, and especially on the large scale, tends to discolour the product; (2) The specific gravity is too high, crystallisation of the sugar taking place sooner or later; (3) loss of iodine results from volatilisation by the heat generated during digestion of the materials in a flask, also as hydriodic acid during the subsequent boiling, and finally as ferrous iodide absorbed by the filter paper. No allowance being made for this loss, the syrup cannot contain the stated amount of FeI_2 , as 4.3 grains per fluid drachm is the exact equivalent of the quantity of iodide produced by the 2 ozs. of iodine in the formula.

A far more permanent and elegant syrup of iodide of iron may be obtained by the use of a small proportion of hypophosphorous acid. Pharmacists holding strictly purist views have severely discountenanced such an addition, but until the minute amount present (about 1/12th per cent. real H_3PO_2) can be shown to have the slightest physiological effect, or to modify in any way whatever the therapeutic action of the syrup, no serious objection can be raised to the authorisation of this process in the Pharmacopœia. Solution of ferrous iodide preserved from oxidation by hypophosphorous acid has been in general use by medical practitioners and pharmacists throughout the country for years past, and there is no evidence to show that the medicinal value of syrup prepared from it is not equal in every respect to that of the official syrup.

The following is suggested as an amendment of the present formula:—

Take of—

Iron (wrought nails) $\frac{1}{2}$ oz.
 Iodine 2 "
 Refined sugar 26 "
 Distilled water 13 fl. oz., or a sufficiency.
 Hypophosphorous acid 40 m.

Place the iron in a porcelain dish with 3 fl. ozs. of the water, and add the iodine in three or four successive portions, allowing combination to take place and the liquid to cool between the additions. When a drop of the liquid taken out on a glass rod is seen to be free from yellow tint, heat the contents of the dish to gentle ebullition for five minutes. Filter the hot liquid, washing the dish and contents of filter with distilled water to make the filtrate measure $3\frac{1}{2}$ fl. ozs. To this add the hypophosphorous acid, and mix thoroughly. Prepare a syrup by dissolving the sugar in 10 ozs. of water with the aid of a little heat. Filter whilst warm, and wash the filter with distilled water to $27\frac{1}{2}$ fl. ozs. Mix with the solution of iodide of iron, and make the product weigh 2 lbs. 10 ozs. by the addition, if necessary, of distilled water. The specific gravity should be about 1.355. It contains about 4 grains of iodide of iron in 1 fl. drachm. A quantitative test for FeI_2 might also be inserted here.

(To be continued.)

DETERMINATION OF CREATININE.—R. Kolisch proposes for the determination of creatinine in urine a new method, by precipitation with mercuric chloride. Two hundred C.c. of urine is precipitated with milk of lime and calcium chloride (together 20 C.c. of solution) and filtered. Of the filtrate 200 C.c. is acidified with acetic acid and concentrated; the residue is exhausted with alcohol, and to the solution the following reagent is added: Mercuric chloride, 30.0; sodium acetate, 1.0; acetic acid, 3 drops; absolute alcohol, 125.0. The creatinine is precipitated and can be determined by determining the nitrogen or by decomposing the precipitate with sulphuretted hydrogen and titrating the creatinine. Kolisch finds that a concentrated solution of mercuric chloride precipitates both creatinine and urea, but the urea precipitate dissolves in acetic acid, whilst the creatinine and mercuric chloride compound is insoluble (*Wiener Klin. Rundsch. and Pharm. Centralh.*, xxxvi., 323).

THE OLD FIRM OF GODFREY.

BY JOSEPH INCE,

*Late Director of Godfrey's Laboratory.**(Continued from page 169.)*

Godfrey viewed in his trade relations was wise even in his generation, for he recognised the value of bold advertisement. He informs his customers that, as "Chymist in London," he continues to prepare faithfully all sorts of remedies, Chemical and Galenic. Good cordials may be had at his establishment, as well as Royal English Drops, Powders of Kent, Zell and Contrajerva, Cordial Red Powder, Gaskoin's Powder, with and without Bezoar, English Smelling Salts, true Glauber Salt, Epsom Salt, and Volatile Salt of Ammonia, stronger than the former. Human Skull (quoted as Mummy in the old price book, at 2s. 6d. per ounce), Essence of Ambergris, a list of Essences, including Essence of Viper and Essence for the Hair, together with Sundry Spirits and Arquebusade, are respectfully offered to the public.

Godfrey also adds, "for the information of the curious," that he is the only one in London who makes inflammable Phosphorus which can be preserved in water, Phosphorus of Bolognian Stone, Flowers of Phosphorus, Black Phosphorus and that made with Acid Oil, and other varieties. All unadulterated; every description of good drugs. He sells wholesale and retail.

N.B.—He sells solid Phosphorus wholesale, fifty shillings an ounce, and retail, three pounds sterling the ounce. It is clear that Ambrose had an eye to business; his view was, not so much to keep a shop, but that the shop should keep himself and family, and these prices rendered the matter feasible. Contemporary records prove that this was about the character of the pharmacy of the seventeenth and eighteenth centuries. Besides the dispensary of the Society of Apothecaries, established in 1623, and the manufacturing chemical laboratory added to it in 1671, establishments, such as that of Godfrey, were few. There was little competition, and success depended upon the personal reputation of the proprietors. Some of these were probably apothecaries who preferred to confine their attention to pharmacy rather than follow the prevailing tendency to cultivate medical practice. But at the same time a class of men rose who were totally disconnected from the medical profession, and were not apothecaries; they prided themselves on choice drugs and special preparations, and to them we may trace the origin of pure pharmacy as a separate and honourable calling. Some light will be thrown upon the actual condition of pharmacy by recollecting that this special period marks the date of the commencing distrust in, and final emancipation from, the belief in alchemy, a creed hard to die; a creed, moreover, which had previously influenced some of the wisest and best men of the age.

Alchemy was a groping after truth, and it ceased naturally when science step by step was based on accurate investigation and direct experiment. Medicine, chemistry, and pharmacy threw off the yoke of empiricism, and there began to appear the true physician, chemist, and pharmacist. The intermediate stage was the apothecary: but soon individual chemists became famous not only for their preparations, but for the character of their drugs. They found sufficient scope for their exertions in this enlarged field of labour, and to them is due the foundation of Historic Houses and the creation of the class now called Chemist and Druggist.

It is unnecessary to enter into details, as the history of this period has been graphically described by Mr. Jacob Bell in his 'Historical Sketch of the Progress of Pharmacy in Great Britain.' It may be mentioned that the House of Corbyn was founded about 1690; Plough Court, circa 1715, by Sylvanus Bevan, an apothecary, the establishment being rendered famous by the admission of William Allen in 1794, who for a time was in partnership (1797) with Luke Howard. Still later in date came the House of Savory, founded in

1794 by Mr. Paytherus, surgeon and apothecary, and that of John Bell and Co. in 1798.

Some few establishments in the country also trace their origin to this period—for instance, Randall and Son, Southampton; Reynolds and Branson, Leeds; Southalls, Birmingham, and others, to which future reference will be made.

It can hardly be said that contemporary medical literature was much help to the progressive chemist. Most of the works belonging to the close of the seventeenth and the commencement of the eighteenth century are disfigured by puerilities which first excite amusement and then weariness. Samuel Smith,

bookseller, in St. Paul's Churchyard, published his list of medical books imported into England from different parts of Europe, 1687, at the Sign of the Prince of Wales. In the list we find 'Saxonix Opera Medica,' 1680; 'Collectanea Chymica Leydensia,' 1684 Charas, 'Pharmacopeia Regia,' 1683 (a modern translation); in its day a celebrated treatise, with regard to which Professor Tilden writes, that in the fourth part we have a collection of recipes, amongst which, whatever its value, an "Ointment to catch Fish," compounded of man's and cat's fat and powdered mummy, can hardly be thought to hold a fitting place in a Royal Pharmacopœia. 'La Chimie de Lemery,' 1685. Van Helmont, 'Fundamenta Medica,' 1682. Matthœi 'Experimenta Chymica,' 1683.

We must not forget to mention an edition of 1685 of 'Sydenhami Opera Omnia,' nor the first edition of Pomet's 'Histoire Générale des Drogues,' published in Paris in 1694. Pomet kept a shop in the Rue des Lombards, which corresponds to our Mincing Lane. Daniel Hanbury remarks (1870), "No work of its class has enjoyed a more deserved and extensive reputation than Pomet's 'History of Drugs.'" The Dispensatorium of Valerius Cordus, 1690, is a remarkable

21 March 1740

To the Church Wardens & Overseers of St. Paul
Covent Garden

Gentlemen

Whose names are unwritten do desire ye will
get Jonathan Probach, a Lunatick, an Inhabitant in the said
Parish, to Bethlem; we having procured a Petition for that
purpose. He who are near neighbours to him, and in continual
fear of his setting his dwelling on fire. If timely care be
taken of him, he may be cured, & be enabled to get his bread,
& ease the parish of the daily troubles & fears he gives it.

Yrs

SPECIMEN OF GODFREY'S HAND-WRITING.

treatise, containing as it does the description of the "Perfect Pharmacist," who should be the right hand of the physician.

In these and similar productions we have no longer the amazing disquisitions which abound in the sixteenth century, but we may take the 'Pharmacopœia Bateana,' edition 1688, the book on which Godfrey had to depend for his pharmacy, as typical of the rest; the well-known Dispensatories and Pharmacopœias, John Quincy; 'The New,' James Alleyne, Dr. Radcliffe's 'Practical,' and others appeared at a later date. Dr. Bate had been physician to Charles I., Cromwell, and Charles II. His Pharmacopœia is a collection of recipes now obsolete. Dr. William Salmon brought out an amended edition, "completed with above six hundred chemical processes, and their explanations at large, various observations thereon, and a rationale upon each process." To these were added, with much vaunting, Goddard's Drops. As these turned out to be a product of the distillation of Humane (*sic*) Bones, or rather Skulls, well dried, we may gauge how far Godfrey was indebted to the medical literature of the age for his ultimate success.

Right down to the time when Godfrey became a business man, alchemy had not quite passed away. There is a pamphlet written in his own handwriting describing how a charlatan had possession of Boyle's laboratory for some months, and endeavoured to palm off to distinguished visitors, the philosopher included, his method of transmuting the baser metals into gold. I gave the manuscript to Daniel Hanbury. The style of handwriting is shown in the reduced, facsimile (see p. 205). It may be admired as being extremely legible and also for perfect uniformity.

Ambrose Godfrey died in January, 1741. He left three sons: Boyle Godfrey, the eldest, turned physician, and he wrote a book [Miscellanea vere Utilia] under the title of 'Observations.' John, the third son, came to grief. The second son, Ambrose, succeeded literally to his father's name and

to the business—his career was prosperous and uneventful, and he wrote a book, 'The Compleat Course of Chymistry.'

The accompanying illustration is taken from the Prospectus of the work.

The sons of the second Godfrey had the misfortune to inherit a business for which they had little taste; they started life with too much money, an open door to poverty, and gradually they were bought out by Charles Gomond Cooke, so, for the second time, an assistant became the sole proprietor of the ancient firm.

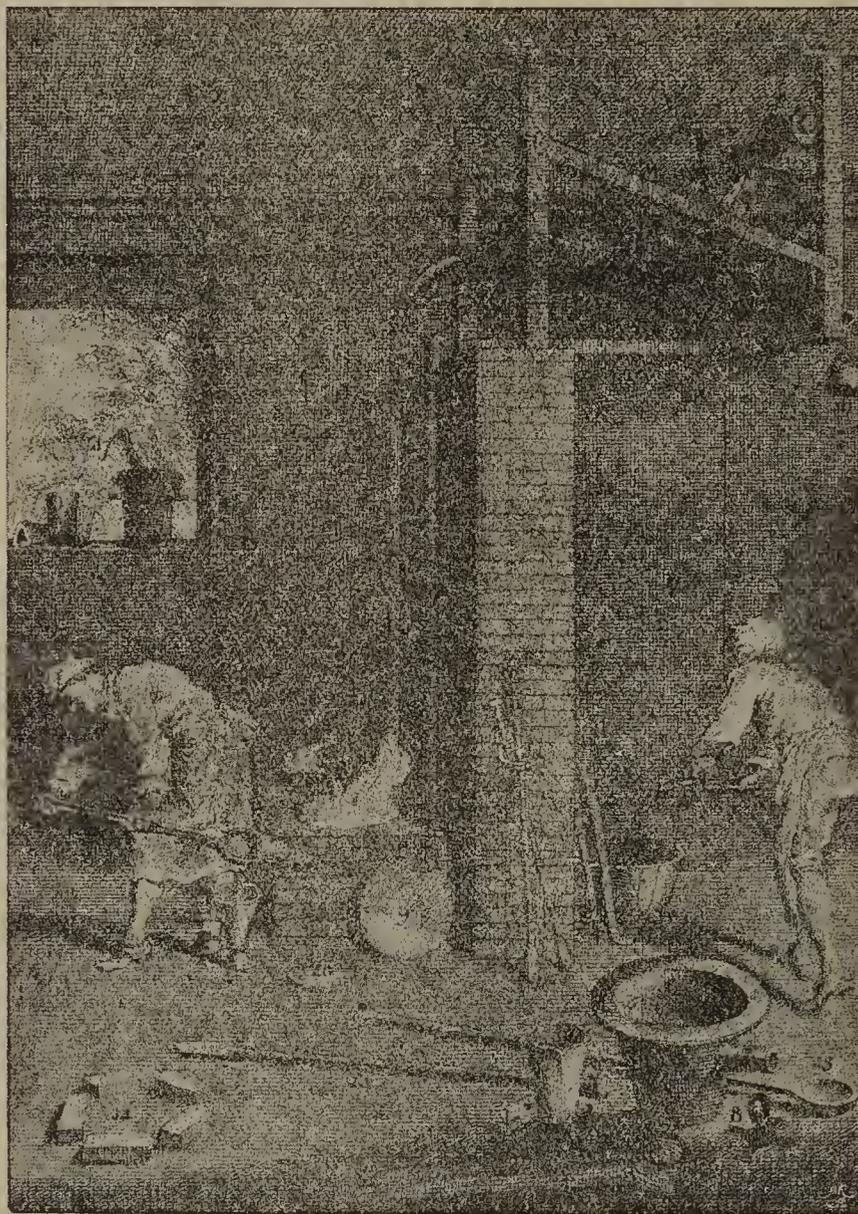

One of these last descendants of the Godfreys devised a Fire-Annihilator, which was brought under the notice of William Pitt.

It was on the plan of a hand grenade, which, on being flung into the flames, would burst with explosive violence and thus subdue the conflagration. The apparatus proved a failure.

On the succession of Mr. Cooke a new phase of pharmacy began and the mediæval ended. This third representative of the house, though short in stature, was an extremely handsome man, whose manner inspired a sort of reverential feeling, which, indeed, was characteristic of the age.

The "Master" was a personage surrounded by respect akin to awe, and was looked up to as a superior being by his subordinates. I never saw him in his own business, but once a year we, as children, were admitted to the august presence, the interview being terminated by the gift of a newly coined sovereign.

There were occasions on which the great man went to church — St. Paul's, Covent Garden, described by the giver, a former Duke of Bedford, as the handsomest barn in England. There was Godfrey's pew in the front gallery, and there on the cushion were the stately row of Bibles and Prayer-books, bound in elaborate and costly fashion. No sooner did Mr. Cooke make his appearance than the ancient dame who was pew opener made a bee-line to "Mr. Godfrey's" seat, and was rewarded with a golden honorarium. Sincere was her regret that he was not more

FROM THE PROSPECTUS OF 'THE COMPLEAT COURSE OF CHYMISTRY.'

as a superior being by his subordinates. I never saw him in his own business, but once a year we, as children, were admitted to the august presence, the interview being terminated by the gift of a newly coined sovereign.

FIRE ANNIHILATOR. TEMP, CIRCA 1784.

constant in his devotions. One day he went down into the cellarage and quickly reappeared, saying that he felt cold. He sat down by the counting-house fire and shivered; urged to go to bed he reluctantly complied, but the chill proved fatal.

Mr. Cooke's only daughter, who had become the wife of Samuel Platt, a barrister, now succeeded as sole proprietor of the firm, and so continued until the final exodus from Southampton Street.

(To be continued.)

CASTOR OIL SOAP.

BY J. F. BROWN, DOVER.

Having recently dispensed a prescription for pills, one ingredient of which was saponis castor, which was interpreted to mean a soap prepared from ol. ricini, a brief note of the experience gained in making it may be of some service. One ounce of the oil was boiled in an evaporating basin with 60 grains of caustic soda dissolved in 1 ounce of distilled water, for ten minutes, and then 2 drachms of salt dissolved in another ounce of water added, the mixture well stirred, and let stand until cold; $3\frac{1}{2}$ ounces of firm white soap was obtained, and only a little moisture left in the dish. On the lines of Mr. Wood's instructions for making an almond oil soap, *Ph. J.*, 2nd series, vol. xi., p. 415, I dissolved the cake in half-a-pint of boiling distilled water, and stirred in another 2 drachms of salt in 1 ounce of water. After cooling it appeared that the whole of the soap was held in solution, as only a very light flocculent precipitate was perceptible. The same quantities of oil and soda solution formed on cooling a soft semi-transparent jelly, with a somewhat tough skin, which appeared ineligible for pharmaceutical use. On heating it and adding 4 drachms of salt dissolved in 2 ounces of boiling water a cake of soap formed, which when dried in blotting paper weighed $3\frac{1}{2}$ ounces; three-quarters of an ounce only of liquid was left in the dish. When air-dried the soap weighed 3 ounces, and when, after slicing, it was dried again— $2\frac{3}{4}$ ounces. The product is white and firm, but rather crumbly. In order to fit it for use in pharmacy the removal of the remainder of the salt seems necessary, but how to accomplish it in the face of its solubility in a larger quantity of brine is not apparent.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

DONATIONS.

At a meeting of the Library, Museum, School, and House Committee, held on Wednesday, the 11th inst., the Librarian presented the following report of donations:—

To the Library (London).

H.M. Secretary of State for India:

Report of the Indian Hemp Drugs Commission, 1894.

Surgeon-Major C. J. H. Warden, Calcutta:

Seventeen Photographs taken for the Indian Hemp Drugs Commission.

Pharmaceutical Society of Ireland:

Calendar, 1896.

Royal College of Physicians of London:

List of Fellows, etc., 1896.

Kaiserliche Leopoldinisch-Carolinische Deutsche Akademie der Naturforscher, Halle a/S.:

Nova Acta, Bd. 61-64.

Katalog der Bibliothek, Lief. 5-6.

Professor Ed. Schär, Strassburg:

Neuere Beobachtungen über Alkalinität von Pflanzenbasen.

Ueber die Anwendungen der Guajakharz-Lösung (Guajak-tinctur) als Reagens.

Professor François Gay, Montpellier:

Une lignée d'apothicaires Montpelliérains, 1896.

Herr A. Schlickum, Marburg:

Morphologischer und anatomischer Vergleich der Kotyledonen untersten Laubblätter der Keimpflanzen der Monokotylen, 1895.

The following report of donations was presented by the Curator:—

To the Museum.

Sir F. von Mueller, K.C.M.G., M.D., F.R.S., Melbourne:

Kino of *Eucalyptus regnans* and *E. globulus*.

Messrs. Horner and Sons, London:

Specimen of Oil of Aniseed, and of the "Green Aniseed from Cyprus," from which it was distilled.

To the Herbarium.

Messrs. Parke, Davis and Co.:

Specimens of *Grindelia robusta*.

EVENING MEETING IN LONDON.

The evening meeting for March was held on Tuesday the 10th, at 8 o'clock, Mr. Michael Carteighe, President, in the chair. The paper read was on "The Pharmacy of Phosphorus," by Mr. Martindale. It is printed at p. 201, and gave rise to the following discussion:—

Mr. PARKER said phosphorus was very freely prescribed in combination with other ingredients, and he should doubt whether there would not be a difficulty in using the oil of theobroma formula where it had to be mixed with aqueous extracts. The strength of the solution, 1 in 75, might be open to objection, as being an odd number, and he did not see why 1 in 100 should not be employed. He thought there was an objection to having an official formula for solution of phosphorus at all, particularly one containing so volatile a constituent as carbon bisulphide; this would naturally evaporate, especially in the summer, and it would be difficult to know what the exact strength of the solution was except by the fluidity or otherwise of the solution, which was rather a hap-hazard way of judging. He preferred making phosphorus pills *ab initio* from a clean cut piece of phosphorus weighed at the time of dispensing. He had found the formula he worked with very satisfactory, the only objection brought against it being that there was a very small trace of the bisulphide left; but that was not really material, because an almost odourless bisulphide could now be obtained, and the trace which was locked up in the mass could only be found by cutting the pill in two. He had a sample made the previous day in a bottle, which he would hand to the President to open, and see if any smell were perceptible. He had submitted a sample of the mass after it had been made an hour to three pharmacists, and they reported that any smell of bisulphide there might be was completely covered by that of phosphorus.

Mr. JOSEPH INCE thought it very undesirable to have any official solution of phosphorus to be used for the purpose of making pills. It was infinitely preferable to make them from fresh, perfectly unoxidised phosphorus. He knew nothing about the making of such pills on a large scale, but only in retail dispensing, and he was glad to see the three formulæ shown, any one of which might be used in place of the undesirable B.P. method. It was absolutely necessary with phosphorus to have it equally disseminated throughout the entire mass, and from that point of view the B.P. formula was, to his mind, unsatisfactory, and even dangerous. No doubt with extreme care and skill satisfactory pills could be made, but it would be much better to have a method which could be used by anyone of ordinary skill. There was extreme difficulty in getting the phosphorus in such a comminuted form that it could be dispersed with absolute regularity throughout the mass, and he knew of no better way of accomplishing that than by dissolving it in carbon bisulphide. He found Allen and Hanburys' method gave a very good result. Phosphorus had sometimes to be administered in cases of mania and insanity in a more concentrated form in solution, and he remembered such a case where it was required to be given in combination with strychnine, iron, and chloroform. He dissolved the phosphorus in the chloroform, the strychnine in rectified spirit, and those two solutions being mixed, the iron was added in the form of the old tinctura ferri muriatis. The result was a perfect solution, which, on being kept five months, showed no change, and was then used, and continued to be employed for a long time. An attempt was made to use perchloride of iron, but that was a perfect failure. At the same time it was desired to exhibit a dose of 1 grain of phosphorus by itself and in very small bulk, and that was accomplished by dissolving it in oil of cloves.

The PRESIDENT asked if the preparations described by Mr. Ince were found to produce beneficial results.

Mr. INCE said he presumed so. They were prescribed by Dr. Forbes Winslow, and were used by him up to the time of his death.

Dr. SAINSBURY said it was very interesting to a medical man to hear of these difficulties and the way they were overcome by pharmacists. It made him appreciate more than before the meaning of the words *secundum artem*, as used in prescriptions.

Mr. MACEWAN said the chief objection to the formula suggested by Mr. Martindale was that it was not adapted to pill-making by machinery. Possibly it would be better if in such a case manufacturers went back a bit and had all the pills made by hand, but still it would be well if present-day requirements could be met. A large quantity of medicines—he thought too large a quantity—was distributed by medical men, who were bound to procure them from

large manufacturers, and therefore unless they went back to hand-made pills, some other formula must be devised. He did not quite appreciate Mr. Parker's objection to the solution method, as it was quite possible to prevent evaporation either by capped-stoppered bottles, or a good cork. Still, for extemporaneous dispensing, he preferred Mr. Parker's method, which he used to a considerable extent some years ago and found quite adequate. It was absurd to look for mathematical accuracy in such matters; a pill said to contain $1/33$ grain might probably vary from $1/28$ up to $1/40$, and it was doubtful whether the human system was capable of taking in even $1/33$ grain of phosphorus daily, so that a certain amount of oxidation might occur without any great disadvantage to the therapeutic result. He heard what Mr. Martindale said about Mr. Ashburton Thomson's solution with great interest, because at one time he made large quantities of it, and, until Mr. Williams read his paper, used to follow Mr. Thomson's directions, dissolving the phosphorus by prolonged boiling in alcohol, and afterwards adding the glycerin, etc. Mr. Williams then suggested dissolving the phosphorus in the glycerin, which reduced the time required from hours to minutes, the only difference in the result being that there was a very fine deposit of phosphorus on cooling at the bottom of the bottle. Now in Mr. Thomson's process there was undoubtedly a solution of a small amount of free phosphorus with much larger quantities of phosphorus oxides, and the question arose whether it was quite right to adopt Mr. Williams' improvement, because it might possibly be that the therapeutic effect was as much due to the oxides as to the free phosphorus; that was a question for medical men to decide. Mr. Martindale's formula was a great advance on that of the Pharmacopœia, but he still had a hankering after the old one of Mr. Parker, and thought if it were possible to combine the two it would be an advantage. Mr. Ince did not state how much oil of cloves was required to dissolve the grain of phosphorus, but he feared any preparation of phosphorus and oil would not contain much phosphorus after standing for five months.

Mr. COLLIER asked if the demand for phosphorus in prescriptions was as great as formerly. For many years he had not been called upon to dispense it, though some years ago it was a very fashionable remedy. At that time they used a considerable quantity of phosphorus pills, but the great objection to them was that they were not soluble, and he did not see how pills containing yellow wax could be, and should prefer pills containing phosphorated oil. But his idea was that phosphorus was going out of use.

Mr. WRETTS said phosphorus was still prescribed not infrequently. In his opinion phosphorated suet was the best form in which to exhibit it. He had found Mr. Parker's method answer very well in the winter, but in the height of summer he often noticed considerable phosphorescence in the mass. The great objection to the Pharmacopœia mass was that it was extremely difficult to ensure an even diffusion of the phosphorus.

MR. MARTINDALE, in reply, said he quite agreed with Mr. Wretts. There was a considerable demand for phosphorus amongst surgeons in the West-End, either alone or in combination with iron, nuxvomica, etc. With regard to the pill mass made by his method, he understood from manufacturers that it piped fairly well, and that the only difficulty was with the cutters. In fact, he borrowed the idea from what he saw in Vienna, where acacia and oil of theobroma in combination were used for making bougies, being passed through a kind of piping machine. It had been suggested that the substitution of syrupy glucose for the syrup, and about half the acacia, would give the mass a greater body, so that it would not block the cutters, and the pills could be rounded more easily, as they would not be so sticky. There was no difficulty in combining the emulsion of the fat, acacia and syrup, or glucose with aqueous extracts, but a 40 per cent. solution would probably be preferable for combining with other medicaments. He suggested that the strength should be 1 in 75, because 1 in 100 would require a still larger excess of carbon bisulphide, which would be objectionable. On the other hand, with a less proportion of bisulphide there was a difficulty in keeping the phosphorus in solution, even in combination with the oil of theobroma. The advantage of using the latter was that it tended to fix the bisulphide and prevented evaporation. This solution would keep well for a good time, but it need not be made in very large quantities, and if it deteriorated a fresh supply could be made, and it would greatly facilitate the making up of prescriptions which were wanted immediately.

The PRESIDENT said of all the drugs which he had read about or handled, he had been more puzzled by phosphorus than any. He

had satisfied himself by personal experiment that certain reputed potent drugs did produce certain effects, but with regard to phosphorus he was completely puzzled. He felt more difficulty in conceiving how it acted therapeutically than any other drug, but it was certainly regarded as a very useful medicine either alone or in combination. A number of careful observers were satisfied that good results followed its use in their practice, and that being so they were perfectly right to continue its use, and it was highly desirable that pharmacists should be able to supply it as far as possible in an unoxidised condition. He proposed a hearty vote of thanks to Mr. Martindale for his paper.

Mr. BOTTLE remarked that in his early days phosphate of soda was largely in demand, and was apparently regarded as a very useful drug, but as far as he knew, it had quite gone out of use in his district.

The PRESIDENT said it was the same in London.

Crystalline Carbonate of Lime.

Mr. BOTTLE then exhibited a specimen of a substance which had been found choking the feed-pipe of a new boiler recently put up by the Dover Gas Co., the feed-pipe being at the top of the boiler instead of at the bottom, as had been the case with the old boiler. He said it was a lump of flocculent material, which was easily broken down, and then had much the appearance of Gregory's powder, but on investigating he found it was crystalline carbonate of lime, slightly stained with iron from the boiler. The water from which it was deposited came from a chalk well, and had seventeen and a half degrees of permanent hardness and eleven and a half degrees of temporary hardness, which he was accustomed to have removed by boiling for washing purposes. That morning he tried some of the water from the Dover Waterworks, and found that just before it boiled a light scum rose to the top, and on gathering some of this and putting it under the microscope he found it was perfectly crystalline. It occurred to him whether this was a sesqui-carbonate, because they looked upon bicarbonate of lime as a soluble substance and carbonate as that which settled at the bottom, but here was something which floated on the top in considerable quantity. He thought the matter would be worth further investigation by those who had to deal with chalky waters.

The PRESIDENT said this observation confirmed many which he made many years ago when experimenting on the influence of carbonic acid gas under pressure on various forms of calcium carbonate and the corresponding alkaline earth, popularly known as magnesia. It was then believed that there were such things as bicarbonate of calcium and magnesium, but later knowledge showed this to be an error. A solution of carbonate of magnesium or calcium, in water saturated with carbonic acid gas, was nothing more than a solution, not a definite compound, but the process of solution gave a hydrous carbonate in transparent crystals.

Mr. MACEWAN remarked that most of the precipitated chalk in the market was really made in the process of softening water at large waterworks, and it was crystalline, though one might expect that it would be thrown down in the form of an amorphous powder by the addition of lime.

Mr. BOTTLE said he hardly knew how to reconcile the influence of the chemical union of a second equivalent of carbonic acid with the difficulty he always found in getting still water from a chalk water free from carbonic acid. They were always obliged to boil it for a quarter of an hour or longer, simply because it was so highly charged with carbonic acid.

The PRESIDENT said it was open to doubt whether perfectly normal carbonate of magnesium was soluble in a mixture of water and carbonic acid gas or not. He was disposed to think it was not, and that the solubility of any form of the so-called commercial carbonates, which were really hydro-carbonates, in water containing carbonic acid gas, was in direct proportion to the amount of magnesium hydrate, and not magnesium carbonate. He had been unable, with a perfectly neutral carbonate, grinding it as fine as possible, and rubbing it down with water, to produce the slightest effect, as regarded solubility, by a pressure of gas of 120 lb. to the square inch. Probably, early notions about bicarbonates were derived from the fact that oxy-carbonates existed which remained in solution, and when the gas was boiled off a crystalline hydrated carbonate was thrown down. He had been unable to make bicarbonate of either calcium or magnesium by evaporation over sulphuric acid at

normal pressure, or by evaporation *in vacuo*. He proposed a vote of thanks to Mr. Bottle for his communication.

The New Photography.

Professor GREENISH then exhibited on the screen a series of photographs taken by Mr. A. A. C. Swinton with the X or Röntgen rays, including the following:—Coins, etc., in purse; spectacles in case (very good); corkscrew, etc., in pocket; rat; frog; puppy dog, two days old; plaice; sole (bones very distinct); hand; foot; ankle; elbow; injury to index finger of hand. A vote of thanks was passed to Mr. Swinton for the loan of the slides.

PROCEEDINGS UNDER THE PHARMACY ACT.

CASE UNDER SECTION 17.

THE SALE OF WEED-KILLER BY SEEDSMEN.

At Chester City Police Court on Thursday, March 5, before Mr. Alderman Charles Brown and Dr. Stolterforth, the firm of Messrs. Dicksons, Limited, seed growers and nurserymen, carrying on business at Chester, was summoned at the instance of the Pharmaceutical Society of Great Britain, for contravening Section 17 of the Pharmacy Act, 1868.

Mr. E. L. Vaughan Williams (instructed by Messrs. Flux, Thompson, and Flux, London) prosecuted, and Mr. Frank E. Roberts, of the firm of Roberts, Dickson, and Barnes, Chester, defended.

Mr. Vaughan Williams, in opening the case, said that the object of the Pharmacy Act of 1868, as their Worships would be aware, was to protect the public against the sale of poisons by other than qualified persons. The present proceedings were taken under Section 17 because that Section had been held to be the one which peculiarly applied to limited companies. In this case the learned counsel contended that the Section had not been complied with in several material respects. From information that came to the knowledge of the Society they caused the purchase to be made at the shop of Dicksons, Limited. On January 31 this year Mr. Foulds went to the shop and inquired for an article known as "Smith's Perfect Powder Weed-Killer." He obtained a tin, and on its being subsequently analysed by the analyst of the Pharmaceutical Society it was found to contain a very large quantity of arsenic, 80 per cent. of the whole being composed of that very dangerous poison. On going into the shop, Mr. Foulds asked one of the assistants if they kept the weed-killer. The latter seemed to be in doubt about it, but after speaking to the manager, he asked who it was for. Mr. Foulds then gave the name of "Mr. Johnson, of Frodsham." The assistant then said if he would pay for it then he would send the weed-killer on to him, but Mr. Foulds said that would not do, as he wanted to take it with him. The assistant then asked what time his train went. Mr. Foulds replied "2.50," and the assistant said he would send it down to him at the station. Mr. Foulds agreed to that, and a boy met him at the station with the weed-killer, which was wrapped up in brown paper, on the outside of which there was a label bearing the words "From Dicksons," and addressed to "Mr. Johnson, Frodsham." That constituted beyond all doubt a sale by Dicksons, Limited. It might be contended that Dicksons were not liable for what their assistant did, but the Act provided that "for the purpose of this Section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller." From the evidence he would call he thought it would appear that Mr. Foulds was in no way known to the seller of the poison, that there was no introduction of Mr. Foulds by anyone, that no entry was made in the book by the seller, and that the name and address of the seller was not upon the tin. The name and address of the manufacturer was on the tin, and, if necessary, he should quote the case of *Templeman v. Trafford* to show that that was not sufficient compliance with the Act, which required the name and address of the actual seller to be placed on the tin, the wording of the Act being that "any person selling otherwise is liable to a penalty."

Evidence bearing out this opening statement having been given, Mr. Roberts said defendants admitted that the preparation contained arsenic, though they had no personal knowledge of it. He submitted, however, in the first place that this was not a sale within

the meaning of the Act by Messrs. Dicksons. Proceeding to explain his clients' mode of conducting this branch of their business, he said they had been most anxious to avoid any possible infringement of the Act. These weed-killers had been advertised all over the country, and a trade got up for them by seedsmen for the benefit of the original chemists who compounded them, and it was a little ungenerous on the part of chemists that they should thus utilise all the expense incurred for the benefit of themselves. These tins of weed-killer were supplied by Messrs. Dicksons to their customers through Messrs. Cheers and Hopley, chemists, Chester; defendants adopting that step in order to be as exactly within the Act as they could, and any order received for weed-killer, as this was received on the evidence which had been given, was not taken as an order for an article to be supplied by Messrs. Dicksons, but as one for an article which they had to obtain.

Proceeding, Mr. Roberts said that defendants had most honourably endeavoured to prevent any possible infringement of the Act, and the following notice was displayed in their shop: "Please note that none of the undermentioned articles can under any circumstances be sold to any customer across the counter: Weed-killers, ant destroyers, and wasp destroyers." Therefore, he submitted, on the merits of the case, defendants had done all in their power to prevent any infringement of the Act, and if there had been an infringement, it had been done unwittingly, and contrary to their urgent instructions and strong wish. Mr. Roberts went on to argue that this Section did not refer to corporations and companies, in proof of which he quoted from the judgment of Lord Justice Bramwell in the case of the Pharmaceutical Society *v.* the London Provincial Supply Association, Limited, in which it was held that the word "person" did not include a corporation.

Mr. Vaughan Williams did not think his friend's attention had been called to a further report of the case. The case afterwards went to the House of Lords, where it was held that the word person in this particular Section of the Act included a corporation.

The Magistrate's Clerk further pointed out that subsequent to that decision the Interpretation Act had been passed, which said that in the construction of every enactment relating to an offence punishable on indictment or summary conviction the word "person," unless a contrary intention appeared, included corporations.

Mr. Roberts was not aware that the case had been to the House of Lords, and he admitted that that being so it ended the point he had raised. He submitted, however, that in this case the sale was not made by Messrs. Dicksons, who had in the most careful way guarded themselves against a charge under the Act. They had since done away with a good many of the things sold which contained poison, and had taken steps to ascertain from the manufacturers what the ingredients were, so as to prevent anything of the kind from occurring in the future. He submitted, in conclusion, that Messrs. Cheers and Hopley were the vendors in this case.

Mr. G. P. Miln, one of the managers of the defendants, stated that he had taken steps to prevent the possibility of the Pharmacy Act being infringed in respect of these weed-killers. A considerable sale had sprung up for these weed-killers with seedsmen, and when they became aware that the sale came under the Pharmacy Act they agreed with Messrs. Cheers and Hopley to stock them for them. They had done so, and Messrs. Dicksons had not kept any weed-killer on their premises. Consequently their assistant was unable to supply the gentleman who procured the tin in question, but had to get it from Cheers and Hopley. The latter handed it to them and they simply sent it to the station. They had taken every precaution not to stock anything of the kind, and to comply with the Act as far as their knowledge went. Every assistant in the shop had verbal as well as written instructions that nothing of the sort was to be sold over the counter, and also that they were not to hand over the counter anything of the kind obtained from Messrs. Cheers and Hopley. That system was most carefully adhered to. The witness stated that the notice read by Mr. Roberts was affixed to every counter in the shop, and also that the bill-heads referred to were in use.

After some argument as to who were the actual sellers—in the course of which it was explained that Messrs. Cheers and Hopley allowed a commission on all sales effected by Dicksons, Limited—the Bench retired, and on their return the Chairman said: The magistrates, after due consideration of the case, feel they are bound to convict. We have decided to inflict a penalty of 20s. against Dicksons, with the costs of the court.

REVIEWS AND NOTICES OF BOOKS.

CHEMICAL RECIPES. By the Atlas Chemical Company, Sunderland. Pp. 316. (Sunderland: Hills and Co., 19, Fawcett Street. 1896.)

The recipes published in this book are in great measure of a nature not usually found in such works, and should prove of especial value to the proprietor of what is euphoniously known in the trade as a "mixed" business. The actual value of the recipes can, of course, only be determined by practical experience, but many of them bear the stamp of feasibility. Amongst the subjects treated are pigments; glazes for pottery, etc.; liquid gold; carbonated drinks, essences and cordials; paints; metal polishes, blackings, etc.; varnishes, stains and lacquers; printing and other inks; sealing waxes, soaps, dyes, lubricants, and the innumerable articles concerning which interest the druggist more or less, such as baking powders, starch gloss, spices, relishes, disinfectants, essences, extracts, scents, beverages, etc., etc. In most cases, all that one can reasonably expect from a recipe is an idea on which to base a working formula, and the reader of this book should reap a rich harvest of such ideas.

GLEANINGS FROM THE PATENT LAWS OF ALL COUNTRIES. By W. LLOYD WISE. First portion: Argentine Republic—Germany. Pp. 208. Price 2s. (London: Cassell and Co., Ltd. 1895.)

Judging from his varied experience, the pharmacist of this country would appear likely to develop into a prolific inventor, and in many cases there is little doubt that large sums might have been secured to members of the craft had they protected ideas that occurred to them whilst pursuing their daily round behind the counter. To realise the benefit of legal protection to the fullest extent, it is of course necessary to patent an idea abroad as well as at home, and in such a case the book now under consideration should prove of the greatest possible utility. Twenty-two countries are dealt with in this first portion of the complete work, and in each case the information given is classified under the following heads:—Application, procedure, grant, area, population, productions, etc., of the country; assignment and transfer of patents; dates of laws, fees; kinds of patents; subject matter; term; who may obtain a patent; working. The would be patentee is thus enabled to decide upon the adaptability of his idea to the purposes of the inhabitants of any given country and the possible extent of business to be done there, in addition to finding in a concise form all the particulars he can possibly need regarding the methods of procedure. The book should have an extensive sale and the succeeding portion, including Great Britain and Ireland, will be awaited with much interest.

THE DYNAMICS OF LIFE: An Address delivered before the Medical Society of Manchester, October 3, 1894. By W. R. GOWERS, M.D., F.R.S. (London: J. and A. Churchill.)

In this address we have a profound and philosophic consideration of that extraordinary physiological process which is called a stimulus, from one who may be justly regarded as the ablest of living neurologists. A very large part of the address is devoted directly and indirectly to the discussion of that "most obtrusive manifestation of energy" known as an epileptic fit. Dr. Gowers acted very wisely in publishing this admirable brochure, and all who read it cannot fail to profit by it. To young physicians and physiologists it will act as a powerful stimulus and encourage them to study the sources of the wonderful energy connected with nervous and muscular tissues.

PARLIAMENTARY INTELLIGENCE.

SELECT COMMITTEE ON ADULTERATION.—The first meeting of this Committee was held on the 5th instant, when Mr. T. W. Russell, Parliamentary Secretary of the Local Government Board, was elected chairman, and the course of the Committee's procedure was agreed upon. As a large amount of expert evidence given before the Select Committee which sat during 1894 and 1895 is available, it is probable that very little additional oral evidence will be necessary, and the Committee does not propose to call for much personal testimony. It will be remembered that the Committee of 1894 was far advanced with its labours, and, indeed, was almost ready to report when the General Election occurred; in fact, the present Committee may be regarded as having been appointed chiefly to complete the interrupted work of its predecessor. Evidence from the druggist's point of view was very ably put before the Committee by Mr. Charles Umney on May 22 last (*Ph. J.* [3], xxv., p. 1078). Mr. R. A. Robinson was also heard on behalf of the Kensington Vestry (*Ph. J.* [3], xxv., p. 1186). The Committee has, however, heard some evidence during the past week, and on Tuesday, Mr. Otto Hehner attended to present the views of the Society of Public Analysts. Mr. Hehner's remarks were more or less confirmatory of what has been previously said by Mr. Umney, but the position he assumed in respect of the qualification necessary for a public analyst may not be pleasant to every chemist and druggist. He is reported to have expressed the opinion that a number of chemists and druggists who had been appointed were not fully qualified, and that in his opinion no one should be appointed who was not a Fellow of the Institute of Chemistry and had not passed an examination as a competent analyst.

SHOPS (EARLY CLOSING) BILL.—Reference has already been made (*ante*, p. 198) to the commitment of this Bill to the Standing Committee on Trade. The Committee has now been allotted its chairman in the person of Mr. John Ellis, who represents Rushcliffe, Nottingham. Fifteen additional members have been placed on the Committee in respect of the consideration of the Shops Bill, and as these gentlemen represent all shades of opinion there should be ground for hope that what is good in the Bill will be separated from that which is calculated to prove harassing. No doubt the Committee will give due weight to the fact that petitions in favour of Sir John Lubbock's Bill have been presented to the House from Birmingham and Glasgow.

AMENDMENT OF THE COMPANIES ACTS.—The Bill to amend the law relating to limited liability companies, to which reference was made in the Queen's Speech, has now been introduced into Parliament. It made its *début* on the 15th inst. in the House of Lords, under the guardianship of Earl Dudley, Parliamentary Secretary to the Board of Trade, and was then read a first time. No date has been assigned for the second reading. The clause providing for the winding-up of companies in certain cases remains the same as in the draft Bill, referred to in the Journal for August 10 last (page 129). With reference to this Bill, which, by the way, is officially styled the Joint Stock Companies Law Amendment Bill, it is noteworthy that on Monday last Sir Albert Rollit elicited the reply from Mr. Ritchie that it had been thought best to follow the usual practice and have the Bill referred to Committees of both Houses.

METRIC SYSTEM.—According to the *Times*, Mr. Arnold Forster, M.P. for West Belfast, will take an early opportunity of ascertaining the opinion of the House as to the use of metric measures in specifications by promoters of private Bills. The Examiners of Bills have decided that the employment of such system of measurements constitutes non-compliance with Standing Orders. That decision is perfectly logical under the present law regulating to weights and measures, but there will be many persons in the United Kingdom whose sympathy will be with Mr. Forster in his efforts to remove what he thinks is an absurd restriction.

THE SELECT COMMITTEE ON PUBLIC PETITIONS has just made its first report on petitions presented to Parliament from February 11 to March 2. From the report it appears that four petitions with 6448 signatures have been presented in favour of the Early Closing Bill, and that four petitions with ten signatures have been submitted urging the House to sanction the adoption of the metric system of weights and measures in this country.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, MARCH 14, 1896.

THE AUSTRIAN 'ARZNEI-TAXE' FOR 1896.

A GLANCE over the 'Arznei-Taxe,' or regulations affecting the dispensing and sale of medicines in the Austrian Empire, shows, as might be expected, a very marked difference between the methods in vogue there and those to which we in this country are accustomed. The practical monopoly which the apotheker enjoys is rather dearly bought by the rigid and numerous rules to which he has to conform. A few extracts from the book may be of interest. The preface recites that this 'Arznei-Taxe' for the year 1896, based on the Austrian Pharmacopœia for 1889, shall come into force on January 1, 1896, and directs that every apotheker shall provide himself with a copy. It contains copies of various Ministerial decrees affecting pharmacy which are now in force; a list of the prices to be charged for drugs and chemicals; the charges to be made for various pharmaceutical operations; for the vessels in which medicines are dispensed; for bandages; and for veterinary medicines. Four schedules are appended. The first gives a list of the most dangerous poisons, which are directed to be kept in a locked-up cupboard; the second, a list of strong medicines, which are to be kept apart from others; the third, a table of the maximum doses; and the fourth, a list of articles which may only be sold by the order of a medical man.

It is directed that all prescriptions shall be clearly and legibly written; and that no medicine shall be dispensed from a prescription the meaning of which is not clear to the dispenser, without previously seeing the prescriber. If the physician has omitted to write the name and address of the patient on the prescription, this is to be done by the dispenser. In case the patient refuse the information it is ordered that a private mark be put on the prescription, so as to evade any chance of substitution or alteration. Repetition of prescriptions is only allowed for the original possessors. Where there is reason to fear misuse of the medicine, the physician is to write *ne repetatur*, and the apotheker is forbidden to repeat a prescription so marked. Before sending out any medicine the prescription from which it has been prepared must be clearly marked with the price of ingredients, labour, and containing vessel—bottle, box or pot. In open pharmacies the person who prices the medicine must also mark on the prescription the date when dispensed,

the name of the firm, and his own name (? initials). The sender-out of the medicine must put the date of despatch and his initials on the label. Doses in excess of the pharmacopœial maximum may only be dispensed if the sign (!) is appended; and the quantities must be written in words as well as expressed in figures. (This is an excellent regulation, and would save dispensers much doubt and worry if it were in force here.) The use of the words *Secundum meam prescriptionem*, or of any sign denoting a private understanding between prescriber and dispenser is forbidden; but if the physician wishes a specially low charge to be made to a patient he may write *Fiat expeditio simplex*, and the dispenser may then give the medicine in its cheapest form, and charge accordingly. Prescriptions may be dispensed below the official prices, but the ingredients must be of full weight and of best quality. In this case the rebate must be marked on the prescription. Any infraction of the foregoing regulations is punishable with fine up to 200 gulden (£20), or fourteen days' "arrest." Preparations for which formulæ are given in the Pharmacopœia must be prepared and sold in exact accordance with it. Newly introduced and untried remedies (*e.g.*, in 1889, resorcin, thallin, sulphonal, etc.) may only be supplied on the order of a practising physician.

Inventors of pharmaceutical specialties must content themselves with devising improved methods of administration of recognised medicines—such as copaiba, sandal, cubeb, and male fern—as for instance in capsules, dragées, coated pills, etc., calculated to make them pleasanter to the eye and taste. When a physician prescribes a remedy which is found in the shops in both the refined and crude states, but omits to say which he means, the purer or more refined is always to be used. (This rule would settle the question of what should be used when chrysarobin is ordered.) Similarly, when there are two or more dilutions or degrees of strength of a pharmacopœial preparation, the weaker should always be used in case of doubt. A complete set of reagents and apparatus for testing must be kept in every pharmacy, and must be in good order. The articles in the price-list, which are printed in heavy type, may only be sold on the order of a physician; with the exception of carbolic acid, zinc sulphate, and copper sulphate, when used as disinfectants, and of chloroform, when forming a part not exceeding 20 per cent. of a liniment. The right of preparing and selling medicines and pharmaceutical preparations is reserved to the apotheker, as is the sale of drugs and chemicals, except for use in the arts; but dietetic and cosmetic articles, most dental appliances, mineral waters, and surgical bandages, may be sold by others. Certain herbs, also, of which a list is given, may be sold by herbalists, who, however, must prove their competency to recognise them. The charge for preparing an ordinary decoction (up to 800 grammes) is 18 kreuzers; the charge for preparing an infusion, 15 kreuzers; dispensing a simple powder in paper (up to 200 gr.), 3 kreuzers; dispensing an ointment (up to 200 gr.), 5 kreuzers; making an emulsion (up to 200 gr.), 12 kreuzers; making an electuary (up to 200 gr.), 15 kreuzers; spreading a plaster (100 C.c.), 15 kreuzers; the leather for the same, 10 kreuzers; making a pill mass (up to 10 gr.), 10 kreuzers; rolling thirty pills, and dusting with lycopodium, 10 kreuzers; making a suppository mass (up to 15 gr.), 10 kreuzers; making the suppositories, each 5 kreuzers; each weighing a drug, or counting of drops, 1 kreuzer. The kreuzer is worth about a farthing.

THE SHOPS (EARLY CLOSING) BILL.

IN view of the interest now being manifested in Sir JOHN LUBBOCK'S Bill by correspondents, it may be useful to recall attention to its original provisions. Section 1 provides that on written application being made.

"and on being satisfied that not less than two-thirds in number of the occupiers of shops within the district, or the part thereof belonging to the class or to each of the classes to which the application relates, have signed the application, the local authority may if they see fit make an order giving effect to the application."

The hour to be fixed for closing may on any one specified day of the week be any hour not earlier than 2 p.m., and not earlier on any other day than 7 p.m. Section 6 provides that the penalty for a first offence under the Act shall not exceed five shillings, in case of a second conviction the limit may extend to twenty shillings, and in the case of a third or subsequent conviction the penalty may be increased to five pounds. If the offence has been committed by some agent or servant of the occupier, he shall be liable to the same fine as if he were the occupier. The saving clause for chemists, in Section 9, provides that—

"A pharmaceutical chemist or chemist and druggist shall not be liable to any fine under this Act for supplying medicines, drugs, or medical appliances after the hour appointed by an order made under this Act for the closing of shops, but this Section shall not be deemed to authorise the shop of a pharmaceutical chemist or chemist and druggist to be open after the said hour, save so far as may be necessary for the purpose aforesaid."

The Bill has been referred to the Standing Committee of the House of Commons on Trade, particulars regarding which will be found on page 210 of this week's Journal.

PHARMACISTS AND THE PHARMACY ACT.

THE weed-killer case, reported on page 209, affords an apt illustration of the difficulty experienced in proceeding under the Pharmacy Act against limited liability companies. It is remarkable that evasion of the provisions of the Act should be encouraged and assisted by those who might naturally be expected to take pains to secure their due enforcement. But there is reason for believing that the case now referred to is not an isolated instance of facilities being afforded by registered chemists and druggists to persons desirous of evading the Act, and the question may fairly be asked, what is the use of the Pharmaceutical Society endeavouring to persuade the public of the desirability of confining the retail trade in poisons to the hands of examined and registered individuals, if the latter countenance the delegation of the duty to unregistered persons, and even aid and abet them in breaking the law? From the chemists' point of view, also, it is clear that, whilst such conduct does not tend to secure the safety of the public, it prevents the due application of the provisions of the Act for the protection of those engaged in pharmacy.

CHLOROFORM FROM ACETIC ACID.

IN the latest number of the *Ephemeris*, Dr. E. R. SQUIBB, publishes a paper on the manufacture of acetone and of acetone-chloroform from acetic acid. A large rotary still, 12 feet long and 2 feet in diameter, is employed, which can decompose, in 126 hours, about 1700 pounds of absolute acetic acid, giving about 90 per cent. of the theoretical yield of acetone. The patentees of processes for making acetone from acetates, however, object to this process and to the use of the new apparatus, as being in conflict with their patents.

ANNOTATIONS.

THE ANNUAL DINNER.—A general meeting was held at the Pharmaceutical Society's house, 17, Bloomsbury Square, W.C., on Wednesday, with the object of making preliminary arrangements for the twenty-fourth annual dinner on Tuesday, May 19 next. Mr. M. Carteighe, the President of the Society, was in the chair, and there were present a number of prominent pharmacists. It was decided to hold the dinner in the King's Hall, Holborn Restaurant, and to have arrangements similar to those adopted in former years as to meeting the expenses of entertaining guests. The price of the dinner tickets is one guinea, and the Honorary Secretary, Mr. R. Bremridge, is the only person from whom tickets can be obtained. The following Committee was appointed to carry out details:—The President, Vice-President, and Treasurer of the Pharmaceutical Society, Messrs. C. B. Allen, Attfield, Bourdas, Butt, Feaver Clarke, Albert Cooper, Eastes, Hills, Hopkin, Paul, R. A. Robinson, Taylor, C. Umney, and Warren. Gentlemen desirous of assisting in making the twenty-fourth annual dinner a successful one are invited to send their names to Mr. R. Bremridge for addition to the list of stewards.

PHARMACEUTICAL DEGREES.—A grotesque example of the ineptness of the desire manifested by certain institutions in the United States to grant degrees to pharmacists who have undergone a course of instruction, is referred to by *Merck's Report*. It appears that an institution in New York State has a Bill before the Legislature by which powers are sought to confer the degree of Doctor of Pharmacy. The equipment of this College (or is it a University?) is described as barely sufficient for present purposes and wholly unfit for an advanced course of work. Moreover, it has no reserve fund, and is unable to pay its professors \$400 per annum.

'SCIENCE PROGRESS' for March opens with an article based on a lecture delivered at the Royal Institution by Dr. J. Burdon Sanderson, in which he shows how the science of physiology as we know it came into existence fifty years ago with the beginning of the active life of Karl Ludwig, in the same sense that ontology as we know it came into existence with the appearance of Darwin's 'Origin of Species.' In the order of time physiology had the advantage, for the new physiology was accepted some ten years before the Darwinian epoch. The introduction to the article is followed by a section devoted to Ludwig as an investigator and teacher, and finally the old and new vitalisms are discussed. Professor Reynolds Green's survey of what is known concerning the reserve materials of plants is concluded in this number, Professor J. Bretland Farmer writes on recent advances in vegetable cytology, W. Garstang on the morphology of the Mollusca, and G. F. Scott Elliott on African grass fires and their effects.

CRYPTOGAM EXCHANGE.—An exchange office for Cryptogams exists in Vienna, by means of which botanists are enabled to exchange or sell specimens. Every member is expected to send before September 15 two lists of those plants he undertakes to furnish until October 15, such list containing the name and address of the remitter, the Latin name and author of the plant, the place of origin, the number of specimens available, and any special information that may be useful. The plants are valued by the director of the exchange office, and an annual catalogue is published every December. Full particulars of the exchange will be sent to anyone interested on application to the Director, J. Brunthaler, IV., Wiedner Hauptstrasse 91, Vienna.

MR. M. A. LAWSON, F.L.S., the Government Botanist and Director of the Cinchona Plantations on the Nilgiris, died at Madras on February 14. Mr. Lawson was formerly Professor of Botany at Oxford, and went to India in 1883, where he formed an extensive herbarium of plants, and interested himself in the manufacture of quinine at Naduvatam. He was a corresponding member of the Pharmaceutical Society.

PHARMACEUTICAL FOOTBALL AND CRICKET CLUB DINNER.—The annual dinner of this Club will be held at the Holborn Restaurant, on Wednesday next, March 18, when the chair will be taken by Professor Attfield, at 7 p.m. The members of the Dinner Committee, Messrs. Senter, Stamp, and Tickle, will be glad to receive applications for tickets (5s. each) without further delay, at 17, Bloomsbury Square, W.C. Old students of the School of Pharmacy are specially invited to join their successors on this occasion.

"ETIDORPHA, OR THE END OF THE EARTH."—Some time ago a book with the above title was privately published by Professor John Uri Lloyd, of Cincinnati, U.S.A., whose long and wide connection with pharmacy renders any work produced by him of interest to pharmacists. In a large and handsome volume, perfectly printed, magnificently illustrated, and altogether elaborately produced, the author interweaves romance with science and mystery in a skilful and remarkable manner. He reveals himself as possessing a considerable grasp of science and philosophy, conjoined with an attractive literary style. The author's edition of the book having been exhausted, it is to be reprinted by the Robert Clark Company, of Cincinnati, at the exceedingly moderate price of \$2.

THE RESPONSIBILITY OF THE UNITED STATES PHARMACIST.—Pharmacists, observes *Merck's Report* (U.S.A.), are now all expected before the law to test their drugs. If they do not they cannot shift their responsibility on to the shoulders of others. The patient and his friends have a case against the pharmacist, and the outcome would be doubtful if the latter afterwards brought an action against the wholesale dealer or manufacturer, in view of contributory negligence on his part in not testing his goods. The higher the average education of pharmacists becomes, concludes our contemporary, the greater their responsibilities in this direction are sure to be.

MR. P. L. SIMMONDS, F.L.S., has been elected an honorary member of the Philadelphia College of Pharmacy as a mark of respect for his scientific researches and acquirements.

BRITISH ASSOCIATION.—The following is the list of sectional presidents for this year's meeting of the British Association, to be held at Liverpool in September, under the presidency of Sir Joseph Lister, who it will be remembered is also President of the Royal Society for the year:—Section A (mathematics and physics), Professor J. J. Thomson; section B (chemistry), Dr. Ludwig Mond; section C (geology), Mr. John Edward Marr; section D (zoology), Professor E. B. Poulton; section E (geography), Major Leonard Darwin; section F (economics), Leonard Courtney; section G (mechanical science), Sir Charles Douglas Fox; section H (anthropology), Mr. Arthur Evans; section I (physiology and pathology), Dr. Walter Holbrook Gaskell; section K (botany), Dr. D. H. Scott. It is expected that the evening discourses will be given by Professor Flinders Petrie and Sir Andrew Noble, and the lecture to working men by Professor Fleming.

PROCEEDINGS OF SOCIETIES.

Chemical Society.—An ordinary meeting of the Society was held on March 5, Mr. A. G. Vernon Harcourt, President, in the chair. The Röntgen rays were the attraction at this meeting, and it was very clear that the new photography was responsible for the almost overflowing meeting and the good sprinkling of ladies among the audience. Although the subject had not been published in the list of papers to be read, it was evident that the absorbing interest attaching to the subject justified its being sandwiched between two of Professor H. B. Dixon's papers. Mr. Jackson, of King's College, was the author of the paper on the "Use of Phosphorescent Substances to Show the Röntgen Rays," and he came to the meeting equipped with a full set of the apparatus necessary for an effective demonstration. Of the many fluorescent substances he had tried, he had found the platino-cyanide of potassium by far the best. A solution of the salt was painted on the cardboard screen, and was only effective when moist—a condition of things very difficult to keep up. It had to be kept constantly moistened with water. Crookes' tubes were considered the best, but as many as seventy tubes had been tried in order to get a perfectly satisfactory result. Mr. Jackson had tried almost every gas in the tubes to ascertain whether they would influence the rays in any way, but they made no difference whatever. Argon was the only one that had not been tried. Mr. Jackson, after having all the lights turned out, proceeded to demonstrate. The phosphorescent disc was quite visible, and so were sundry objects seen moving about in front of this disc. They might have been fingers or somebody's razor-case, but however plainly the anatomy or the metal blade stood out to those within half a dozen inches of the screen, the experiment did not by any means satisfy those outside of this somewhat short range.

In the discussion which followed, Professor Armstrong complimented Mr. Jackson, and paradoxically remarked that he had not been working in the dark, a piece of humour keenly appreciated by the audience, who were still blinking their eyes from the effects of the newly turned-up lights.

Sir Joseph Lister, at the President's request, made a few remarks as to the possible applications of the new photography in surgery. He said nothing, however, that has not already been suggested, merely emphasising the desirability of its being readily applied in the case of the whole body.

Professor H. B. Dixon's papers on "The Explosion of Cyanogen" and "The Mode of Burning Carbon" were of a somewhat controversial nature. He had worked for many years on these subjects. A large spark is necessary for the explosion of cyanogen, a small spark having no effect. In the presence of a certain amount of oxygen the carbon burns first to carbonic oxide, but if oxygen be in excess, the carbonic oxide formed in the first instance burns to carbon dioxide. Carbon monoxide and oxygen would not explode with moisture, or in the presence of bodies which would give up the elements of water. The drawing out of the flame is a problem, and there seems to be no explanation of the cause. It appears that the length of the pipe makes no difference. In the carbonic oxide explosion the flame is hardly perceptibly drawn out, it is a mere speck, whilst with carbon dioxide the flame is drawn out some three or four feet. Several photographs and diagrams of these flames were thrown on the screen.

A paper on "The Combination of Carbon and Hydrogen," by Dr. W. A. Bone and Mr. D. S. Jerdan, was read. The authors had been investigating the action of hydrogen and carbon (1) at a red heat, and (2) at the temperature of the electric arc. The carbon and hydrogen for these experiments were purified from all hydrocarbon substances. The purified gas was conducted through a porcelain tube (of the apparatus shown on the bench), in a suitable condition to prevent diffusion. Much difficulty was found in introducing the carbon into the tube quite dry. The products of the action contain roughly 1 per cent. of methane. No other unsaturated hydrocarbon was produced. The percentage of methane rose in other experiments. In the arc experiments the carbon was heated very strongly to expel gases. The apparatus was filled with hydrogen, and the arc passed from half-an-hour to two hours at 40 to 160 volts. The authors invariably found methane in the gas, and it increased with the time of the arc passed from 1.3 per cent. up to 3 per cent. Acetylene was found in considerable quantity, from 7 to 8 per cent. in several hours.

This terminated the business, and then there was a rush for the bench where Mr. Jackson was to show the Röntgen rays again.

The following papers were taken as read:—"Note on the *αα*-Dimethylglutaric Acids," by W. A. Bone, and W. H. Perkin, jun.

"The Symmetrical Dimethylsuccinic Acids," by W. A. Bone, and W. H. Perkin, jun.

"The Cis- and Trans-Methylisopropylsuccinic Acids," by W. H. Bentley, W. H. Perkin, jun., and J. S. Thorpe.

Plymouth, Devonport, Stonehouse and District Chemists' Association.—The junior section of this Association held its monthly meeting, last Thursday, at the Foresters' Hall, Plymouth Octagon. Mr. C. J. Park, President, presided, and a lecture was given by Mr. J. Kinton Bond, B.Sc., on "The Metric System." He fully explained the decimal system in weights and measures as used in France and many other countries, and pointed out the distinct advantage of such. Mr. Bond's address was thoroughly comprehensive throughout, and the members present were afforded an interesting and at the same time clear view of the whole affair. Mr. Bond was warmly thanked for his services.

Plymouth, Devonport, Stonehouse and District Chemists' Association.—A special committee meeting of this Association was held last Monday night at the Foresters' Hall, Octagon, Plymouth, to consider the candidature of the President of the Association (Mr. C. J. Park) for the Council of the Pharmaceutical Society, to take the place of Mr. G. F. Schacht, of Clifton. The following resolution was proposed by Mr. J. G. Netting (Vice-President):—"That this Committee heartily approves of Mr. C. J. Park, pharmaceutical chemist, 1, Mutley Plain, Plymouth, as a candidate for the Council of the Pharmaceutical Society, and strongly recommends the members of the Plymouth, Devonport, Stonehouse and District Chemists' Association to give him their hearty support."—Mr. H. D. Davey seconded, and the resolution was unanimously carried.—Mr. C. J. Park, when called before the Committee, returned thanks for the hearty support accorded him, and expressed his desire, if elected, to represent the commands of the members of the Society, and particularly those situated in the West of England.—It was agreed to issue notices calling a general meeting of the Association at Plymouth next Monday, March 16, to confirm the action of the Committee.

Leeds Chemists' Association.—A committee meeting was held on Friday, March 6, Mr. G. Ward, President, in the chair, when the following resolution was carried:—"The Committee of the Leeds Chemists' Association having met for the consideration of the subject of the Proprietary Articles' Trade Association's proposal, wishes to express its sympathy with the objects of the Association, and will be glad to call a meeting of the trade if the details of the scheme, when prepared, meet with its approval." Moved by Mr. Ward, seconded by Mr. Yewdall.

Midland Chemists' Assistants' Association.—A musical and social evening of this Association was held on March 4 at Exchange Rooms, Birmingham. Mr. John Barclay, B.Sc., occupied the chair. Several artistes whose names were on the programme were unfortunately unable to be present. Nevertheless, Mr. P. C. Arlaster, who had the arrangements in hand, was able to present some excellent performers, among whom were:—Messrs. Rogers, Williams, Firkin, France, Cornish, Osborne, Jones, Bindloss, and Ash (who accompanied). During the evening, it was announced that Mr. R. Darton Gibbs, President of the Midland Pharmaceutical Association, had consented to preside at the forthcoming dinner.

Edinburgh Chemists', Assistants', and Apprentices' Association.—The seventh meeting of the eighteenth session was held in the Pharmaceutical Society's Hall, 36, York Place, on Friday, March 6, at 9.15 p.m. Mr. J. Mackintosh Cameron, President, in the chair.

The minutes of last meeting having been read and approved, Mr. A. S. Birnie read a paper on "The Darwinian Theory," in which he subjected to a critical examination the arguments for and against the evolutionary theory as applied to the descent of man, and concluded by citing certain objections to the theory which have been satisfactorily dealt with by its supporters.

Mr. A. Thwaites then read a paper on "Fluid Extracts," in which he advocated the process of percolation as preferable to the present official methods. He illustrated his remarks by reference particularly to fluid extracts of cascara and ergot, of which he exhibited

samples. He expressed a hope that fluid extracts would be more largely introduced as a feature of British pharmacy as a means of attaining greater uniformity in the strength and greater reliability in the action of drugs.

The reading of the papers was followed by a discussion, taken part in by Messrs. Birnie, Cameron, Dey, McBain, Reid, Rowlands, G. Sinclair, D. Sinclair, and Thwaites, and on the motion of the Chairman, hearty votes of thanks were awarded to the authors.

Glasgow and West of Scotland Pharmaceutical Association.—At the usual fortnightly meeting, held on Thursday the 5th inst., Mr. W. L. Currie presiding, notes were submitted on "Aromatic Waters," by Mr. Alexr. Boyd, and on "Mucilage of Gum Acacia," by Mr. A. McKellar.

Before these were called up, the Secretary was desired to submit the following memorial to the meeting, as it had been drafted by the Law and Parliamentary Committee, and approved by the Council:—

"We, the members of the Glasgow and West of Scotland Pharmaceutical Association, urge upon the Council of the Pharmaceutical Society of Great Britain the advisability of directing the attention of the Home Office to the manner in which the Pharmacy Acts are represented in the Scottish Law Courts. In our opinion, the Pharmaceutical Society, to which the enforcement of these Acts has been entrusted, is unduly hampered in its administration, and its purpose in prosecuting offenders is misrepresented by the Judges, so that the public sympathies are abused; and convictions against offenders are not represented by the Bench in a manner calculated to prevent further offences, or to give due significance to the fact that the law has been infringed. These circumstances are subversive of a due regard for the observance of the law, and wanting in the spirit of equity. We particularly cite the following trials:—

"1. On October 23, at Dundee, before Sheriff-Substitute Campbell Smith, in the case of the Pharmaceutical Society v. Stewart; and also on the 25th, v. Finlayson.

"2. On October 26, at Edinburgh, before the Lord Justice Clerk, Lord Young and Lord Trayner, in the appeal cases the Pharmaceutical Society v. Turnbull and v. Hume.

"3. On December 16, at Glasgow, before Sheriff Fyfe, in the case of the Pharmaceutical Society v. Kerr.

"From these cases it will be seen that the comments made and the modified penalties inflicted are calculated to negative the good effects sought to be produced by securing convictions.

"We regard amendment of the Pharmacy Acts as being urgently needed; but, while they remain on the Statute Book we look to seeing them enforced in legal equity with a view to the attainment of that at which they are aimed."

The President rose to move the approval of the memorial.

Mr. A. Laing, in seconding the motion, said he would have preferred the responsibility to have rested on the Association rather than on the Pharmaceutical Society, and that it had gone forth in the name of all the chemists in Scotland. He did not think a single chemist would be contrary minded; even the *Chemist and Druggist* had written leaders condemning the procedure on the part of the judges.

The motion was carried unanimously.

At this point the President had to leave the meeting, and Mr. Jas. Robb occupied the chair, and Mr. Boyd introduced the first subject—"Aromatic Waters." He regretted that chemists were not freely allowed to use the still, as he considered distillation the best method of impregnating water with aromatic oils. Of other methods, if the oil were dissolved with alcohol and shaken with water, acetic acid developed after a time. He had tried pumice, phosphate of lime, precipitated chalk, carbonate of magnesia, and paper pulp. The powder in the finest state of comminution best fulfilled the requirements, but there was the objection that the powders were slightly soluble. If one drop of rose otto were shaken up with an ounce of hot water, the aroma was finer than by using powder, and he found paper pulp not nearly so good as magnesium carbonate. The method he adopted was to put the oil in a stone jar, with capacity for twice the quantity to be made, add the water at the boiling temperature, and shake.

Mr. McKellar then gave notes on mucilage of gum acacia, stating its weaknesses, that it turned strongly acid, and developed sugar. Various plans had been tried to prevent these defects, such as storing in six ounce bottles and keeping in a cool place, using lime water or solution of tolu. He had tried a saturated solution of acetanilide (2 grains to the ounce), which prevented mould, but the

mucilage ferments. Aluminium sulphate was a good preservative for paste, and might be for mucilage, though it was not desirable for medicinal use. He had a sample of chalk mixture made two days previously, and already a strong smell of SO₂ was evident. He could not detect the presence of sulphur in any of the ingredients. It had been suggested to him that the acacia powder might have been bleached with sulphurous acid.

Comments were made by various members, and several points of interest brought out. Mr. McKellar prepared aromatic waters by putting the oil on a plug of absorbent cotton and running the water through, and Mr. Blair, of the Western Infirmary, said chalk mixture made with chloroform water kept a reasonable time; several made their mucilage from the powder as required. Mr. Laing thought mucilage kept best uncorked, with a plug to keep out dust and microbes. Mr. Robb thought gum acacia had not been so good since the Soudanese war. The Chairman intimated the business for next meeting, "Coal and Coal Gas," by Mr. R. Tocher, of Maybole. Votes of thanks were accorded to Messrs. Boyd and McKellar for their notes, and to Mr. Robb for presiding over the meeting.

Liverpool Chemists' Association.—The first general meeting of the forty-seventh session of this Association was held on Thursday evening, February 20, the President, Mr. M. Conroy, F.C.S., in the chair. Messrs. C. A. Bentley and Harry Dyson, were admitted under the new rules as Associate members. A couple of good prints from Röntgen negatives were exhibited by Dr. Symes—one of a human hand, and the other a set of metal mathematical instruments in a wooden case.

An instructive and highly interesting lecture by Professor Boyce, of University College, was then delivered on the "Bacterial Analysis of Water," during which the lecturer rapidly and lucidly demonstrated the presence of various bacteria in water, described the commoner types, discussed the conditions favourable to their growth and development, their probable number and means of ascertaining it, their distribution, and lastly the absolute necessity of carefully conducted bacteriological examinations of drinking water generally.

Micrococci and bacilli of the common types, non-pathogenic, were shown on the screen with the optical lantern, and various chromogenic, gas-forming and phosphorescent bacteria were mentioned as among what might be called the weeds of the water, bacteria multiplying so rapidly that they absorb the pabulum necessary to bacterial life, and therefore crowd out and soon starve the more highly-developed pathogenic bacteria, such as those of typhoid fever. Cultures of the principal chromogenic bacteria were handed round, some reared on gelatin, others on agar-agar. The rapidity of growth of ordinary micro-organisms in water was explained by means of diagrams, as was also the effect of crowding out the typhoid bacillus by the bacteria of ordinary sewage. The excretory products of these common bacteria had a very destructive action on the pathogenic or highly-specialised bacteria, quite irrespective of this crowding or starving out, and it was stated that the purer the water was, and the freer from these bacterial weeds, the better it was adapted to the growth of the higher and dangerous bacteria, distilled water being the most favourable medium to their rapid development. Among the factors to be considered as unfavourable to the growth of bacterial weeds were high temperatures and sunshine, this latter being especially antagonistic to their propagation, and consequently vegetative activity of water micro-organisms is much less in summer than in winter. The life history of a bacterium was then shown by an excellent series of micro-photo slides, which gave a very clear idea of the numerous shapes and modifications a bacterium takes on at different stages of its life. The methods of estimation, counting, isolating, and obtaining pure cultures of the noxious bacteria in water were touched upon, the various pieces of apparatus were shown and explained, and the lecturer in conclusion reminded his audience that chemical analysis could only indicate the probable suitability of water for potable purposes, but it was only by a thorough bacteriological examination that such a water could be absolutely pronounced upon. The recent epidemic at Worthing was an exemplification of this. The town was being supplied with water which was certified by analysts as pure, until Dr. Klein on a bacteriological investigation isolated the typhoid bacillus.

In the discussion following the paper, Mr. Edward Davies, F.I.C., F.C.S., said that whilst being quite prepared for Professor Boyce's deprecation of the mere chemical analysis of water as a means of discovering pollution, he was somewhat surprised to have the

Worthing case given as an example of what bacteriology could effect where chemistry had failed. Three doubtful bacilli found in the water after the epidemic had been rampant for months and previous examinations had been fruitless, could scarcely with justice be claimed as a triumph of the bacterial examination of water over the chemical. The most fruitful source of the failure of chemical water analysis was the incompetence of the chemist who undertook it. When Medical Officers of Health were supposed to be competent to undertake water analysis after two or three weeks' experience in a laboratory before obtaining their diploma, it was not to be wondered at that chemical analysis should fall into disrepute. He held that given a competent and properly trained analyst water pollution could be detected with ease chemically, in all but very exceptional cases, whilst bacteriology only answered in exceptional cases, and then only when too late to be of utility. He proposed a vote of thanks to Professor Boyce for his interesting paper, and for the excellent manner in which the various points had been illustrated.

The vote was seconded by Mr. A. C. Abraham, F.I.C., F.C.S., who had intended, he said, to traverse much the same ground in his remarks as Mr. Davies had already done in such an able manner. He would draw attention to an extract from a paper by Dr. Thresh in the *Analyst*, for May, 1895, page 98, bearing on the points Mr. Davies had mentioned.

Professor Boyce shortly replied, assuring Mr. Davies that he did not imply that the chemical analysis of water was useless to detect pollution, but that it should always be followed by bacterial analysis, when from the united results an accurate and true estimate of the water's value could be obtained.

Chemists' Assistants' Association (London).—The eighteenth annual dinner of this Association, held on Thursday, March 5, was a brilliant success. The place of entertainment was the fine new King's Hall, at the Holborn Restaurant, and for what is believed to be the first time on record the chair was taken by the President of the Association. The results of this experiment proved completely satisfactory, the duties of the position being fulfilled by Mr. E. W. Hill in a manner that left nothing to be desired. The number present was about 240, the visitors including Professor F. T. Roberts, M.D., Mr. Michael Carteighe, Mr. John Harrison, J.P., Mr. Wm. Martindale, Mr. C. B. Allen, Mr. Richard Bremridge, Professor J. Reynolds Green, Professor H. G. Greenish, Mr. J. C. Hyslop, and many prominent members of the wholesale trade, including Messrs. Francis, Rogerson, J. C. Umney, and Slinger Ward. The toast of the "Medical Profession," proposed by Mr. A. R. Melhuish, was responded to in a happy fashion by Professor Roberts, who concluded by a sympathetic reference to one of his former pupils—Dr. Jameson—which was received with enthusiastic applause. Mr. Carteighe responded for the Pharmaceutical Society, in a speech that was remarkably non-didactic and of commendable briefness. Mr. John Harrison proposed the toast of the "Chemists' Assistants' Association," and Mr. Hill, in responding, referred to the ever-changing nature of the membership of the Association, some sixty new members joining every year and as many old ones resigning. The last toast—that of the "Visitors"—was proposed in a humorous speech by Mr. T. Morley Taylor, and Mr. Martindale briefly responded. The musical programme was excellently rendered by Messrs. J. C. Lyons, Wallis Arthur, S. W. Dawson, and Miles, the harp solos by the last-named performer being much appreciated, and the proceedings were brought to a close by the singing of "Auld Lang Syne."

Liverpool Pharmaceutical Students' Society.—A conversation was to have been held by the members of this Society on Thursday evening, March 5, but in consequence of the visit of the Pharmaceutical Conference to Liverpool later on in the year it was decided to postpone the function until then, and, instead, to have an exhibition of lantern slides on the night in question.

The exhibition was held in the Lecture Theatre at University College, the President, Mr. T. S. Wokes, in the chair, and was honoured by a good muster of members and their lady friends.

Mr. H. Wyatt, jun., gave a short communication to the effect that he had been experimenting with the prescription brought before the members at the last meeting by Mr. Mitchell (*ante*, p. 177), with the object of finding a method of preventing the decomposition taking place between the ingredients without having recourse to the use of mucilage. The result was that it was found possible to obtain by the use of glycerin a clear and elegant mixture, which would stand with but a faint deposit, easily diffused by shaking even after a lapse of a week. The formula advised was:—

℞ Ferri et quiniæ cit.	gr. 80.
Butyl chloral hydrat.	gr. 90.
Tinct. gelsemii.....	℥ 120.
Glycerini	ʒiv.
Aquæ, ad	ʒviii.

Heat the butyl chloral and glycerin with ʒii. of water in a capsule until solution takes place, then put into the bottle, and add half the water (ʒiv.); when cold, add the rest of the water with the citrate of iron and quinine dissolved in it and shake.

Mr. Jackson, whilst admitting that the sample passed round showed the modification to be both practical and elegant, thought that mucilage was preferable, as it was the most used in such cases. A prescription dispensed as Mr. Wyatt suggested would have an entirely different appearance to one in which mucilage had been used, and might lead to friction with the customer in case of a repetition at another chemist's.

In reply, Mr. Wyatt reminded Mr. Jackson that the first dispenser, if a member of the Liverpool Students' Society, would certainly not neglect following the good advice so often given by their President, Mr. Wokes, but would mark any such addition or alteration on the prescription for the guidance of future dispensers.

The lantern slide exhibition was then opened by an interesting series of Spanish views, explained by Mr. T. H. Wardleworth, who had visited the places shown and taken many of the photographs himself, concerning which he related several amusing anecdotes. Some well-selected bits in Wales, others from Bolton Abbey, and rural pictures taken in the neighbourhood of Liverpool were next exhibited by Mr. R. H. Mitchell, several of the plates toned to a warm sepia tint by the uranium process having a very pleasing effect. Pictures from the Wirral peninsula, and some excellent Italian architectural views and landscapes taken by Mr. H. B. Morgan, the Honorary Secretary of the Society, then followed, the final portion of a very enjoyable and instructive evening being occupied by Mr. Penketh, who showed pictures illustrating a tour in the Isle of Man, which were, without exception, well-finished and artistic productions. Refreshments were served at the close of the meeting. The University authorities are deserving of the gratitude of the "students" for the readiness with which they provide the optical lanterns, electric light, and other necessaries used during these meetings.

Exeter Association of Chemists and Druggists.—A meeting of chemists and druggists in the Exeter district, organised by this Association, was held at the Arcade Lecture Hall, Exeter, on Thursday afternoon, March 5, to consider the objects of the Proprietary Articles Trade Association. Mr. G. R. Barclay (Barclay and Sons, Limited, a member of the Council of the Trades' Association), presided, and there were also present Messrs. H. Gadd (Evans, Gadd and Co., President of the Exeter Association), A. Tebbutt (W. Sutton and Co.), and H. S. Norris (Condal Water Co., also members of the Council), Glyn-Jones (Secretary), J. H. Lake (Vice-President, Exeter Association), P. F. Row-ell (Hon. Secretary, Holman, Ham and Co.), Jackson (Crediton), Dyer (Honiton), J. Bartleet (Heavitree), W. F. Sanders (Budleigh Salterton), J. Foster (Collumpton), H. W. Gadd (Exeter), Robson (Tiverton), D. Reid (Exeter), T. C. Milton (Exeter), Lake, junr. (Exeter), E. R. Hoblyn (Exeter), and E. F. Stone (Exeter).

Mr. Rowsell read letters, regretting inability to be present, from Messrs. E. Lemon (Exeter), S. Thornton (Exmouth), J. Cornelius (Newton Abbot), N. V. Stone (Newton Abbot), A. Richards (St. Thomas), H. B. Penberthy (Sidmouth), O. W. Catford (Crewkerne), Vinden (Exeter), W. Wright (Newton Abbot), and Pratt (Barnstaple).

In calling upon Mr. Glyn-Jones to address the meeting, the Chairman said he was sorry to say that up to now the movement had not had that ready support as they expected it would have had from the trade. Several manufacturers and most of the London wholesale houses had, however, he was glad to say, joined the Association, and since they had been holding such meetings as this a large number of retailers had joined.

Mr. Glyn-Jones, after thanking the Exeter Association for organising the meeting, and having given a *résumé* as to the origin and history of the anti-cutting movement, said it had often occurred to him that the bulk of the three branches of the trade were really anxious that something should be done with respect to the sale of proprietary articles. He believed that the manufacturers had at last come to the conclusion that their best friends were the legitimate trade, and that if they were prepared to ensure a living profit on the sale of their goods, retailers were prepared to handle them, but

they one and all would say that they would not keep open shop and stock their goods without any remuneration whatever being received. They who used to be the friends of the proprietor had become the greatest stumbling blocks to the sale of his goods, and he candidly confessed he hoped it would go on until every manufacturer under the sun recognised that it was to his interest to guarantee to men who would distribute his goods fair profits for distributing them. He believed eighty or ninety per cent. of the trade were quite willing to distribute these goods, provided they received fair profits. The wholesale trade, he was glad to say, were with them. Mr. Gadd for instance, had taken a most lively interest in the movement from the beginning, and had, with other gentlemen, given valuable support. If goods were to-day distributed at five per cent. profit upon the price originally paid for the articles, he asked how on earth could the wholesale distributors make a profit, and give the retailer a profit too? On the previous Tuesday they had a very important meeting of the manufacturing section of their Council, and at that meeting they decided unanimously to adopt the principle of a minimum price being fixed for each article. As an Association they strongly advocated that the minimum price should be the full price; that if a man advertised the article to the public he should advertise and sell it at its proper value. There were some manufacturers who were prepared to say their goods should not be sold under market price. These manufacturers would combine together for this purpose:—A man who cut one of these goods would not be able to obtain any of them except at such prices as would prevent him cutting. In order to do that it was necessary to have the support of the wholesale houses and retailers in this matter. He could not help feeling a certain amount of sympathy for the Pharmaceutical Society. He candidly confessed that he used to be one of those men who did nothing else but growl at that body. He now found that the Association could no more do what they wanted to without the assistance of the retailer than they could without the Pharmaceutical Society. This was a question the Pharmaceutical Society could not very well take up, but now it had been taken up, he looked to them for support. They had succeeded well at Bristol and at Plymouth. At Bristol they had enrolled twenty-five members, and at Plymouth over thirty, whilst Mr. Norris, who had been in the neighbourhood for the past week or two, had obtained about twenty more members.

Mr. H. Gadd then proposed the following resolution:—

"That this meeting, having heard the report of the representatives of the Proprietary Articles' Trade Association, pledges itself to support the organisation in its endeavour to place the trade in proprietary articles upon a sound and equitable basis."

On behalf of the Exeter Association Mr. Gadd thanked the deputation for coming there to address that meeting, which he was pleased to say was thoroughly representative of the district. Friends at Dawlish and Teignmouth, who were unable to be present that day, but who had been seen by Mr. Norris, had promised to support the movement. His opinion was that cutting was going from bad to worse, and by and bye they would be left something like the proverbial animal that had subsisted on a straw a day. But they did not want to feel that the profit they were making in one section was being lost in another. How was it possible to pay rates, rent, taxes, and salaries out of the profit they got in handling those articles? If it was a severe punishment to the retail chemist, how much more so must it be to the wholesale chemist! Their loss was far greater, and he pitied any firm that had to entirely depend on the sale of patent medicines and proprietary articles. He admitted that at first he looked with suspicion on the movement and thought it was doomed to failure, but after meeting with Mr. Barclay and other gentlemen, he felt that the scheme was not so unpracticable as it at first appeared to be. Whilst there were thousands of articles which came under the head of proprietary articles and were liable to be cut by the trade, the articles on which they depended for the principal sale were very few indeed, and if they could get a small number protected at first, they would be on a fair way to having their wishes realised with regard to the rest. With respect to the Pharmaceutical Society, if one and all had joined that Society instead of so many remaining outside, more would have been done for the retail chemist in the past, and if they were all united on this question, he quite hoped and believed there was a better day in store for them.

Mr. J. H. Lake seconded, and spoke of the value of the Pharmaceutical Society. It would be better for the trade if outsiders joined the Society. He thought that in supporting this new Association they were doing a right thing.

The resolution was carried unanimously.

Mr. D. Reid then moved the following resolution:—

“That this meeting of registered chemists in Exeter and its neighbourhood requests the Council of the Exeter Association of Chemists and Druggists to act as a local executive in connection with the Proprietary Articles' Trade Association.”

He thought they would be standing in their own light if they did not take advantage of the present scheme in order to get something like a fair profit on the sale of proprietary articles. Therefore he had pleasure in supporting the movement, and hoped it would be brought to a successful issue. He, however, did not think for a moment that many chemists who had spent a good deal of talent and time in getting some preparations of their own would abandon them in favour of these articles. Retail chemists would do well to stick to their own preparations, but, still, if the manufacturers were willing to give them a decent percentage for retailing proprietary articles they would sell them without demur.

Mr. Dyer seconded the resolution and Mr. Tebbutt supported. It was his firm conviction that with the support of the trade the Association would put the sale in proprietary articles upon a more equitable basis. It could only be done by strong combination between the manufacturers, wholesale distributors, and the retail trade.

The resolution was carried unanimously.

Mr. Norris then proposed the following resolution:—

“That this meeting of registered chemists in Exeter and its neighbourhood desires to express its pleasure at seeing that a large number of influential manufacturers have already joined the Proprietary Articles' Trade Association, and to assure them and all other manufacturers that any steps they may take in connection with the Association to ensure fair profits would meet with the approval and cordial support of every legitimate retail trader.”

He thought that the placing of a minimum price on the article made a loophole for cutting, and that it should be sold at the price which was put on the label. He had maintained his prices in face of the store trade. The movement was solely in the hands of the retail traders, and the manufacturers. If the retailer did not support the proprietor and the manufacturer he would have no hesitation for one in dropping the scheme. They could only have, say, 25 per cent. profit by combining together to forward the objects of this Association.

Mr. Milton seconded the resolution. He came to the meeting with a certain amount of suspicion, but Mr. Glyn-Jones had placed the matter clearly before them, and he, equally with others, would be only too glad to subscribe to any association which would help them to increase their profits. He dared say he was regarded in Exeter, to an extent, as one of the cutters, but he denied that. He had traded for many years on one system, and he would continue to do so. His system was not to allow chemists, grocers, or the stores to cut below his prices. He had never cut anyone knowingly. He thought there should be two prices. Every cash payer should be encouraged. He considered that 1s. 1½d. articles should be booked at 1s. 1½d., but that the cash price should be 1s. They would, he thought, be satisfied if they got 15 per cent. clear profit.

Mr. Hoblyn complained of the manner in which poisonous patent medicines were being cut. He thought the full and proper price should be put on them.

Mr. J. H. Lake said the sale of poisonous patent medicines was entirely in the hands of chemists themselves.

Mr. Jones, in reply to various questions, said he did not suggest that chemists should not push the sale of their own preparations, but he thought that without any binding clause they would be prepared to sell without question over the counter any goods upon which they made a clear profit of 20 or 25 per cent. What they wanted was for everyone to be on the same level, and making a profit. If they would give an undertaking not to sell the goods under a certain price, they would promptly deal with the cutters. If they found a man cutting they would at once communicate with the Secretary, who would investigate the case. If they could not get the man to conduct his business in a fair way, his name would be added to a list of persons to be debarred from obtaining goods at other than the full or maximum prices. With regard to the question of poisons, he must say they stood before the country in a ridiculous attitude. They had organisations on all hands, and even the dock labourers could put their heads together and get 6d. where before they used to get 4d. But there were eight or nine thousand chemists in the country who had the sole right to sell poisonous patent medicines, and yet they allowed them to be cut. He suggested that a personal canvass of the chemists in the district should be made, with a view to getting them to support the movement.

Mr. Rowsell said he thought the margin of profit should not be less than 20 or 25 per cent.

Mr. Milton said he suggested 15 per cent. as the minimum, not the maximum margin.

Mr. Rowsell here read a letter regretting inability to be present from Mr. Holloway, of Fleet Street, Torquay, who said: “It has been suggested to me that mine is an ambiguous position as a member of your Council, I being a leading cutter, but it seems to me these are the very men you want in this scheme, with which I am in full sympathy.”

The resolution was carried unanimously, and on the motion of Mr. Bartleet, seconded by Mr. Jackson, a vote of thanks was accorded the representatives of the Proprietary Articles' Trade Association, and the meeting terminated.

ENGLISH NEWS.

LORD RAYLEIGH ON LIGHT.—In his lecture on light at the Royal Institution on Saturday afternoon, Lord Rayleigh remarked that colours on passing through a lens were dispersed and the rays bent. If the bending was greater for one colour than another no perfect image could be formed. They might, however, by an arrangement of glasses overcome all that, and also all the refraction, as in the telescope. He went on to speak of the discussion of this which took place in the time of Newton, and said it had been determined that it was possible to make achromatic glasses, and that the eye was not achromatic. By experiments with crown and flint glasses he showed how the dispersion of colours was overcome, and remarked that the same thing applied to lenses. Turning next to speak of the colours of thin plates, he said that the main facts were developed with much success by Newton in his “Optics,” but Young was the first to explain the colours of these plates from the point of view of the wave theory, and to show that on that basis all the complicated effects admitted of simple explanations. Lord Rayleigh exhibited some figures of “Newton's rings” on the screen, and said that in order to analyse the phenomena Newton suggested light from one side of the spectrum only. By the way in which he thus used the red and the blue Newton got the key to the formation of colours when white light was employed, and so established the scale of colour. Lord Rayleigh next proceeded to make some interesting experiments by means of films or bubbles, which proved most successful, notwithstanding his promise that it was difficult to get a good soap solution for the purpose, and that a chemist who devoted his attention to that point would confer a great benefit. They wanted soap film, he said, that would stand some amount of knocking about. The first of these rings or bubbles was shown with the Newton rings of colour brightly marked at the top, but fading away towards the bottom. To the next a little air was applied, and some really fine effects of colour were obtained, the difference in the thickness of the colours being described as due to differences in the thickness of the film. One of the best films was spoken of in general terms as made of collodion, though there were certain details of preparation that had to be followed, a final step being to lift it off the surface of water by means of a ring, when it could be kept for some time. Lord Rayleigh had two of these films prepared, and with them showed some of the most gorgeous effects of brilliant and varying colours. In that case, however, the colour was not due to thickness, but to the film being double. One fact in relation to soap films, he said, was that their capillary tension did not depend on the thickness of the films, as, in spite of different thicknesses of the film, the tension was practically the same. This led him to speak in some detail of the effect of the interference of light and reflection.—*Daily News.*

A COMPLAINT AGAINST THE BRITISH PHARMACOPEIA.—In his annual report to the West Riding County Council, Mr. Alfred H. Allen, the public analyst for the West Riding, says the number of drugs submitted during 1895 was largely in excess of any number analysed in any previous year. He thinks it a misfortune that the current edition of the British Pharmacopœia is very defective in many of its definitions and descriptions of the articles authoritatively recognised therein, and it is additionally unfortunate that the law does not in so many words constitute the British Pharmacopœia the official standard for the drugs described therein.

DEFICIENT SWEET SPIRIT OF NITRE.—Mr. Walter James Ward, chemist, of Conisborough, was charged at the Doncaster Court, on

Saturday, with having sold adulterated sweet spirit of nitre. On February 25, Mr. Wilson, of Rotherham, went to Mr. Ward's place of business and bought 4 ozs. of sweet spirit of nitre. On analysis the liquid was found to contain 65 per cent. of spirit and 35 per cent. of water. The defence was that the spirit was all right when it left the main shop for the branch at Conisborough. Since the nitre was purchased the man in the shop had received notice to leave.—A fine of 40s., including costs, was imposed.

INLAND REVENUE PROSECUTION.—At Marlborough Police Court, on March 4, Richardson J. Dodd, a chemist, of 70, Tottenham Court Road, answered to five summonses taken out at the instance of Thomas Cusack, an officer of Inland Revenue, for selling certain medicines without having the necessary stamp attached to each bottle and box.—Mr. Alpe, barrister, prosecuted on behalf of the Inland Revenue authorities, and Mr. Robert Todd, solicitor, defended.—The defendant pleaded guilty, his solicitor urging that he was not present when the articles were sold to the Inland Revenue officer, and that he was greatly in the hands of his assistants.—Mr. Alpe pointed out that the defendant had been fined previously for a similar offence.—Mr. Hannay imposed fines amounting to £40.

ILLEGAL USE OF METHYLATED SPIRIT.—At Clerkenwell Police Court, on March 6, Ebenezer Marshall, of 36, St. Paul's Road, St. Pancras, was summoned for having on January 1 sold an article capable of being used internally as a medicine, viz., "Marshall's Red Bottle," in the preparation of which methylated spirit had been used, contrary to the Statute.—Defendant pleaded guilty and ignorance of the law.—A solicitor who appeared for the Excise Authorities stated that the penalty was £100. The preparation should have been made with ordinary spirit of wine, which paid duty at the rate of 16s. per gallon. As methylated spirit paid no duty, the Revenue was defrauded. Persons who made the preparation in a proper way were also unfairly handicapped. The defendant sold the stuff at a private house.—Mr. Horace Smith imposed a fine of £10.

THE NECESSITY OF THE POISON LABEL.—An inquest was held at Cockington Farm, Alvington, on March 5, on the body of Studley Lee, aged about three months, son of H. Samuel Lee, farm labourer.—The father of the deceased deposed that his wife had recently been suffering from phlebitis, and had been using a kind of paint. On the previous Monday two of his children drank some of the contents of the bottle.—Dr. Matthew Richard Gooding, of Bideford, stated that the preparation was "belladonna and glycerin," to be used as a paint. It was intended only for outward application, but was a poison in excess. Witness was not in the habit of labelling a mixture of that kind "poison." People knew it was only to be applied externally. He found the deceased suffering from the poison, but the elder child did not seem much affected. He used the stomach pump and antidotes and stimulants, staying nearly an hour. The deceased died from the effects of belladonna poisoning.—The Coroner, in summing up, said he did not think there was much blame attaching to the father for leaving the bottle about.—The Jury found a verdict of "Death from misadventure."

THE HOLBORN EXPLOSION.—Dr. G. Danford Thomas resumed the inquest upon the body of Mr. A. F. St. George, who was killed by the explosion of an iron cylinder while making an experiment in connection with a patent for the manufacture of candles, at 15, Red Lion Square, Holborn, on February 20.—Colonel Sir Vivian Majendie represented the Home Office.—Mr. T. W. Glass, assistant to Messrs. Redwood and Hailes, said the final operation in connection with the work that the deceased was engaged upon was to fill the cylinder with stearic acid, glucose, and alcohol. On the Wednesday night deceased commenced heating the cylinder, but postponed it until next day. He placed the cylinder on the furnace at 12.25 p.m., and twenty minutes later a noise was heard in the vessel. Deceased, however, said he was not of opinion that the noise came from the cylinder, and he was holding an instrument on the top of it when the explosion occurred. Witness was injured about the face.—By Colonel Majendie: There were also a little acetic acid and a few iron nails in the cylinder. There was a valve to the cylinder, but it was closed. Deceased wished to get a pressure of two atmospheres on the substance he was working. Witness did not feel there was any danger, as the deceased was an expert chemist.—Dr. Dupré, chemical adviser to

the Explosives Department of the Home Office, produced the cylinder, which was rent from top to bottom. Stearic acid expanded much more quickly than water when heated, and, in his opinion, the explosion was caused by the overheating of the cylinder, which was a good one of its kind. The mistake lay in filling the cylinder quite full and overheating.—By Colonel Majendie: There was not the slightest fault in the cylinder.—The Jury returned a verdict of "Accidental Death."

SCOTTISH NEWS.

ACONITE FOR HORSERADISH.—A distressing case of poisoning occurred in Aberdeen on Friday last (6th), James Robertson, 20, residing at Mount Street, was working on some ground near the Allenvale Cemetery, and ate a root which he dug up. He was seized with illness, and showed symptoms of poisoning. He went home, where he told his mother that he was dying, having eaten a root which he thought was horseradish. He expired twenty minutes afterwards. It has since been proved that the root eaten was taken from an aconite plant.

PROPOSED REVIVAL OF A WESTERN CHEMICAL INDUSTRY.—Owing to the discovery of a new process of making chlorine and bleaching powder, the industry will in all probability be resuscitated in Glasgow on a large scale at an early date. The new process is the joint invention of Mr. Adolph Vogt, chemical engineer, and Mr. A. Ross Scott, manager of the Carntyne Chemical Works, and experimental plant has been in operation at the works of the Carntyne Chemical Company, Parkhead, Glasgow, with highly satisfactory results. The process is as follows:—Gaseous hydrochloric and nitric acids are brought into contact in a specially designed and constructed apparatus, through which a constant stream of heated sulphuric acid flows. The sulphuric acid absorbs the water formed by the inter-action of the two gases, and while it passes out of the apparatus into an overflow, and is concentrated to be used again, chlorine and a compound of chlorine with nitrous oxide go forward to a series of towers. In these the nitrous oxide and some hydrochloric acid are removed, and the chlorine in a pure state passes on, either to be absorbed by lime in the usual way, forming a bleaching powder of high strength, or to be condensed into liquid chlorine. The nitrous gas recovered in the towers is re-converted into nitric acid, to be again used in the process of manufacture. Apparatus for the re-conversion of the nitric acid has also been erected for experimental purposes, and has been found to give thoroughly satisfactory results. As the outcome of the complete process, it is stated that the whole of the chlorine and salt used can be converted into bleaching powder, a result hitherto unattained, whilst only a very small percentage of the acids used in the process is lost.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND.—The monthly meeting of the Council was held on Wednesday the 4th instant, the President, Mr. W. J. Wells, jun., in the chair.

The President expressed regret at the result of the recent case of the Pharmaceutical Society of Ireland *v.* Boyd, in which the Queen's Bench Division of Ireland held that a limited liability company was not a "person" under the Pharmacy Acts, and therefore not liable to be dealt with as such for carrying on the business of a pharmaceutical chemist. The case had been most ably fought for the Society by their counsel, Messrs. Gordon, Q.C., Campbell, Q.C., and Day. Unfortunately as the question was brought before the Divisional Court on a "case stated," there was no appeal. He was bound to say that the judges did not go out of their way to give a decision in favour of the Society. That was hard to understand when the Society was carrying out a duty for the protection of the public. In the smaller courts throughout the country the Society got anything but sympathy. It was the duty of the Council not to take this decision of the question as final, and they waited the advice of their solicitor and counsel as to whether it could not be carried to the House of Lords in some other case. Meantime it would not be a bed of roses with the limited companies, for if they employed unqualified persons to compound or sell poisons, those persons would be liable to prosecution.

Mr. Turkington asked, would not the limited companies have to put the names and addresses of their qualified assistants on the labels they used? The President said that was a nice point which had not yet been raised.

In reference to the case of Mr. Cleeland and the nine assistants and apprentices of Gratton and Co., Limited, who had sent in a memorial asking to be admitted to the examination for the licence, a letter was read from Messrs. Casey and Clay, the Society's solicitors, after which Mr. Beggs moved that the applications of Mr. Cleeland and the nine other memorialists be acceded to. Mr. Grindley seconded the motion. The President said Mr. Clay had told him that the only way in which they could admit these young men was by rescinding the regulation which kept them out. If the Council did that it would be giving up the whole situation. Mr. Turkington and Mr. Conyngham strongly opposed the motion, which after considerable discussion was carried by 7 votes to 2.

ULSTER PHARMACEUTICAL ASSOCIATION.—A social meeting of this Association was held on the 3rd inst. in the rooms of the Society, 5, Royal Avenue, Belfast, Mr. William Prott, M.P.S.I. and E, presiding. There was a very large attendance of Belfast pharmacists. Refreshments were served, after which an excellent musical programme was presented by members and friends of the Association, every item being rendered in artistic style, and well received by the large and appreciative audience.—On the motion of Mr. G. H. Waugh, M.P.S.I., seconded by Mr. R. S. Moore, Ph. Ch., a hearty vote of thanks was passed to the performers for the excellent programme, which was responded to by Mr. F. Picton, Mr. W. Imrie, and Mr. Fred. Smith. Herr Louis Werner, conductor Belfast Operatic Society, and Mr. Picton, Mus. Bac., Oxon, played the accompaniments in a faultless manner.—A vote of thanks to the Chairman, on the motion of Mr. R. W. McKnight, M.P.S.I., seconded by Mr. R. Ritson, M.P.S.I., and the playing of "Auld Lang Syne" by the band, brought a most successful meeting to a close.

A PRESCRIBING CHEMIST.—Dr. Kenny, M.P., Dublin City Coroner, at an inquest, held on Monday last on the body of a girl aged ten, severely censured a Mr. Popham Allen, L.P.S.I., for prescribing for deceased whose death was found to be due to peritonitis. Mr. Allen said as he had served his time to his father, a medical man, he thought he had a right to prescribe in minor cases; but the Coroner told him he had no such right.

NO SECRET MEDICINE will be permitted by the Irish Local Government Board to be charged on the rates; and they have notified the Carlow Poor Law Guardians to that effect regarding "French's Cure for Epilepsy," which the medical officer had requisitioned for.

AN UNOFFICIAL REPORT has been received by the Irish Local Government from an infirm inmate of the North Dublin Workhouse, complaining of the management of the infirmary, of which he had nearly three years' experience. In the course of his letter he stated: "All the medicine and poisonous ointments and lotions for external use are in the hands of inmates, which I believe is contrary to the law of Her Most Gracious Majesty the Queen." On the part of the workhouse officials it was suggested that the complaints were due to the stopping of a "stimulating" mixture, which the inmate had been receiving.

OBITUARY.

ATKINSON.—On February 23, E. S. Atkinson, Chemist and Druggist, Knottingley. (Aged 68.)

SWINGBURN.—On February 27, R. H. Swingburn, Pharmaceutical Chemist, South Molton. (Aged 54.) Mr. Swingburn was local secretary for South Molton, and was a former student in the Society's School of Pharmacy.

BROWN.—On February 27, William Brown, Chemist and Druggist, Monkwearmouth. (Aged 59.)

GRINDELL.—On March 2, William Grindell, Chemist and Druggist, Hull. (Aged 73.)

THOMAS.—On March 3, Henry Thomas, Pharmaceutical Chemist, St. Lawrence. (Aged 85.)

PENTELOW.—On March 8, Harry Pentelow, Chemist and Druggist, late of Lincoln. (Aged 38.)

CORRESPONDENCE.

THE DECAY OF PRESCRIBING.

Sir,—The abolition of pharmacology as an examination subject will, I fear, in the near future exert a prejudicial effect on the work and status of the skilled pharmacist. For many years it has fallen to my lot to have to impart to medical students, on the point of presenting themselves for their final examinations, some knowledge of the art and mystery of prescribing, a subject concerning which they are usually profoundly ignorant. A man may be an accomplished diagnostician and a profound pathologist, and yet be unable to write the simplest prescription. His difficulty is not so much in prescribing the right thing as in prescribing anything at all. If this has been the experience of the past, what are we to expect in the future? What chance is there of teaching therapeutics when the student knows nothing of the very foundation on which it rests? It is true that pharmacology is still retained as a lecture subject, but no student will devote much attention to a subject on which he knows he will not be examined. We can compel his bodily attendance in the lecture-room, but his thoughts will be elsewhere. We may play on the pharmacological pipe, but we cannot make him dance; he will remain ignorant of the action and uses of drugs, and will, in due course, be sent out into the world without knowing how to prescribe for the commonest symptom or the most simple disease. In five or six years from now we shall have growing up around us men who from sheer timidity will rarely venture to prescribe anything but the simplest remedies. The pharmacist may display the time-honoured inscription, "Prescriptions dispensed with care," but there will be no medicines for him to compound. The unfortunate qualified practitioner, whilst cursing the stupidity of the authorities who made him devote the best years of his life to the acquirement of much useless knowledge, and left him ignorant of the means of alleviating the sufferings of his patients, will in despair, fall back on the preparations of the advertising chemist. When he has a case of sciatica he will prescribe someone's "Antisciaticine"; when a patient complains of lumbago he will recommend him to try "antilumbagine," and when hæmorrhoids engage his attention, he will have nothing better to suggest than a careful application of the popular remedy "antipiline." These and similar preparations—all made in Germany and of unknown composition—will be his stock-in-trade. Patients will cease to consult him, unless, perchance, they want an autopsy performed, and the pharmacist finding his occupation gone, will endeavour to eke out a miserable subsistence by competing with the grocer and the oil shop in the sale of patent medicines and druggist sundries "at store prices."

Welbeck Street, W., March 5, 1896. WILLIAM MURRELL, M.D.,
Lecturer on Pharmacology and Therapeutics
at the Westminster Hospital.

SHOPS (EARLY CLOSING) BILL.

Sir,—I have been inclined to believe that the Council of the Pharmaceutical Society was a sufficiently intelligent body to support Sir John Lubbock's Bill *nem. con.*, therefore, the remarks made by Mr. Hampson at the Council meeting were particularly displeasing to me in tone and sentiment. "Individual Liberty" may be a cry in keeping with a trader's sense of liberty, in which character Mr. Hampson uses it and shows a mind undisciplined to an extent I would not have given him discredit for; but when a two-thirds majority of the traders involved is necessary to make the Bill operative individual liberty is amply provided for. It is a senseless cry, suited to an Eastern despot only. I cannot conceive of the English people being degraded by a wise control under statute laws, which the more intelligent Scotch, and English too—else we would never have had this Bill—know to be for the good of the whole. I look to the Council for support of the Bill, strenuous if need be; but certainly unequivocal.

Glasgow, March 10, 1896.

ALEX. LAING.

EARLY CLOSING FOR CHEMISTS.

Sir,—In your article under this heading of last week you court an expression of opinion by those who hold views favourable to the general intentions of the Bill. In my opinion there is very grave reason why we should take advantage of everything that will help us in this way. We are all the time grumbling because the trade is so dissociated, but what time have we for meeting together at an hour which would be generally convenient? As a calling we are largely outside all public bodies and institutions of every description, and we wield by no means the influence that our education and status should carry with it, mainly because nearly all such work is done after other people's business is over, but while we have the full strain. When are our young men to educate themselves for their life's work? In this town we are specially fortunate in having a most highly organised and efficient technical school, but I make bold to say that there are very few pharmaceutical students there. It is all but impossible for them to be spared. Why should they need to be "spared"? They ought to be free to go. "Early Closing," does not appear to me to complain of the place where he undergoes "slavery," but rather seems to complain of the general conditions ruling almost everywhere, which cannot be escaped by going from one employ to another. There is but one pharmacy in this town closed before nine o'clock, and there are several open after ten, and on Saturday nights busy between eleven and twelve midnight. The thing is disgraceful, but no one can help it. You say the Bill proposes legal restraints on trade. We say it does nothing of the sort, but only restraint on the time of trading and of some selfish traders who will always hang about for the last bawbee that is to be had. You want to be told why those who as assistants fretted under these conditions continue the practice as employers. To an extent we do not. Matters are better than a generation ago, but only slightly, and, despite your argument to the contrary, we are all only a part each in a great whole. There may be a strong man here and there who can stem the tide and act individually, but these are few and far between. Let the Council and the Journal act in sympathetic appreciation of those whose business is largely trading, and for the next election let all the grumblers do their grumbling practically by inaugurating a Council more to their ideas. This can be done, but only the grumblers can do it.

Riverside Pharmacy, Cardiff.

W. J. SANDERS.

SHOPS (EARLY CLOSING) BILL.

Sir,—I am amazed at the apathy of the general body of shopkeepers in regard to the Shops "Early Closing" Bill, now being rushed through the House of Commons. A correspondent some time ago in one of the daily papers described it as a "Small Tradesman's Annihilation Bill," a very true and accurate description. I suppose they will continue to slumber on in blissful ignorance until it finds its way on to the Statute Book, and they wake up to the fact of what it means. I have before me a copy of this Bill, which bears upon every page of it the stamp of the professional agitator, who has over everything to gain and nothing to lose; a Bill, I maintain, most unjust, and one calculated to lead to (and will if passed) endless trouble and annoyance—in fact, I believe it will mean simple ruin to numbers of small tradesmen. It is a direct interference with lawful trade. I am obliged to Messrs. Hampson, Martin, Allen, Hills, and Gostling for the stand they have taken upon this question in the Council. I regret exceedingly the Council did not see its way to oppose it to the utmost as a needless, impracticable, and vexatious Bill, a restraint upon honest industry.

I know it is said, "But you will still have the two-thirds majority?" Yes; but I hold, sir, that a two-thirds majority have no moral right to coerce the remaining one-third in a matter so serious—the obtaining an honest livelihood. The stale argument usually resorted to, as you observe, "because others keep open," is simple nonsense, and in no sense a valid reason, but really and truly a bogey. Let those who can afford it close early if they think proper, and be thankful they are able to do so. I confess I cannot afford it (when I can I will undertake to say my neighbour will not influence me), and to coerce the remainder (one-third) will lead to very serious consequences. I, for one, do not think that the shopkeepers in general, and the chemists in particular, will quietly submit to such restraints being put upon legitimate trade. Close early, and the public will shop early, it is said. Nothing of the kind; a great part of it would never be done at all. Is it not a fact that the larger part of the shopkeepers do the bulk of their business in the evening? Are there not numbers of chemists who have no need for an assistant

except at night? Close early, and no assistants would be required in numberless cases. Again, who is going to decide for us this sacred line of demarcation between things lawful and unlawful? That I suppose will be left to the P.C. on the beat, to step inside whenever he may think proper and see what is going on. I am quite willing that the rights of the assistant should be safeguarded to the fullest extent, but that I am not to be permitted to carry on my business as I may choose without his aid is, in my judgment, a unique piece of injustice. Sir J. Blundell Maple and other members also recognise the dangerous character of the Bill, and I am pleased to see their names added to the grand committee, and I trust he will do his utmost, on behalf of the small tradesman, that the principle of his own amendment be incorporated in the Bill. I do not hesitate to say not simply as a chemist, but as a tradesman, that if this Bill becomes law, as it now stands, it will mean simply ruin to large numbers.

May I offer you, Mr. Editor, my respectful sympathy or congratulation on the onslaught "Early Closing" has seen fit to make upon you and the Society, threatening to leave you stranded high and dry; do not fear, we shall not all leave you thus. Let "Early Closing" wait until he is the happy possessor of a model pharmacy of his own, around which there springs up half a dozen cutting stores, coupled with the regular periodic demand for rent, rates, taxes, salary, and sundry other trifles, he will then be competent to express an opinion. You are right, sir, these gentlemen who scream the loudest when they are employed, are the greatest offenders when they are employers. I do not think there are many assistants exhibiting such a dissatisfied spirit as "Early Closing." I know many, personally, who have good reason to congratulate themselves upon the conditions under which they serve.

London, March 10.

M. P. S.

"CASH CHEMISTS."

Sir,—I perfectly agree with Mr. Henry's remarks in last week's issue, and am greatly interested in the matter, as no doubt thousands of other men are. It is high time something was done to prevent limited companies from using the title "Cash Chemists." It is very unfair to men who have been compulsorily educated at considerable expense in order to pass the examinations of the Pharmaceutical Society, and whose prospects in the near future will be entirely ruined if companies are allowed to trade in the same manner as legally qualified chemists. I have been in business nearly seventeen years, and have gradually found my trade going to the so-called cash chemists, Slippers and Boots, Limited. The public are greatly deceived and misled by the above title. The Act was never intended to apply to limited companies but only to individual persons, and why this sort of thing has been allowed to progress, which it is doing to a very serious extent in this city, is a puzzle to many. If the Pharmaceutical Society wish to become popular they must use all the means in their power (and that soon) to stop this company trading under false colours.

Sheffield, March 9, 1896.

SMILAX.

ANSWERS.

"ENQUIRER."—The readiest method is to dissolve an aniline colour in water with the addition of a little gum.

"LIGNUM."—We do not know the formula for "liq. ferri phosph. magnetic, Lightfoot." Possibly some reader of the Journal may be able to oblige, but it is doubtful if the formula has ever been published.

"ASSISTANT."—You might get Gorham's 'Tooth Extraction' (H. K. Lewis, London, 1s. 6d.). Of course, you only require the book for reference, and will learn the art under a skilled teacher.

W. E. MEATS.—Probably during the present publishing season, but the fact is not yet announced.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Bartlett, Bayley, Bindloss, Callis, Cracknell, Dewson, Dixon, Durbin, Ellinor, Ferguson, Hagon, Hill, Hinde, Hoseason, Ince, Laing, Meats, McKnight, Netting, Pollitt, Russell, Sanders, Smith, Volans.

Several communications are unavoidably held over on account of want of space. Correspondents are requested to write as briefly as possible.

JAVANESE PATCHOULI.

BY J. CH. SAWER, F.L.S.

The word "Dilem," which is now rapidly coming into use to designate patchouli leaves from Java as a special production of that island, is very inaptly applied, and very misleading—for several reasons. In the first place, there are two distinct varieties of the plant grown in Java (as hereafter explained and illustrated). Secondly, the word "dilem" is not a pure local word, but a common Malay word, which has long been in use in the Straits Settlements to designate the ordinary patchouli* produced in those districts. This fact came to my certain knowledge quite twenty years ago:—I had been requested by the late Eugène Rimmel to supply to his firm five bales of fine Malayan patchouli herb; fortunately, Mr. John Fisher was then in London, and he kindly gave me the most accurate information concerning the plant. The bales were delivered from a large parcel which had recently been shipped from Singapore to London, and I had one bale opened at the London Docks to inspect and sample. A portion of the sample thus taken I have handed to Mr. E. M. Holmes, F.L.S., for purposes of comparison with more recent importations from the Straits or elsewhere. I venture to state that such comparison will show that the character of the leaf formation has remained constant; also that such character is quite in accord with that of the plants vended by Louis Van Houtte, of Ghent, as *Pogostemon patchouli*.

After minutely describing to me the methods of cultivation of the plant, and distillation of the oil on his estate, Mr. Fisher informed me that the ordinary name of the herb in the Straits Settlements was "Dilem," meaning a mattress stuffed with these leaves (a very common practice, as I explained on page 80 in the last volume of this Journal). Considering that Mr. Fisher was resident for many years in Province Wellesley, and was probably the largest grower and distiller of patchouli, his information was beyond doubt; but yet, finding that great stress is now laid upon

the word "dilem" as meaning purely a Javanese specialty, I wrote to Dr. Romburgh, of the Botanic Gardens, Buitenzorg, Java, for specimens. These he very kindly supplied at once; from these specimens I made the drawings here reproduced, showing the flowering variety, Fig. 1, and the non-flowering one, Fig. 2. The Fig. 2 A is a facsimile of a leaf of the non-flowering plant and Fig. 1 A the same of the flowering one from different parts of the stalk (of course, the nearer the flower-spike the smaller the leaf). Dr. Romburgh says that in the wet season the leaves of the non-flowering plant attain a larger size than the specimen sent.

The main differences in the appearance of these two plants from each other, and from the well-known Malayan plant, are apparent at a glance from the figures here given, but Mr. E. M. Holmes has kindly undertaken to thoroughly describe their botanical structure, and to compare them with already known species of *Pogostemon* and *Plectranthus*.

The oils from these two plants differ from each other very considerably in odour; also from the Malay oil. The odours of both are intensely powerful and persistent, so much so that after sniffing one of them, the second one cannot be fairly appreciated if smelt at once; and if the least particle of oil should come into contact with a hair in the nostrils that nose is good for nothing during the rest of the day. In testing the odours of such powerful oils it is best to smell them in a diluted state, or, by allowing a minute drop of oil to evaporate from a sheet of paper in one room and the same from another sample in another room.

Messrs. Schimmel and Co. state, in their report of April, 1895, that "supplies of the beautiful Java variety of leaves have been completely wanting for a long time"; also, in their report of October, 1895, "the sale of patchouli oil has been greatly affected by the present rage for strong scents, and the oil is one of those in daily use in perfumery."

In view of the large business which may be done in these Javanese oils, it would be well to identify the plants by absolute

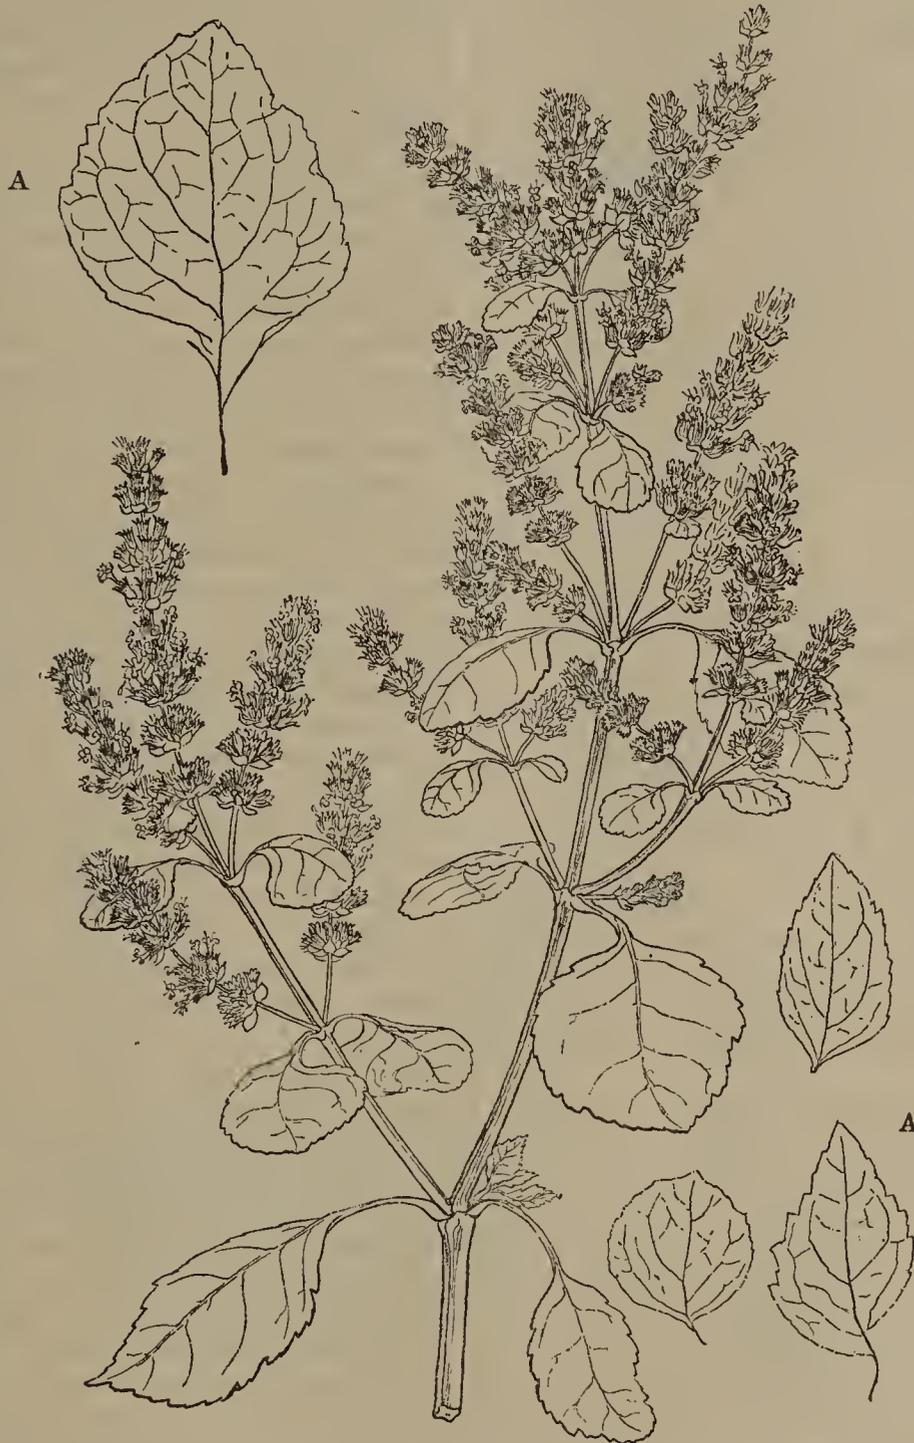

FIG. 1.—JAVANESE PATCHOULI.—THE FLOWERING VARIETY. Two-thirds Natural Size.

* 'Odorographia,' pp. 293-308.

specific names, and to drop the word "dilem" altogether. It is with this object that the present paper is written. The two Javanese

FIG. 2.—JAVANESE PATCHOULI.—NON-FLOWERING VARIETY.
Two-thirds Natural Size.

plants do not appear to have been previously figured in any work or journal, and may therefore be of interest.

NOTE ON DILEM AND PATCHOULI.

BY E. M. HOLMES, F.L.S.

Dilem.—The occurrence in commerce of a volatile oil called dilem, resembling oil of patchouli in odour, but differing from it in some respects, has led, as Mr. Sawyer has justly pointed out, to some degree of confusion, since the name dilem, or nilam, seems to be applied to several plants of the genus *Pogostemon*, as well as to patchouli.

The plants which pass under this name in the Soudanese and Malay languages are *Pogostemon menthoides*, Bl.; *P. comosus*, Miq.; *P. gracilis*, Hassk.; *P. cristatus*, Hassk.; *P. fraternus*, Hassk.; and *P. tomentosus*, Hassk. By the natives of Java the name dilem is applied to *Coleus atropurpureus*, Benth. ('Filet, Woordenboek,' 1888, p. 79). Whether any of these or all of them have the odour of patchouli I have at present no means of ascertaining, but only one of these, viz., *P. menthoides*, is stated by Miquel ('Flor. Ind. Batav.,' (2), p. 962, 964, 1856) to be placed among clothes to keep off insects. It may be here mentioned that the word dilem (or tilam, as it is given in Swettenham's 'Malay Vocabulary,' p. 119) means a mattress, in allusion to this use of patchouli.

The statements concerning the dilem used for distilling the oil are as follows:—In the 'Verslag 'Slands Plantentuin te Buitenzorg,' 1893, p. 53, it is pointed out that the plant cultivated in the garden under the name of *Pogostemon patchouli*, but of which the identification was still uncertain, has a growth less strong than the other (i.e., ordinary patchouli), and that it flowers freely, and can be propagated from seeds as well as from shoots. It would appear that the plant received by Mr. Sawyer as the "flowering plant" is the plant recognised at Buitenzorg as the dilem of com-

merce, for it is further stated in the 'Verslag,' 1893, p. 55, that Messrs. Schimmel have obtained from the "flowering plant" an oil from this plant resembling patchouli, but with a slight anise odour, sp. gr. 0.961, there seems to be little doubt that this is the one yielding the dilem oil prepared by them. In order to determine which species this plant may be it is necessary to know the species of *Pogostemon* which occur in Java, which are given by Miquel as follows:—

1. *P. patchouli*, Pell. (cultivated); 2. *P. heyneanus*, Benth.; 3. *P. plectranthoides*, Desf.; 4. *P. gracilis*, Hassk.; 5. *P. cristatus*, Hassk.; 6. *P. tomentosus*, Hassk.; 7. *P. comosus*, Miq.; 8. *P. menthoides*, Bl., to all of which the name of dilem is applied. The only other species of the genus mentioned, as found in Java, is 9. *P. fraternus*, Miq. The dilem plant would, therefore, appear to be referable to one of these.

On comparing the descriptions given by Miquel with the flowering plants received by Mr. Sawyer, it is noticeable that in the latter the hairs on the leaves and stem are closely appressed, the hairs being so thinly present that the veins show of a red-brown colour. In *P. gracilis* and *P. cristatus* the leaves are glabrous; in *P. menthoides* the hairs are short and spreading, or deflexed; in *P. tomentosus* and *Coleus atropurpureus* the hairs are spreading; and in *P. fraternus* the few hairs present are erecto-patent. The only three species having the hairs closely appressed are *P. plectranthoides*, *P. heyneanus* and *P. comosus*. The first has leaves with a finely biserrate margin, more rigid, and of a lanceolate outline different to that of true patchouli, and large bracts, which exceed the calyx in length. *P. heyneanus* has fewer flowers in the verticillasters, which are from one inch apart below to a quarter of an inch apart at the apices, larger more oval-lanceolate leaves of a thin substance, and bracts equalling the calyx in length. With *P. comosus*, Miq., Mr. Sawyer's plant agrees well in the close approximation of the verticillasters, in the lanceolate bracts equalling the calyces, and in the number of flowers in each verticillaster. The specimen with which I have compared it is one collected in Java, by Horsefield, and is deposited in the Kew Herbarium.

It may, therefore, I think, express the opinion that the dilem plant of European commerce is the *Pogostemon comosus* of Miquel; but how far this species is distinct from *P. heyneanus*, Benth., is another matter. So far as can be judged from herbarium specimens, *P. heyneanus* is a variable species. The typical specimen in Wallich's herbarium,* No. 1532, from Heyne's herbarium apparently consists of two plants, of which the right-hand specimen agrees in the small widely separated verticillasters (in which it resembles *P. paniculatus*, Benth., with the two other specimens in the same herbarium, and may therefore be supposed to be the type of *P. heyneanus*. In the British Museum herbarium, the same form occurs under the names of *P. heyneanus*, Wallich, No. 1532, *P. glabra*, Benth., var., and *P. patchouli*, Hooker and Thoms. In the herbarium of the Pharmaceutical Society there is a specimen of the same form from Singapore, received from Mr. H. N. Ridley, M.A., labelled *P. patchouli*, and I have seen similar plants from Ceylon under the same name. This would, therefore, appear to be a distinct form, if not a species; I therefore regard this plant which has small, distant, few-flowered verticillasters and thin leaves, with sub-entire, or only slightly-toothed margins, as the typical *P. heyneanus* of Wallich. The left-hand plant on Wallich's specimen, No. 1532, from Heyne's herbarium, has more triangular, not linear-lanceolate calyx, teeth, and approximated verticillasters, and appears to correspond well with Wright's figure 'Icones,' 1440), which I should refer to *P. comosus*, Miq., and not to *P. heyneanus*, Wall., as is done in the 'Flora of British

* Wallich's herbarium is in the possession of the Linnean Society of London.

India.' As to the specific rank of the two plants, I can offer no opinion, but as distinct forms met with in different localities, and easily recognisable as different in habit, it is convenient to distinguish the two plants by different names.

With respect to the non-flowering plant from Java, I cannot pretend to offer an opinion. It differs from *P. patchouli*, Pell., in its acute, almost acuminate, sharply serrated leaves and less tapering base, but agrees with it in the character of the densely crowded erecto-patent white hairs, which mark out the lateral veins like white lines.

Patchouli.—In looking through the genus *Pogostemon* in our National Herbarium, I have gained some light on the geographical origin of the true patchouli plant, which has hitherto not been definitely ascertained. Professor Tenore (Parlatore, in 'Giorn. Botanico Ital.', 1847, p. 48) states that he obtained the plant described by him as *Pogostemon suavis* from the Paris Botanic Gardens, but that its origin was not certainly known there is clear from the fact that he suggests China with a note of interrogation (possibly because Chinese ink is known to be perfumed with it?)

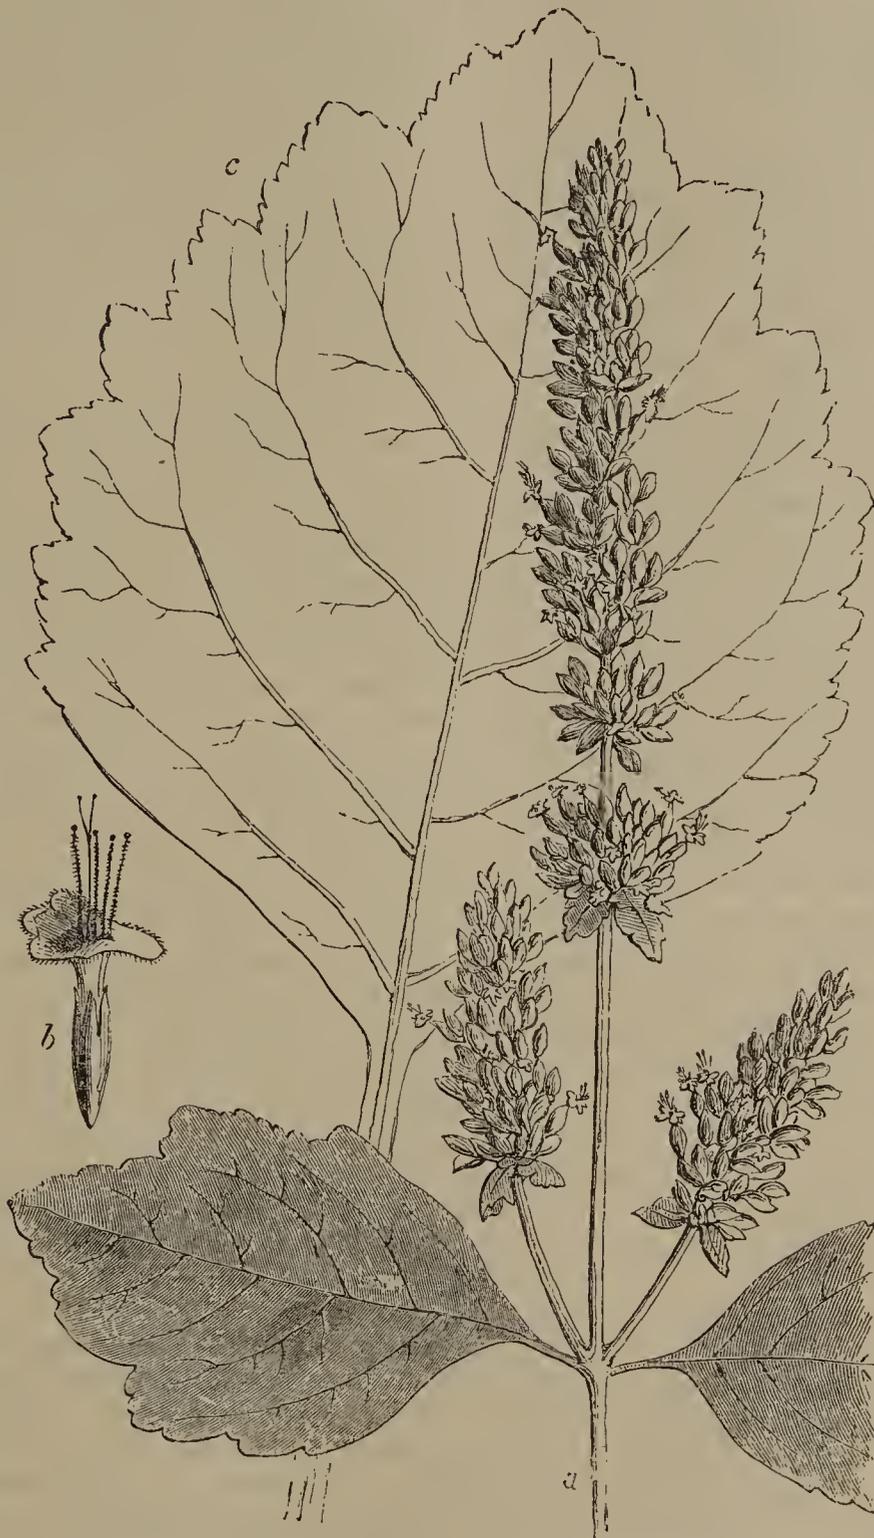

A plant brought by Mrs. Bentham from Professor Tenore and cultivated at Kew subsequently flowered there, and was figured in 'Hooker's Journal of Botany' and 'Kew Miscellany' (1849), i., p. 329, tab. xi., and of which the original is now in the Kew Herbarium. The plant was also figured and fully described by Dr. Pelletier-Sautelet in the *Mem. de la Soc. Roy. des Science d'Orléans*, v., No. 6, 1845; it flowered at Orleans in the month of February. A translation of this article with the figures of the leaves and flowers of the plant appeared in the *Pharm. Journ.* [1], viii., pp. 574-576 (reproduced here). These are, I believe, the only figures of the plant extant. As a rule, it flowers very sparingly, as is the habit of many plants which are cropped before they flower, or which are grown under circumstances calculated to develop foliage luxuriantly. Thus in Mr. Sawyer's 'Odorographia,' pp. 294-295, Mr. Wray, of Perak, is quoted as stating: "Patchouli is a very shy flowerer, so much so that by the natives it is said never to flower, and Mr. Hardouin told me that though he had grown it and bought it for the last thirty years, he had never seen or heard of such a thing as a flower. The plant cultivated on Mr. Fisher's estate at Province Wellesley does not

flower, and a plant introduced from Penang into the Botanic Garden at Calcutta did not exhibit during ten years any disposition to bloom." This plant, *P. patchouli*, is easily distinguished from *P. heyneanus* by its stouter, broader leaves, obtusely crenate-serrate, and by the lateral veins being quite hidden by a dense coating of slightly erecto-patent, not appressed, white hairs, so that the veins look like white lines. The figure of the leaf given in 'Odorographia,' on p. 295 is quite characteristic.

This plant, which was first correctly described as a *Pogostemon* under the name of *P. patchouli* by Dr. Pelletier-Sautelet in 1845, was subsequently described by Tenore in 1847 as *P. suavis*, but by Bentham, in De Candolle's 'Prodromus,' vol. xii, p. 153, the earlier name of *P. patchouli* is rightly retained. At that date Bentham had apparently not seen a plant, which he enumerates as *P. (C) cablin*, described by Blanco in the 'Flora de Filipinas' (1837), p. 473, under the name of *Mentha cablin*. A specimen of this plant appears to have been presented to the Kew Herbarium in 1883, but as Bentham had placed the species in the section of *Pogostemon* having dense, simple, spike like inflorescence, it was far removed from the patchouli plant. On going through the genus, however, I was struck with the remarkable similarity of the plant to the true patchouli, and on comparing it closely I found it agreed in every particular. In this identification both Mr. N. E. Brown and Mr. Rolfe, who were in the Herbarium at the time, agreed. It may therefore be regarded as certain that the plant is indigenous to the Philippine Islands, the plant in the Kew Herbarium bearing the label: "Calamang, Luzon, October, 1833. S. Vidal." The native names for the plant are cablin, carlin, cadlin, catloen, and gablin.

This plant is certainly cultivated at Penang, and in Java as well as in India.

Neither *P. patchouli*, Pell., nor *P. heyneanus*, Benth., nor *P. comosus*, Miq., can possibly be confounded with the patchouli plant of Khasia and Assam (*Kew Bull.*, March, 1888, p. 74, and 'Fl. Brit. India,' iv., p. 624), which is there placed under the genus *Plectranthus* as *P. patchouli*, Clarke. It has cordate-ovate, acuminate, crenate-serrate leaves, with scattered spreading hairs and flowers, in which the upper lip is hooded almost as in *Scutellaria*, whilst the inflorescence forms a loosely-panicked cyme.

Pogostemon patchouli, Pell.; (a) branched inflorescence, (b) flower, (c) leaf (natural size).

It is now placed in the new genus *Microtoena* as *M. cymosa*, Prain. In conclusion, the results arrived at are as follows:—The "flowering" plant from Java is *P. comosus*, Miq. This plant is the dilem of German manufacturers of essential oils. The non-flowering plant from Java cannot be identified at present, in the absence of flowers. The non-flowering plant from Singapore is *P. patchouli*, Pell., which is a native of Luzon, in the Philippine Islands.

The plant known as patchouli in Khasia and Assam is now called *Microtoena cymosa*, Prain.

EUCALYPTUS OINTMENT.

BY J. BOSISTO, C.M.G.,
Victoria, Australia.

Honorary Member of the Pharmaceutical Society of Great Britain.

The diverse opinions expressed by writers in the *Pharmaceutical Journal* of Great Britain upon the subject of eucalyptus ointment appear to refer only to the adjunct best adapted with eucalyptus oil for the purpose of forming the ointment. An ointment of eucalyptus containing simply the volatile oil does not supply the full virtues of its vegetation for ointment purposes. Of the numerous species, all of which contain medical or sanitary properties, none possesses an emollient principle in any degree equal to that of the *E. amygdalina*, which, in conjunction with the oil, produces an unguent of considerable importance. This species presents a delicate leaf surface, differing from most of the other species. It contains an essential oil, 1.30 per cent., an oleo-resin, a persistent liquid acid (termed eucalyptic acid), and tannin (a trace), together with chlorophyll. The chief active agent of amygdalina oil is phellandrene, a much milder principle, and better adapted for the purpose than eucalyptol. It is an antiseptic of no mean order. The abundant oleo-resinous substance in the leaves imparts to an unctuous body its emollient character; the remaining proximate principles assist in forming an elegant and valuable ointment.

Per this mail I have sent a parcel of the leaves of *Eucalyptus amygdalina*, carefully dried for export. The Research Committee can investigate for themselves; and if they so wish can, through the Society, report accordingly to the B.P. commission. In Australia the fresh leaves are employed, but the leaves carefully dried for export will only be at the expense of the pigment of the chlorophyll. The formula here employed is as follows:—

Eucalyptus leaves (green or dried) of the <i>Amygdalina</i> species	1b. i.
Prepared lard	1b. ij.
Yellow wax	2 ozs.

1. The leaves are crushed into a coarse powder.
2. Melt the lard over a water bath, add the contused leaves, allow to simmer for two hours, and strain.
3. Dissolve the wax, add it to 1 and 2 whilst warm, allow it to cool gradually.

It would be advisable when the dried leaves are employed to add say one ounce of the amygdalina oil to the above formula. In Victoria this ointment has been employed with great success in fetid suppurations, indolent wounds, ulcerated sore legs, boils, etc. These observations are presented with the desire that a correct formula (if desired) should be available.

FORMALIN IN OPHTHALMIC PRACTICE.—Dr. Mackenzie Davidson finds a 1 in 2000 or 1 in 3000 solution of formalin an excellent antiseptic in cases of injury to the cornea and other wounds resulting in septic ulcerations. The solution is applied freely once every hour into the eye with a dropper or teaspoon. In a case of corneal ulcer accompanied by pustulous eczema of the eyelids and face, equally good results were obtained with the hourly application of a 1 in 2000 formalin lotion (*Lancet*, I., 96, 145).

NOTES ON THE PREPARATIONS AND FORMULÆ OF THE BRITISH PHARMACOPŒIA.

SYRUPS.

(Continued from page 204.)

Syrupus Ferri Iodidi (continued).—When working on a larger scale the use of calico (washed in boiling water to remove starch) is preferable as a filtering medium for the solution of ferrous iodide, paper filters almost invariably giving way under the weight of the liquid. And as a practical point in connection with the manufacture of iron solutions for syrups by the reaction of metallic iron with either a halogen or an acid, it may be remarked that commercial wrought iron is generally covered with a film of grease and plumbago, the removal of which, by washing with hot solution of caustic soda, facilitates chemical action and materially enhances the brilliancy of the product. As heating may be conducive to oxidation, it may be avoided by adopting a formula based upon that of the French Codex or the U.S.P.:—

R Iodine.....	8	ozs.
Iron wire	4	ozs.
Water, freshly boiled but cold	10	ozs.
Simple syrup to	10 $\frac{3}{4}$	lbs.

Digest the iron with the iodine in the water in the usual way until all free iodine has disappeared. Then filter into some of the syrup, and make up to the given weight or volume, whichever is preferable. This syrup is equivalent to the B.P. one in strength (4 $\frac{1}{2}$ grs. in ℥i.), but has a specific gravity of 1.330.

Several pharmacists have from time to time advocated replacing 50 per cent. of the sugar with glucose (Hammen, *Ph. J.* [3], vol. xiii., 1079; Klié, 'National Dispensatory,' 1559). This is hardly necessary, for if a freshly-prepared syrup and recently boiled distilled water are used, any proneness there may be to the reduction of the iron is greatly reduced. A syrup like the one given will keep for a considerable time in perfectly fresh condition, provided it is not unduly exposed to the air. The opinions as to the best method of preserving this syrup are not concordant. Some observers advocate exposure to direct sunlight, others diffused daylight, and some that it should be protected from the light. The French Codex directs that it shall be protected from the light (*Ph. J.* [3], vol. xviii., 1022; 'Nat. Disp.,' 5th edit., 1559). In the face of such conflicting evidence it would scarcely be expedient that any such directions be given, but let each one use his own discretion. It might be an advantage to give one or two tests to preclude the use of deoxidising agents, such as hypophosphorous acid, citric acid, etc., and also to state a process whereby the strength of the ferrous iodide may be estimated, by titrating with silver nitrate solution or else determine the amount of free iodine liberated by chlorine or hydrogen peroxide. A note as to storage in small bottles filled to the neck would give a finishing touch to the formula.

Syrupus Ferri Phosphatis.—Viewed from the standpoint of our present knowledge of pharmaceutical chemistry, this formula cannot be said to be up to date. The preparation of ferrous phosphate by precipitation is open to objection on the score of inconvenience, trouble of manipulation, and the great difficulty, if not impossibility, of obtaining the precipitate in a well-washed, and at the same time unoxidised condition. As a very small amount of ferric salt is sufficient to communicate a tinge of brown, the official syrup is generally wanting in the pale sea-green tint characteristic of pure ferrous phosphate. The large excess of phosphoric acid employed renders the syrup unpalatable and consequently unpopular; it also promotes discoloration by its action on the sugar.

Alterations appear to be called for in the directions of substituting a better process for the production of the solution of ferrous phosphate, and considerably reducing the phosphoric acid. The process dependent on the direct solution of metallic iron in phosphoric acid has now had many years' trial, and is generally admitted to be the most convenient, reliable, and in every respect the best for the purpose. R. Wright, in a paper read before the British Pharmaceutical Conference in 1888, showed that about half the quantity of phosphoric acid ordered in the B.P. formula was sufficient to ensure perfect solution of the ferrous phosphate and prevent precipitation on dilution. So strongly acid is the official syrup that an ordinary dose, one fluid drachm, contains free acid equivalent to more than the maximum dose of acid. phosph. dil. B.P.

The formula suggested by Wright is as follows:—

Iron.....	45 grains.
Concentrated phosphoric acid	6 fl. drachms.
Distilled water	9 fl. drachms.
Syrup	8 fl. ounces.

Mix the acid with the water, place in a glass flask, add the iron, plug the neck of the flask with cotton-wool, and heat gently until solution is effected. Filter into the syrup, and wash the filter with sufficient distilled water to make the product measure 12 fluid ozs.

Syrupus Ferri Subchloridi (B.P. Addendum).—The number of grains of anhydrous ferrous chloride per fluid drachm which this syrup is supposed to contain might be stated. The form was introduced in the Addendum of 1890, but has not apparently been popular with the medical men; though pharmaceutical it is almost an ideal syrup. It is proposed to delete it in the next edition, and apparently its fellow preparation, the syrup of ferrous bromide, is to take its place.

Syrupus Hemidesmi is now only used as a flavouring agent, and is of little medicinal value. Its omission from the Pharmacopœia would help to make room for more important syrups at present unofficial.

Syrupus Limonis.—Adherence to the official instructions results in a product which, although possessing an excellent taste and aroma of lemon, is also distinguished by its liability to change and crystallise. The lemons ought to be peeled of both rind and pith, then cut into small slices and pressed. The juice thus obtained should be heated in an enamelled pan for about ten minutes, which causes a more complete separation of the albuminoid matter than when simply heated to 212° F., and withdrawn as at present directed. Heat at this point of the process has no deleterious effect on the juice. Then add to the liquor whilst hot the thin peel, allowing it to infuse for fifteen minutes. Strain off the juice on to the sugar whilst hot. When the sugar has dissolved, pass the resulting syrup through a flannel filter. A bright full-flavoured syrup can be readily made this way, which does not become turbid very readily if at all. It is unnecessary to allow the peel to remain in the juice for so long, as now directed, since all the necessary aroma of the peel can be abstracted by a fifteen minutes' infusion without obtaining an unnecessary amount of inert extractive. The quantity of sugar might with advantage be reduced, so as to make a gravity of 1.320.

A better formula, from a pharmaceutical standpoint, is the following:—

Lemon juice strained.....	1 pint.
Refined sugar	2½ lbs.
Tincture of lemon peel	7 fl. drachms.

Heat the lemon juice to the boiling point, and having filtered it quite bright by the aid of a little washed kaolin, allow to cool, and dissolve the sugar in the filtered liquid by agitation without heat. Add the tincture, and, if necessary, make the specific gravity 1.315 – 1.320 by the addition of distilled water.

Syrupus Mori.—This is one of the syrups which the Committee of Revision proposes to omit. It has not acquired a great reputation as a flavouring agent amongst medical men, and only a few seem to appreciate its tinctorial properties. The formula as it now appears is satisfactory, for with ordinary precautions it will keep fresh for at least twelve months, which is essential, since it can only be prepared annually. Pharmacists do not seem to regard with much favour the fermentation process so largely used on the Continent and elsewhere. This preparation is well adapted for it and improved by it.

Syrupus Papaveris.—The essential points to be observed in the preparation of this syrup so that it may be free from any tendency towards fermentation are (1) strict observance of the official instructions, and (2) care in storage. The period of twenty-four hours during which the powdered poppy capsules are to be infused before packing in the percolator, would probably bear reduction, but in other respects the formula is a good one. To make this syrup in small quantities, however, is a matter of considerable difficulty and expense. On the other hand, working on a more extensive scale as a manufacturer does, it is a very simple process, and the product a desirable one. The quantity of water required to properly exhaust the drug is considerable, and the consequent evaporation demands special appliances not generally to be found in a retail business. Then the fact of having to loose the spirit by evaporation is a matter of consequence to the average pharmacist, who cannot generally afford to do so, and seldom has the apparatus to recover it. In a wholesale laboratory both these processes—the evaporation and recovery of spirit—are simple operations of daily occurrence, and consequently they can produce a better article at a less cost than that made in working on a small scale.

Squire suggests dissolving the sugar in the concentrated infusion without driving off the spirit. This is a practical suggestion, and worth consideration. A method similar to that employed in syrup of senna makes a good preparation, viz., evaporate the infusion to the final volume, add the spirit to precipitate the albuminoid extractive, filter, and in the filtrate dissolve the sugar without heat. Finally strain through flannel. In the French Codex this syrup is prepared from the solid extract. This is a good method, for it is easily prepared, and the product is uniform, but it does not appear to be so efficacious as the B.P. form. The remarks on storage made under "syrupus" apply even more forcibly to this syrup and *syrupus rheados*. A short sentence indicating the best manner of preservation might not be out of place amongst the official directions.

(To be continued.)

DETECTING SULPHATES, SULPHITES, AND THIOSULPHATES IN THE PRESENCE OF EACH OTHER.—If preliminary tests indicate the probable presence of thiosulphate, only very dilute solution should be used, according to R. Greig Smith (*Chem. News*, lxxii., 39), or decomposition of the thiosulphuric acid into the sulphur and sulphuric acid will speedily take place. Barium chloride in excess is added together with a good quantity of ammonium chloride, which acts as a flocculant. Hydrochloric acid is then added drop by drop until the barium precipitate is no longer acted upon, and only the sulphate remains undissolved. The solution is then filtered bright through a double filter. To the bright filtrate iodine solution is added until the colour is just permanent. A white precipitate indicates the presence of sulphite which has been oxidised to sulphate. Traces may be detected comparing treated and untreated halves of the filtrate. After again filtering, bromine water is added, when any thiosulphate is oxidised into sulphate, and again a white precipitate occurs.

FLAME TESTS.*

BY GEORGE COULL, B.SC.

There is a tendency among pharmaceutical students to minimise the value of dry-way reactions, and rather to pin their faith on taking a substance, or mixture of substances, through the "chart" by the wet method. One reason, and perhaps the strongest for this mode of procedure, is the scant reference to dry-way tests in most of the ordinary text-books of chemistry,† and also the small amount of attention given to the subject by teachers. On a previous occasion,‡ I am advertised strongly against this method of blindly taking a substance through the "tables" without some previous preliminary testing, which in all probability would give nearly all the information required, and in much less time than by the wet way.

In the *Zeitschrift für analytische Chemie*, 1866, Fresenius edits the report on the progress of the "Caemical Analysis of Inorganic Substances," and says at p. 351:—"R. Bunsen|| has, in a highly interesting communication, shown the great value of flame tests for analytical purposes. The rich contents of this important work do not admit of its being abstracted without losing in value, and I therefore gladly avail myself of the author's permission to reprint it unabridged." These words of Fresenius show the high opinion that he, the world-renowned analyst, held concerning the value of Bunsen's paper. I am informed that dry-way tests are very commonly used in Germany, and most text-books have a section dealing with the subject.

I propose to discuss the matter under the following heads:—

- A. Flame of Bunsen lamp.
- B. Heating substance by itself.
 1. Infusible bodies.
 2. Flame coloration.
 - (a) Blue glass.
 - (b) Spectroscope.
 3. Film tests.
- C. Heating substance with reagents.
 1. Cobalt nitrate on charcoal.
 2. Sodium carbonate.
 - (a) On platinum.
 - (b) On charcoal (match test).
 3. Borax.

Bunsen's complete list contained thirty-five elements, with all their flame tests. It will be sufficient now to mention only those elements which are comparatively common and likely to be met with in ordinary practice.

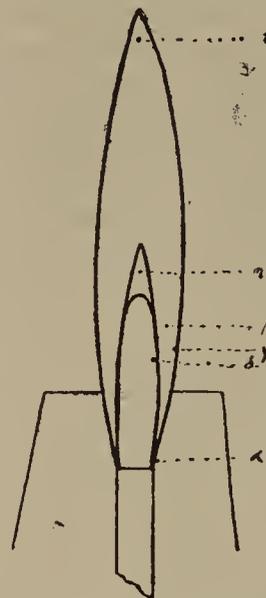

All the tests may be performed by means of the flame of a Bunsen lamp. The lamp ought to be provided with a sliding regulator at the air-holes and have a conical tin chimney on a gallery to steady the flame, which should not show the slightest trace of luminosity when the air-holes are fully opened. When the regulator is turned a little to partially cut off the supply of air and give a slightly luminous tip to the flame, the latter is seen to consist of three parts.

1. The *dark inner cone*, which is comparatively cold and contains a mixture of unburnt gas and air.

2. The *flame-mantle*, containing a mixture of gas and air in a state of combustion.

3. The *luminous point*, in which there is not enough air to completely burn the gas.

Examining the diagram of the flame more in detail, we find in the above three chief parts the following six reaction zones.

a. The *base of the flame* is the coldest part, this is due to the conduction of heat by the metal tube and to the ascending current of cold air. Many easily volatilised substances may be recognised here. In a mixture containing potassium and sodium chlorides heated cautiously in the base of the flame the colour due to the more volatile potassium salt is seen first.

β. The *fusion zone* is the hottest part of the flame, it is at about three-fourths of the height of the dark cone, where the flame-mantle is thickest; there is complete combustion of the gas here.

γ. The *lower oxidising zone* is at the outer margin of the zone of fusion, and is hotter than the next, ε.

ε. The *upper oxidising flame* is the highest point of non-luminous flame when the air-holes are wide open.

δ. The *lower reducing flame* is on the inner margin of the zone of fusion, and owing to the presence of some oxygen from the air, its power as a reducing agent is not so great as the next.

η. The *upper reducing flame* lies in the luminous tip formed by lessening the supply of air, and though containing a considerable quantity of unburnt hydrocarbons, it ought not to deposit any soot on a cold porcelain basin held in it. It is such a tip that must be used for performing Bunsen's film tests.

Behaviour of substances by themselves at high temperatures.—In order to take full advantage of the Bunsen flame, one must work with very small quantities, and use very thin platinum wire. If one worked with large quantities of material and a thick wire, there would be so much heat lost by radiation and conduction as to lower the temperature below the point at which the reaction occurs. Bunsen says the wire used must not be much thicker than a horse-hair, and one decimetre should weigh not more than 34 milligrammes. For substances which attack platinum, fibres of asbestos may be used.

By heating a substance by itself in the flame, we may obtain information as to its nature by observing its light emission, fusibility, volatility, or the colour it communicates to the flame. Infusible bodies, such as lime, magnesia, silica, and alumina emit intense white light when heated in the zone of fusion, *i.e.*, the hottest part of the flame; others, erbia, for example, emit coloured light. The relative fusibility may be roughly determined by exposing the substance in different parts of the flame and noting the kind of light emitted by the platinum wire—not by the substance—when the latter fuses. Bunsen distinguishes the following six grades:—(1) Below red heat; (2) Commencing red heat; (3) Red heat; (4) Commencing white heat; (5) White heat; (6) Strong white heat.

Characteristic colours are imparted to the flame of a Bunsen lamp by many substances, notably the metals of the alkalis and of the alkaline earths. Sodium gives a yellow colour; potassium, violet; lithium and strontium, crimson; calcium, reddish; barium, yellowish-green. In a mixture containing potassium and sodium, the latter, when heated, completely masks the violet colour of the flame, due to the former; by viewing the flame through blue glass, the yellow sodium rays are absorbed, and the potassium rays transmitted appearing of a crimson-red colour. Other substances, such

* Lecture delivered before the Edinburgh Chemists', Assistants', and Apprentices' Association, February 7, 1896.

† Attfield makes only one reference to the borax bead, namely under *malgarese*.

‡ *Pharm. Journ.* [3], xix., 359.

|| *Annalen*, 138, 3.

as chloride, bromide, and iodide of copper, indium, tellurium, selenium, antimony, arsenic, thallium, and lead can be distinguished by the practised eye.

The only way to attain perfect certainty, however, is to analyse the colour by means of a spectroscope, and compare the spectrum obtained with the diagrams in the various text-books. With some of the simpler spectra, such as those of sodium, potassium, and lithium, there is no difficulty, but when we come to examine complex spectra containing many lines it is advisable to identify the several lines by comparison with the spectra of known pure substances. This may be done by covering one-half of the slit with a reflection-prism, and adjusting it to receive the light from a flame containing the known body, so that the rays are reflected in the direction of the axis of the tube, the light from the flame containing the substance under examination being received directly in the line of collimation of the spectroscope. It is evident that two spectra will be seen one above the other. If all the lines of the known body are found in the spectrum of the unknown coinciding exactly, then the presence of the former in the latter is proved. Another device for measuring the position of the lines is to have a tube fitted with a lens at the end nearest the prism and a transparent scale at the other, which can be illuminated by a lamp, the focal length of the lens being equal to the length of the tube. By moving this tube and focussing it we can get a clear image of the scale in the telescope, and by this means the position of any line is referred to the same place on the scale.

It is to be noted that it is as a rule the metal that determines the colour. If a metallic compound gives no colour, heat it in the reducing flame and moisten with hydrochloric acid, a volatile chloride will be formed and the colour may be observed. The extreme delicacy of these spectroscopic tests is shown when it is said that 1/3,000,000th milligramme of sodium chloride and 1/100,000th milligramme of lithium chloride, inconceivably minute quantities, can be detected.

Film tests.—When the oxides of certain volatile metals (or the compounds of these metals that are easily changed into oxides in the flame) are heated in the luminous tip of a Bunsen flame, they are reduced to the metallic state in the condition of vapour. The condensation and collection of these vapours form what are called metallic films.

Metallic films.—The *modus operandi* is as follows:—Regulate the air-holes of the lamp to form a luminous tip which should be just visible and no more, and should not cause a deposit of soot on a glazed porcelain basin held in it. Place a very small portion of the substance under examination on the end of a filament of asbestos and heat it in the upper reducing flame (the luminous tip). Hold a glazed porcelain basin—containing cold water if necessary, to cool it—close above the asbestos, when the presence of any volatile metal is indicated by a dark deposit on the dish. These deposits may be divided into three classes according to their behaviour with cold 20 per cent. nitric acid.

Insoluble.....	Arsenic, antimony.
Very slowly dissolved.....	Bismuth, mercury.
Instantly dissolved.....	Lead, cadmium, zinc.

Antimony may be distinguished from arsenic by its insolubility in sodium hypochlorite, and mercury from bismuth by its grey colour, all the others being black or brown, according to thickness of film. By observing the colour communicated to the flame when performing the test the presence of lead and arsenic may be indicated. Arsenic colours the flame lavender, giving off white fumes of arsenic trioxide, and lead colours it pale blue.

(To be continued.)

REVIEWS AND NOTICES OF BOOKS.

THE VALLEY [OF KASHMIR. By WALTER R. LAWRENCE, I.C.S., C.I.E., Settlement Commissioner, Kashmir and Jammu State. Pp. 478, with illustrations. Price 12s. net. (London: Henry Frowde, Oxford University Press Warehouse, Amen Corner, E.C.)

Situated among the Himalayas at an average height of about 6000 feet above the sea, the valley of Kashmir is approximately eighty-four miles long and twenty to twenty-five miles broad. It is described in this most interesting book as a resting-place for adventurous traders who seek the distant markets of Yarkand and Central Asia, whilst it furnishes a base whence military operations have been in recent years directed against the wild and turbulent tribes of the Shinaki country to the north and north-east.

Commencing with an attractive descriptive chapter, mainly geographical, the author successively turns his attention to the geological features of the district, the flora, fauna, archaeology, political and physical history, statistics, social life, religions, races and tribes, agriculture and cultivation, live stock, industries and occupations, trade, and government of "Cachemire, the Paradise of the Indies." Here, then, it will be seen, is much matter for criticism. The vast amount of information supplied, however, arouses genuine interest and disarms criticism, besides which it would be beyond the capacity of the most captious and versatile critic to deal satisfactorily with such varied matter. The most that can be attempted in the limited space now available is to give a somewhat faint idea of the valuable contents of the book under consideration.

In discussing the geological features of the Kashmir valley, the author devotes some attention to the mineral resources of the country. Sulphur, saltpetre, salt, gypsum, copper, iron, and gold are said to exist, but the Kashmiris are said to detest the very name of mining, and little or nothing appears to be done in the direction of realising this hidden wealth. The plants observed in the valley are classified according to their economic uses and properties. Thus we find the seeds of *Carum* sp. and *Daucus carota* mentioned under the head of condiments; *Cannabis indica* and numerous other plants are classed as drugs (see *ante*, p. 131); *Datisca cannabina*, *Rubia cordifolia*, and *Geranium nepalense* appear to be employed as dyes; and deodar, spruce, apricot, alder bark, and pomegranate rind as tans. Kashmir is also very rich in fibres, more than a dozen native plants yielding suitable material for ropes, etc. Fodders, foods, and fruits are plentiful; *Euphorbia thomsoniana*, *Aconitum* sp., and *Corydalis falconeri* are used to make hair washes; the roots of *Jurinea macrocephala* furnish incense; *Pedicularis brevifolia*, *Saussurea lappa*, and *Salix caprea* are esteemed for their perfume; whilst a great variety of timber is produced in the extensive forests. The *jamen* or wild thyme is commonly employed for *hhamir* or leaven, and other plants serve a similar purpose. Finally, it is stated that adulteration prevails to some extent, yew bark and strawberry roots being used as a substitute for, or adulterant of, tea, the dried leaves of *Rhododendron campanulatum* is added to snuff to increase its sternutatory action, and the seeds of *Daucus carota* are used as an adulterant of caraway seeds, whilst many roots find their way into parcels of the valuable *chob-i-kot* (*Saussurea lappa*). The extended tabular list of the Kashmir flora occupies twenty-two pages of the book, full particulars being given in each case.

The fauna includes monkeys, leopards, the mongoose, martens, otters, bears, porcupines, and the musk-deer. Two hundred and eight species of birds were noted, and numerous reptiles, insects, and fish. The archaeological and historical details are of more than

ordinary interest, as indeed are the contents of several subsequent chapters on social life and customs, etc. The saffron crocus, tobacco plant, and opium poppy are amongst the regular crops, and very detailed information is given respecting the cultivation of the first named. Above all else, however, Kashmir appears to be a country of fruits, the apple, pear, plum, vine, walnut, and pomegranate being indigenous, whilst many others have spread from cultivation. Almost all the vegetable products that exist in a temperate climate can be grown in the district, and there is every prospect of a great future for agriculture. The book is concluded with a glossary of English words and phrases, with their Kashmiri equivalents. The numerous plates that illustrate the work are excellent specimens of photogravure, and these are supplemented by charts, and an excellent map. Indeed, everything has been done that the publisher's art could suggest to make the volume complete, and the result is highly creditable to everyone concerned.

THE ART OF COMPOUNDING: A Text-book for Students, and a Reference Book for Pharmacists at the Prescription Counter. By WILBUR L. SCOVILLE, Ph.G. Philadelphia. Pp. 264. Price 12s. (Philadelphia, U.S.A.: P. Blackiston, Son, and Co. London: Kegan Paul, Trench, Trübner and Co., Ltd., Charing Cross Road.)

This is a book which will be found useful to a student somewhat advanced in the ordinary practice of compounding. There are treatises already which relate chiefly to the practical side of dispensing and modes of manipulation; excellent guides some are, and indispensable; while much current pharmaceutical literature has the same object.

Dispensing pharmacy has assumed such proportions, and so great attention is now devoted to its details as a distinct study, that there is almost a necessity to limit the range of instruction, and keep to one definite department. Still it has been a matter of regret that information has been too scanty with regard to the principles on which Compounding should be based; and the young pharmacist has to rely on long and varied experience before he can gain a sure knowledge of his art.

Skill he can never get without constant practice and equally constant observation. No book, discourse it ever so wisely, can be a substitute for work behind the counter; but it is a step in the right direction to teach him the reasons on which that work depends; the only means by which he will be saved from perpetual error, and acquire an intelligent control over what otherwise must be a series of mechanical operations.

Professor Scoville states in his preface the two objects he has had in view: first, "to enunciate and classify the principles underlying each subject, so that the student may understand the reasons as well as the facts of dispensing; second, so to illustrate and detail the principles as to show their range and variety of application, and make them of practical utility at the prescription counter." Hence he divides his chapters into explanatory lectures, followed by more than the usual number of practical illustrations. Both are good and are comprehensive without the fault of being too diffuse.

They treat of introductory matters and proceed to mixtures, emulsions, confections, pills, lozenges, powders, suppositories, ointments, sundries, and homœopathic pharmacy, concluding with a more elaborate study of the vexed question of incompatibility.

It appears that infusions are much less frequently prescribed in America than in England and Europe, and that they are considered rather as an annoyance. Yet they are not to be classed as weak galenic preparations, for they have a specific therapeutic action; only the water-soluble principles are desired, and a diluted tincture or fluid extract is never a proper substitute; both the tincture and

fluid extract of digitalis lack principles which are contained in the infusion. Percolation is advocated in making certain cold infusions. The novel term bacills is applied to short, rod-like lozenges, the form in which the smallest troches are sometimes made. The method of mixing powders suggested by Mr. Peter Boa is wisely recommended.

The hot and cold process for chloral suppositories may also be noted. For the former, melt 2.5 grammes of spermaceti, and mix with 4 grammes of warm cacao butter. Dissolve the chloral in the warm (not hot) mixture, add enough cacao butter to make up to the full volume of the moulds, mix well, and pour into the chilled moulds. For the cold process, the chloral is powdered and incorporated with cacao butter and formed into suppositories. Exception must be taken to the Table of Latin Terms, which seems to need revision as far as printer's errors are concerned. Whatever view may be taken of nomenclature, uniformity should be observed in the system which has been adopted. On page 33 are found granum, grana, a grain, grains; a form in general use and accepted in the United States, hence so given in Remington; while on page 15 there is the following prescription:—

℞ Morphine Sulphatis, granas duas.

In the preceding paragraph, "fiant in pilulæ xx. numero," let them be made into twenty pills, can hardly pass. Fac suppositorias vj. numero, for suppositoria, one is not disposed to question, though it is not in accordance with other standard authorities. The following is submitted as an amendment to the text (pp. 29-40):—

Ad secundam vicem; ad gratam aciditatem, agita donec refrigerat; aqua gelida, concusus; concute, conserva, conterantur, donec leniatur dolor, hora decubitûs, horis intermediis, horæ unius spatio, ingerendo capsulas gelatinosas, in lagenâ bene obturâ, inoruntur [? invergantur], lapideus a-um, macerentur, macera per sextam horæ partem, misceatur, misceantur, misceatur fortiter, omni nocte, retineatur, scrupulus, stibium, vomitus-ûs, or vomitio-onis.

'The Art of Compounding' is a valuable addition to galenic literature, and will repay an attentive perusal of its contents, both for purposes of study and as a reference book.

MNEMONIC AIDS IN PHARMACY FOR THE USE OF MEDICAL AND PHARMACEUTICAL STUDENTS. By E. L. HENRY. Part I.—Tinctures and Ointments. Pp. 8. Price 6d. (London: Bowles and Co., Brushfield Street, E.C. 1896)

In the brief space of eight pages the author classifies the tinctures according to strength and method of preparation, and then gives mnemonic rhymes for learning the strength and composition of official tinctures and ointments. Here are some specimens of the new pharmaceutical poetry:—

"Friar's Balsam contains these ingredients few,
Powdered Benzoin, Storax, Soc. Aloes, Tolu."

"Paregoric has Camphor and Opium as well.
Both the Acid Benzoic and Anise we smell.
The spirit is proof, and the strength don't neglect;
A fourth of a grain in a drachm is correct."

"With Simple Ointment Plumbi Carb.'s allied
Hyd. Ammon. Lead and Red Mercuric Iodide.
Then Elemi and Antim. Tartar. note,
Resinæ, Hamamelis, Creosote."

Presumably, the demand for such effusions as this will continue so long as students preparing for examination are led to consider it necessary that they should burden their memories with a mass of details, which every sensible individual is content to know can be found in the pages of the Pharmacopœia. Seriously, however, it can hardly be maintained that students will either economise time or develop their intellects by assimilating such doggerel.

SOCIÉTÉ DE PHARMACIE DE PARIS.

At the annual general meeting of this Society, M. Julliard, the retiring President, in his address felicitated the Society on the number of distinguished names on the roll of pharmacists who had by their researches assisted in the advancement of science. Professor Villiers being elected to the chair, a review of the contributions during 1895 of the members to the knowledge of pharmacy and allied sciences was read by the Secretary, M. Patein, some of the most important features of which are given below:—

Mineral Chemistry.

Mention was first made of the revolution effected in metallurgy by M. Moissan by the agency of his electric furnace. During the year he has made known a method for the isolation on a large scale of several of the rarer metals, such as titanium and molybdenum. He manufactures the latter by fusing molybdate of ammonium, mixing the resulting oxide with carbon procured from sugar, and subjecting the mixture to the action of the electric furnace, when the metal is obtained entirely free from carbon. M. Moissan found that when charcoal is exposed to an enormous heat in his furnace it is partially reduced to vapour without previously passing into the liquid state. On collecting the vapour it was observed that condensation took place in the form of graphite. The question presented itself, was it possible to obtain carbon in a liquid state? M. Moissan states that to do so would necessitate the use of immense pressure, such as is produced by the congelation of iron in masses (the process which has resulted in the formation of small diamonds). M. Moissan has also published two methods for making boride of iron, one of which yields yellow crystals of the salt several millimetres in length.

Turning his attention to the newly-discovered element—argon, he demonstrated the resistance of this gas to form chemical compounds, and that, when mixed with fluorine and submitted to the induction spark at ordinary temperatures, no combination of the elements took place.

The presence of argon in mineral water has been observed by M. Bouchard in the Raillère Spring, and a mixture of argon and helium was found by M. Moureu in a gaseous emanation from the lithiated water of the Maizières Spring (Côte d'Or).

Professor Villiers has contributed to our knowledge of mineral analysis by a process for the detection of minute quantities of nickel in a cobalt solution. Tartaric acid is first added to the presumed nickel and cobalt solution, and soda in large excess. Potash must not be used, and the tartaric acid prevents precipitation of the metallic oxide by the alkali. A stream of H_2S to completely precipitate the cobalt is passed through, and the liquid quickly filtered. If the filtrate is colourless, entire absence of nickel is proved; that metal may be recognised by the fluid assuming a more or less brown or black colour, according to the quantity present.

In making this experiment, an interesting fact was observed by M. Villiers, which was that the sulphide of nickel formed remained dissolved in the alkaline sulphuretted solution, whilst precipitated sulphide of nickel would not dissolve in the same, if care be taken to avoid presence of free sulphur and access of air. From this he deduced that at the moment of its formation, the precipitated sulphide of nickel behaves differently in the presence of the sulphide of sodium, and he explains this difference by a molecular modification which takes place almost immediately, the rapidity of which change is increased by a rise of temperature, so that at boiling point the whole of the salt is precipitated. This action is not peculiar to the sulphide of nickel. Sulphide of zinc, which is amorphous when first formed, and dissolves in the sulphuretted sodium solution, becomes after a time insoluble, and takes a crystalline form.

M. Villiers gives the name of proto-morphic state to the condition of salts at the moment of formation, and shows that the same molecular modification can be produced by cold as well as by heat. The amorphous sulphide of zinc is changed into crystalline sulphide, pink sulphide of manganese into green sulphide, and ordinary copper oxide into a crystalline variety, turquoise blue in colour.

Absolutely nothing is known of the complex physical and chemical action which takes place during contact of medicinal agents with the tissues of the body. All that is known is that isomeric bodies are frequently vastly different in their physiological properties. M. Prunier has shown that this same difference occurs also in simple bodies in their various allotropic forms. Sulphur may be taken as an example, and he has given some interesting information concerning this element from a therapeutic point of view.

Of the three varieties which occur in pharmacy, he states that the roll sulphur or octahedric modification is almost medicinally

inert. Flowers of sulphur, or prismatic, is the most used, and is very active when recently manufactured, but on keeping it changes to the octahedric form. Precipitated sulphur, which is amorphous, contains, according to M. Prunier, hydrogen bi-sulphide, from which H_2S is generated, and to this it owes its peculiar activity, but this form by a gradual constant process is also transformed to the octahedric.

Thus while the two latter sulphurs are the more active, yet, from being unstable, their degree of activity is necessarily indefinite. M. Prunier considers that some combinations of this body in a crystalline state, such as the iodide, where the elements are present in an easily dissociable condition, appear most favourable to therapeutic action.

Organic Chemistry.

M. Behal, by working on camphoroxime, has prepared two campholenic amides, one fusible at $86^\circ C.$, the other at $130^\circ.5 C.$ The latter is convertible into the former, and both combine molecule for molecule to produce a third amide, fusible at $106^\circ C.$, which crystallises from water or toluene without dissociation, but breaks up when crystallised from alcohol.

E. Moureu has supplemented the work of Tiemann upon the chemical constitution of eugenol and methyl eugenol present in the essential oil of *Asarum europæum*, which is largely used for the artificial manufacture of vanillin. He has synthetically prepared methyl eugenol by causing iodide of allyl to react on veratrol with powdered zinc. Hydriodic acid was eliminated, but instead of being liberated, demethylised a portion of the veratrol, and gave guaiacol and pyrocatechine. By this process methyl eugenol was proved to be allyl-veratrol and eugenol allyl-guaiacol.

Many readers will have been surprised to find in the more recent standard works mention made of chemical compounds with no indicated formulæ, whilst some of the combinations included do not even exist. As an example, MM. Patein and Dufau have demonstrated that the so-called valerianate of antipyrine is nothing more than antipyrine tainted with valerianic acid, consequently had this substance been carefully investigated, its name would not have figured as a definite chemical in any work.

It having been shown that antipyrine combines in the cold with the naphthols, molecule for molecule, and stated by MM. Roux and Barbey that it forms crystalline bodies with the phenols, mono, di and tri atomic, without formulæ being given, MM. Dufau and Patein have investigated the subject in order to find what rules were followed by antipyrin in these latter combinations, and further, whether there was no variation according to the number of the phenylic hydroxyls. They have arrived at the conclusion that whilst pyrocatechine and hydroquinone combine with two molecules of antipyrin, resorcine and its homologues combine with one only; that the monatomic phenols combine with one molecule, the diatomic with two molecules (with the exception of resorcine and its homologues), but the triatomic phenols do not combine with three, but molecule for molecule only.

Pharmacy.

M. Bourquelot, comparing the formulæ given in the various pharmacopœias for syrup of iodide of iron, remarks that the proportion of ferrous iodide differs in an extraordinary manner, so much so that a syrup prepared in Holland is 38.5 times stronger than one prepared in Greece. Such diversity of strength shows the necessity of an international understanding among pharmacists. At the last Congress held at Buda Pesth, the project of a universal pharmacopœia was discussed, but no signs are yet shown of its possible realisation. M. Bourquelot, passing in review the various explanations given for the discoloration of the syrup, considers as the most plausible, that ascribing it to the absorption of oxygen from the air, this is corroborated by the alteration being retarded on the addition of a small quantity of citric acid, as recommended in the Swiss Pharmacopœia. A little inverted sugar is formed, which, acting as a reducing agent, hinders the oxidation of the ferrous iodide. He has also given an interesting method for the estimation of the iodine present.

MM. Bertrand and Bourquelot have pointed out the active part taken by laccase in the change of colour produced in certain vegetables when cut and exposed to the air. Besides laccase, they contain a colourless substance which can be isolated by macerating the vegetable in alcohol. This substance does not change in colour on exposure to the air, but darkens quickly under the combined influence of air and laccase.

Among the many bacteria found in the mouth the coli bacillus had hitherto only been observed in cases of persons suffering from

certain throat affections. MM. Grimbert and Choquet have collected statistics of its occurrence in the healthy subject. They found that out of sixty persons examined it was present in twenty-seven, *i.e.*, 45 per cent., and that the germ was encountered principally on the tonsils.

Analytical Chemistry.

M. Burcker, occupying himself with analyses of wine, announces that the total volatile acidity of sound wine should not exceed 0.70 gmes. per litre (expressed as H_2SO_4) for that produced in France, and 1.6 gmes. per litre for the Algerian and Tunisian wines.

The presence of boric acid in wine having been frequently pointed out, MM. Villiers and Fayol have decided the question that had arisen, whether the chemical occurred as a natural product, or had been added for purposes of adulteration. They have been unable to find a trace of it in genuine French wines, but in some produced in Algeria small quantities were found, and its origin was attributed to the substances used in clarification.

The attention of the Society has been called by M. Bourquelot to the necessity of including in the French Codex simple tests for the recognition of galenic preparations, such as are found in most pharmacopœias, and also to the advisability of defining the percentage of the active substances in pharmaceutical preparations in the manner that the strength of the solutions is indicated at present. Mention was also made of the tables formulated by M. Bocquelin for indicating the yield of aqueous and alcoholic extracts prepared from plants recently introduced into pharmacy; and to the facility with which physicians' prescriptions may be photographed when necessary by means of a simple system proposed by M. Guichard.

A list was read of the foreign and corresponding members who had contributed papers, of the awards given by the Society, and the names of the members by whom honours had been received. The Secretary next referred to the pleasant manner in which their séances had been relieved by the interesting lectures of M. Planchon (Director of the École de Pharmacie) on the "History of Pharmacy." In one of these he described the relaxations of apothecaries three centuries ago, and the honours to which their profession entitled them. They constituted one of the six guilds to whom the privilege was accorded of attending State ceremonies, and supporting the canopy on the entry of royal processions into Paris. In concluding the report, the Secretary indulged in a prospective view of the state of pharmacy after the lapse of a century, depicting in a sanguine manner the progress which will have been effected in the knowledge of remedial agents. He alluded as an example to the possible perfection of serumtherapy, at present in its infancy. He terminated by congratulating the Society on the uniformity with which its scientific traditions had been upheld, and asserted the right of the members to command the respect of their successors by the disinterestedness of their work, and their honourable efforts on behalf of humanity.

FORMIC ALDEHYDE IN THE PRESERVATION OF MILK, AND ITS DETECTION THEREIN.—Since a dilute solution of formic aldehyde (formalin) is being used as a milk preservative, R. T. Thomson has contributed to the *Chemical News* (vol. lxxi., 247) a note on its preservative action and an analytical method for its detection. The author finds that a 40 per cent. solution of formalin is at least four times as effective as a mixture of boric acid and borax and equal to salicylic acid; he also notes that boric acid alone is much less effective than when used with borax. To detect the presence of formic aldehyde in milk, 100 C.c. are distilled until about a fifth comes over; this is transferred to a stoppered tube, and about 5 drops of ammonio-nitrate of silver solution added. This solution consists of 1 part of nitrate of silver in 30 parts of water, dilute ammonia being added until the precipitate at first formed is dissolved, care being taken to avoid an excess, then the whole is made up to 50 parts with water. The mixture of milk distillate and silver solution is then allowed to stand for from 12 to 18 hours in a dark place, when if formic aldehyde is present, a strong black colour or deposit will be produced. A light brown colour must be disregarded, nothing short of a distinct black tint being sufficient to indicate the presence of formalin. When as little as 2 grains of formalin per gallon of milk has been used, a distinct reaction is obtained. The author finds that 4 or 5 drops of formalin added to 100 C.c. of milk will enable samples to be kept for six weeks, which have given the same results on analysis after that time as were obtained from the samples when fresh. Formalin should therefore, prove useful in preserving samples of milk which may be required at a later period for analytical reference.

PARLIAMENTARY INTELLIGENCE.

THE INSPECTION OF BOILERS.—A Bill to effect the inspection and registration of boilers has been introduced into the Commons, and bears the names of several Lancashire members of Parliament as supporters. The title is not one that is likely to attract the attention of chemists, but, nevertheless, the measure is, by the meaning given to the word "boiler," invested with a certain degree of interest to them as manufacturers of pharmaceutical preparations. Clause 16 defines "boiler" to mean "any closed vessel which is used for generating steam or for heating water or for heating other liquids." It would not be just to charge the framers of the Bill with a desire to interfere with the calling of pharmacy or the work in chemical and other laboratories, but it should be made clear to them that the above definition might bring an ordinary retort under the necessity for registration, and that chemists making their own pharmaceutical preparations would certainly employ utensils in the nature of a legal "boiler." There is a special exemption in favour of domestic boilers in private houses (too often a highly dangerous form of the genus), but no expressed saving for any scientific or pharmaceutical apparatus. True there is the following general provision:—"That where the Board of Trade are satisfied that owing to the special character of any boiler or class of boiler it is expedient that the same should be exempted from all or any of the provisions of this Act the Board may make an order" to that effect. But as this safety valve is only operative after representations to a Government Department, many persons would prefer a speedier and less troublesome alternative. The object of the Bill, as stated by its promoters, is to prevent boiler explosions and to save human life, and it does not seem inconsistent with that object to have a saving clause inserted for the prevention of a possible hardship to pharmacists, analysts, or chemical investigators.

MANUFACTURING CHEMISTS using steam power, and others similarly situated would, of course, be directly affected by the Bill referred to in the above paragraph. It may, therefore, be apropos to briefly sketch its salient features. In the first place, boilers are to be periodically examined and certified as safe by competent and fit inspectors selected by the boiler owner, who is responsible for the fitness of the inspector employed. (2) Certificates of safety are to be granted by the inspectors and forwarded to the Board of Trade, which Department will issue, in exchange, a certificate of registration. (3) Certificates of safety are to be renewable every thirteen months, with certain exceptions. (4) It is to be illegal to work a boiler without a certificate of registration; maximum penalty, £1 a day before notice, £5 a day afterwards. The explosion of an unregistered boiler would involve the owner in a penalty not exceeding £100. (5) The boiler owner is to pay his inspector for each examination, and the Board of Trade a fee of one shilling for each certificate of registration. The Bill is down for second reading on April 22.

THE SELECT COMMITTEE ON PETROLEUM has now been nominated. The following members have been selected:—Rt. Hon. Jesse Collings, Under-Sec. Home Office; Sir T. Carmichael (L.) (Midlothian); Alexander Cross (U.) (Camlachlie, Glasgow), of A. Cross and Sons, seed merchants, Glasgow; J. F. Flannery (U.) (Shipley); Col. Sir E. Hill (C.) (Bristol, S.); F. Wootton Isaacson (C.) (Stepney); J. Keynon (C.) (Bury, Lancs.); Rt. Hon. A. J. Mundella (L.) (Brightside, Sheffield); H. F. Pollock (U.) (Spalding); Harold Reckitt (L.) (Brigg); J. Compton Rickitt (L.) (Scarborough); Sir J. B. Stone (C.) (Birmingham, E.); and J. Kelly (N.) (S. Leitrum). Mr. Jesse Collings is placed upon the Committee because of his official position in the Home Office, and not on account of any unsuspected connection between agriculture and petroleum, but the special qualification of the other members of the Committee for dealing with the subject under inquiry is not readily apparent to the uninitiated.

THE COMPANIES BILL, to give it the short title, is down on the House of Lords Orders for second reading on the 19th instant. The question as to the sufficiency of the winding-up clauses from a pharmaceutical point of view is understood to be occupying the attention of the Pharmaceutical Society's Law and Parliamentary Watch Committee.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australasia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, MARCH 21, 1896.

THE PHYSIOLOGICAL CHEMISTRY AND PHARMACOLOGY OF THE THYROID TREATMENT.

WITH the view of extending what is known of the mode of action of thyroid preparations when administered by the mouth, E. ROOS (*Zeitschr. für Phys. Chemie*) has made a series of investigations on dogs; some in a state of health and others after they had been deprived of their thyroid glands. The food was measured so that the quantity and composition remained uniform during the period occupied by the investigation, the urine was carefully collected and the daily output of nitrogen, sodium chloride, or phosphorus pentoxide carefully determined. The general results of a laborious series of observations, which are recorded in tabular form, are somewhat as follows:—Large doses of dried thyroid gland cause increased output of nitrogen, sodium chloride and phosphorus pentoxide, after allowing for the amounts of these substances contained in the dose of dry thyroid. The marked increase in the separation of chlorine was of shorter duration than that of the nitrogen or phosphorus pentoxide. In animals that had been deprived of their thyroids the increase of excretion of nitrogen and sodium chloride was more, and that of phosphorus pentoxide less than in the case of the normal animal. Thus it would appear that thyroid substance increases proteid metabolism, and in this respect its action may be compared to that of phosphorus. The thyroid substance would also seem to have a decided influence on fat, since the body-weight of the animals experimented on sensibly diminished, but the doses were relatively large, and before thyroid treatment can be regarded as established as a remedy for obesity, careful observations of the effects of smaller doses on human subjects must be tried.

The effect of removal of the thyroid is to diminish the amount of phosphorus pentoxide excreted to one-half. After administration of thyroid the quantity of phosphorus pentoxide in the urine increases in a marked degree. This seems to show that thyroid has a definite influence on the metabolic processes which lead to the formation of phosphoric acid in the body. Two different hypotheses may be framed to explain the fact; either (1) in the absence of sufficient

thyroid secretion an inadequate amount of phosphorus is used for the nourishment of the tissues, or (2) there is a retention of phosphorus pentoxide in the body. The first supposition would explain many of the features of cretinism and myxœdema, such as the arrested development of the bones in the former, and the defective cerebration in the latter; but the second view would better explain one symptom observed after removal of the thyroid, viz., tetany, as the result of acute retention of phosphorus pentoxide—a result which may be compared to the convulsions of uræmia. That phosphoric acid plays an important part in affections of the thyroid seems also to be shown by an observation due to KOCHER, who found that sodium phosphate greatly alleviated all the symptoms of a patient suffering from GRAVES' disease, which is marked by an increase in the activity of the thyroid gland. The explanation of this course of events may be that the disease was associated with a too rapid using-up of phosphorus compounds in the body, and that the administration of the phosphate supplied phosphorus to the tissues. So little is known of phosphorous metabolism that the author can only regard his results as suggestive rather than conclusive.

A second series of experiments was made with a view of testing the efficacy of thyroid preparations made in various ways. For this purpose the preparations were administered to patients suffering from goitre—

1st method.—4.1 grammes of dried sheep's thyroid was rubbed up with 10 C.cm. 5 per cent. hydrochloric acid and allowed to stand twenty minutes, neutralised with sodium carbonate, evaporated on a water bath, and dried over sulphuric acid. This preparation proved effective in diminishing the size and consistency of the goitres of two patients.

2nd method.—4.1 grammes dried thyroid rubbed up with 10 C.cm. of 10 per cent. hydrochloric acid and allowed to stand for one hour, neutralised and dried as before. This preparation proved equally effective with the first.

3rd method.—This experiment was made with a view to ascertain to what extent the active principle can be obtained by water extraction; 16 grammes of fresh crushed gland was digested for twelve hours with 200 grammes of water, then digested on the water bath, and finally boiled for a short time over the flame and filtered. What remained on the filter was again digested with water extracted by boiling, and filtered.

The reddish grey opalescent filtrate, when evaporated and dried, yielded 3.4 grammes of extract, was mixed with 1.6 gramme of milk sugar, and divided into five parts in order that each part should be equivalent to 1 gramme of dried thyroid (16 grammes of fresh thyroid being equivalent to 5 grammes of dried gland). This water extract proved effective in reducing the goitre in the case in which it was tried. The remains of the 16 grammes of gland left after the double water extraction were dried and administered to another patient. The tumour in this case also diminished appreciably in size. Thus the author concludes that the active principle is soluble in water, but after two extractions it is not wholly removed. The fact that the active principle of the thyroid resists boiling proves that it does not belong to the class of ferments, such as pepsin, etc.

PRESENTATION TO MR. J. R. YOUNG.

MANY readers of the Journal will be greatly interested in the report of the presentation to Mr. J. R. YOUNG, of Edinburgh, which appears on p. 237, and older members of the Society generally will recall the excellent work done by Mr. YOUNG for pharmacy, which rivals that so handsomely acknowledged by his medical friends.

SHOPS (EARLY CLOSING) BILL.

THE Standing Committee on Trade met on March 12, and again on Monday last. Several amendments to Clause I. were dealt with, and the clause as amended in Committee is as follows, the added words being in square brackets:—

1.—(1.) If an application in writing is served on the local authority of any district, praying that, as regards all shops within the district (or any part of the district) belonging to any class or classes specified in the application, an order may be made for the closing of such shops on each day or any specified day or days of the week at such hour or hours, not earlier than the hours hereafter in this section mentioned, as the local authority may determine, the local authority shall give such public notice of the application as will enable those interested to appear before them; and on being satisfied that [the occupiers of] not less than two-thirds in number of the shops within such district, or the part thereof belonging to the class or to each of the classes to which the application relates, have signed the application, the local authority may [after due consideration of the area and of the classes affected by the application, and of any other matter affecting the question], if they see fit, make an order giving effect to the application. [Where an application is made as regards any part of a district, the proposed boundaries shall, if required by the local authority, be shown by reference to a map.]

(2.) [Provided that, save as otherwise expressly provided in this Act, an order made in pursuance of this section shall not apply to shops belonging to any of the classes mentioned in the Schedule to this Act.]

(3.) The hour to be fixed for the closing of shops in pursuance of this section may on any one specified day of the week be any hour not earlier than one (originally "two") o'clock in the afternoon, but save as aforesaid shall not on any day be earlier than seven o'clock in the evening [and in neither case shall be earlier than any hour named in the application].

PHARMACY STUDENTS' DINNER.

THE annual dinner of the Pharmaceutical Football and Cricket Club was held in the Duke's Salon, Holborn Restaurant, on Wednesday evening last, when the chair was taken by the President of the Club, Professor ATTFIELD, F.R.S. The Pharmaceutical Council was represented on this occasion by Mr. WALTER HILLS, and Mr. C. B. ALLEN; the School of Pharmacy by Professors ATTFIELD and GREENISH, Mr. JOSEPH INCE, Mr. E. J. EASTES, and Mr. H. A. D. JOWETT; the Board of Examiners had a solitary representative in Mr. W. MURTON HOLMES; and Mr. RICHARD BREMRIDGE, the Secretary and Registrar, was also present with other members of the Society's permanent staff. Mr. C. B. ALLEN, in proposing the toast of the "Pharmaceutical Football and Cricket Club," commended indulgence in such games as likely to conduce to better school work. Mr. FOTHERGILL, the Captain of the Club, and Mr. G. SENTER, honorary secretary, responded, and showed that the season's record was a good one. Mr. F. U. STAMP proposed the next toast, that of the "Pharmaceutical Society of Great Britain," in a neat speech, and Mr. WALTER HILLS, in responding, proved the fallaciousness of Mr. ALLEN's suggestion that members of Council, except one, no longer knew how to make speeches. He briefly indicated how the Society had fulfilled its three objects—benevolence, education, and defence—and pointed out how much more thoroughly pharmaceutical interests could be defended if the Society received more general support. Mr. HILLS was also delegated to propose the last toast—that of "The Chairman"—and Professor ATTFIELD, in responding, dwelt upon his long term of service with the Society and the various organisations in the institution of which he had been instrumental. He concluded by inculcating the necessity of loyalty to one's fellow-craftsmen. The musical programme was exceptionally attractive, and, except for a somewhat unnecessary array of empty seats round the tables, the arrangements reflected great credit on those responsible.

ANNOTATIONS.

MR. EDWIN WHEELER, chemist and druggist, Clifton, has presented to the British Museum 2449 water-colour drawings of British fungi. They are contained in twelve large volumes, and are now at South Kensington. Sir W. H. Flower, director of the Natural History Museum, in conveying to Mr. Wheeler the special acknowledgments of the trustees of the British Museum for his generosity in presenting the drawings, observes that the serious difficulty in the way of preserving colour character in herbarium specimens makes the donation one of particular value and importance. The trustees have expressed their high appreciation of the extreme accuracy and beauty with which the characters of the fungi are delineated.

THE NEW PHARMACOPŒIA.—According to the *British Medical Journal*, whilst "satisfactory progress" is being made in the task of preparing a new edition of the British Pharmacopœia, it is hardly probable that the work can be completed in time for the autumn session of the General Medical Council. It is hoped, however, that the volume may be ready for presentation to the Council at its meeting in May, 1897.

THE CHOLERA IN HONG KONG.—It is satisfactory to learn that the services rendered by Mr. Crow, of the Government Civil Hospital at Hong Kong, and his assistant, Mr. Frank Browne (both old "Square" men), in connection with the stamping out of the plague lately raging at Hong Kong, have been suitably recognised by the Government.

FRIENDLY SOCIETIES AND THE SALE OF DRUGS.—Scottish pharmacists are threatened with a new source of danger, one of the speakers at a meeting of delegates of Dundee friendly societies on Saturday last having proposed that dispensaries should be founded in connection with the societies, and that they might then sell drugs to the general public at a reasonable profit. If the societies supplied the drugs, the speaker continued, all ground would be removed for the suspicion that the doctors were inclined to give inferior drugs in order to benefit their own pockets. This motion was seconded and agreed to unanimously, a committee being appointed to prepare a schedule for the establishment of a dispensary in Dundee.

INDIAN HEMP DRUG LEGISLATION.—It has been officially stated in the House of Commons that the Bill to amend the Excise Act, 1881, introduced into the Legislative Council of India by Sir James Westland, was introduced to give effect to the restrictive suggestions of the Hemp Drugs Commission, and that object will be kept in view. Lord G. Hamilton remarked that, as regards Burma, the existing law gives powers to grant licences for the growth, preparation, and possession of ganja, which are not now exercised. The amending Bill introduces no change in this respect, and it is not proposed to make any use at present of those powers. As regards the rest of India, the Bill does not alter the existing law, and it renews the provision that no unlicensed person may have in his possession more than five tolas of the drug.

SERUM IN DIPHTHERIA.—During the year 1894-95, 411 diphtheria patients were treated at the Am Urban Hospital, Berlin, and 245 of these were subjected to the serum treatment. According to the Berlin correspondent of the *Standard*, the number who succumbed under serum treatment was 28 per cent., and of the others 41.9 per cent. No injurious after-effects from the use of serum were observed, and the general deduction is that, though not infallible, serum is a highly valuable remedy in diphtheria.

EVENING MEETING IN EDINBURGH.—There appears little probability of any Evening Meeting of the Pharmaceutical Society being held in Edinburgh this month, the arrangement depended upon having fallen through on account of ill-health and pressure of work affecting the gentleman who had promised to lecture. In addition, the incidence of examination work and other official matters has prevented other arrangements being made in the limited time remaining before the usual date of meeting.

UNIVERSITY COLLEGE, LIVERPOOL.—The arrangements in connection with the new pharmaceutical department at University College, Liverpool, are being actively proceeded with, and it is hoped that a prospectus of the classes will be issued shortly. The medical faculty of the College has invited Mr. Prosper H. Marsden, of the Royal Infirmary, Liverpool, to undertake the duties of lecturer on pharmacy and demonstrator in materia medica.

THE CAUSE OF SUNBURN.—At the Camera Club, last week, Dr. Bowles gave an interesting account of the results at which he has arrived after investigating the subject of sunburn for the past fifteen years. He considers that the violet or ultra-violet rays, after reflection from snow, water, mist, etc., behave very like x -rays in their power of penetrating human tissues, and that sunburn, snowburn, snowblindness, sunstroke, and sun fever may all be associated with penetrating light rays instead of being due to the action of heat. To prevent the action of the rays upon the skin the use of pigments is recommended, something a little deeper than flesh colour having been found quite effectual in preventing sunburn.

WHAT IS A POISONOUS DOSE OF OXALIC ACID?—If the report in a local newspaper is to be credited, the house surgeon at the Royal I.W. Infirmary and County Hospital, Ryde, requires some education with regard to poisonous doses. A patient at the infirmary who had swallowed some oxalic was charged with attempted suicide, and the house surgeon is reported to have said, in giving evidence, that he should hardly think an ounce (!) of oxalic acid would be sufficient to destroy life. Cases are recorded in which a similar quantity of the acid has been swallowed and the patients have recovered after prompt treatment, but on the other hand as little as sixty grains has proved fatal. Is there a decay of medical posological knowledge as well as of prescribing?

MR. FREDERICK BIRD, chemist and druggist, of Spon Street, Coventry, has been unanimously elected chairman of the Coventry School Board. Mr. Bird, who was elected to membership of the Pharmaceutical Society in 1873, has been a member of the School Board ever since its formation in 1870, and became vice-president in 1891.

THE APRIL EXAMINATIONS.—Pharmacy in Great Britain would appear to be yet far from the least desirable of occupations, if one may judge from the number of names entered for the April examinations. The entries are as follows:—

	London.	Edinburgh.	
Minor	240	191	= 431
Major	28	5	= 33

Total number of entries 464

The above is probably a record number for the Minor examination. The figures for the Major examination, however, appear to indicate as clearly as ever of late years that students either do not appreciate the advantage of advanced knowledge, or require some extra inducement—say a Fellowship—to tempt them to proceed,

PATHOGENIC YEASTS.—Disease-producing characteristics have only quite recently been imputed to the yeast class, no species possessing pathogenic properties having been known until Busse last year announced the existence of one such species. Colpe and Sanfelice have described others, and seven out of fifty varieties examined have since been found by Dr. L. Rabinowitsch to possess pathogenic properties. These yeasts appear, observes *Nature*, to be distinct from the pathogenic varieties isolated by other observers. One variety, *Monilia candida*, was found to be fatal to rabbits and mice, but not to guinea-pigs. Another yeast, fatal to mice, was obtained from figs which had been allowed to ferment, whilst a so-called "wild" yeast found on grapes, and a form isolated from ale by Professor Delbrück, killed both rabbits and mice. The effects produced are apparently due to direct infection through copious multiplication of the yeast cells within the animal's system rather than to intoxication from products elaborated by the yeasts.

THE HUXLEY MEMORIAL.—The amount promised and received in connection with the Huxley Memorial Fund now exceeds £2300, a sufficient sum being thus guaranteed for two objects the Committee definitely decided upon—a statue at the British Museum of Natural History, and a medal at the Royal College of Science, London. A further appeal is now being made for the third object proposed by the Committee—the furtherance of biological science in some manner. The foundation of exhibitions, scholarships, or lectureships has been proposed, but a considerable sum will be required for this purpose. Local committees are being organised, however, in all parts of the world, and it is trusted that their efforts will effect the desired result. Donations may be sent to the honorary treasurer, Sir John Lubbock, Bart., to Messrs. Robart, Lubbock and Co., 15, Lombard Street, E.C., or to the honorary secretary, Professor G. B. Howes, Royal College of Science, South Kensington.

THE RÖNTGEN RAYS have, it is reported, been successfully applied by Dr. Hall-Edwards, of Birmingham, to obtain prints showing the human vertebræ and spinal cord in full detail. The Birmingham postal authorities have also been shown how the rays may be utilised to detect coins and other forbidden articles enclosed in letters. The position of a sovereign wrapped in several folds of newspaper was clearly revealed in a print, and by means of the cryptoscope a sixpence was found between the leaves of a book containing more than nine hundred pages. At St. Thomas's Hospital, London, much interest is being taken in this subject, and elaborate arrangements are being made to conduct experimental work. Mr. A. F. Stanley-Kent, working there, is said to have secured prints showing the bone of the pelvis, the spinal column, and the lower ribs. The position of the kidney is also indicated, whilst renal calculi have been found to be sufficiently opaque to the x -rays to render it possible to differentiate them clearly from the surrounding tissues.

AN "ELECTROGRAPHIC" LABORATORY.—Acting on the advice of several eminent physicians and surgeons, Mr. A. A. C. Swinton has decided to equip a special laboratory at 66, Victoria Street, Westminster, S.W., for the practical application of the Röntgen rays in surgery and medicine. The laboratory is being fitted with the most improved and up-to-date apparatus, and is expected to be in working order in the course of a few days. The work will be conducted by Mr. H. L. Tyson Wolff, under the direct supervision of the director.

MADAME PASTEUR has had the pension voted by the French parliament to her late husband, settled upon herself. The annual value of this pension is 25,000 francs.

PROCEEDINGS OF SOCIETIES.

Linnean Society of London.—At the meeting held on March 5, Mr. W. Percy Sladen, Vice-President, in the chair, Mr. Ivor Richards was admitted, and Mr. S. H. Bickham was elected a Fellow of the Society. On behalf of Capt. J. Marriott, Mr. Harting exhibited an antler of the Burmese deer (*Cervus Eldi*), and described a singular condition in another example which for eight years had continued to exude a blood-coloured liquid from a puncture on the under surface of the brow-tine. Professor Stewart, to whom some of the substance had been submitted for examination, had found no blood-corpuscles therein, and considered it to be grease in a semi-fluid condition, the nature of the colouring-matter being as yet undetermined. Mr. Druce thought the substance exuded might be the excretion of the larvæ of some insect feeding upon the internal surface of the horn, and suggested the examination of a section, if possible. Mr. Harting exhibited a drawing from life of a Klipspringer antelope (*Oreotragus saltator*), lately received (for the first time in this country) at the Zoological Society's Gardens. He directed attention to the singular position of the hoofs and the enlarged condition of the fetlocks, suggestive of injury during capture. It was difficult to believe (as alleged) that this was the natural condition of the animal, so very dissimilar to that of other species allied to it. Mr. Thomas Christy exhibited several cases of butterflies collected by Mr. Horace Billington in Old Calabar, on which remarks were made by Messrs. W. F. Kirby and H. Druce. Mr. B. D. Jackson, in directing attention to an English translation by Mr. J. Lucas of that portion of Pehr Kalm's "Travels" which relates to England, remarked that few persons were aware that Kalm, a pupil of Linnæus, had in 1748 spent six months in this country and had diligently noted the plants which he met with. Thus he had recorded no less than sixty plants for Hertfordshire alone, deriving some of his information from an examination of the contents of two haystacks in that county—in this way anticipating by more than a century one of the methods employed by Sir John Lawes and Sir J. H. Gilbert, and also by Professor Fream.

On behalf of Professor Gustav Gilson, of Louvain, two papers entitled "Studies in Insect Morphology" were communicated by Professor Howes. In the first of these—"On Segmentally Disposed Thoracic Glands in the Larvæ of *Trichoptera*"—the author found that in *Limnophilus flavicornis* the prothoracic prominence gives exit to an underlying tubular gland. In *Phryganea grandis* each thoracic sternum gives exit to a glandular apparatus of the same category, the prothorax alone developing a prominence. Passing on to a consideration of the glands themselves, it was shown that in *Phryganea* they are slightly monilated branching tubes of a paired nature, which unite in the middle line. They were found to bear a cuticular lining, and to secrete an "oily" fluid, which Dr. Hanseval had found, on analysis, to be identical with the secretion of the maxillary glands of *Cossus*. The author gave reasons for regarding these glands as inherited structures, preserved under the tubiculous habit, and not as organs newly acquired in correlation with that. In discussing the homology of the glands, he instituted comparisons with the "Bauchdrüse" of certain non-tubiculous caterpillars and the "salivary glands" of *Peripatus*; and concluded that they are nephridial rather than coxal, pointing out that by their discovery representatives of segmentally-disposed glandular organs may be said to occur throughout the length of the Hexapodan body. In the discussion which followed, Mr. A. R. Hammond referred to the saccular reservoir on the ventral surface of the prothorax of the larva of the Puss Moth (*Cerura vinula*), from which an acid fluid is said to be ejected; also to the large pear-shaped glandular cells which underlie the integument of the thoracic segments in the larva of *Dicranota bimaculata*, as described by Professor Miall ('Trans. Entom. Soc.,' 1893, p. 235). The function of these cells appeared to be the secretion of an oily fluid.

In the second paper by Professor Gilson and M. J. Sadones—"On the Larval Gills of *Odonata*"—the authors described in each branchial lamella of *Libellula depressa* three conical processes which are functional in preventing adherence of the lamella to its fellows, and in maintaining full exposure to the surrounding medium. The authors showed that the tracheal ramifications are looped tubules running parallel with the surface of the gill, which at all points lie embedded in a subcuticular protoplasmic syncytium. Stress was laid upon the fact that the in-and-out-going tracheal tubules are related to one and the same branchial main tracheal trunk, and that the air within the gill does not circulate regularly

through the tracheal system. Turning to physiological considerations, it was pointed out that gaseous interchange between the contents of the gill-laminæ and the surrounding medium must of necessity take place through the living protoplasm of the lamellar syncytium; and, on consideration of the fact that the death of an epithelium is known to profoundly alter the osmotic properties of the tissue which it composes, the conclusion was drawn that absorption of oxygen must here involve something more than a mere physical process. Attention was then directed to the existence of a "pre-rectal vesicle" from which there depend into the lumen of the guts a couple of epitheloid disks. It was suggested that this structure, together with a similarly differentiated epithelium lying about the bases of the gills, might be possibly concerned in the removal of carbonic anhydride. The authors accordingly discriminated between the air-vascular (tracheal) system, as concerned in the absorption and dissemination of oxygen, and the blood-vascular as concerned in nutrition and the removal of waste. In the discussion which followed, Mr. A. R. Hammond expressed his satisfaction at finding that the author's observations on the gills of *Odonata* confirmed to some extent his own views as to the syncytial condition of the hypodermis in aquatic larvæ. In the larvæ of the red-blooded species of *Chironomus* this condition appeared to be most strikingly exemplified.

School of Pharmacy Students' Association.—A meeting of this Association was held on Thursday, March 12, Mr. Harold Brown occupying the chair. After the minutes of the previous meeting had been passed, a "Report on Inorganic Chemistry," by Mr. H. Read, was read in his absence by the Secretary. The report dealt with argon, helium, the oxidation products of ammonium hydrosulphide, and the metallic carbides. Observations on the report were made by Messrs. Henry, Spurge, Senter, Grier, Tickle, and the Chairman.

A "Report on Pharmacy" by Mr. W. Moore, followed. In this the controversial points recently brought forward with regard to the constituents of ergot were summarised, and Cripp's work on belladonna was fully dealt with and favourably commented upon. Caseinate of iron, hæmol, and several other of the newest preparations of iron came in for critical comment. The method of preparing and using the solutions suggested by Dr. Schleich for producing local anaesthesia by infiltration was explained. A "Finot" cachet apparatus recently introduced was shown, and the method of using it explained. It was examined at the conclusion of the paper by several of the members, who admired the elegant way in which the machine served its purpose. Remarks were offered by Messrs. Grier, Henry, Tickle, Senter, Spurge, Umney, Wilson, and the Chairman, after which the meeting adjourned.

Midland Chemists' Assistants' Association.—On Wednesday of last week, at Exchange Rooms, Birmingham, Mr. R. M. Williams, Vice-President, occupied the chair, and the following short papers were read:—

"PHOTOGRAPHIC NOTES," BY F. FOSTER.

The author devoted his paper to the new so-called photographic light. The materials required for producing photographs by the x -rays were enumerated and described. The exposure might vary from three or four minutes to half an hour or more. The time might be shortened by warming the plate to about 100° F. It was found that collodion plates were remarkably insensitive to the x -rays; on the other hand, gelatino-bromide, gelatino-bromo-iodide, and gelatino-chloro-bromide plates were all sensitive to the rays. A pure gelatino-bromide emulsion in the form of a highly-sensitised plate gave the best results. An apparatus has been lately devised for examining with the naked eye shadows of articles without going to the trouble of exposing and developing the plate. This was recently described in the *Pharmaceutical Journal* (see *ante*, p. 193). By means of this apparatus it can be ascertained whether the Crookes' tube was working to the best advantage. After explaining at some length the various theories put forward as to what these x -rays actually were, Mr. Foster gave his opinion that they might be ascribed to the longitudinal waves in the ether, although he was conscious that this hypothesis required more solid foundation. A spark (he said) would not pass through a perfect vacuum, therefore it was necessary for molecules of some kind to exist in the Crookes' tube, but these molecules were as far removed from gaseous matter as gaseous is from liquid.

The next paper read was on—

“GRANULAR EFFERVESCENTS,” BY W. T. C. CLARKE.

Mr. Clarke first called attention to the B.P. process for making eff. sod. phosph. The object of heating the phosphate of soda until it had lost 60 per cent. of its weight was simply to render it anhydrous, and in the second stage the ingredients were heated to about 212°F. to drive off any water retained mechanically and absorbed from the air. This was best done by a water bath. The sifting was a point of nicety of appearance rather than a necessity. The granulation might be done admirably with a fork having three or four prongs so bent as to be from 3/16th to 1/4th inch apart. In effervescent salts there were briefly two essentials, namely the base (consisting of the acid, carbonate and sweetening agents, to which the preparation owed its effervescence and palatability) and secondly, the active principle. With regard to the base there was no hard and fast formula for general use. After many experiments he had found the following the best:—Bicarbonate of soda, 17 parts; citric acid, 6 parts; tartaric acid, 6 parts; white sugar, 9 parts. The finished preparation would be slightly acid, which he considered an advantage. Concerning the second essential, the active ingredient, this had merely to be weighed and mixed with the base in the proportion required.

The mixture was granulated thus:—Place an enamelled basin with an oval bottom over a water bath, and when quite hot and dry add, say, half a pound of the ready mixed powder. Allow to remain about a quarter of a minute (longer or shorter according to temperature), when the powder begins to “cake.” Now take the fork and so manipulate it as to make the whole of the salt pass through its prongs. Remove from source of heat and continue trituration, gradually diminishing the pressure until the granules become cold and brittle. The size of the granules depends greatly upon the rate of trituration, therefore too much energy is to be avoided. The drying, it was explained, is best done by the sun, as the preparation should be at normal temperature when bottled. The original salt lost 1/19th of its weight by the granulation.

The author found that mag. cit. efferves. cost him 11d. per pound, against manufacturers’ price, 1s. 3d. Antipyrine, five grains in one drachm, he made at 5s. per lb., against manufacturers’, 7s. As the base was the same for all preparations, the comparison was equally favourable with all other preparations. The reasons he advocated home-made preparations were, apart from the satisfaction of being “up-to-date,” 1st, the strength of active principle is assured; 2nd, the preparations are quite as good as any manufacturers’, and cost less; 3rd, the expense of keeping a large stock (which in the majority of cases will deteriorate on keeping) is obviated. Seven specimens of effervescent salts, made by Mr. Clarke, were exhibited—all excellent samples.

The next paper read was entitled—

“DISPENSING QUERIES,” BY H. M. BINDLOSS.

The author said that in dispensing a bottle of mixture or a pot of ointment there may be several ways—all different—and all probably correct, and it was on account of there being many ways of arriving at a correct result in dispensing that his notes would be particularly open to criticism and discussion.

Bottles for Gargles, etc.

He also called attention to the advisability of some rule being established as to the style of bottle in which gargles, throat sprays, etc., should be dispensed. He was strongly of the opinion that an intermediate bottle between the blue fluted poison bottle and the white glass dispensing bottle should be used for such preparations, the reason of his opinion being as follows:—If a dispenser treated a gargle or throat spray as he would a lotion and sent it out in the usual blue fluted bottle, a patient would naturally hesitate before following such directions as “To be used freely” or “Use frequently,” and then, on the other hand, if he treated the gargle or throat spray as a mixture and sent it out in a clean bottle, exceptions would certainly have to be made to the rule in prescriptions like the following:—

℞ Hydrarg. Perchlor. gr. i
Glycerini ʒi. Solve

“The throat to be painted at bedtime.”

Therefore if an intermediate bottle were used it would obviate that irregularity which we so frequently come across with patients who are travelling from one town to another, as this could be used for all medicines which are taken into the mouth or nostrils, but not into the stomach, and would include, of course, all gargles, spray-solutions, throat-paints, mouth washes, and applications for tongue,

nostrils, and gums. All applications not intended for the mouth or nostrils would be dispensed in the ordinary blue poison bottle. In this way a fast rule could be made, only those medicines which are actually swallowed being treated as mixtures, and the patient would then get his remedies dispensed in the same style everywhere.

Dispensing Alkaloids.

Mr. Bindloss next pointed out the advisability of always attaching a “shake the bottle” label when dispensing an alkaloidal liquor in a mixture containing an alkali. This, he stated, was a safe rule, and one that should always be observed; at the same time it was well to remember that most alkaloids are slightly soluble in water, for instance, morphine, 1 in 1000; strychnine, 1 in 7000, which meant that six ounces of water are capable of dissolving all the strychnine contained in 40 minims of the official liquor, and all the morphine in 280 minims of any of the official morphine liquors, even supposing it were all deposited. Therefore, as far as actual necessity goes, liquor morphine seldom requires a “shake,” and liquor strychnine only occasionally.

Capacity of Ointment Pots.

Attention was then drawn to the mistake in ointment pots being made to contain avoirdupois instead of troy ounces, for to dispense a prescription for 1 oz. of ointment, in most cases a 1½ oz. jar would be required. The opinion was expressed that all ointments should be weighed, and then the smallest jar chosen which would hold that quantity.

Mist. Ferri Co.

Reference was also made to a note on “mist. ferri co.—a wrinkle” which recently appeared in the *Pharmaceutical Journal* (ante, p. 184). This was as follows:—“Dissolve the sugar with the iron sulphate instead of mixing it with the myrrh and potassium carbonate The emulsion of myrrh, pot. carb., and rose water was more easily formed and more milky without the sugar.” This method the writer could not agree with for the following reasons, viz.:—(1) Sugar has without doubt remarkable power in extracting and diffusing the aromatic fragrance of the myrrh when in contact. Its power is noted in similar way with tolu, lemon, and many other odorous drugs. A vanilla bean, Mr. Ince said recently, immersed in powdered sugar diffuses its aroma throughout the whole mass. The better the myrrh, the greater, therefore, is the necessity of using the sugar. (2) If lump sugar be used—which was recommended—the myrrh can be powdered quicker and finer, and the resulting emulsion will be better than that omitting the sugar. Experience led the speaker to think that sugar did not in any way interfere with a gum resin emulsion.

Curious Prescriptions.

In conclusion, Mr. Bindloss handed round copies of several prescriptions having slight peculiarities, which had come under his notice:—

No. 1.

℞ Quin. Sulph. gr. iij.
Ac. Hydroch. dil. ℥v.
Am. Carb. gr. v.
Aq. Chlorof. ʒi.

The only satisfactory way of dispensing this, he found, was to neutralise the acid with the am. carb., rub the quinine down with mucilage, and add one to the other.

No. 2.

℞ Bismuth Carb. gr. 120.
Potass. Bicarb. gr. 90.
Spt. Am. Arom. ʒiij.
Tr. Cardam. Co. ʒiij.
Aq. Calcis ad ʒviiij.

The colour of the tinct. card. co. in above is discharged.

No. 3.

℞ Liq. Potassæ,
Spirit. Ætheris Nitros, aa ʒi

This acquires an amber colour with a slight precipitate.

No. 4.

℞ Zinci Brom. gr. 16.
Sodii Brom. ʒss.
Tr. Nucis Vom. ℥64.
Aq. ad. ʒviiij.

As a flocculent precipitate occurred in this, and two drops of acid. hydrobrom. was sufficient to clear it, that in his opinion ought to be added.

No. 5.

℞ Cocain. Hyd. gr. iij.
Argent Nit. gr. ʒ.
Aq. Dost. ʒss.

In dispensing the last, silver chloride would be precipitated, which he was sure the prescriber did not intend, and therefore, nitrate of cocaine should be used in place of the hydrochlorate.

An animated discussion on each paper was taken part in by the following:—Messrs. Lawton, Shields, Foster, Meggeson, Williams and others.

Plymouth, Devonport, Stonehouse and District Chemists' Association.—A special general meeting of this Association was held last Monday evening, at the Foresters' Hall, Octagon, Plymouth, to consider the following resolution submitted by the Committee:—

"That this Committee heartily approves of Mr. C. J. Park as a candidate for the Council of the Pharmaceutical Society of Great Britain, and strongly recommends the members of the Plymouth, Devonport, Stonehouse and District Chemists' Association, to give him their hearty support."

The chair was occupied by Mr. J. G. Netting (Vice-President), and amongst those present were Messrs. J. C. Park (President); G. Breeze, J.P.; J. Cocks (Secretary), R. H. Bailey, H. O. Westcott, W. H. Woods, Green, R. H. Roper, J. Johnson, A. D. Breeze, H. Hunt, O. A. Reade, Condy U'Ren, F. Maitland, Davey, J. Maurice, and Goddard Clarke, J.P. (London).

The Chairman, having read the Committee's resolution, said that he felt great pleasure in supporting the candidature of Mr. Park for the western district, and for the Pharmaceutical Society in general. He thought Mr. Park was entirely fitted for the post in more ways than one.

The Secretary (Mr. J. Cocks), then read letters from Messrs. Gadd, J. D. Turney, J. Lake (Exeter), and Barge, all regretting absence and wishing Mr. Park every success in his candidature. The minutes of the previous committee meeting were next read, and the Chairman invited questions to be put to Mr. Park.

Mr. Park, in reply to these questions, said he should be pleased to see any chemist and druggist elected on the Council who had been in business previous to and during 1868. With regard to making associates in business members of the Pharmaceutical Society, he thought representation should be proportionate. It was open for every one to rise to the top of the tree, and yet men entered pharmacy simply for commercial purposes. They did not want to pass any examinations at all if they could open a shop and trade without doing so. He would favour any desirable extension of the poisons schedule, and he thought a little favouritism should be extended to chemists in the matter of stamp duty. When a chemist put a recommendation of a medicine into print it was liable to duty—practically, such a duty was a tax on ill-health. He should like to see the Inland Revenue approached on the subject. He was in favour of the Early Closing Bill with the exemption given in a recent issue of the *Pharmaceutical Journal*. He was in favour of a new Pharmacy Act restricting the sale of poisons to qualified men only. If elected on the Council he would always endeavour to represent the views of the majority of those whom he represented. He went primarily as the candidate of the local association, and in important matters where he was in doubt as to the opinion of the Association he should ask to have a meeting called, and vote according to the voice of the majority. He was also in favour of military dispensers being legally qualified.

THE ANTI-CUTTING MOVEMENT.

Mr. Cocks then proceeded to explain that he attended the recent meeting in London of the Proprietary Articles' Trade Association, and as that meeting decided to support any candidate in sympathy with the movement he mentioned Mr. Park, whose name was received with approbation. He afterwards learned, however, that that meeting wanted Mr. Park to run entirely in the interest of the Trade Association. He said that was entirely a matter for Mr. Park, and Mr. Jones (Birmingham) remarked that if Mr. Park would not run as their candidate, they would very soon get another. The "anti-cutting" people were willing to pay Mr. Park's expenses, and felt sure of getting him on the Council if he would stand. He asked that the matter might be allowed to stand over until that meeting.

Mr. C. J. Park said he had received a pressing letter from Mr. Glyn-Jones, asking him to run entirely in the interest of the Proprietary Articles' Trade Association. Mr. Glyn-Jones wanted him to decide as quickly as possible so that he could arrange meetings in the North for him to give election addresses. He said he had decided to write asking him to become a candidate before Mr. Cocks mentioned the matter at the London meeting. Mr. Park then read a letter which he proposed to send to Mr. Glyn-Jones, in which he said that he had been already selected as the candidate of the

Plymouth Chemists' Association, but that if elected he would heartily support the "anti-cutting" movement. He felt sure that if he was returned as the representative of the local association he would have more influence on the Council in supporting the "anti-cutting" movement than if he were merely the representative of the Proprietary Articles' Trade Association.

Mr. G. Breeze next moved—

"That this meeting of the members of the Plymouth, Devonport, Stonehouse and District Chemists' Association heartily approves of Mr. C. J. Park, pharmaceutical chemist, 1, Mutley Plain, Plymouth, as a candidate for the Council of the Pharmaceutical Society of Great Britain, and will support him at the coming election, and strongly recommends all members and associates in business to vote for him at the next election of the Council."

He felt assured that all western chemists hoped to see Mr. Park occupy a very good position on the poll. The opinions of the candidate were sound, and he was pleased at the decision Mr. Park had come to with regard to the "anti-cutting" movement. He would very much like to see the medicine stamp abolished altogether, as it would tend to increase the public confidence in them as chemists and druggists. He suggested that they would be sufficiently protected if a guinea were demanded from everyone dealing in medicines. He had the heartiest sympathy with the resolution, and promised to do his very best to promote Mr. Park's candidature. He believed that chemists below Bristol had never been represented on the Council, and felt it was quite time they were.

Mr. Hunt, of Plymouth, local secretary of the Pharmaceutical Society, seconded the motion, and thought that the Association could not have picked a better man than Mr. Park. He did not think much of the difficulty about patent medicine, and if the stamp duty was abolished altogether believed that street vendors would take to selling patent medicine. He sided with the view Mr. Park had taken in the "anti-cutting" matter.

Mr. Maitland, of Stonehouse, local secretary of the Pharmaceutical Society, heartily supported the candidature, and recognising how difficult it was for any man to leave his business and sacrifice his time, thought special thanks were due to Mr. Park for standing. Mr. W. H. Wood also supported, and the resolution was unanimously carried.

Mr. Park returned his best thanks for their action and their kind promises of support. He was not going to assume for one moment that he could fill the place of so thoroughly capable a man as Mr. Schacht, of Bristol, but promised to do his utmost on behalf of those whom he hoped to have the honour to represent.

Mr. Goddard Clarke, J.P., congratulated the Association on procuring such an excellent candidate as Mr. Park, and promised to give him his best support. It was quite time, he said, that the West of England should have a representative on the Council, and no longer be left out in the cold.

The members of the Plymouth, Devonport, Stonehouse and District Chemists' Association Committee were appointed to assist Mr. Park in his candidature, and a unanimous vote of thanks was accorded Mr. J. G. Netting for presiding.

Chemists' Assistants' Association.—At the meeting held on the 12th inst., when the President (Mr. E. W. Hill) occupied the chair, there was an excellent attendance to hear Mr. A. W. Gerrard read a paper "On Nutrient Beef Foods."

Allusion was made to the paucity of literature dealing with the subject, and surprise was expressed that pharmacists have shown so little desire to improve the existing methods of preparation, and thus identify themselves prominently with such a rapidly extending industry. This is especially remarkable in England, where joint considerations of climate, pasture, and breeds of cattle supply advantages far exceeding those of other countries, and the author expressed the opinion, derived from a lengthy and intimate acquaintance with the medical profession, that the use of good nutrient foods of English manufacture would be heartily welcomed and encouraged. After a description of the chief constituents of beef muscle, the effect of water at different temperatures was described. Thus, if finely minced lean beef muscle is placed in water heated to 60° C., and well stirred for ten minutes, a large portion of the albumin and albuminoids, together with some of the extractives, pass into solution, whilst the myosin and much of the gelatin is left unchanged. The result is different if boiling water is used, coagulation and fixation of the albumin in the muscle taking place, the latter becoming hardened. If the boiling is prolonged for several hours, gelatin, extractives, and salts pass into solution, leaving behind the insoluble myosin and albumin. It will therefore

be seen that a proteid or albuminous beef-tea fairly rich in nitrogen can be prepared by infusing beef below the coagulating point of albumin, but on the other hand boiling the beef merely yields a solution of the extractives, accompanied by some gelatin. Hence it follows that the most abundant and valuable constituent of beef—myosin—does not pass into solution in the processes either of infusion or decoction, and recourse is had to the agency of the gastric and pancreatic juices in order to convert this substance into peptone. It should be noted that it is not advisable to carry the conversion further than the formation of proteoses, because complete peptones are bitter, unavoury products, partaking more of the nature of poisons than foods. Mr. Gerrard then proceeded to describe processes for preparing meat peptone and essence, and the peptonisation of beef by means of the pancreas, formulæ being given and full details regarding the methods of procedure. These we are unavoidably prevented from publishing in the present issue of the Journal.

In the discussion which followed, the President, Messrs. Robins, Guyer, Taylor, Moore, Crouch, and Roberts took part, and a hearty vote of thanks was awarded to Mr. Gerrard, on the proposition of Mr. Moore, seconded by Mr. Robins.

FOREIGN NEWS.

MEDICINE IN THE COLOMBIAN REPUBLIC.—The political troubles which have recently upset and paralysed scientific work generally in Santa Fé de Bogotá being at an end, the *Revista Médica*, the organ of the National Academy of Medicine, has again resumed circulation. According to that paper, a medical institution called La Policlínica has just been called into existence in Bogotá, mainly by the endeavours of Doctors Lisandro Reyes and Eduardo Herrera, for the purpose of providing lectures in special medical subjects. Bacteriology will be undertaken if the Government will assist with a grant of money to form a laboratory. Chemical analysis has been made a special feature, and a well-equipped laboratory has been inaugurated for the examination of urine and other organic liquids of importance pathologically. Doctor Fortunato Pereira is the director.

PINE SEEDS AS AN ANTHELMINTIC.—In a letter to *La Revista Médica de Bogotá*, Doctor Eloy E. Gonzalez suggests that the fruit called "piñuela," from a species of pine tree growing in Colombia, should be examined by the Academy of Medicine with a view to discovering its active principle, as he has noticed in the case of three children that the consumption of the fruit caused the expulsion of large quantities of tæniæ. He hopes that the piñuela will provide an efficient and indigenous substitute for the expensive imported pelletierine.

ASSAY OF IODINE IN COD-LIVER OIL.—M. Gorges, pharmacien at Saint Mandé, publishes in the *Journal de Pharmacie* an improved method for determining the amount of iodine in cod-liver oil. Twenty-five grammes of the oil are weighed into a shallow capsule with 25 grammes of nitrate of potash and 5 grammes of caustic potash, previously dissolved in 25 grammes of alcohol. This is saponified in a water bath and the soap desiccated by means of a sand bath, and subsequently incinerated at a low red heat. The residue, consisting principally of carbonate and iodide of potassium, is treated with dilute acetic acid until a slight acid reaction is obtained and the solution transferred to a glass separator. Five C.c. of 5 per cent. solution of persulphate of ammonia is added to liberate the iodine, which is then absorbed by agitation with bisulphide of carbon. The iodine solution, after separation, is titrated with centinormal solution of hyposulphite of sodium.

SCOTTISH NEWS.

SERIOUS EXPLOSION WHILE PREPARING OXYGEN.—Mr. Arthur Allan, Gorebridge, Midlothian, met with a serious accident on Saturday night, 14th inst., while preparing some experiments for exhibition during a lecture on "The Air we Breathe," which he was to give in Heriot Schoolhouse, about five miles from Gorebridge. He was engaged in mixing in a mortar what was understood to be chlorate of potassium and black oxide of manganese to be used in the preparation of oxygen gas. Mr. Allan lifted the pestle in his right hand, and on allowing it to drop again with some force into the mortar the mixed powders exploded violently, and several people were attracted by the report. Mr. Allan's right hand was severely burned and otherwise wounded, and he received the force of the explosion

chiefly on the right cheek, his eyes being burned and filled with black débris. He was immediately driven five miles to Gorebridge, but he seemed so severely injured that the medical attendant had him immediately removed to the Royal Infirmary, Edinburgh, where an examination showed that his eyes were fortunately not so seriously injured as at first sight appeared. The chemicals employed by Mr. Allan had been procured for him by a gentleman, not a chemist, who had arranged for the lecture. It is supposed that some error may have occurred, and an inquiry is being made to determine the purity of the substances employed. Mr. Allan is quite a young man and fortunately very tall, otherwise the accident would almost certainly have had more serious consequences. He had only recently been appointed an assistant in the analytical laboratory of Messrs. Tatlock and Readman, F.C.S., Edinburgh. This case illustrates the value of the caution given by Bloxam ('Chemistry,' page 38) as to the necessity of trying the effect of heat on a small quantity of the potassium chlorate and the supposed black oxide of manganese before working with a large quantity.

MR. WILLIAM WRIGHT, chemist and druggist, High Street, Lockerbie, has been appointed travelling secretary to the Scottish National Union of Y.M.C. Association, and S.M.F. Associations.

ROYAL MEDICAL SOCIETY OF EDINBURGH.—The annual dinner took place in the Royal Hotel, Prince's Street, Edinburgh, on Friday, 13th inst., Dr. Joseph E. Bowes, senior President, in the chair. These was a distinguished company, including Dr. Watson Cheyne, of London; Professors Crum Brown, Rutherford, Greenfield, Chiene, and Simpson. In the course of the evening, Professor A. R. Simpson, M.D., in the name of the fellows and members of the Royal Medical Society, presented to Mr. J. R. Young, pharmaceutical chemist, 17, North Bridge, Edinburgh, a handsome silver bowl on ebony stand, in token of their high appreciation of the manner in which he had filled the position of honorary treasurer to the Society during the long period of twenty years. Mr. Young said Professor Simpson had been appointed as successor to the late J. F. Macfarlan. The splendid work he had done for the cause of education in connection with the Edinburgh Merchant Company was well known to them all. He was one of their best known and most honoured citizens, and for many years had filled the position of a Justice of the Peace for the City of Edinburgh. The bowl, which was specially designed and manufactured by Brook and Son, George Street, measures 11½ inches in height by 14 inches in diameter, and weighs about 90 ozs. There was also presented at the same time by the Society to Mrs. Young a handsome gold and diamond bracelet. Mr. Young, who, in his reply, exhibited much of his old eloquence and vigour, gave many interesting reminiscences of the history and progress of the Society during his tenure of office.

ODONTO-CHIRURGICAL SOCIETY OF SCOTLAND.—The annual dinner of the Society took place on Friday, 13th inst., in the Balmoral Hotel, Edinburgh, Mr. J. S. Amooore, Vice-President, in the chair, and Mr. O. Fergus, as croupier. Among others present were Emeritus Professor Struthers, President of the Royal College of Surgeons; Dr. P. A. Young, Treasurer of the Royal College of Physicians; Mr. Rees Price, Secretary Scottish Branch of the British Dental Association; Mr. J. Laidlaw Ewing, Chairman of Executive North British Branch of the Pharmaceutical Society, etc. Dr. James proposing the toast of the evening, "The Odonto-Chirurgical and Sister Societies," said that they—dentists, physicians, surgeons, and pharmacists—were all of one lot as it were, because they were all directly concerned in utilising their energies for the benefit of humanity. The dental profession was simply a part of the great medical profession, and he thought its members, in their department, might reasonably claim pre-eminence over every other. Mr. Oswald Fergus, Glasgow, proposed the toast of "The Licensing Bodies," coupled with the names of Professor Struthers, for the Royal College of Surgeons; Dr. P. A. Young, for the Royal College of Physicians; and Mr. J. Laidlaw Ewing, for the Pharmaceutical Society of Great Britain. Mr. Ewing, in replying, said like other licensing bodies the Pharmaceutical Society had recently adopted the plan of appointing outside examiners, who were engaged as professional teachers of the respective sciences in which they examined. Speaking from what he had seen of the working of the new plan in Scotland, he was able to say that it worked well. He had observed that previous speakers had referred somewhat pointedly to the advertising dentist, and it occurred to him to suggest that they should also remember the unqualified practitioner of dentistry,

who was no less objectionable than the unqualified practitioner of pharmacy. He had noticed that quite recently the dental profession had, like the Pharmaceutical Society, been appearing before Sheriff Campbell Smith at Dundee, in an endeavour to prevent the illegitimate assumption of a professional function by unskilled persons, who, in the interests of public safety, were legally prohibited from so acting. They were equally unfortunate to find that the Sheriff in both cases seemed to think the unqualified person was as good as the duly qualified, and that he was equally inappreciative of the legislative restrictions applying to both professions was shown by the fact that in each case he imposed the nominal penalty of one shilling and costs. Other toasts were honoured, and songs and recitations were contributed at intervals.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.—The annual supper of the Association took place in the Imperial Hotel, Market Street, on Friday, the 13th inst. Mr. J. Mackintosh Cameron, President, occupied the chair, and Messrs. J. McBain, Vice-President, and G. Sinclair, Hon. Sec., acted as croupiers. About eighty gentlemen sat down to supper, including Messrs. W. L. Currie, Vice-Chairman North British Executive Pharmaceutical Society, and President of the Glasgow and West of Scotland Pharmaceutical Association, Peter Boa, President, J. Bowman, Vice-President, and C. F. Henry, Hon. Sec. of the Edinburgh District Chemists' Trade Association, Parish Councillor D. Maclaren, G. Lunan, J. A. Forret, Divisional Secretary for Central Edinburgh, J. Brown, President, and J. P. Gibb, Hon. Sec. Edinburgh Pharmacy Athletic Club, W. Duncan, W. B. Cowie, J. Rutherford Hill, etc.

Apologies for unavoidable absence were intimated for Mr. J. Laidlaw Ewing, Chairman of the North British Branch Executive of the Pharmaceutical Society, Mr. D. Storrar, Kirkcaldy, Professors J. Gibson and P. Geddes, and Mr. George Coull, B.Sc.

The loyal toast having been duly honoured, Parish Councillor Mr. D. Maclaren proposed "The Pharmaceutical Society of Great Britain," which was acknowledged by Mr. W. L. Currie, Vice-Chairman of Executive. The toast of "The Edinburgh District Chemists' Trade Association" was proposed by Mr. J. Rutherford Hill, and acknowledged by Mr. P. Boa, the President.

Mr. W. L. Currie, Glasgow, in proposing the toast of the evening, "The Edinburgh Chemists', Assistants', and Apprentices' Association," said the Association had stood the test of time, being now in the eighteenth year of its existence, with the interest in its meetings still maintained, and good work being done. He had to congratulate the members of the Association on the character of their contributions, which indicated that they were alive to the necessity of keeping well to the front in educational and scientific matters. It might not be absolutely novel, but it would be new to some, and it was well to remember, that—

"Thought delivered is the more possessed;
Teaching we learn, and giving we receive."

At the same time it was well to bear in mind that the general goodness of education was not to be tested by the quantity of knowledge acquired. The true test of education was action, and the educated man was he who had all his faculties strong and active, so that he could perform his part rightly and efficiently in whatever sphere he might be placed. Here, he would say, it was of the utmost importance to every young man starting in life to fix in his mind the greatest principle of all moral philosophy, that the real dignity of individuals lies not in what they have but in what they are. In that Association they had a splendid opportunity of acquiring knowledge to fit them for their future work. Possibly some of those he was now addressing might have a vast deal to do with a better conducting of pharmaceutical affairs than existed at present. History might repeat itself, and as Edinburgh had in the past given notable men to the ranks of pharmaceutical politics, such, for instance, as John Mackay, so she might in the rising generation produce a man who would restore to their profession that *esprit de corps* which had in some measure been lost. If he might refer to the modern methods of conducting the business of pharmacy or the remedy for eradicating the evil, he would say that if there existed sufficient *esprit de corps* among those who held the qualification of the Pharmaceutical Society to refuse service with limited companies and drug stores the evil would vanish to-morrow without the aid of legislation. He heartily congratulated the assistants and apprentices of Edinburgh on their pre-eminence, and hoped their Association would continue to flourish. The toast was acknowledged by the Chairman. Other toasts were, "The Edinburgh Pharmacy Athletic Club," proposed by Mr. George Lunan, acknowledged by Mr. J.

P. Gibb; "The Ladies," proposed by Mr. Alfred Thwaites, acknowledged by Mr. Wm. Duncan; and "The Chairman and Croupiers," proposed by Mr. John Bowman, and acknowledged by the Chairman. The very agreeable proceedings of the evening were pleasantly diversified by songs, recitations, and instrumental music contributed by Messrs. W. Duncan, J. P. Gibb, C. Brown, W. L. Currie, J. Robertson, Sid. Cornish, A. Murray, J. Crichton, R. H. Tweedie, R. Butchart, J. Rowlands, and W. Arres, Mr. James Crichton acting efficiently as accompanist.

IRISH NEWS.

PHARMACEUTICAL SOCIETY OF IRELAND.—The Preliminary examination will be held on Tuesday, the 7th proximo (instead of Easter Monday). The last day for lodging applications will be Tuesday, the 24th inst. The Pharmaceutical Licence examinations will be held on Wednesday, the 8th proximo, and following days. The last day for lodging applications for same will be Wednesday, the 25th instant.

PHARMACEUTICAL CHEMISTS' AND APOTHECARIES' ASSISTANTS' ASSOCIATION OF IRELAND.—At Dublin on Friday last the inaugural meeting of this Association in the rooms of the Pharmaceutical Society of Ireland took place in the spacious Council chamber. There was an extremely large attendance, close on 100 being present, the visitors including representatives of the medical profession, Pharmaceutical Council, and a number of leading pharmaceutical employers. Amongst others were Dr. Duffy, Government Inspector (Privy Council); Dr. Ninian Falkiner, F.R.C.P.I.; Dr. H. U. Byrne, M.D.; Dr. J. A. Walsh, L.R.C.P. and S., proprietor of Messrs. Graham's State Pharmacy; Mr. John Smith, Examiner to the Society; Professor C. R. C. Tichborne, LL.D., Governor Apothecaries' Hall; Dr. Lemon, J. S. Corcoran, L.P.S.I., Mr. Corrigan, L.P.S.I., Councillor Henry Conyngham, Mr. James B. Alister, M.P.S.I. (President), etc. On the motion of Mr. J. S. Corcoran, L.P.S.I., Mr. W. F. Wells, President of the Pharmaceutical Society of Ireland, took the chair.

Mr. Wells said his first duty was a very pleasant one, being that of bidding the assistants, in the name of the Pharmaceutical Society, a very cordial welcome to that house. He assured them that the Council was most anxious to assist them in every way in their power. The Council had always recognised the value of such organisations. There was an idea also of again trying the experiment of evening meetings and opening a reading-room for the students, to which assistants and apprentices could resort for friendly intercourse, and it was the hope of the Council that the junior association would further that experiment at the proper time and, with the assistance of the large number of members present, form the nucleus of a Students' Association and induce others to become members of it.

The Hon. Secretary (Mr. W. Hardy, L.P.S.I.) read the minutes of the last meeting, which were signed by the Chairman, and Mr. Wells then called upon Dr. Ninian Falkiner, the Society's Lecturer in Materia Medica and Botany, to deliver his lecture on "The History of Pharmacy"

The lecture, which was of a most instructive and entertaining character, dealt with pharmacy from the most remote antiquity, and it was shown to what a high degree of excellence in some respects the ancient Egyptians had brought the apothecary's art. Much amusement was afforded by the reading of an apothecary's bill some 300 years old, which for five days' supply of medicine to one patient totalled more than £17. The full text of the lecture will be published in the Journal later.

At the close of Dr. Falkiner's lecture, Mr. J. B. Alister, M.P.S.I. (President of the Association), said it was unnecessary to remark how indebted they were to Dr. Falkiner for his very instructive and entertaining lecture. He briefly commented on the various points mentioned by the lecturer, and concluded by proposing a very hearty vote of thanks to Dr. Falkiner for his kindness in delivering the lecture they had the privilege of hearing. Mr. W. Payne, in a few well-chosen words, seconded the vote of thanks, and said Dr. Falkiner as a teacher had a happy knack of imparting instruction, so that even the dullest could grasp it readily. Mr. Ashe, in supporting the previous speaker, said, with the kindness of the Council on the one hand, and the support of Dr. Falkiner and his medical colleagues on the other, he saw no reason why the Association should not improve its members both

mentally, morally, and physically. Dr. Duffy said although an outsider, he felt a very great interest in the Pharmaceutical Society of Ireland. He believed that one of the greatest supports the Society could have was the support of the fine body of young men he saw present. He was glad his name had no terror for the students. It could not be denied that the formation of classes in connection with the Society would be for the benefit of pharmacy. As in most other things, the secret of success lay in general education. He might claim the credit of having inserted one or two things in the pharmaceutical curriculum, and he must say that at all times his suggestions received the support of the Society, and he hoped to be able to still further assist the Society until it became equal in every respect to the sister Association in England. Doctors Walsh and Byrne, and Mr. Henry Conyngham (Councillor of the Pharmaceutical Society), having spoken in felicitous terms of the Association,

Mr. Wells, President of the Pharmaceutical Society, in conveying the vote of thanks, said the lecture showed a great amount of research by Dr. Falkiner. He thought he knew a little himself about the history of pharmacy, but he scarcely expected he would have had the pleasure of hearing a history so far back as the time of the Egyptians. They in Ireland had a grievance in regard to the compilation of the new pharmacopœia. There was not a word of reference in it to the Pharmaceutical Society, but they had some able men on the committee who would do their duty. The present pharmacopœia contained a number of things not used in Dublin. The question suggested itself, did they want a pharmacopœia at all? Some medical men did not seem to be aware that such a volume existed. There were in Dublin, however, a lot of medical men who were loyal to the Pharmacopœia, and who found in its pages enough to suit their requirements. Those who ignored the Pharmacopœia were doing themselves considerable injury. He advised the pharmacist to stick loyally to the Pharmacopœia, and hoped that the medical faculty would follow Sir Richard Quain's example in regard to the use of nostrums. With respect to the students' classes, the Council was anxious to have them. It was the wish of the members of the Council to educate the students, and they had in view the formation of pharmacy classes, besides which they had decided to offer a prize of a gold medal for the best score in the twelve months' examination, and if the funds permitted they would also award a silver and a bronze medal.

Dr. Falkiner, in replying, hoped the Association would not merely consist of assistants and students, but that it would include many of the employers and others. He suggested that the Council would take a lively interest in the Association, and look up pharmaceutical points of interest for discussion. He would gladly help in that direction.

Mr. Wells was heartily thanked for his kindness in presiding, and Dr. Walsh and Mr. Henry Conyngham having been unanimously elected as honorary vice-presidents, the meeting then terminated.

A SHORT VISIT to the United States is being paid by Mr. Henry Dixon, B.A., Assistant Professor of Botany in the Society's School. His duties are being temporarily taken by Mr. R. A. Rossiter, T.C.D.

OBITUARY.

MILLHOUSE.—On January 27, at Heckington, Lincs., Henry How Millhouse, Pharmaceutical Chemist. (Aged 37.) Mr. Millhouse joined the Society in 1872, and continued his connection through the various stages of studentship, associateship, and membership until his death. The deceased gentleman, who was a past-president of the London Chemists' Assistants' Association, took a great interest in pharmaceutical matters, and would undoubtedly have taken a prominent position in the craft but for his long-continued ill-health. His death will be regretted by all who knew him.

JONES.—On March 11, T. Glynn-Jones, Chemist and Druggist, Stockton. (Aged 42.)

MILLS.—On March 12, John Mills, Pharmaceutical Chemist, Chester. (Aged 56.) Mr. Mills had carried on business for about 32 years, and was one of the earliest members of the Chester Society of Natural Science, in the affairs of which he took very great interest.

GOWANS.—On March 12, James Gowans, Chemist and Druggist, Perth. (Aged 79.)

BEARD.—On March 16, Albert Edward Beard, Pharmaceutical Chemist, Norwich. (Aged 31.) The late Mr. Beard was a life Member of the Pharmaceutical Society.

CORRESPONDENCE.

UNDUE CUTTING IN THE RETAIL TRADE.

Sir,—Referring to "Analyst's" reply to my letter, I am quite aware that difficulties would arise with some organic compounds, but the bulk of the so-called "patent" medicines are not of the complex character that "Analyst" depicts. As a matter of fact, they are usually composed of one or two potent or active ingredients and a diluent, all of which yield to expert analysis. I can take a patent medicine list and mark dozens that will present little or no difficulty from an analytical point of view. I know from practical experiment that the qualitative difficulties in a great number of preparations are almost *nil*; when quantitative results are required more labour is involved. Patents obtained at different times often vary in strength considerably. The analyst also has the advantage of using his synthetical skill and differentiating the results. A few experts at £5 per week each would get through such difficulties quite comfortably. "Analyst" says, "what about the consequences of a published mistake"? Probably the plaintiff would say defendant's analysis is wrong. Defendant would ask him to prove it. When he had proved it, the analysis would be right. I am afraid Mr. "Analyst" if I appeared before you with a patent medicine in one hand, and two £10 notes in the other, your isomerism, polymerism, and other dreadful difficulties would perform a similar feat to Macbeth's witches—vanish into thin air. Ultimately you would have the notes, and I the analysis.

Mr. Johnson's moral deductions, and the suave manner in which he introduces his pet association of manufacturers of so-called "Patent" medicines is unique. I agree with him on one point, however; he says "Retailers are ripe for a revolution of some sort." I take it that the object of the association he mentions is to prevent cutting by controlling the supply of patent medicines, etc., and that they bind themselves together by rules or laws, and that manufacturers who do not join the association will be classed as Patent Heathens, and that the association will from time to time send out missionaries to try to convert them, and should any member disobey the laws of the association he will be at once excommunicated. But that will not stop cutting. Practically, a law ceases to be a law when the power to enforce it ceases. The association has no legal power. Consequently it would be as easy for the leader to stand on his head on the cross at the top of St. Paul's as for the association to stop cutting by such means. It simply temporises with the difficulty and will ultimately resolve itself into a kind of elaborate confidence trick. Chemists consider the matter well before you step into that "Little parlour." The process that will stop cutting must, to a certain extent, be automatic and not dependent on the caprice of a few interested manufacturers. I again repeat that patents are the principal cause of the retailers' troubles; in my letter of February 29 I propose a radical cure. I should like to hear the opinions of some gentlemen in business on the subject, or perhaps they will propose some more simple scheme.

56, Cheapside, E.C., March 9, 1896.

WM. FERGUSON.

PHARMACIST OR CHEMIST?

Sir,—Mr. Martindale in a speech reported in the issue of the Journal for March 7 remarked: "That in some respects pharmacists and the proprietors of stores stood in an entirely different position. The latter looked simply to the total amount of turnover to be obtained on their capital, and wished to make it as large as possible; whereas the chemist recognised that with regard to certain articles in which he dealt, such as poisons and nostrums containing poisons, certain restrictions on their sale were necessary in the interest of the public safety. . . . It was very desirable that co-operative stores and limited companies should be bound to strictly observe the letter of the law." It will be noted that Mr. Martindale used the terms "pharmacist" and "chemist" alternately, thereby implying that they are one and the same. Again, Mr. Martin stated that "he thought it would be placing the 'pharmacist' in an invidious and humiliating position to be subjected to the surveillance of an inspector." Further, Mr. Allen remarked, in regard to early closing, "that he thought 'pharmacists' were specially affected, and might reasonably ask for separate treatment from other shops."

My object for intruding on your space is to try to obtain some clear definition of the meaning of these two terms, "pharmacist" and "chemist," for Mr. Allen's remarks would seem to indicate that in his opinion pharmacists occupy a position totally different from

that of the proprietors of "other shops," the difference is not very apparent, in view of the fact that, according to the Pharmacy Act, all persons carrying on a chemist's business must be properly qualified and duly registered. I shall be grateful if you, sir, or any of your numerous correspondents will kindly enlighten me on these questions:

London, March 11, 1896.

"PERPLEXED."

SHOPS (EARLY CLOSING) BILL.

Sir,—I am strongly of opinion that earlier closing would be an unmixed benefit, and that it cannot be obtained by any other method than an Act of Parliament. My reasons are—That the present hours of the drug trade are such that in the majority of cases the chemist is debarred from taking any active interest in the affairs of the community, entailing a consequent narrowing of his own views on general subjects. He is debarred from enjoying active outdoor exercises. He is debarred from social gatherings. He is debarred from attendance on lectures or any of the evening classes arranged for the instruction of men whose position necessitates their daily labour. As educated men, chemists are fitted to occupy prominent positions, but owing to the disadvantages under which they labour—the hours of business especially—it is the exception rather than the rule for such to be the case. I think it quite beside the mark to cite what some chemists have done in the shape of earlier closing—the question is what can the majority do? A few of the favoured ones may, without loss, disregard what their rivals do, but the number is infinitesimal.

March 7, 1896.

WALES.

Sir,—I for one would be only too pleased for an Act to be passed to-morrow compelling all chemists to close daily at 6 p.m. Talk about infringing the liberty of the subject and grandmotherly legislation! Why, we should then enjoy a good deal more liberty and freedom than is at all possible under present conditions. Now we chemists are kept in to sell night-lights, etc., "because the grocers are closed," and only yesterday (Sunday) I had a customer, who usually buys tea at a grocer's, come for $\frac{1}{4}$ -lb. tea; of course "because grocers are closed." That is the point of the whole question. We are kept in late every night for the convenience of those white slave drivers, the B.P., not for anything ever required to be made up according to the B.P. If you knew retail chemists as I do you would know that nothing can remedy the present "slavery" but legislation, and as you ask for opinions I send mine, and do not fear to state that they are what are held by retail chemists generally. Perhaps you will allow me to add that, as an assistant in good dispensing businesses, my hours were very reasonable, but the businesses that employ assistants are not ordinary retail chemists but the exception to the rule. I now close at 6 p.m. once a week, but am the only one in this town—where there are thirteen chemists—who does so. Is this as it should be?—Yours faithfully,

Lowestoft, March 9, 1896.

A. H. HINDE.

Sir,—I was glad to see among your correspondence a letter signed "Early Closing," calling attention to your remarks on the Early Closing question, although I cannot see why those remarks should make him consider whether he will remain connected with the Society or not. . . . I would like to urge upon all readers of the Journal who are interested in the Bill to make their opinions known. Already in the Council Meeting Messrs. Hampson, Martin, Allen, Hills, and Gostling have objected to the State protecting assistants from the greed of employers. These gentlemen have not the welfare of the assistants at heart, and I would ask your readers to remember them at the next election of the Council.

Putney, March 6, 1896.

H. E. DURBIN.

Sir,—I strongly disapprove of an "early closing" Bill as applied to any body, as I think such a Bill belongs to a class of legislation tending to interference with the liberty of the subject; it is a pity our legislative body is not occupied continuously with really urgent reform instead of so much of the "grandmotherly" type. That pharmacists should be included in this Bill is derogatory to their status as professional business men, but that they should tamely submit to it is still more so. What the Society can do in the matter I do not know, but I have every confidence in the Executive. The policy of the Society, what little time I have observed it, is expressed by the motto "Fortiter sed Suaviter"; what can be done for the general welfare of the body, under the circumstances, is

undoubtedly being done by the only body which can or ever has done anything for pharmacists. No registered chemist has any excuse for not joining and supporting his representative headquarters, and it is a standing reproach to him all the while he remains an alien.

Forest Hill, S.E. March 16, 1896. C. GARRETT WILLISHER.

EARLY FLOWERS.

Sir,—As an example of the extremely mild winter, I send you a list of flowers picked in January and February by a friend and myself in this district. Most are extremely early, as the usual time for flowering will be found between June and October:—*Chrysosplenium oppositifolium*, *Luzula campestris*, *Lychnis diurna*, *Veronica hederifolia*, *Veronica polita*, *Lamium purpureum*, *Viola canina*, *Potentilla tormentilla*, *Fussilago farfara*, *Heracleum sphondylium* (pink), *Ruscus aculeatus*.

8, Edgcombe Street, Plymouth,
March 16, 1896.

J. A. BUCKLEY.

MAJOR EXAMINATION.

Sir,—I have often wondered how it is that in the Major examination a little latitude is not given in the answering of materia medica and botany questions. In chemistry and physics a choice of questions is given, the candidate is required to attempt not more than six out of eight or nine. This, I think, is much fairer all round, and is adopted by most examining bodies. Why should one course be followed in chemistry and physics and another in botany? Surely materia medica and botany are wide subjects, and a candidate can hardly be expected to be equally well up in every question that may be asked. Botany of late years has made enormous strides, and different botanical terms are continually being given. In fact, if an old student who had let the subject drop for a time were to pick up some of the new editions of well-known botanical works, he would be puzzled with some of the terms used; a student may be very well up all round and yet be unfortunate in getting one or two questions he is not familiar with, whilst another student may just happen to know the questions asked, although his general knowledge is far below that of the other man. Many will say, But every man has an equal chance, and it is as fair for one as another. Quite so, but the element chance ought to be done away with as far as possible. Of course the examining body may have, and I have no doubt have, very good reasons for the course they adopt. I have often had the same question asked, and not being able to give a satisfactory answer, thought I would try and hear the opinion of others on the subject. I shall be pleased if you or any of the readers of the Journal can give any information.

Liverpool, March 7, 1896.

ENQUIRER.

ANSWERS.

GLYCYRRHIZA.—It is difficult to suggest any book which covers exactly the ground required. A good book for the inorganic is Fisher's 'Chemistry,' and any of the recently published small organic chemistry books, such as Remsen, Turpin, or Scarf, will contain more than enough for the organic part of the syllabus. Everett's 'Physics' is also required.

E. T. ELTONIAN.—We are hardly competent to express an opinion in the matter you mention.

E.R.S.—We cannot say if the oleate would be of any use, but no ill-effect would be likely to accrue from trying it. The other preparation you mention is undoubtedly the best.

QUERIES.

"D.M." wishes to know if any correspondent can give information concerning the hanging of anaglypta paper on match boarding, particularly whether the boards cause it to crack?

"SEARCH LIGHT" asks if any reader can give good formulæ for *mistura bismuthi et pepsinæ*, *liquor papain et iridin co.*, and for *chrysarobinum glycerinum saponatum* of Hebra.

COMMUNICATIONS, LETTERS, ETC., have been received from Messrs. Bennett, Bosisto, Buckley Bennett, Cocks, Coleman, Cope, Cox, Dott, Gilligan, Happold, Hardy, Hill, Hinde, Ince, Jasper, Jones, Line, Lucas, Miller, Reynolds, Rook, Shepherd, Simmonds, Strachan, Thompson, Willsher.

Several communications are unavoidably held over on account of want of space. Correspondents are requested to write as briefly as possible.

“THE MONTH.”

Reduction of $\text{AgNO}_3 \cdot 2\text{NH}_3$ by Sugars. J. Henderson finds that when dextrose, levulose, and galactose are heated with ammoniacal silver nitrate, under certain given conditions, a definite factor can be obtained in each case.

Cane sugar, starch, and dextrin, however, exert no reducing action when heated with the nitrate under the same conditions, and in the case of lactose and maltose a definite factor cannot be got, owing to gradual hydrolysis of the disaccharide molecules by the ammonia (*Journ. Chem. Soc.*, lxi., 145).

Luteolin. A. G. Perkin has studied the behaviour of the yellow colouring matter obtained from “weld” (*Reseda luteola*), when acted upon by acids.

Luteolin was isolated from “weld” by Chevreul, and subsequently studied by Moldenhauer, who assigned it the formula $\text{C}_{20}\text{H}_{14}\text{O}_8$. Schützenberger and Paraf, however, thought the formula should be $\text{C}_{12}\text{H}_8\text{O}_5$, whilst Hlasiwetz and Pfaundler later ascribed to it the formula $\text{C}_{15}\text{H}_{10}\text{O}_6$, which is isomeric with paradiscetin, obtained by the action of fused alkali on quercetin. Acting on luteolin with nitric acid, Rochleder obtained oxalic acid, and with fused alkali protocatechuic acid and a substance considered to be in all probability phloroglucin. The results of Perkin’s analyses agreed well with the formulæ $\text{C}_{15}\text{H}_{10}\text{O}_6$, and $\text{C}_{20}\text{H}_{14}\text{O}_8$, but he has been able to prepare a sulphate, hydrobromide, hydrochloride, and hydriodide of the compound, the first of which is of a normal character and shows that the true formula of luteolin is $\text{C}_{15}\text{H}_{10}\text{O}_6$. The compounds with the haloid acids are peculiar, as they appear to crystallise with one molecule of water, differing in this respect from the corresponding compounds of quercetin, fisetin, and morin, which do not contain water of crystallisation (*Journ. Chem. Soc.*, lxi., 206).

Carvacrol and Thymol Derivatives. L. C. Urban has prepared new halogen derivatives of carvacrol and thymol. The substance known commercially as aristol, he points out, is produced by the action of iodine upon thymol in alkaline solution. The same derivative of dithymol is formed by adding a solution of chlorinated soda to an alkaline solution of thymol in which an alkaline iodide has been dissolved. A carvacrol iodide, said to be prepared in an analogous manner to aristol, has been described as a bulky, yellowish-brown amorphous powder, melting at about 90°C .

Urban, however, has prepared a carvacrol iodide, quite different from this, by dissolving carvacrol, 2 Gm., and potassium iodide, 3.8 Gm., in 40 C.c. of a 10 per cent. aqueous solution of sodium hydroxide. He then added gradually a solution of chlorinated soda, and stirred continually until no more precipitate was formed. The precipitate was washed with slightly alkaline water, then pure water, and when dried formed a bulky, greyish-yellow or buff-coloured amorphous powder, having a faint aromatic odour. It is described as soluble in ether, chloroform, benzine, and fixed oils, the iodide being precipitated from the ether and chloroform solutions by alcohol, and a paler product thus obtained. At 200°C . this purified product became black and tarry, but had not liquefied. The same compound results on adding very slowly, and under continuous stirring, an aqueous solution of iodine and potassium iodide to a solution of carvacrol, 2 Gm., in 40 C.c. of a 10 per cent. aqueous solution of sodium hydroxide. It combines the antiseptic properties of carvacrol with those of iodine, is four times as bulky as iodoform, and nearly odourless. Analogous bromine and chlorine derivatives have also been prepared from both thymol and carvacrol (*Pharm. Review*, xiv., 58).

VOL. LVI. (FOURTH SERIES, VOL. II.). No. 1344.

New Metallic Carbides.

H. Moissan has been successful in preparing cerium and lithium carbides by the aid of the electric furnace. Cerium carbide, CeC_2 , is a crystalline body analogous to calcium carbide, and is decomposed in the presence of cold water, a gaseous mixture of acetylene, ethylene, and methane being evolved, and a mixture of liquid and solid carbides left. The density of the compound is 5.23. Lithium carbide, LiC_2 , is obtained as a transparent crystalline mass, its density being 1.65 at 18°C . When decomposed by water it yields pure acetylene gas, the reaction being rapid at ordinary temperatures and violent at 100°C . One kilogramme of it yields 587 litres of acetylene gas. This carbide is comparable in every respect with the carbides of calcium, barium, and strontium. Manganese carbide, Mn_3C , discovered by Troost and Hautefeuille, has a density of 6.89 at 17° , according to Moissan. A temperature of 1500° to 3000°C . is required to produce it. Water reacts with it to form a white hydrated oxide, and the gas given off consists of a mixture of equal parts of methane and hydrogen. Moissan and Étard have also prepared the carbides of yttrium and thorium. The former, Y_2C_3 , has a density of 4.13, and forms a white hydrated oxide when treated with water, whilst giving off acetylene, methane, ethylene, and hydrogen. It is seen under the microscope to consist of yellow crystals. Thorium carbide, ThC_2 , also consists of small yellow crystals, has a density of 8.96, and gives off the same gases as yttrium carbide when acted upon by cold water, liquid and solid hydrocarbons being formed in small quantity at the same time (*Comp. rend.*, cxxii., 357, 362, 421, 573).

Borides of Nickel and Cobalt. H. Moissan also describes two new metallic borides, obtained at a temperature of 1200°C ., nickel boride, NiBo , and cobalt boride, CoBo . Both occur in brilliant prisms several millimetres in length, and are magnetic. Their densities at 18° are about the same—nickel boride, 7.39; cobalt boride, 7.25. The properties of the borides are analogous to those of iron boride (*Ph. J.* [3], xxv., 753), and the compounds serve for the introduction of boron into a metal such as iron when at a high temperature. It has been demonstrated that both boron and silicon can displace the carbon in molten iron when added in a suitable form (*Comp. rend.*, cxxii., 424).

Thiophosphites. M. Ferrand has obtained a new series of compounds, corresponding to the general formula PS_3M_3 , by heating mixtures of sulphur, red phosphorus, and different metals. Thiophosphites have thus been prepared of copper, $\text{Cu}_6(\text{PS}_3)_2$; iron, $\text{Fe}_3(\text{PS}_3)_2$; silver, Ag_3PS_3 ; nickel, $\text{Ni}_3(\text{PS}_3)_2$; chromium, $\text{Cr}_3(\text{PS}_3)_2$; zinc, $\text{Zn}_3(\text{PS}_3)_2$; cadmium, $\text{Cd}_3(\text{PS}_3)_2$; mercury, $\text{Hg}_3(\text{PS}_3)_2$; and aluminium, $\text{Al}_3(\text{PS}_3)_2$ (*Comp. rend.*, cxxii., 621).

Rhodinol. The chemical identity of the alcohol constituting the principal liquid constituent of rose-oil, with that in various other oils, was announced some time ago by Bertram and Gildemeister, and confirmed later by Erdmann and Huth (see *ante*, p. 173). Ph. Barbier and L. Bouveault now re-assert the identity of the alcohol constituting the chief portion of the essence of *Pelargonium odoratissimum* with the rhodinol extracted by Eckart from essence of roses, and claim that they have already shown the alcohol in essence of pelargonium to be different from the lemonol or geraniol in essence of *Andropogon schenanthus*. They also state that the product they extracted from essence of pelargonium was really a mixture of lemonol and another alcohol, the rhodinol of Eckart being declared to be a mixture of the same two alcohols. Hesse has proposed to name the second alcohol “réuniol” (*ante*, p. 173); but the authors prefer to retain for it the name rhodinol, formerly applied to its

mixture with lemonol. The composition of the new rhodinol is stated to be represented by the formula $C_{10}H_{20}O$, the same as proposed by Markownikoff and Reformatsky. The purified alcohol is described as a colourless oily liquid, boiling at $110^{\circ}C$. under a pressure of 10 Mm., possessing an agreeable odour of roses, and having a density at 0° of 0.8731. Its acetate boils at 115° . The proportion in which rhodinol exists in the two essences examined—rose and pelargonium—is estimated at 20 per cent. If these results are verified, they should remove much of the confusion that has been caused by the discordant results of other workers (*Comp. rend.*, cxxii., 529).

P. van Tieghem calls attention to the interesting fact that the normal polarity of the embryo-sac in plants is occasionally reversed. The normal position of the embryonic vesicles and of the antipodals is invariably maintained in those plants in which the embryo-sac is produced within the nucellus of a tegumented ovule, with its apex turned towards the micropyle, whether the mode of impregnation be porogamic or chalazogamic. But in certain of the Loranthaceæ, where the embryo-sac arises on the inner surface of the carpel, and when there is, therefore, strictly speaking, neither placenta nor ovule, the oosphere and the synergids are located at the lower, the antipodals at the upper end of the embryo-sac. A similar phenomenon is presented by the genus *Arceuthobium*, which van Tieghem proposes to remove from the Loranthaceæ, and to make the type of a new order Arceuthobiaceæ, intermediate between the Loranthaceæ and the Santalaceæ. For this mode of impregnation van Tieghem proposes the term "basigamous," as contrasted with the ordinary "acrogamous" mode. A similar mode of impregnation, accompanied by chalazogamy, occurs in certain Balanophoraceæ with naked ovules. It had already been noticed by Tretiakof in the case of *Allium odorum*, that the antipodal cells may sometimes be impregnated by the pollen-tube, that is, may assume physiologically the rôle of embryonic vesicles (*Morot's Journal de Botanique*, 1895, p. 465).

Professor O. Kirchner had observed that while the roots of *Soja hispida* produce tubercles abundantly in its native country, Japan, none are formed when it is grown in European botanic gardens. In order to ascertain the cause of this difference, he infected the European plants by growing them in soil obtained from Japan. The result was the production of abundance of root-tubercles, showing that they must be caused by a microbe present in the soil. In their anatomical structure, the root-tubercles of *Soja* agree most closely with those of *Phaseolus*. For the special microbe producing them the author proposes the name *Rhizobacterium japonicum*, substituting this generic name for Frank's *Rhizobium*, in consequence of the name *Rhizobius* being already appropriated in the animal kingdom (*Cohn's Beiträge zur Biologie der Pflanzen*, vol. vii., 1895).

In the *Minnesota Botanical Studies* for 1895 (the organ of the Geological and Natural History Survey of Minnesota), Mr. Roy W. Squires has an interesting note on the result of a series of experiments on the temperature of a trunk of *Acer Negundo* between January and June. He states that as a general result the temperature of the tree is lower than that of the air in the morning and at noon, while it is higher in the evening. The mean temperature of the tree, as compared with that of the air, was $1.31^{\circ}C$. higher in January, nearly the same in February, nearly 1° lower in March, 0.85° higher in April, and 1.13° lower in May.

Mr. A. J. Ewart contributes to the *Proceedings of the Liverpool Biological Society* the results of a series of observations on this subject, made in connection with Professor J. Reynolds Green.

In some plants, e.g., *Lilium*, *Narcissus*, *Tulipa*, and *Scilla*, minute round or oval pores were detected in the apex of the pollen-tube, through which solid particles had been extruded. These particles probably consisted of granules of a zymogen, by means of which the pollen-tube disintegrates the tissues of the style, through which it forces its way. These pores appear, however, to have only a temporary existence, closing up again after the granules have forced their way through the apex of the tube. In some cases a very large and wide terminal opening is formed, which may be from one-half to two-thirds the diameter of the pollen-tube. Both direct sunlight and total darkness were found to be unfavourable to the growth of pollen-tubes, a feeble light being the most advantageous. The optimum temperature for this growth is between 20° and $30^{\circ}C$. Branching and septation are both not uncommon phenomena in pollen-tubes, the septa being the result of ingrowths of the wall of the tube. The branching may be either dichotomous or apical. Pollen-grains of *Mercurialis* were seen to emit two, or even three separate tubes.

From observations made on about twenty species of Myrtaceæ, Dr. G. Lutz gives the following general account of the structure of these receptacles. They are never in the form of a canal, but are usually globular or ellipsoidal. They are generally formed at an early period from one or two epidermal cells, which are distinguished from the rest by their granular contents. The original cell or cells divide, and the receptacle is formed schizogenously by the separation of the daughter-cells. The so-called "resinogenous layer" is formed on the walls of the secreting cells, in the form either of caps or of a continuous coating. It consists of a mucilaginous ground-substance, in which granules and rods are imbedded. The secreting cells become obliterated at an early period; hence Tschirch has termed this kind of receptacle "oblito-schizogenous" secretion receptacles. At a later period the walls of the receptacle become suberised. The secretion is developed in the "resinogenous layer," which disappears as the secretion is formed. When the receptacle is fully formed, the intercellular spaces become filled with the secretion, and the resinogenous layer disappears entirely, or nearly so. The receptacles vary greatly in diameter, between 20 and 230μ (*Botanisches Centralblatt*, vol. lxiv., 1895).

Dr. G. Eisen contributes to the *Proceedings of the Californian Academy of Sciences* for 1895 an historical account of the means employed for producing fertile figs from the earliest times downwards. Caprification, or artificial pollination, has been practised from a very early period. The author distinguishes the following four varieties:—(1) The caprifig, or wild fig (*Ficus carica sylvestris*). It is in this variety that the *Blastophaga* or fig-wasp breeds, and goes through its various transformations. It bears three crops of fig, those produced from the male flowers only attaining maturity without assistance; the female flowers require artificial pollination. (2) The Smyrna fig (*Ficus carica smirniaca*). This produces neither male flowers, nor gall flowers, only female flowers, which require caprification in order that the figs may mature. (3) The common cultivated fig (*Ficus carica hortensis*). This contains no male flowers; but it requires no caprification to produce mature fruit, the female flowers being fertilised by the *Blastophaga*. (4) The San Pedro fig (*Ficus carica intermedia*). This kind produces no male flowers. The

first crop consists of mule flowers only, and is not susceptible of impregnation. The second crop consists of female flowers only, and requires caprification in order that the figs may mature.

A new tæniifuge from French Guinea has recently been described by Messrs. Heckel and Schlagdenhauffen. It consists of the seeds and root-bark of *Connarus africanus*, Lam., of which an illustration is given by the authors. The native name, séribéle (red medicine) indicates the colour of the seeds. These are about one inch long and one-third of an inch in diameter, and in shape resemble a kidney bean; for about one-third of their length they are enveloped in a red fleshy arillus. In Conakry and the greater part of French Guinea the seeds are employed, but in Bramaya the root-bark is used. The drug has been experimented with by Dr. Maclaud, chief of the *Service de Santé* at Conakry. He reports that in four cases its use was followed by success. The dose employed was sixty grammes of the ground seeds, given in the form of decoction in a glass of warm water. Dr. Drevon administered a smaller dose of twenty-five grammes, which was allowed to macerate for twelve hours, and was then given with the water in which it had been macerated. In three out of five cases the head of the tape-worm was passed. A dose of brandy was usually given after the drug, and preparation for taking it made by previous fasting. The authors made a chemical examination of the drug, but have not detected any special active principle. It contains about five per cent. tannin, giving a dark blue coloration with ferric chloride, a neutral fat, and an orange colouring matter, which adheres very persistently to the fat, also crystalline fatty acids, consisting of three parts of stearic to one of palmitic acid. The colouring matter seems to be a compound consisting of a rose and of a yellow substance. The constituents of the root-bark are similar, but the crystalline fatty acids are not present. The quarto coloured plate given with this paper illustrates the leaves, flowers, fruit, and details of the seed. Little is known of the plants of this family, except that a few are known to possess poisonous properties (*Annales de la Faculté des Sciences de Marseille*, tom vi., fasc. 2).

J. Jean gives the following method for quantitative determination of this constituent of kola and its preparations. By treatment with lime and chloroform the caffeine and theobromine are first separated: the residue is then extracted with 90 per cent. alcohol in a Soxhlet apparatus, and the alcohol distilled off from the solution containing kolanin, tannin, and colouring substances. The residue is treated with water, which leaves kolanin undissolved, and after washing with warm water it can be dried and weighed (*Rép. de Pharm.* [3], vii., 99).

Professor J. U. Lloyd publishes a report of a detailed examination of this drug, in which he shows that the average amount of ash left by an ordinary specimen of commercially fair asafoetida is quite considerable, ranging in the samples examined from 16 to about 20 per cent., whilst in some cases as high an average as 50 per cent. was observed. Selected tears, yielding to alcohol as much as 76 per cent. of their weight, left not more than 1.78 to 2.55 per cent. of ash. The opinion is expressed that purified asafoetida should be the only kind official for pharmaceutical use, and that the U.S.P. should give directions for ascertaining the absence of white turpentine and colophony resin. The acid number of asafoetida seems to be higher for dry tears than for asafoetida in mass. It varied, in these experiments, from 61.9 to 68.8 for dry tears, and from 37.7 to 40.4 for the mass. Asafoetida yielding at least 60 per cent. of its weight to alcohol, as stipulated by the U.S.P., is stated to be difficult to obtain in the American market (*Pharm. Review*, xiv., 54).

Oil of Russian Anise.

The chief constituent of this oil is anethol and little was known until quite recently respecting its other constituents. G. Boucharlat and M. Tardy have lately shown that the oil remains liquid at 5° C., and contains anisic aldehyde and a ketone, together with a small quantity of anisic acid (*ante*, p. 164). They now state that in addition to an enormous proportion of anethol, C₂₀H₁₂O₃, there are present very small quantities of estragol, anisic aldehyde, anisic ketone (C₂₀H₁₀O₄), anisic acid, anisic camphor or fenchone (C₂₀H₁₆O₂), several carbides of the formula C₃₀H₂₄, and some tarry matters. The total of the other substances, however, does not amount to more than one-twentieth the weight of the anethol present (*Comp. rend.*, cxxii., 624).

Silver Salts as Antiseptics.

It has recently been observed that various micro-organisms are killed when brought into contact with metallic silver. Other metals have a similar effect though in a lesser degree, and in some instances they exercise a prejudicial influence on living tissues. In a lecture delivered at the Medical Society of Dresden, Dr. Credé has drawn attention to the use of metallic silver as a dressing for wounds in the same manner that it has been applied in the Johns Hopkins Hospital at Baltimore. Silver foil being somewhat inconvenient, Dr. Credé has employed a loosely woven textile fabric coated with metallic silver. In the course of experiments with this material it has been found that the silver enters into combination with a secretion of the micro-organisms containing lactic acid, and that silver lactate is formed. This is the substance which is destructive to the micro-organisms; a solution containing one thousandth part of silver lactate kills them in five minutes; one part in 50,000 retards their development. These facts have been established by Behring, Miller, Schill, Bolton, etc., but no one had attempted to make a useful application of silver lactate until Dr. Credé induced the firm of von Heyden to prepare the salt for use under the name of "actol." Some practical objections to the use of this salt have led to further investigation, resulting in the introduction of silver citrate under the name of "itrol." This salt has not the irritating effect of the lactate, and, while perfectly harmless, it is described as having a very powerful antiseptic action when applied in the form of ointment or in powder, by dusting over the surface of wounds (*Pharm. Centrbl.*, xxxvij., 157).

The Mezereon.

At the present time, and indeed for some weeks past, one of the most attractive occupants of our shrubberies has been the purple and white varieties of *Daphne mezereum*. A bed near the ruined arch in the Royal Gardens, Kew, filled in the centre with *D. mezereum*, var. *album*, bordered with the variety *grandiflorum*, is now quite a mass of white blossom, the leafless branches of each plant being thickly covered with flowers. The purple variety appears to be more sparing in its flowering habit than the white, and, moreover, it is some three or four weeks earlier in flowering than the white. In clumps of a few plants together in shrubberies or in masses in a bed the Mezereon is equally attractive. The plant averages from one to four feet in height, and has an erect stem and few ascending branches. The flowers are sessile on the previous year's branches, and are produced from buds in the axils of the fallen leaves. In Britain the plant is not considered a true native, but is probably a garden escape, and is found mostly in the southern counties. It is also found in subalpine districts throughout Europe, frequent in the central and eastern parts, but more rare in the west. Mezereon bark was formerly collected in Kent and Hampshire. Most of that now seen in commerce comes from Germany. As a flowering plant it is quite worth growing.

THE OLD FIRM OF GODFREY.

BY JOSEPH INCE,

*Late Director of Godfrey's Laboratory.**(Concluded from page 207.)*

My father, the late William Ince, entered the firm of Godfrey when he was twenty-three years old.

He had been to school at Liverpool, had served an apprenticeship at Chester, where the home arrangements were poor, and other circumstances wretched.

The position held by the chemist's assistant of former days stands sharply in contrast with that which he now enjoys. The age itself has changed, and under the genial influence of the universal spread of education, mutual respect has been created between the employer and the employed.

Those were weary times during the apprenticeship at Chester, calculated rather to wean from a trust in earthly things than to inspire a taste for pharmacy and its associations. The premium was £100; the duration of "serving one's time" was seven years.

The house had this disadvantage that it was lower than the city walls, and in consequence during most part of the winter the apprentices had to stand on bricks to keep themselves above the water; the business was what is usually termed "mixed," to which might be added, mixing. My father in common with other men whose names we hold in honour, recognised that pharmacy was not to blame but ignorance, and this in his own person he determined to remove—rising at four o'clock to read.

The 'Chemical Catechism,' by Samuel Parkes, was his first introduction into serious study, a treatise he referred to with gratitude in after years.

Then came experiment and practical laboratory work conducted under circumstances which might have seemed to forbid continuance, for study was regarded with suspicion, and books as a sort of dynamite, to be hid away in corners by the assistant who might grow wiser than the master and imperil the situation.

Great was my father's satisfaction when he entered Godfrey's Old Firm at Southampton Street, which he viewed in the light of a reward for former hardships.

His son draws attention to the fact, that men who had passed through much the same ordeal as William Ince, resolved fifty-five years ago to break up this miserable condition of affairs, and they have handed down to a younger generation, not only an infinitely higher social position, but a means of gaining a livelihood worthy the acceptance of an educated individual.

Having duly performed his duties as assistant, he had the sole charge of the laboratory for some time during Mr. Cooke's life and at that gentleman's decease, became responsible manager and director.

In that capacity he remained until his death in 1853, aged 58, having been connected with the house for thirty-six years.

The present writer then succeeded, the financial management having been assumed by Mr Samuel Platt.

The old premises have been pulled down, and the very structure over which the phoenix watched for more than two centuries has made way for modern improvements.

Leaving the *personnel* of the firm, let me advert to some characteristic business details.

Certain trade items aided the financial position of the house: the first was the manufacture of carmine, entirely soluble in ammonia; sun-dried, and intended for the use of artists. It had a peculiar bloom distinct from foreign makes, which for many years secured for it a high price. Competition from abroad set in, and the sale was materially affected even before the west-end departure.

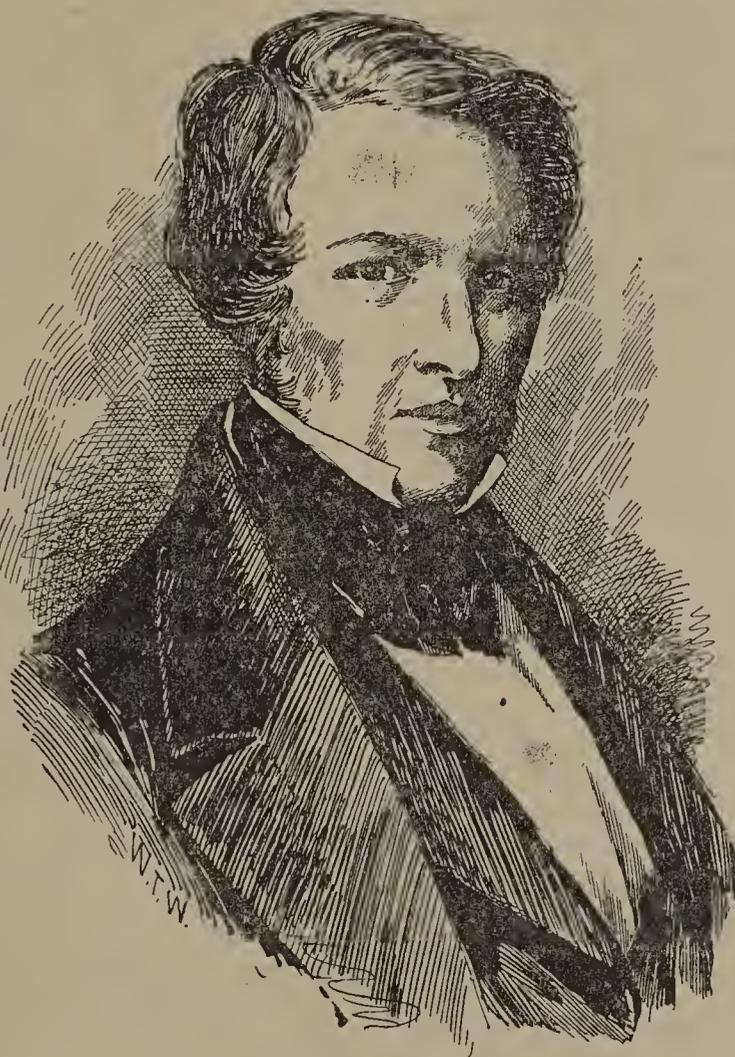

The next was Bismuth Trisnitrate; the precipitate underwent a fortnight's washing in distilled water; the whiteness was due to its being dried in the sun and never by artificial heat; diffusion in large excess of water resulted in an impalpable, non-crystalline powder. As it was unaffected when tested by a stream of sulphuretted hydrogen, and therefore was unchanged when exposed to gaseous fumes, it was patronised by operatic singers, actresses, and by premières danseuses at Her Majesty's in the Haymarket, and at the Opera House in Covent Garden. The third was ammonia and its preparations, the chief being smelling salts and spirit of sal volatile.

Modern formulæ containing ammonia are in some instances at a disadvantage, owing to the banishment of spirit of ammonia from the Pharmacopœia; the difficulty, which need not exist, is got over by adding strong liquor ammoniæ gradually, and shaking together with an alcoholic aromatic preparation until the formation of a clear solution. Linimentum camphoræ-compositum is in evidence, so, shaking apart, is Spiritus ammoniæ aromaticus.

Dr. Paris was no friend at this time to the business. He writes [edit., 1822, quoted], in the Pharmacologia, about one of Mr. Cooke's favourite preparations, the Essential salt of bark: "It

is highly necessary that the public should know that the preparation sold under this empirical title has no relation whatever to the late discoveries of Pelletier. It is merely an extract prepared by macerating the bruised substance of bark in cold water and submitting the infusion to a very slow evaporation." So far he was correct, but the author does not allude to the art of scaling, of which it was a good example, and which gained for it a reputation at a time when quinine sulphate (originally muriate), was not so beautifully prepared as it is now.

Dr. Paris was quite right when he came to describe "Godfrey's smelling salts." "This highly pungent preparation is obtained by re-subliming the common subcarbonate of ammonia with pearl-ash and a proportion of rectified spirit. The subcarbonate of potass.

WILLIAM INCE.

President of the Pharmaceutical Society, 1850-51.

in this case abstracts a fresh portion of carbonic acid from the ammoniacal salt. Its atomic composition has not yet been ascertained, but it will probably be found to consist of equal atoms of carbonic acid and ammonia." Pereira, as reporter to the Great Exhibition [1851], came to much the same conclusion.

The original formula was as follows:—

Ammonia Sesquicarbonatis	40 lbs.
Rectified Spirit of Wine (56 O.P.)	5 qts.
Pearl-ash.....	7 lbs.
Sublime.—C.W., C.M. (common weight, common measure).	

With this was connected the trade in smelling-bottles with gold and silver spring-caps. They were sold at a fancy price, the wonder being how so large a section of the public could afford to buy them. But they were beautifully made by a skilled workman in the employ of Mr. Diller, of Soho. No gilding or electroplating was allowed—the caps were solid gold or silver.

Diller in his day had a fortunate experience; he lent Louis Napoleon money, when the Prince was in sore strait for want of funds. Things turned out well in Paris, and Diller was not only commissioned to design the toilet requisites for the future Empress, but had to take them in person to the Tuileries. The money loan was discharged in full, and the silversmith received a most handsome remuneration for his work which, previous to its dispatch, was exhibited on Godfrey's counter.

Strange eagerness is displayed in the desire to obtain private formulæ, in the hope that their publication may disclose the secret of prosperity. The one secret, the publication of which is worth a straw, is that to buy the best and purest drugs, to make preparations of undoubted excellence and to have a genuine capacity for business, is the surest pathway to success. The fascination which surrounds secret remedies once led Mr. Cooke astray—he bought 'Ward's Preparations.' It is difficult to understand the inducement, as it was so entirely opposed to the general method of the firm. These included the red pill (sulphuret of antimony), Ward's white drops, an antiscorbutic remedy.

Original Formula.

Acid Nitrous	℥xxvj.
Volatile Salt Nost.	7 ozs.
[Ammonium carbonate re-sublimed.]	
Argentii Viv.	5 ozs.
Aquæ Destillatæ.....	5 lbs.

The acid and salt to be first carefully mixed by degrees; the quicksilver to be added in the same manner.

Ward's Essence (for headache).—Lin. Camphoræ Comp. P.L.

Ward's Red Drop.—Vinum Antimonii Tartarizati, made double strength (grs. iv. : ℥i.), sherry selected for colour, and the emetic tartar previously dissolved by heat in a little distilled water.

The Ward's drop bottles, holding 2 fluid drachms, have survived as a trade name, and Ward's Paste for fistula and piles has, in an altered and much simpler form, been enshrined in our Pharmacopœia under the title of Confectio Piperis. It was the only one of the series that yielded a profitable return.

Compare the official confection, and the formula given in the Pharmacologia, with the original:—

Ward's Paste.

Coriander	20 lbs.
Black Pepper.....	10 lbs.
Fennel	14 lbs.
Elecampane	12 lbs.
to form a species,	
Species ut Suprà	4 lbs.
Mellis	3 lbs.
Sugar	2 lbs.

12 ounces in a pot.

Ward was a footman in attendance on his master who was travelling on the Continent—there he picked up his nostrums. The

incident is not unique, for Mr. Jacob Bell used to relate how he called upon a celebrated dentist, whom he found in like manner to have been his footman, once engaged at Langham Place.

A mass of other recipes remain, altered and re-altered by the two Godfreys, Mr. Cooke, and others, so as in some cases to be almost illegible. As curiosities, a few are here selected:—

Balsam of Mecca.

Ol. Myristicæ.....	℥ss.
Otto Rosarum.....	gtt. v.
Ol. Cassiæ	gtt. xx.
Bals. Canadense	ad 16 ozs.

[Oils by measure.]

Eau à Brûler.

Spirit Rectif.	2 quarts. [C.M.]
Bals. Peruv.	1 oz.
Tinct. Benzoini (simpl.).....	℥iv.
Ess. Bergam	℥i.
Ol. Lavand. angl.	℥i.
Ol. Rosmarini.....	℥i.

Essentia Ambergris.

Ambergris	2 ozs.
Musk	℥iv.
Spirit. Rectif.....	℥xxxij.

Gregory's Powder.

[Original autograph.]

℞ Magnesiæ (ustæ).....	grs. vi.
Pulveris Rhei palmati.....	grs. ij.
— Amomi Zingiberis	gr. j.
Mi ce. Sig. Magnesia and Rhubarb.	J. G.

Hamilton's Hair Oil.

Strong Decoction of—

Colocynth Pulp	℥xxx
Rum,	
Ol. Olivæ	aa ℥x.

Huxham's Tincture of Bark, 1788.

Tinctura Corticis Peruviani Composita.

Cinchona Lancifolia bark, powdered.....	2 ozs.
Exterior Peel of Seville Orange, dried	1½ oz.
Virginian Snake Root, bruised.....	3 drachms.
Saffron	1 drachm.
Cochineal powdered.....	2 scruples.
Proof Spirit of Wine	2) ozs.

Digest 14 days and strain.

Huxham's actual formula was made with brandy and larger quantity of saffron (80 grains).

The official comment by the College of Physicians, date as above, deserves to be recorded.

"This medicine has been celebrated under the name of Huxham's Tincture. There is reason to fear that these spirituous remedies may sometimes have led the way to dram drinking, especially among the more delicate part of the human race—a consideration certainly of the utmost importance."

Laudanum.

[Laudatur ejus efficacia, quasi Laudatum medicamentum. Paracelsus.]

Opium	7 lbs. sliced.
Dissolve in water and press. Strain.	

Mum.....	2 gallons. [C.M.]
Spirit. Rectif.	1½ gallon. [C.M.]
Caryoph. Contus.....	8 ozs.
Aquæ Destillatæ	

Ad 7 gallons, Common Measure.

Note.—The Mum was not so much to increase the strength as to give a definite drop. A thick, treacly sort of beer, originally made by a German, called Mumme.

Artificial Musk.

Ol. Succini	℥vj.
Acid. Nitrous.....	℥xxiv.

The tincture was 4 ozs. of the resinous solid formed, dissolved in one gallon, common measure, rectified spirit.

Note.—The oil of amber, purified by a second distillation, was

found to give a poorer yield than the impure dark-coloured oil obtained in the first instance.

In consequence, rectified oil of amber was never sold.

Paraguay Roux.

Spilanthus Oleacea	4 ozs.
Rad. Pyrethri	2 ozs.
Spirit. Rectif.	3xxxij.

Spiritus Salis Dulcis.

Ether Chloric.	5i.
Spirit. Vini Rect.	5 j.

[Chloric ether by distillation, not mixture.]

Spiritus Etheris Nitrici.

[Original old formula.]

Acid Nitric	5xij.
Spirit. Vini. Rect.	1 gallon [C.M.]

Distil over into receiver containing spirit, let stand 3 days with 3lb. Potass. Sub-carb. and re-distil in balneo.

Note.—Potassii Bicarb. used at a later date in place of K_2CO_3 as above.

Williams' Tincture of Cayenne.

Essent. Cayenne	5ivss.
Spirit. Vini. Rect.	ad 3xvi.
[Ess. Cayenne, Pulv. Capsici 1. Sp. Vin. Rect. 3.]	

Tinctura Odontalgica.

Camphor	1 oz.
Sp. Vin. Rect.	3ij.
Ext. Opil	3ij.

Lower's Tincture.

Guaiacum Chips,	
Elecampane,	
Liquorice Root,	
Senna Leaves,	
Coriander, of each	12 ozs.
Sweet Fennel	6 ozs.
Raisins	6 lbs.
Spirit. Anisi	4½ gallons. [C. M.]
[Spirit. Anisi. Ol. Anisi, 5iiss.; Sp. Vin. Rect., 2 gallons; Aq. Destillat., 3 gallons; Powdered Sugar, 8 ozs.]	

Vinum Ferri

(by direction of Sir Benjamin Brodie).

Brown Sherry	5 gallons. [C. M.]
(From a well-known importer.)	
Ferri Potassio-Tart.	10 ozs.
Small iron tacks	q.s.

Macerate not less than three months in covered vessel with occasional agitation.

Vinum Hunt.

Sem. Santonic	1 oz.
Rad. Rhei Incis	1 oz.
herry (brown)	3xxx'j.

Note.—Had become obsolete: cannot trace the date.

Watchmaker's Oil deserves a passing notice as a distinctive trade article, if only on account of the memorandum in the price book—"not to be sold on Sundays." All else was physic, pure and simple; it was the golden age of medicine, for homœopathy was not as yet in the ascendant, and hygiene was not practically included in the healing art.

Daniel Hanbury states (1867) that "all druggists know that forty or fifty years ago liquid medicines for internal use were very commonly prescribed in the form of draughts or doses, each contained in a single bottle," and he proceeds to comment on the dangers of extreme concentration as exhibited in "drops." In my recollection, when medical practice was exemplified in the West-end by Dr. Chambers and Dr. Seymour, draughts and mixtures were alone prescribed. I cannot call to mind a single recipe ordered in a concentrated state by either of these physicians—nor one by Dr. Paris. Draughts usually involved repeats, and I have known three hours employed in this branch of dispensing; indeed, during the season it was no occasional task. The time came when there was scarcely a repeat to be dispensed; "drops" wrought the transformation. Before their advent, fashionable society, includ-

ing the whole family circle and the servants, pinned their faith upon continuous doses, three tablespoonfuls of which seemed to inspire confidence; quiet households followed their example, and in my own time I regularly made over-night four dozen "pill and draughts" for the market gardeners who came up to town on Saturday morning. Forty-eight shillings cash was no bad commencement of the day's work.

The continuous domestic use of aloetic pills and of rhubarb appears remarkable. A celebrated divine had radix rhei cut in cubes to be chewed, not swallowed, a practice persevered in till old age. The continuous use of Opium preparations, specially the Acetate of Morphia, may be considered as distinctive, but of this I am not sure. There were patients who took half-grain doses of Morphia daily throughout the year; others who continued the use of tincture of opium in heroic doses in the same manner.

The following recipe was dispensed for a considerable period:—

Anodyne Mixture.

R Morphine Acetat.	3ij.
Tinct. Cardam. Comp.	3-s.
Syrup. Simpl.	3ij.
Mist. Camphoræ ad.	3iv.

Misce.

Two dozen bottles were supplied at regular intervals.

I never feel sure, without reference, of the official posology of these remedies, nor yet of iodide of potassium.

Prices, as illustration of a period, may fairly be mentioned. Twice in my own experience they were reduced, and the alteration gave instant dissatisfaction; they had to be put back to the accustomed figure, which incidentally proves the date to have been anterior to the Stores. I have mentioned the London season. It meant from the middle of March to the Goodwood races; after that event came so dull an interregnum that for some weeks during the lull the old firm might nearly have closed its doors.

The staying power of an assistant may be included as characteristic of the times.

When I entered Southampton Street as a junior I was in the anomalous position of being a young man; the rest had seen years of service, while their predecessors had remained longer still, and had only left to commence business on their own account, namely, William Hooper, who was more than successful in Great Russell Street, Covent Garden, and Charles Linder, who went into partnership with Joseph Gifford in the Strand. Then the old order changed, and juniors began to come and go as is the fashion of these latter days. The gold fever broke out in Australia: incontinently one went to the diggings—there he endured hardships innumerable, till in despair he and some others tramped to Melbourne, where he became rich, so rich that on his return visit to London he offered to buy the firm. His fortune was made by the introduction of English flowers and seeds.

A second took his departure as hastily, but for a different cause; he came from a provincial town, and was set to make two dozen opium powders, one grain each. His powder-papers were spread out before him in due order, but his method had not that accuracy which dispensing feeling would desire, for he proceeded to dib out his pulvis opii with a palette knife, as the French say, *à la grâce de Dieu*. The elders looked on in silence. "Is that your usual method?" said my father; finding that it was, the junior was presented with a month's salary and a return railway fare, accompanied by the valediction, "Perhaps, on the whole, it would be better for you to go home and gain more experience." A third made strychnine pills, and ventured on his next batch in the same mortar, observing that it was nearly clean, reminding one of Sir Walter Scott's hedge doctor, who trusted to "two simples, calamy and laudamy." A fourth, on retiring, had an ingenious style of com-

position, stating that he had been for years with Messrs. Godfrey : he had been two.
